In the above, “best possible match” refers only to the characters in the second operand. In the example above, if the next two characters of the second operand (the string) are AB, and these are the last two characters of the second operand, the best possible match is on AB, even though there could be a match on ABC if the second operand included one more byte containing C.

Expansion is normally always repeatable. An index symbol is always expanded to exactly the character symbol it represents unless an exception that causes termination is recognized.

3. During expansion, if at least one unused byte position remains in the first operand location, COMPRESSION CALL may completely process the next index symbol in the second operand before it determines that the first-operand location does not have sufficient unused byte positions to contain the expanded data that would result from the next index symbol. If that next index symbol causes encountering of bad dictionary entries, the result can be either a data exception or condition code 1.

COMPRESSION CALL immediately sets condition code 1 when processing of an index symbol exactly fills the first-operand location, except that
it sets condition code 0 if the end of the second-operand location also has been reached. Immediately setting condition code 1 has the advantage that data can be compressed using one dictionary and then followed immediately, possibly on a bit boundary, by a different type of data compressed using another dictionary. The compressed data can be successfully expanded if, during the expansion of the data compressed using the first dictionary, the length of the first-operand location is specified to be exactly the length of the expanded data that will be produced. Condition code 1 will then be set when the first-operand location is full, at which time the specification of the dictionary can be changed in order to expand the remainder of the compressed data using the second dictionary. If the definition allowed condition code 1 not to be set, it might be attempted to expand the next index symbol, which resulted from use of the second dictionary, by means of the first dictionary, and this might cause recognition of a general-operation data exception. For example, the next index symbol, which properly designates a character entry in the second dictionary, might designate the second half of a format-1 sibling descriptor in the first dictionary, and that second half might begin with a character, such as 0 (F0 hex), that would appear to be an invalid partial symbol length in a character entry.

4. A nullifying access-exception condition due to a reference to a dictionary or the symbol-translation table may result in the storing of data at or to the right of the location designated by the final address in general register R1. This storing and the processing needed to produce the data stored will be repeated when COMPRESSION CALL is executed again to continue processing the same operands. The repeated processing will reduce the performance of the instruction execution, and it should be avoided by ensuring that the environment in which the program is executed is one in which page-translation-exception conditions for the dictionaries and symbol-translation table are infrequent.

5. Following is an example of how the compressed-data bit number (CBN) is used and set. In this example:

- The operation is an expansion operation.
- The CDSS in general register 0 is 0010 binary. Therefore, there are 1K entries in the expansion dictionary, and the length of an index symbol is 10 bits.

- The second operand (compressed-data operand) begins at location 6000 hex and has a length of five bytes. The initial CBN is 7. Therefore, there are three index symbols to be expanded, and the final CBN will be 5.

- The compressed data beginning at location 6000 hex is 0081FF9FF8 hex. Therefore, the three index symbols are 103, 3FC, and 3FF hex.

- The first operand (expanded-data operand) begins at location 5000 hex and has a length of 64 bytes. The three index symbols are expanded to a total of 14 bytes of expanded data.

The following figure shows the initial and final contents of general registers R1, R1+1, R2, and R2+1, the contents of locations 6000-6004 hex in binary, and the way a cursor corresponding to the CBN is advanced during the expansion operation.

6. The reason for allowing a parent to have no more than 260 children is as follows. The parent can contain five identical child characters. Then, 255 different sibling characters are possible — all of these must be different from the child characters and each other, or else they may be wasted (never matched against), depending on the implementation. Thus, every possible child is permitted.

7. Symbol translation is for use by VTAM. VTAM will begin by doing compression by means of software and an adaptive dictionary. When the adap-
tive dictionary has matured such that the degree of compression becomes sufficiently good (crosses some threshold), VTAM will “freeze” (stop adapting) its dictionary, inform the other end of the session to freeze also, transform its adaptive dictionary to the dictionary form used by COMPRESSION CALL, and then use COMPRESSION CALL to continue on with the compression. The other end of the session can continue to use its frozen adaptive dictionary.

Following is clarification about the STT offset. Assume VTAM uses a 4K-entry adaptive dictionary, which is the largest size VTAM uses. All of the entries in this dictionary correspond to character symbols because there are no sibling descriptors in the VTAM dictionary. The VTAM dictionary cannot map one-to-one to a COMPRESSION CALL dictionary because the latter requires that some of the entries be sibling descriptors. Therefore, VTAM must have an 8K-entry dictionary for use in the basic compression operation. Only the first hundred or so entries in the second 4K of the 8K need to be used, and these entries compensate for (take the place of) the entries in the first 4K that must be sibling descriptors. The STT can and should, to save space, begin immediately after those hundred or so entries in the second 4K. In this example, the index symbols will be 13 bits but will be transformed to 12-bit interchange symbols.

8. A program may place the dictionaries in pages that are managed by means of chaining fields at their beginnings. In this case, either the parts of a dictionary have to be moved to be compacted into contiguous locations or there have to be holes in the dictionaries. The definition of COMPRESSION CALL contains nothing explicitly to support holes. However, assuming there is at least one character that never appears in the expanded data, that character can be used as a child character in a parent entry or as a sibling character in a sibling descriptor to specify a child or children that will never be referenced, thus creating a hole.

9. The references to the operands, dictionaries, and symbol-translation table for COMPRESSION CALL may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

10. Setting the ZP control to one may provide improved performance on models in which the CMPSC-enhancement facility is installed.

11. Zero padding is not necessarily performed in every case where it is permissible.

12. Figure 7-184 on page 7-162 and Figure 7-185 on page 7-164 show possible forms (not the only possible forms) of the compression and expansion processes. The figures do not show testing for or the results of dictionary errors.

13. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

Note: If PPTR>256, the action can be:

Store PPTR as char in DST. Advance 1 index in SRC. Advance SYMLEN bytes in DST.
COMPUTE INTERMEDIATE MESSAGE DIGEST

KIMD  R1,R2  [RRE]

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R1 field are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-186 and Figure 7-187 show the assigned function codes for COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST, respectively. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for COMPUTE INTERMEDIATE MESSAGE DIGEST are as follows.

Explanation:
— Not applicable

1 For all data blocks except the last block. The size of the last data block ranges from 1 to one less than the value shown.

Figure 7-187. Function Codes for COMPUTE LAST MESSAGE DIGEST

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R2 and R2 + 1 are ignored for the query function. For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the chaining value. For COMPUTE
LAST MESSAGE DIGEST, the operation also uses a message bit length in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R2 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R2 general register. The number of bytes in the second-operand location is specified in general register \( R_2 + 1 \).

As part of the operation, the address in general register \( R_2 \) is incremented by the number of bytes processed from the second operand, and the length in general register \( R_2 + 1 \) is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register \( R_2 \) constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register \( R_2 \), carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register \( R_2 \) are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register \( R_2 \) constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register \( R_2 \), carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register \( R_2 \) is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register \( R_2 \) constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register \( R_2 \) and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register \( R_2 + 1 \) form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register \( R_2 + 1 \). In the 64-bit addressing mode, the contents of bit positions 0-63 of general register \( R_2 + 1 \) form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register \( R_2 + 1 \).

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers \( R_2 \) and \( R_2 + 1 \), always remain unchanged.

Figure 7-188 on page 7-167 shows the contents of the general registers just described.

In the access-register mode, access registers 1 and \( R_2 \) specify the address spaces containing the parameter block and second operand, respectively.

The result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. The operation is ended when all source bytes in the second operand have been processed (called normal completion), or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the chaining-value field overlaps any portion of the second operand, the result in the chaining-value field is unpredictable.

For COMPUTE INTERMEDIATE MESSAGE DIGEST, normal completion occurs when the number of bytes in the second operand as specified in general register \( R_2 + 1 \) have been processed. For COMPUTE LAST MESSAGE DIGEST, after all bytes in the second operand as specified in general register \( R_2 + 1 \) have been processed, the padding operation is performed, and then normal completion occurs.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in \( R_2 + 1 \) is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in \( R_2 + 1 \) is nonzero.

When the second-operand length is initially zero, the second operand is not accessed, general registers \( R_2 \) and \( R_2 + 1 \) are not changed, and condition code 0
is set. For COMPUTE INTERMEDIATE MESSAGE DIGEST, the parameter block is not accessed. However, for COMPUTE LAST MESSAGE DIGEST, the empty block \( L = 0 \) case padding operation is performed and the result is stored into the parameter block.

A PER storage-alteration event may be recognized for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the second-operand location and for the parameter block. When PER events are detected for one or more locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Access exceptions may be reported for a larger portion of the second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST functions. Further description of the secure hash algorithm may be found in Reference [13.] on page xxviii. Further description of the GCM (Galois/counter mode) multiplication over \( \text{GF}(2^{128}) \)
may be found in Reference [15.] on page xxviii.

**KIMD-Query (KIMD Function Code 0)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.

The parameter block used for the function has the following format:

```
Symbol | Explanation
------ | -----------
<n>    | Length of item in bytes
bda    | Block digest algorithm
ICV    | Initial chaining value
M      | Message block
OCV    | Output chaining value
```

**Figure 7-193. Parameter Block for KIMD-Query**

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE INTERMEDIATE MESSAGE DIGEST instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KIMD-Query function completes; condition code 3 is not applicable to this function.

**KIMD-SHA-1 (KIMD Function Code 1)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.
The parameter block used for the function has the following format:

<table>

*Figure 7-196. Parameter Block for KIMD-SHA-256*

A 32-byte intermediate message digest is generated for the 64-byte message blocks in operand 2 using the SHA-256 block digest algorithm with the 32-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-197.

**KIMD-SHA-256 (KIMD Function Code 2)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.

**KIMD-SHA-512 (KIMD Function Code 3)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.
A 64-byte intermediate message digest is generated for the 128-byte message blocks in operand 2 using the SHA-512 block digest algorithm with the 64-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-197.

**Figure 7-198. Parameter Block for KIMD-SHA-512**

The GHASH for the 16-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the hash subkey and the 128-bit chaining value.

The first message block is exclusive-ORed with the initial chaining value (ICV) in the parameter block. The result of the exclusive-OR operation and the hash subkey (H) are multiplied using a Galois/counter-mode (GCM) multiplication operation over a Galois field (GF(2^{128})) to produce the chaining value for the next message block. The process is repeated until all message blocks have been processed, or until a CPU-determined number of message blocks have been processed.

The GHASH, called the output chaining value (OCV), is stored into the Initial-chaining-value field of the parameter block. The operation is shown in Figure 7-201 on page 7-170.

**Figure 7-200. Parameter Block for KIMD-GHASH**

**KIMD-GHASH (Function Code 65)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.

**Figure 7-199. KIMD-SHA-512**

**Figure 7-201. KIMD-GHASH**

**KLMD-Query (KLMD Function Code 0)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.
The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Status Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
```

*Figure 7-202. Parameter Block for KLMD-Query*

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE LAST MESSAGE DIGEST instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KLMD-Query function completes; condition code 3 is not applicable to this function.

**KLMD-SHA-1 (KLMD Function Code 1)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.

The parameter block used for the function has the following format:

```
 | H0 |
 | H1 |
 | H2 |
 | H3 |
 | H4 |
```

*Figure 7-203. Parameter Block for KLMD-SHA-1*

The message digest for the message (M) in operand 2 is generated using the SHA-1 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the length of the message in operand 2 is equal to or greater than 64 bytes, an intermediate message digest is generated for each 64-byte message block using the SHA-1 block digest algorithm with the 20-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-204 and repeats until the remaining message is less than 64 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-205 is performed. If the length of the message or the remaining message is between one byte and 55 bytes inclusive, then the operation in Figure 7-206 is performed; if the length is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-207 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

**Additional Symbols Used in KLMD Functions**

The following additional symbols are used in the description of the COMPUTE LAST MESSAGE DIGEST functions.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Explanation for KLMD Function Figures</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>Byte length of operand 2 in storage.</td>

Figure 7-207. KLMD-SHA-1 Partial-Block Case 2 (56 ≤ L ≤ 63)

Figure 7-208. Parameter Block for KLMD-SHA-256
The message digest for the message (M) in operand 2 is generated using the SHA-256 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 64 bytes, an intermediate message digest is generated for each 64-byte message block using the SHA-256 block digest algorithm with the 32-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-209 and repeats until the remaining message is less than 64 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-210 is performed. If the length of the message or the remaining message is between one byte and 55 bytes inclusive, then the operation in Figure 7-211 is performed; if the length is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-212 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.
The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.

The parameter block used for the function has the following format:

<table>
<thead>
<tr>
<th>0</th>
<th>8</th>
<th>16</th>
<th>24</th>
<th>32</th>
<th>40</th>
<th>48</th>
<th>56</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>
<td>H0</td>
<td>H1</td>
<td>H2</td>
<td>H3</td>
<td>H4</td>
<td>H5</td>
<td>H6</td>
<td>H7</td>

</tr>
<tr>
<td>ICV &lt;32&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The message digest for the message (M) in operand 2 is generated using the SHA-512 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 128 bytes, an intermediate message digest is generated for each 128-byte message block using the SHA-512 block digest algorithm with the 64-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-214 and repeats until the remaining message is less than 128 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-215 is performed. If the length of the message or the remaining message is between one byte and 111 bytes inclusive, then the operation in Figure 7-216 is performed; if the length is between 112 bytes and 127 bytes inclusive, then the operation in Figure 7-217 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

---

**Figure 7-212. KLMD-SHA-256 Partial-Block Case 2 (56 ≤ L ≤ 63)**

**KLMD-SHA-512 (KLMD Function Code 3)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-188 on page 7-167.

The parameter block used for the function has the following format:

<table>
<thead>
<tr>
<th>0</th>
<th>8</th>
<th>16</th>
<th>24</th>
<th>32</th>
<th>40</th>
<th>48</th>
<th>56</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

The message digest for the message (M) in operand 2 is generated using the SHA-512 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 128 bytes, an intermediate message digest is generated for each 128-byte message block using the SHA-512 block digest algorithm with the 64-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-214 and repeats until the remaining message is less than 128 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-215 is performed. If the length of the message or the remaining message is between one byte and 111 bytes inclusive, then the operation in Figure 7-216 is performed; if the length is between 112 bytes and 127 bytes inclusive, then the operation in Figure 7-217 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

---

**Figure 7-213. Parameter Block for KLMD-SHA-512**

**Figure 7-214. KLMD-SHA-512 Full Block (L ≥ 128)**
Special Conditions for KIMD and KLMD

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
3. The \( R_2 \) field designates an odd-numbered register or general register 0.
4. For \texttt{COMPUTE INTERMEDIATE MESSAGE DIGEST}, the second-operand length is not a multiple of the data block size of the designated function (see Figure 7-186 on page 7-165 for \texttt{COMPUTE INTERMEDIATE MESSAGE DIGEST} functions). This specification-exception condition does not apply to the query function, nor does it apply to \texttt{COMPUTE LAST MESSAGE DIGEST}. 

---

**Figure 7-215. KLMD-SHA-512 Empty Block \((L = 0)\)**

**Figure 7-216. KLMD-SHA-512 Partial-Block Case 1 \((1 \leq L \leq 111)\)**

**Figure 7-217. KLMD-SHA-512 Partial-Block Case 2 \((112 \leq L \leq 127)\)**
**Resulting Condition Code:**

0  Normal completion  
1  --  
2  --  
3  Partial completion

**Program Exceptions:**

- Access (fetch, operand 2 and message bit length; fetch and store, chaining value)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case. |
| 7.B  | Operation exception. |
| 7.C  | Transaction constraint |
| 8.   | Specification exception due to invalid function code or invalid register number. |
| 9.   | Specification exception due to invalid operand length. |
| 10.  | Condition code 0 due to second-operand length originally zero. |
| 11.  | Access exceptions for an access to the parameter block or second operand. |
| 12.  | Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero). |
| 13.  | Condition code 3 due to partial completion (second-operand length still nonzero). |

Figure 7-218. Priority of Execution: KIMD and KLMD

**Programming Notes:**

1. Bit 56 of general register 0 is reserved for future extension and should be set to zero.
2. When condition code 3 is set, the second operand address and length in general registers $R_2$ and $R_2 + 1$, respectively, and the chaining-value in the parameter block are usually updated such that the program can simply branch back to the instruction to continue the operation.

For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

3. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

4. The instructions COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST are designed to be used by a security service application programming interface (API). These APIs provide the program with means to compute the digest of messages of almost unlimited size, including those too large to fit in storage all at once. This is accomplished by permitting the program to pass the message to the API in parts. The following programming notes are described in terms of these APIs.

5. Before processing the first part of a message, the program must set the initial values for the chaining-value field. For SHA-1, the initial hexadecimal chaining values are listed as follows:

   \[
   \begin{align*}
   H_0 &= 67452301 \\
   H_1 &= EFCDAF89 \\
   H_2 &= 98BA5C13 \\
   H_3 &= 10325476 \\
   H_4 &= C3D25106 \\
   H_5 &= 9B05688C \\
   H_6 &= 1F83D9AB \\
   H_7 &= 5BE0CD19
   \end{align*}
   \]

For SHA-256, the initial hexadecimal chaining values are listed as follows:

   \[
   \begin{align*}
   H_0 &= 6A09E667 \\
   H_1 &= BB67AE85 \\
   H_2 &= 3C6EF372 \\
   H_3 &= A54FF53A \\
   H_4 &= 510E527F \\
   H_5 &= 9B05688C \\
   H_6 &= 1F83D9AB \\
   H_7 &= 5BE0CD19
   \end{align*}
   \]
For SHA-512, the initial hexadecimal chaining value are listed as follows:

- H0 = 6A09 E667 F3BC C908
- H1 = BB67 AE85 84CA A73B
- H2 = 3C6E F372 FE94 F82B
- H3 = A54F F53A 5F1D 36F1
- H4 = 510E 527F ADE6 82D1
- H5 = 9B05 688C 2B3E 6C1F
- H6 = 1F83 D9AB FB41 BD6B
- H7 = 5BE0 CD19 137E 2179

6. When computing a message digest, the program may not initially be aware of the total message-bit length; for example, for a message being read from an I/O device, the message-bit length may not be known until the final block is read. When computing a message digest for a message whose length is not known, or for a message where it is known that the last message block is not included in the calculation, COMPUTE INTERMEDIATE MESSAGE DIGEST may be used. When computing a message digest for a message that includes the last block, COMPUTE LAST MESSAGE DIGEST must be used.

7. When processing the last message part, the program must compute the length of the original message in bits and place this length value in the message-bit-length field of the parameter block, and use the COMPUTE LAST MESSAGE DIGEST instruction.

8. For SHA functions, the COMPUTE LAST MESSAGE DIGEST instruction does not require the second operand to be a multiple of the data block size. It first processes complete blocks, and may set condition code 3 before processing all blocks. After processing all complete blocks, it then performs the padding operation including the remaining portion of the second operand. This may require one or two iterations of the designated block digest algorithm.

9. For SHA functions, the COMPUTE LAST MESSAGE DIGEST instruction provides the SHA padding for messages that are a multiple of eight bits in length. If a SHA function is to be applied to a bit string which is not a multiple of eight bits, the program must perform the SHA padding and use the COMPUTE INTERMEDIATE MESSAGE DIGEST instruction.

10. The SHA-224 algorithm is the same as the SHA-256 algorithm, except that the initial chaining values and the final message digest lengths are different. The program may obtain the SHA-224 message digest using the SHA-256 functions with the following two actions:

   a. The following initial hexadecimal chaining values for SHA-224 are used:

      - H0 = C105 9ED8
      - H1 = 367C D507
      - H2 = 3070 DD17
      - H3 = F70E 5939
      - H4 = FFC0 0B31
      - H5 = 6858 1511
      - H6 = 64F9 8FA7
      - H7 = BEFA 4FA4

   b. The 224-bit message digest is obtained by truncating the final message digest to its leftmost 224 bits.

11. The SHA-384 algorithm is the same as the SHA-512 algorithm, except that the initial chaining values and the final message digest lengths are different. The program may obtain the SHA-384 message digest using the SHA-512 functions with the following two actions:

   a. The following initial hexadecimal chaining values for SHA-384 are used:

      - H0 = CBBB 9D5D C105 9ED8
      - H1 = 629A 292A 367C D507
      - H2 = 9159 015A 3070 DD17
      - H3 = 152F ECD8 F70E 5939
      - H4 = 6733 2667 FFC0 0B31
      - H5 = 8EB4 4A87 6858 1511
      - H6 = DB0C 2E0D 64F9 8FA7
      - H7 = 47B5 481D BEFA 4FA4

   b. The 384-bit message digest is obtained by truncating the final message digest to its leftmost 384 bits.

12. For the COMPUTE INTERMEDIATE MESSAGE DIGEST GHASH function, the hash subkey, H, is the result of encrypting a 128-bit zero using the AES encryption algorithm with a 128-bit, 192-bit, or 256-bit cryptographic key.

13. The following applies to the message-bit length (MBL) in the parameter block of COMPUTE LAST MESSAGE DIGEST:

   a. The MBL is completely independent of the second-operand length in general register R2.
b. Regardless of whether the instruction ends with condition code 0 or 3, the MBL is not decremented by the number of bytes processed.

c. In normal usage, the MBL is expected to be eight times the total size of the message in bytes. If the program supplies a MBL that is not a multiple of eight, the results will be algorithmically correct, but may not be usable in any practical application.

d. The secure-hash algorithm described in Reference [13.] on page xxviii allows for message-bit length that are not multiples of eight. COMPUTE LAST MESSAGE DIGEST requires the message-bit length to be a multiple of eight.

### COMPUTE MESSAGE AUTHENTICATION CODE

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R₁ field are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-219 shows the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for COMPUTE MESSAGE AUTHENTICATION CODE are as follows.

Explanation:

— Not applicable

Figure 7-219. Function Codes for COMPUTE MESSAGE AUTHENTICATION CODE

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R₂ and R₂ + 1 are ignored.

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the initial chaining value. The operation also uses a cryptographic key in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R₂ field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.
The location of the leftmost byte of the second operand is specified by the contents of the \(R_2\) general register. The number of bytes in the second-operand location is specified in general register \(R_2 + 1\).

As part of the operation, the address in general register \(R_2\) is incremented by the number of bytes processed from the second operand, and the length in general register \(R_2 + 1\) is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register \(R_2\) constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register \(R_2\), carries out of bit position 40 of the updated address are ignored and, the contents of bit positions 32-39 of general register \(R_2\) are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register \(R_2\) constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register \(R_2\), carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register \(R_2\) is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register \(R_2\) constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register \(R_2\) and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register \(R_2 + 1\) form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register \(R_2 + 1\). In the 64-bit addressing mode, the contents of bit positions 0-63 of general register \(R_2 + 1\) form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register \(R_2 + 1\).

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers \(R_2\) and \(R_2 + 1\), always remain unchanged.

Figure 7-220 on page 7-180 shows the contents of the general registers just described.

In the access-register mode, access registers 1 and \(R_2\) specify the address spaces containing the parameter block and second operand, respectively.

The result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. The operation is ended when all source bytes in the second operand have been processed (called normal completion), or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the initial-chaining-value field overlaps any portion of the second operand, the result in the chaining-value field is unpredictable.

Normal completion occurs when the number of bytes in the second operand as specified in general register \(R_2 + 1\) have been processed.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in \(R_2 + 1\) is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in \(R_2 + 1\) is nonzero.

When the second-operand length is initially zero, the second operand and the parameter block are not accessed, general registers \(R_2\) and \(R_2 + 1\) are not changed, and condition code 0 is set.

A PER storage-alteration event may be recognized for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the second-operand location and for the parameter block. When PER events are detected for one or more locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operand may be multiple-access references,
accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

For functions that perform a comparison of the encrypted cryptographic key with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first and second operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of the second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the COMPUTE MESSAGE AUTHENTICATION CODE functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key. Further description of the data-encryption algorithm may be found in Reference [11.] on page xxviii. Further description of the AES standard may be found in Reference [12.] on page xxviii.

Figure 7-220. General Register Assignment for KMAC

Figure 7-221. Symbol For Bit-Wise Exclusive OR
**KMAC-Query (Function Code 0)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.

The parameter block used for the function has the following format:

```
0 Status Word
```

**Figure 7-226. Parameter Block for KMAC-Query**

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the KMAC instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMAC-Query function completes; condition codes 1 and 3 are not applicable to this function.

**KMAC-DEA (Function Code 1)**

**KMAC-Encrypted-DEA (Function Code 9)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.
The parameter block used for the KMAC-DEA function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Chaining Value (CV)</td>
</tr>
<tr>
<td>8</td>
<td>Cryptographic Key (K)</td>
</tr>
</tbody>
</table>

Figure 7-227. Parameter Block for KMAC-DEA

For the KMAC-DEA function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMAC-Encrypted-DEA function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>8</td>
<td>Encrypted Cryptographic Key (WK_d(K))</td>
</tr>
<tr>
<td>16</td>
<td>DEA Wrapping-Key</td>
</tr>
<tr>
<td>24</td>
<td>Verification Pattern (WK_dVP)</td>
</tr>
</tbody>
</table>

Figure 7-228. Parameter Block for KMAC-Encrypted-DEA

For the KMAC-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-374, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the DEA algorithm with the 64-bit cryptographic key and the 64-bit initial chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-229.

![Figure 7-229. MAC Computation Using 64-bit DEA Key](image)

**KMAC-TDEA-128 (Function Code 2)**

**KMAC-Encrypted-TDEA-128 (Function Code 10)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.

The parameter block used for the KMAC-TDEA-128 function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (CV)</td>
</tr>
<tr>
<td>8</td>
<td>Cryptographic Key 1 (K1)</td>
</tr>
<tr>
<td>16</td>
<td>Cryptographic Key 2 (K2)</td>
</tr>
</tbody>
</table>

Figure 7-230. Parameter Block for KMAC-TDEA-128

For the KMAC-TDEA-128 function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.
The parameter block used for the KMAC-Encrypted-TDEA-128 function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>8</td>
<td>Encrypted Cryptographic Key (WKd(K))</td>
</tr>
<tr>
<td>16</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
</tbody>
</table>

For the KMAC-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-374, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the TDEA algorithm with the two 64-bit cryptographic keys and the 64-bit initial chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-232.

---

**KMAC-TDEA-192 (Function Code 3)**

**KMAC-Encrypted-TDEA-192 (Function Code 11)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.

The parameter block used for the KMAC-TDEA-192 function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (CV)</td>
</tr>
<tr>
<td>8</td>
<td>Cryptographic Key 1 (K1)</td>
</tr>
<tr>
<td>16</td>
<td>Cryptographic Key 2 (K2)</td>
</tr>
<tr>
<td>24</td>
<td>Cryptographic Key 3 (K3)</td>
</tr>
</tbody>
</table>

For the KMAC-TDEA-192 function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31 of the parameter block.
The parameter block used for the KMAC-Encrypted-TDEA-192 function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>8</td>
<td>Encrypted Cryptographic Key</td>
</tr>
<tr>
<td>16</td>
<td>(WKd(K))</td>
</tr>
<tr>
<td>24</td>
<td>DEA Wrapping-Key Verification Pattern</td>
</tr>
<tr>
<td>32</td>
<td>(WKd(VP))</td>
</tr>
</tbody>
</table>

For the KMAC-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-374, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the TDEA algorithm with the three 64-bit cryptographic keys and the 64-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-235.

KMAC-AES-128 (Function Code 18)

KMAC-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.

The parameter block used for the KMAC-AES-128 function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>8</td>
<td>Cryptographic Key (K)</td>
</tr>
</tbody>
</table>

For the KMAC-AES-128 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-31 of the parameter block.
The parameter block used for the KMAC-Encrypted-AES-128 function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>8</td>
<td>Encrypted Cryptographic Key</td>
</tr>
<tr>
<td>16</td>
<td>(WK,&lt;K&gt;)</td>
</tr>
<tr>
<td>24</td>
<td>AES Wrapping-Key Verification Pattern</td>

</tr>
<tr>
<td>56</td>
<td></td>
</tr>
</tbody>
</table>
```

**Figure 7-237. Parameter Block for KMAC-Encrypted-AES-128**

For the KMAC-Encrypted-AES-128 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the AES algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-238.

**Figure 7-238. KMAC-AES-128**

**KMAC-AES-192 (Function Code 19)**

**KMAC-Encrypted-AES-192 (Function Code 27)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.

The parameter block used for the KMAC-AES-192 function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>8</td>
<td>Cryptographic Key (K)</td>
</tr>
<tr>
<td>16</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td></td>
</tr>
<tr>
<td>32</td>
<td></td>
</tr>
</tbody>
</table>
```

**Figure 7-239. Parameter Block for KMAC-AES-192**

For the KMAC-AES-192 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-39 of the parameter block.
The parameter block used for the KMAC-Encrypted-AES-192 function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-15</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>16-47</td>
<td>Encrypted Cryptographic Key (WKa(K))</td>
</tr>
<tr>
<td>48-57</td>
<td>AES Wrapping-Key Verification Pattern (WKaVP)</td>
</tr>
</tbody>
</table>
```

For the KMAC-Encrypted-AES-192 function, the contents of byte offsets 40-71 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-39 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the AES algorithm with the 192-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-241.

```
Figure 7-240. Parameter Block for KMAC-Encrypted-AES-192
```

**KMAC-AES-256 (Function Code 20)**

**KMAC-Encrypted-AES-256 (Function Code 28)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-220 on page 7-180.

The parameter block used for the KMAC-AES-256 function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-15</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>16-47</td>
<td>Cryptographic Key (K)</td>
</tr>
</tbody>
</table>
```

For the KMAC-AES-256 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

```
Figure 7-242. Parameter Block for KMAC-AES-256
```
The parameter block used for the KMAC-Encrypted-AES-256 function has the following format:

```
<table>
<thead>
<tr>
<th>0</th>
<th>8</th>
<th>16</th>
<th>24</th>
<th>32</th>
<th>40</th>
<th>48</th>
<th>56</th>
<th>64</th>
<th>72</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICV</td>
<td>K</td>
<td>AES</td>
<td>XOR</td>
<td>AES</td>
<td>XOR</td>
<td>AES</td>
<td>XOR</td>
<td>AES</td>
<td>OCV</td>
</tr>
</tbody>
</table>
```

For the KMAC-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the AES algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-244.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unsigned or uninstalled function code.
3. The Rx field designates an odd-numbered register or general register 0.
4. The second-operand length is not a multiple of the data block size of the designated function (see Figure 7-219 on page 7-178 to determine the data block size for COMPUTE MESSAGE AUTHENTICATION CODE functions).

Resulting Condition Code:

0  Normal completion
1  Verification-pattern mismatch
2  --
3  Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, and wrapping-key verification pattern; fetch and store, chaining value)
- Operation (if the message-security assist is not installed)
- Specification
**Programming Notes:**

1. When condition code 3 is set, the second operand and address and length in general registers $R_x$ and $R_{x+1}$, respectively, and the initial-chaining value in the parameter block are usually updated such that the program can simply branch back to the instruction to continue the operation. For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

2. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the initial chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

3. Before processing the first part of a message, the program must set the initial values for the initial-chaining-value field. To comply with ANSI X9.9, ANSI X9.19, or Reference [15.] on page xxviii, the initial chaining value shall be set to all binary zeros.

**CONVERT TO BINARY**

For CONVERT TO BINARY (CVB, CVBY), the second operand occupies eight bytes in storage, and, for CONVERT TO BINARY (CVBG), the second operand occupies sixteen bytes in storage. The second operand has the format of signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” It is checked for valid sign and digit codes, and a general-operand data exception is recognized when an invalid code is detected.

For CONVERT TO BINARY (CVB, CVBY), the result of the conversion is a 32-bit signed binary integer, which is placed in bit positions 32-63 of general register $R_1$. Bits 0-31 of the register remain unchanged. The maximum positive number that can be converted and still be contained in 32 bit positions is 2,147,483,647; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -2,147,483,648.

For any decimal number outside this range, the operation is completed by placing the 32 rightmost bits of the binary result in the register, and a fixed-point-divide exception is recognized.
For CONVERT TO BINARY (CVBG), the result of the conversion is a 64-bit signed binary integer, which is placed in bit positions 0-63 of general register R1. The maximum positive number that can be converted and still be contained in a 64-bit register is 9,223,720,368,547,758,077; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -9,223,720,368,547,758,080. For any decimal number outside this range, a fixed-point-divide exception is recognized, and the operation is suppressed.

The displacement for CVB is treated as a 12-bit unsigned binary integer. The displacement for CVBY and CVBG is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Data with DXC 0, general operand
- Fixed-point divide
- Operation (CVBY, if the long-displacement facility is not installed)
- Transaction constraint

**Programming Notes:**
1. An example of the use of the CONVERT TO BINARY instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When the second operand is negative, the result is in two’s-complement notation.
3. The storage-operand references for CONVERT TO BINARY may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

### CONVERT TO DECIMAL

For CONVERT TO DECIMAL (CVD, CVDY), the first operand is treated as a 32-bit signed binary integer, and the result occupies eight bytes in storage. For CONVERT TO DECIMAL (CVDG), the first operand is treated as a 64-bit signed binary integer, and the result occupies sixteen bytes in storage.

The result is in the format for signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” The rightmost four bits of the result represent the sign. A positive sign is encoded as 1100; a negative sign is encoded as 1101.

The displacement for CVD is treated as a 12-bit unsigned binary integer. The displacement for CVDY and CVDG is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Operation (CVDY, if the long-displacement facility is not installed)
- Transaction constraint

**Programming Notes:**
1. An example of the use of the CONVERT TO DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For CVD and CVDY, the number to be converted is a 32-bit signed binary integer obtained from a general register. Since 15 decimal digits are available for the result, and the decimal equivalent of 31 bits requires at most 10 decimal digits, an overflow cannot occur. Similarly, for CVDG, 31 decimal digits are available, the decimal equivalent of 63 bits is at most 19 digits, and an overflow cannot occur.
3. The storage-operand references for CONVERT TO DECIMAL may be multiple-access refer-
CONVERT UTF-16 TO UTF-32

The two-byte UTF-16 (Unicode) characters of the second operand are converted to UTF-32 characters and placed at the first-operand location. The UTF-32 characters are four bytes. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid Unicode character is encountered, whichever occurs first. The result is indicated in the condition code.

The R1 and R2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R1 and R2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers R1 + 1 and R2 + 1, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers R1 + 1 and R2 + 1, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R1 and R2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-246 on page 7-191.
When the ETF3-enhancement facility is installed, the M3 field has the following format:

The bits of the M3 field are defined as follows:

- **Unassigned**: Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

- **Enhanced Well-Formedness-Checking (W)**: The W bit, bit 3 of the M3 field, controls whether enhanced well-formedness checking of the Unicode characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The characters resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted or a CPU-determined number of second-operand characters have been converted.
To show the method of converting a UTF-16 character to a UTF-32 character, the bits of a Unicode character are identified by letters as follows:

<table>
<thead>
<tr>
<th>Unicode Character Bit Numbers</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
<th>13</th>
<th>14</th>
<th>15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>a</td>

<th>22</th>
<th>23</th>
<th>24</th>
<th>25</th>
<th>26</th>
<th>27</th>
<th>28</th>
<th>29</th>
<th>30</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>k</td>
<td>l</td>
<td>m</td>
<td>n</td>
<td>o</td>
<td>p</td>
<td>q</td>
<td>r</td>
<td>s</td>
<td>t</td>
</tr>
</tbody>
</table>

Any Unicode character in the range 0000 to D7FF or DC00 to FFFF hex is converted to a four-byte UTF-32 character as follows:

<table>
<thead>
<tr>
<th>Unicode Character</th>
<th>abcdefghijklmnop</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-32 Character</td>
<td>0000000000000000abcdefghijklmnop</td>
</tr>
</tbody>
</table>

Any Unicode surrogate pair starting with a high surrogate in the range D800 to DBFF hex is converted to a four-byte UTF-32 character as follows:

<table>
<thead>
<tr>
<th>Unicode Characters</th>
<th>110110abcdefghijklmnop</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-32 Character</td>
<td>00000000000000000000000000000000abcdefghijklmnop</td>
</tr>
</tbody>
</table>

where $uvwxy = abcd + 1$

When the ETF3-enhancement facility is not installed, or when the W bit of the $M_3$ field is zero, the first six bits of the Unicode low surrogate are ignored. When the ETF3-enhancement facility is installed, and the W bit is one, the first six bits of the Unicode low surrogate must contain 110111 binary; otherwise, the Unicode low surrogate is invalid, and condition code 2 is set.

The second-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes when the first two bytes are a Unicode high surrogate. The first-operand location is considered exhausted when it does not contain at least four remaining bytes.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register $R_2$ are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register $R_1$ are incremented by the same number. When general registers $R_1$ and $R_2$ are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers $R_1$, $R_1 + 1$, $R_2$, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register $R_2$ contains the address of the invalid Unicode high surrogate that precedes the invalid low surrogate.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the $R_1$ register is the same register as the $R_2$ register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.
Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

**Resulting Condition Code:**
- 0  Entire second operand processed
- 1  End of first operand reached
- 2  Invalid Unicode low surrogate
- 3  CPU-determined number of characters converted

**Program Exceptions:**
- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

**Programming Notes:**
1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UTF-16 TO UTF-32 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The CONVERT UTF-16 TO UTF-32 instruction supports UTF-16 and UTF-32 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.
When the ETF3-enhancement facility is installed, the M3 field has the following format:

```
/ / / W
0 3
```

The bits of the M3 field are defined as follows:

- **Unassigned**: Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- **Enhanced Well-Formedness-Checking (W)**: The W bit, bit 3 of the M3 field, controls whether enhanced well-formedness checking of the Unicode characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid Unicode character is encountered in the second operand.
To show the method of converting a Unicode character to a UTF-8 character, the bits of a Unicode character are identified by letters as follows:

<table>
<thead>
<tr>
<th>Unicode Character Bit Numbers</th>
<th>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

<table>
<thead>
<tr>
<th>Unicode High Surrogate Bit Numbers</th>
<th>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</th>

<tr>
<th>Unicode Low Surrogate Bit Numbers</th>
<th>16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>110111a b c d e f g h i j k l m n o p q r s t</td>
</tr>
</tbody>
</table>

Any Unicode character in the range 0000 to 007F hex is converted to a one-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>Unicode Character</th>
<th>000000000</th>
<th>j k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-8 Character</td>
<td>0 j k l m n o p</td>
<td></td>
</tr>
</tbody>
</table>

Any Unicode character in the range 0080 to 07FF hex is converted to a two-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>Unicode Character</th>
<th>00000f g h i</th>
<th>j k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-8 Character</td>
<td>110f g h i j k l m n o p</td>
<td></td>
</tr>
</tbody>
</table>

Any Unicode character in the range 0800 to D7FF or DC00 to FFFF hex is converted to a three-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>Unicode Character</th>
<th>abcdef g h i j k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-8 Character</td>
<td>1110abcd10ef g h i j k l m n o p</td>
</tr>
</tbody>
</table>

Any Unicode surrogate pair starting with a high surrogate in the range D800 to DBFF hex is converted to a four-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>Unicode Characters</th>
<th>110110abc d e f g h i 110111k l m n o p q r s t</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-8 Character</td>
<td>11110uvw10xy e f g h i j k l m n o p q r s t</td>
</tr>
</tbody>
</table>

When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 field is zero, the first six bits of the Unicode low surrogate are ignored. When the ETF3-enhancement facility is installed, and the W bit is one, the first six bits of the Unicode low surrogate must contain 110111 binary; otherwise, the Unicode low surrogate is invalid, and condition code 2 is set.

The second-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes when the first two bytes are a Unicode high surrogate. The first-operand location is considered exhausted when it does not contain at least the one, two, three, or four remaining bytes required to contain the UTF-8 character resulting from the conversion of the next second-operand character or surrogate pair.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R_x + 1 are decremented by the number of bytes converted, and the contents of general register R_y are incremented by the same number. Also, the contents of general register R_1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_y are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.
In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers \( R_1 \), \( R_1 + 1 \), \( R_2 \), and \( R_2 + 1 \) always remain unchanged.

When condition code 2 is set, general register \( R_2 \) contains the address of the invalid Unicode high surrogate that precedes the invalid low surrogate.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the \( R_1 \) register is the same register as the \( R_2 \) register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the \( R \) field associated with that operand is odd.

**Resulting Condition Code:**

0  Entire second operand processed  
1  End of first operand reached  
2  Invalid Unicode low surrogate  
3  CPU-determined number of characters converted

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)  
- Specification  
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UNICODE TO UTF-8 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The CONVERT UTF-16 TO UTF-8 (CONVERT UNICODE TO UTF-8) instruction supports UTF-16 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

**CONVERT UTF-32 TO UTF-16**

CU42 \( R_1, R_2 \) \( [\text{RRE}] \)

\[
\begin{array}{c|c|c|c|c}
0 & 16 & 24 & 28 & 31 \\
\hline
\text{B9B3} & / & / & / & / \\
\hline
R_1 & R_2 \\
\end{array}
\]

The four-byte UTF-32 characters of the second operand are converted to two-byte UTF-16 characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-32 character is encountered, whichever occurs first. The result is indicated in the condition code.

The \( R_1 \) and \( R_2 \) fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers \( R_1 \) and \( R_2 \), respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers \( R_1 + 1 \) and \( R_2 + 1 \), respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers \( R_1 + 1 \) and \( R_2 + 1 \), respectively, and those contents are treated as 64-bit unsigned binary integers.
The handling of the addresses in general registers $R_1$ and $R_2$ is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers $R_1$ and $R_2$ constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-248 on page 7-197.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-32 character is encountered in the second operand.

To show the method of converting a UTF-32 character to a UTF-16 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or
The bits of a UTF-32 character in the range 0000 to D7FF or DC00 to FFFF hex are identified by letters as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</td>
<td>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
</tr>
</tbody>
</table>

The bits of a UTF-32 character in the range 00010000 to 0010FFFF hex are identified by letters as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</td>
<td>a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

When a CPU-determined number of characters have been processed, condition code 3 is set.

When the contents of the next UTF-32 character are in the range 0000D800 to 0000DBFF or 00110000 to FFFFFFFF hex, the character is invalid, and condition code 2 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R2 + 1 are decremented by the number of bytes converted, and the contents of general register R2 are incremented by the same number. Also, the contents of general register R1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R1 are incremented by the same number. When
general registers R₁ and R₂ are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R₁, R₁ + 1, R₂, and R₂ + 1, always remain unchanged.

When condition code 2 is set, general register R₂ contains the address of the invalid UTF-32 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R₁ register is the same register as the R₂ register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

**Resulting Condition Code:**

0  Entire second operand processed
1  End of first operand reached
2  Invalid UTF-32 character
3  CPU-determined number of characters processed

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UTF-32 TO UTF-16 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The CONVERT UTF-32 TO UTF-16 instruction supports UTF-16 and UTF-32 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

**CONVERT UTF-32 TO UTF-8**

CU41  R₁R₂  [RRE]

```
<table>
<thead>
<tr>
<th>0</th>
<th>16</th>
<th>24</th>
<th>28</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B9B2'</td>
<td>/ / / / / / / R₁</td>
<td>R₂</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The four-byte UTF-32 characters of the second operand are converted to UTF-8 characters and placed at the first-operand location. The UTF-8 characters are one, two, three, or four bytes, depending on the Unicode characters that are converted. The operation proceeds until the end of the first or second operand is reached or a CPU-determined number of characters have been converted, whichever occurs first. The result is indicated in the condition code.

The R₁ and R₂ fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R₁ and R₂, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers R₁ + 1 and R₂ + 1, respec-
tively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers \( R_1 + 1 \) and \( R_2 + 1 \), respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers \( R_1 \) and \( R_2 \) is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers \( R_1 \) and \( R_2 \) constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-249 on page 7-200.

![Figure 7-249. Register Contents for CONVERT UTF-32 TO UTF-8](image-url)

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted or a CPU-determined number of second-operand characters have been converted.

To show the method of converting a UTF-32 character to a UTF-8 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or...
0000DC00 to 0000FFFF hex are identified by letters as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7</td>
<td>0 0 0 0 0 0 0 0</td>
</tr>
</tbody>
</table>

The bits of a UTF-32 character in the range 00010000 to 0010FFFF hex (UTF-16 surrogate pair) are identified by letters as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</td>
<td>a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

Any UTF-32 character in the range 00000000 to 000007FF hex is converted to a one-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</td>
<td>0 0 0 0 0 0 0 0 0 u v w x y</td>
</tr>
</tbody>
</table>

Any UTF-32 character in the range 00000080 to 000007FF hex is converted to a two-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</td>
<td>e f g h i j k l m n o p q r s t</td>
</tr>
</tbody>
</table>

Any UTF-32 character in the range 00000000 to 000007FF hex is converted to a three-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7</td>
<td>0 0 0 0 0 0 0 0 0 j k l m n o p</td>
</tr>
</tbody>
</table>

Any UTF-32 character in the range 00000000 to 00000000 or 0000D7FF or 0000DC00 to 0000FFFF hex is converted to a three-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7</td>
<td>0 0 0 0 0 0 0 a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

Any UTF-32 character in the range 00001000 to 0010FFFF hex is converted to a four-byte UTF-8 character as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7</td>
<td>0 0 0 0 0 0 0 u v w x y e f g h i j k l m n o p q r s t</td>
</tr>
</tbody>
</table>

The second-operand location is considered exhausted when it does not contain at least four remaining bytes. The first-operand location is considered exhausted when it does not contain at least the one, two, three, or four remaining bytes required to contain the UTF-8 character resulting from the conversion of the next second-operand character or surrogate pair.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the contents of the next UTF-32 character are in the range 0000D800 to 0000DBFF or 00110000 to FFFFFFFF hex, the character is invalid, and condition code 2 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R2 + 1 are decremented by the number of bytes converted, and the contents of general register R2 are incremented by the same number. Also, the contents of general register R1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R1 are incremented by the same number. When general registers R1 and R2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R1, R1 + 1, R2, and R2 + 1, always remain unchanged.

When condition code 2 is set, general register R2 contains the address of the invalid UTF-32 character.
When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the $R_1$ register is the same register as the $R_2$ register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the $R$ field associated with that operand is odd.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Entire second operand processed</td>
</tr>
<tr>
<td>1</td>
<td>End of first operand reached</td>
</tr>
<tr>
<td>2</td>
<td>Invalid UTF-32 character</td>
</tr>
<tr>
<td>3</td>
<td>CPU-determined number of characters converted</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UTF-32 TO UTF-8 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The CONVERT UTF-32 TO UTF-8 instruction supports UTF-32 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

**CONVERT UTF-8 TO UTF-16**

The one-, two-, three-, or four-byte UTF-8 characters of the second operand are converted to two-byte Unicode characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-8 character is encountered, whichever occurs first. The result is indicated in the condition code.

The $R_1$ and $R_2$ fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers $R_1$ and $R_2$, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.
The handling of the addresses in general registers $R_1$ and $R_2$ is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers $R_1$ and $R_2$ constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-250 on page 7-203.

When the ETF3-enhancement facility is installed, the $M_3$ field has the following format:

$$
\begin{array}{c}
\text{Unassigned:} \\
\text{Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.} \\
\text{Enhanced Well-Formedness-Checking (W):} \\
\text{The W bit, bit 3 of the $M_3$ field, controls whether enhanced well-formedness checking of the UTF-8 characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.}
\end{array}
$$

![Figure 7-250. Register Contents for CONVERT UTF-8 TO UTF-16](image-url)
When the ETF3-enhancement facility is not installed, the M₃ field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-8 character is encountered in the second operand.

To show the method of converting a UTF-8 character to a Unicode character, the bits of a Unicode character are identified by letters as follows:

<table>
<thead>
<tr>
<th>Unicode Character Bit Numbers</th>
<th>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

<table>
<thead>
<tr>
<th>Unicode High Surrogate Bit Numbers</th>
<th>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>1 1 0 1 1 0 a b c d e f g h i j</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Unicode Low Surrogate Bit Numbers</th>
<th>16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying Bit Letters</td>
<td>1 1 0 1 1 1 k l m n o p q r s t</td>
</tr>
</tbody>
</table>

Conversion of a UTF-8 character to a Unicode character is as follows:

1. When the contents of the first byte of a UTF-8 character are in the range 00 to 7F hex, the character is a one-byte character, and it is converted to a two-byte Unicode character as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>0 j k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unicode Character</td>
<td>0 0 0 0 0 0 0 0 j k l m n o p</td>
</tr>
</tbody>
</table>

2. When the contents of the first byte of the UTF-8 character are in the range 80 to BF hex, the character is invalid. When the ETF3-enhancement facility is installed, the W bit of the M₃ field is one, and the contents of the first byte of the UTF-8 character are in the range C0 to C1 hex, the character is also invalid.

3. When the ETF3-enhancement facility is not installed or the W bit of the M₃ field is zero, and the contents of the first byte of the UTF-8 character are in the range of C0 to DF hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of C2 to DF hex; the character is a two-byte character, and it is converted to a two-byte Unicode character as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>110 f g h i j 10 k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unicode Character</td>
<td>0 0 0 0 0 f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

When the ETF3-enhancement facility is not installed or when the W bit of the M₃ field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M₃ field is one, the contents of the second byte of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

4. When the contents of the first byte of a UTF-8 character are in the range E0 to EF hex, the character is a three-byte character, and it is converted to a two-byte Unicode character as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>1110 a b c d 0 e f g h i j 10 k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unicode Character</td>
<td>a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

When the ETF3-enhancement facility is not installed or when the W bit of the M₃ field is zero, the first two bits in the second and third bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M₃ field is one, the contents of the second and third bytes of the UTF-8 character must be as follows:

- When the first byte is E0 hex, the second and third bytes must be in the ranges A0 to BF and 80 to BF, respectively.
- When the first byte is in the range E1 to EC hex or EE to EF, the second and third bytes must both be in the range 80 to BF hex.
- When the first byte is ED hex, the second and third bytes must be in the ranges 80 to 9F and 80 to BF, respectively.
Otherwise, the character is invalid.

5. When the ETF3-enhancement facility is not installed or the W bit of the M3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of F0 to F7 hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of F0 to F4 hex; the character is a four-byte character, and it is converted to two two-byte Unicode characters (a surrogate pair) as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>11110uvw10xyefgh10ijklmn10opqrstuvwxyz</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unicode Characters</td>
<td>110110abcde f gh i j 110111k lmnopqrst</td>
</tr>
</tbody>
</table>

where zabcd = uvwxyz - 1

When the ETF3-enhancement facility is not installed or when the W bit of the M3 field is zero, the first two bits in the second, third, and fourth bytes of the UTF-8 character are ignored, and the high order bit (z) produced by the subtract operation should be zero but is ignored.

When the ETF3-enhancement facility is installed and the W bit of the M3 field is one, the contents of the second, third, and fourth bytes of the UTF-8 character must be as follows:

- When the first byte is F0 hex, the second, third, and fourth bytes must be in the ranges 90 to BF, 80 to BF, and 80 to BF, respectively.
- When the first byte is in the range F1 to F3, the second, third, and fourth bytes must all be in the range 80 to BF hex.
- When the first byte is F4 hex, the second, third, and fourth bytes must be in the ranges 80 to 8F, 80 to BF, and 80 to BF, respectively.

Otherwise, the character is invalid.

6. When the ETF3-enhancement facility is installed, the W bit of the M3 field is one, and the contents of the first byte of the UTF-8 character are in the range of F5 to F7 hex, the character is invalid.

7. When the contents of the first byte of the UTF-8 character are in the range of F8-FF, the character is invalid.

If an invalid character is encountered, condition code 2 is set, and general register R2 contains the address of the first byte of the invalid UTF-8 character.

The second-operand location is considered exhausted when it does not contain at least one remaining byte or when it does not contain at least the two, three, or four remaining bytes required to contain the two-, three-, or four-byte UTF-8 character indicated by the contents of the first remaining byte. The first-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes in the case when a four byte UTF-8 character is to be converted.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R2 + 1 are decremented by the number of bytes converted, and the contents of general register R2 are incremented by the same number. Also, the contents of general register R1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R1 are incremented by the same number. When general registers R1 and R2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R1, R1 + 1, R2, and R2 + 1, always remain unchanged.

When condition code 2 is set, general register R2 contains the address of the invalid UTF-8 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.
When the \( R_1 \) register is the same register as the \( R_2 \) register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the \( R \) field associated with that operand is odd.

**Resulting Condition Code:**

0  Entire second operand processed
1  End of first operand reached
2  Invalid UTF-8 character
3  CPU-determined number of characters processed

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. When the ETF3-enhancement facility is not installed, or when the W bit of the \( M_3 \) operand is zero, bits 0 and 1 of the continuation bytes of multiple-byte UTF-8 characters are not checked in order to improve the performance of the conversion. Therefore, invalid continuation bytes are not detected.

3. The storage-operand references of CONVERT UTF-8 TO UTF-16 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

4. The CONVERT UTF-8 TO UTF-16 (CONVERT UTF-8 TO UNICODE) instruction supports UTF-16 characters only in the big-endian encoding.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

**CONVERT UTF-8 TO UTF-32**

\[
\text{CU14} \quad R_{1\, R[3\, M_3]} \quad [\text{RRF-c}]
\]

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>16</th>
<th>20</th>
<th>24</th>
<th>28</th>
<th>30</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B9B0'</td>
<td>( M_3 )</td>
<td>/ / /</td>
<td>( R_1 )</td>
<td>( R_2 )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The one-, two-, three-, or four-byte UTF-8 characters of the second operand are converted to four-byte UTF-32 characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-8 character is encountered, whichever occurs first. The result is indicated in the condition code.

The \( R_1 \) and \( R_2 \) fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers \( R_1 \) and \( R_2 \), respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers \( R_1 + 1 \) and \( R_2 + 1 \), respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers \( R_1 + 1 \) and \( R_2 + 1 \), respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers \( R_1 \) and \( R_2 \) is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers \( R_1 \) and \( R_2 \) constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions...
0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address. The contents of the registers just described are shown in Figure 7-251 on page 7-207.

Figure 7-251. Register Contents for CONVERT UTF-8 TO UTF32

When the ETF3-enhancement facility is installed, the M3 field has the following format:

```
/ / / W
0 3
```

The bits of the M3 field are defined as follows:

- **Unassigned**: Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

- **Enhanced Well-Formedness-Checking (W)**: The W bit, bit 3 of the M3 field, controls whether enhanced well-formedness checking of the UTF-8 characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have
been converted, or an invalid UTF-8 character is encountered in the second operand.

To show the method of converting a UTF-8 character to a UTF-32 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15</td>
<td>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
</tr>
</tbody>
</table>

The bits of a UTF-32 character in the range 00010000 to 00010000 hex (UTF-16 surrogate pair) are identified by letters as follows:

<table>
<thead>
<tr>
<th>UTF-32 Character</th>
<th>Bit Numbers</th>
<th>Identifying Bit Letters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</td>
<td>a b c d e f g h i j k l m n o p</td>
</tr>
</tbody>
</table>

Conversion of a UTF-8 character to a UTF-32 character is as follows:

1. When the contents of the first byte of a UTF-8 character are in the range 00 to 7F hex, the character is a one-byte character, and it is converted to a four-byte UTF-32 character as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>j k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-32 Character</td>
<td>0000000000000000</td>
</tr>
</tbody>
</table>

When the ETF3-enhancement facility is not installed or the W bit of the M3 field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M3 field is one, the contents of the second byte of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

3. When the ETF3-enhancement facility is not installed or the W bit of the M3 field is zero, and the contents of the first byte of the UTF-8 character are in the range C0 to DF hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range C2 to DF hex; the character is a two-byte character, and it is converted to a four-byte UTF-32 character as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>110 f g h i j 10 k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-32 Character</td>
<td>000000000000000000000000000000000</td>
</tr>
</tbody>
</table>

When the ETF3-enhancement facility is not installed or when the W bit of the M3 field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M3 field is one, the contents of the second and third bytes of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

4. When the contents of the first byte of a UTF-8 character are in the range E0 to EF hex, the character is a three-byte character, and it is converted to a four-byte UTF-32 character as follows:

<table>
<thead>
<tr>
<th>UTF-8 Character</th>
<th>1110 a b c d e f g h i j k l m n o p</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-32 Character</td>
<td>000000000000000000000000000000000</td>
</tr>
</tbody>
</table>

When the ETF3-enhancement facility is not installed or when the W bit of the M3 field is zero, the first two bits in the second and third bytes of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M3 field is one, the contents of the second and third bytes of the UTF-8 character must be as follows:

- When the first byte is E0 hex, the second and third bytes must be in the ranges A0 to BF and 80 to BF, respectively.
- When the first byte is in the range E1 to EC hex or EE to EF, the second and third bytes must both be in the range 80 to BF hex.
- When the first byte is ED hex, the second and third bytes must be in the ranges 80 to 9F and 80 to BF, respectively.
Otherwise, the character is invalid.

5. When the ETF3-enhancement facility is not installed or the W bit of the M3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of F0 to F7 hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of F0 to F4 hex; the character is a four-byte character, and it is converted to a four-byte UTF-32 character (a surrogate pair) as follows:

| UTF-8 Character | 11110uvw10xyefgh10ijklmn10opqrs | UTF-32 Character | 00000000000uvwxyefghijklmnopqrs |

When the ETF3-enhancement facility is not installed or when the W bit of the M3 field is zero, the first two bits in the second, third, and fourth bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M3 field is one, the contents of the second, third, and fourth bytes of the UTF-8 character must be as follows:

- When the first byte is F0 hex, the second, third, and fourth bytes must be in the ranges 90 to BF, 80 to BF, and 80 to BF, respectively.
- When the first byte is in the range F1 to F3, the second, third, and fourth bytes must all be in the range 80 to BF hex.
- When the first byte is F4 hex, the second, third, and fourth bytes must be in the ranges 80 to 8F, 80 to BF, and 80 to BF, respectively.

Otherwise, the character is invalid.

6. When the ETF3-enhancement facility is installed, the W bit of the M3 field is one, and the contents of the first byte of the UTF-8 character are in the range of F5 to F7 hex, the character is invalid.

7. When the contents of the first byte of the UTF-8 character are in the range of F8-FF, the character is invalid.

If an invalid character is encountered, condition code 2 is set, and general register R2 contains the address of the first byte of the invalid UTF-8 character.

The second-operand location is considered exhausted when it does not contain at least one remaining byte or when it does not contain at least the two, three, or four remaining bytes required to contain the two-, three-, or four-byte UTF-8 character indicated by the contents of the first remaining byte. The first-operand location is considered exhausted when it does not contain at least four remaining bytes.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R1 + 1 are decremented by the number of bytes converted, and the contents of general register R2 are incremented by the same number. Also, the contents of general register R1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R1 are incremented by the same number. When general registers R1 and R2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R1, R1 + 1, R2, and R2 + 1, always remain unchanged.

When condition code 2 is set, general register R2 contains the address of the invalid UTF-8 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R1 register is the same register as the R2 register, the results are unpredictable.
When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

**Resulting Condition Code:**

0  Entire second operand processed  
1  End of first operand reached  
2  Invalid UTF-8 character  
3  CPU-determined number of characters processed

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)  
- Operation (if the extended-translation facility 3 is not installed)  
- Specification  
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. When the ETF3-enhancement facility is not installed, or when the W bit of the M3 operand is zero, bits 0 and 1 of the continuation bytes of multiple-byte UTF-8 characters are not checked in order to improve the performance of the conversion. Therefore, invalid continuation bytes are not detected.

3. The storage-operand references of CONVERT UTF-8 TO UTF-32 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

4. The CONVERT UTF-8 TO UTF-32 instruction supports UTF-32 characters only in the big-endian encoding.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

**COPY ACCESS**

<table>
<thead>
<tr>
<th>CPYA</th>
<th>R1,R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>́B24D́</td>
<td>./././././././.</td>
<td>R1 R2</td>
</tr>
</tbody>
</table>

The contents of access register R2 are placed in access register R1.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Transaction constraint

**DIVIDE**

**Register-and-register format:**

DR  R1,R2  [RR]

```
0 8 12 15
'1D' R1 R2
```

The 64-bit first operand (the dividend) is divided by the 32-bit second operand (the divisor), and the 32-bit remainder and quotient are placed at the first-operand location.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The dividend is treated as a 64-bit signed binary integer. The leftmost 32 bits of the dividend are in bit positions 32-63 of general register R1, and the rightmost 32 bits are in bit positions 32-63 of general register R1 + 1.
The divisor, remainder, and quotient are treated as 32-bit signed binary integers. For DIVIDE (DR), the divisor is in bit positions 32-63 of general register R₂. The remainder is placed in bit positions 32-63 of general register R₁, and the quotient is placed in bit positions 32-63 of general register R₁ + 1. Bits 0-31 of the registers remain unchanged.

The sign of the quotient is determined by the rules of algebra, and the remainder has the same sign as the dividend, except that a zero quotient or a zero remainder is always positive.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed by a 32-bit signed binary integer, a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of D only)
- Fixed-point divide
- Specification
- Transaction constraint

### DIVIDE LOGICAL

**Register-and-register formats:**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DLR</td>
<td>R₁,R₂ [RRE]</td>
</tr>
<tr>
<td>DLGR</td>
<td>R₁,R₂ [RRE]</td>
</tr>
</tbody>
</table>

**Register-and-storage formats:**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL</td>
<td>R₁,Dₓ(X₂,B₂) [RXY-a]</td>
</tr>
<tr>
<td>DLG</td>
<td>R₁,Dₓ(X₂,B₂) [RXY-a]</td>
</tr>
</tbody>
</table>

The 64-bit or 128-bit first operand (the dividend) is divided by the 32-bit or 64-bit second operand (the divisor), and the 32-bit or 64-bit remainder and quotient are placed at the first-operand location.

The R₁ field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For DIVIDE LOGICAL (DLR, DL), the dividend is treated as a 64-bit unsigned binary integer. The leftmost 32 bits of the dividend are in bit positions 32-63 of general register R₁, and the rightmost 32 bits are in bit positions 32-63 of general register R₁ + 1. Bits 0-31 of the registers remain unchanged.

The divisor, remainder, and quotient are treated as 32-bit unsigned binary integers. For DIVIDE LOGICAL (DLR), the divisor is in bit positions 32-63 of general register R₂. The remainder is placed in bit positions 32-63 of general register R₁, and the quotient is placed in bit positions 32-63 of general register R₁ + 1. Bits 0-31 of the registers remain unchanged.

For DIVIDE LOGICAL (DLGR, DLG), the dividend is treated as a 128-bit unsigned binary integer. The leftmost 64 bits of the dividend are in general register R₁, and the rightmost 64 bits are in general register R₁ + 1. The divisor, remainder, and quotient are treated as 64-bit unsigned binary integers. The remainder is placed in general register R₁, and the quotient is placed in general register R₁ + 1.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed as a 32-bit unsigned binary integer for DIVIDE LOGICAL (DLR, DL), or a 64-bit unsigned binary integer for DIVIDE LOGICAL (DLGR, DLG), a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of DL or DLG only)
- Fixed-point divide
- Specification
- Transaction constraint

DSG \( R_1, D_2(X_2, B_2) \) [RXY-a]

\[
\begin{array}{c|ccccc}
0 & 8 & 12 & 16 & 20 & 24 \\
\hline
'E3' & R_1 & X_2 & B_2 & DL_2 & DH_2 & '0D' \\
\end{array}
\]

DSGF \( R_1, D_2(X_2, B_2) \) [RXY-a]

\[
\begin{array}{c|ccccc}
0 & 8 & 12 & 16 & 20 & 24 \\
\hline
'E3' & R_1 & X_2 & B_2 & DL_2 & DH_2 & '1D' \\
\end{array}
\]

The 64-bit contents of general register \( R_1 + 1 \) (the dividend) are divided by the 64-bit or 32-bit second operand (the divisor), the 64-bit remainder is placed in general register \( R_1 \), and the 64-bit quotient is placed in general register \( R_1 + 1 \).

The \( R_1 \) field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The dividend, quotient, and remainder are treated as 64-bit signed binary integers. For DIVIDE SINGLE (DSGR, DSG), the divisor is treated as a 64-bit signed binary integer. For DIVIDE SINGLE (DSGFR, DSGF), the divisor is treated as a 32-bit signed binary integer. For DSGFR, the divisor is in bit positions 32-63 of general register \( R_2 \).

The sign of the quotient is determined by the rules of algebra, and the remainder has the same sign as the dividend, except that a zero quotient or a zero remainder is always positive.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed by a 64-bit signed binary integer, a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of DSG and DSGF only)
- Fixed-point divide
- Specification
- Transaction constraint

EXCLUSIVE OR

Register-and-register formats:

\hline
\end{array}
\]

For X, XC, XG, XGR, XI, X_{IY}, XR, and XY, the EXCLUSIVE OR of the first and second operands is placed at the first-operand location. For XGRK and XRK, the EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

For EXCLUSIVE OR (XC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

For EXCLUSIVE OR (XI, X_{IY}), the first operand is one byte in length, and only one byte is stored. When the interlocked-access facility is installed, accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” on page A-45.

When the interlocked-access facility is installed, EXCLUSIVE OR (XI, X_{IY}) can be safely used to update a location in storage, even if the possibility exists that another CPU or a

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch, operand 2, X, XY, XG, and XC; fetch and store, operand 1, XI, X_{IY}, and XC)
- Operation (XY and X_{IY}, if the long-displacement facility is not installed; XGRK and XRK, if the distinct-operands facility is not installed)
- Transaction constraint (XC)

Programming Notes:

1. An example of the use of the EXCLUSIVE OR instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. EXCLUSIVE OR may be used to invert a bit, an operation particularly useful in testing and setting programmed binary switches.
3. A field EXCLUSIVE-ORed with itself becomes all zeros.
4. For EXCLUSIVE OR (XR or XGR), the sequence A EXCLUSIVE-OR B, B EXCLUSIVE-OR A, A EXCLUSIVE-OR B results in the exchange of the contents of A and B without the use of an additional general register.
5. Accesses to the first operand of EXCLUSIVE OR (XC) – and, when the interlocked-access facility is not installed, accesses to the first operand of EXCLUSIVE OR (XI, X_{IY}) – consist in fetching a first-operand byte from storage and subsequently storing the updated value. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” on page A-45.
channel program may also be updating the location.

**EXCLUSIVE OR IMMEDIATE**

The second operand is EXCLUSIVE ORed with bits of the first operand, and the result replaces those bits of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bits of the first operand that are EXCLUSIVE ORed with the second operand and then replaced are as follows:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Bits Exclusive ORed and Replaced</th>
</tr>
</thead>
<tbody>
<tr>
<td>XIHF</td>
<td>0-31</td>
</tr>
<tr>
<td>XILF</td>
<td>32-63</td>
</tr>
</tbody>
</table>

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

The condition code is set based on the result of the 32-bit EXCLUSIVE OR operation.

**Resulting Condition Code:**

- 0 Result is zero
- 1 Result is not zero
- 2 --
- 3 --

**Program Exceptions:**

- Operation, if the extended-immediate facility is not installed

**Programming Note:** The setting of the condition code is based only on the bits that are exclusive ORed and replaced.

**EXECUTE**

<table>
<thead>
<tr>
<th>EX</th>
<th>R1, D2(X2, B2) [R X-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'44'</td>
<td>R1  X2  B2  D2</td>
</tr>
</tbody>
</table>

**EXECUTE RELATIVE LONG**

<table>
<thead>
<tr>
<th>EXRL</th>
<th>R1, R12 [RIL-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'C6'</td>
<td>R1  0  R12</td>
</tr>
</tbody>
</table>

The single instruction at the second-operand address is modified by the contents of general register R1, and the resulting instruction, called the target instruction, is executed.

When the R1 field is not zero, bits 8-15 of the instruction designated by the second-operand address are ORed with bits 56-63 of general register R1. The ORing does not change either the contents of general register R1 or the instruction in storage, and it is effective only for the interpretation of the instruction to be executed. When the R1 field is zero, no ORing takes place.

The target instruction may be two, four, or six bytes in length. The execution and exception handling of the target instruction are exactly as if the target instruction were obtained in normal sequential operation, except for the instruction address and the instruction-length code.

The instruction address in the current PSW is increased by the length of the execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG). This updated address and the instruction-length code of the execute-type instruction are used, for example, as part of the link information when the target instruction is BRANCH AND LINK. When the target instruction is a successful branching instruction, the instruction address in the current PSW is replaced by the branch address specified by the target instruction.

When the target instruction is any of the following instructions, an execute exception is recognized:

- Another execute-type instruction
- TRANSACTION ABORT
- TRANSACTION BEGIN

---

EXCLUSIVE OR IMMEDIATE

"IBM z/Architecture Principles of Operation"
The effective address of EXECUTE must be even; otherwise, a specification exception is recognized.

When the target instruction is two or three halfwords in length but can be executed without fetching its second or third halfword, it is unpredictable whether access exceptions are recognized for the unused halfwords. Access exceptions are not recognized for the second-operand address when the address is odd.

The second-operand address of an execute-type instruction is an instruction address rather than a logical address; thus, the target instruction is fetched from the primary address space when in the primary-space, secondary-space, or access-register mode.

For EXECUTE RELATIVE LONG, the contents of the RL2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the target instruction in storage.

**Condition Code:** The code may be set by the target instruction.

**Program Exceptions:**

- Access (fetch, target instruction)
- Execute
- Operation (EXRL, when the execute-extensions facility is not installed)
- Specification (EX)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the EXECUTE instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

2. The ORing of eight bits from the general register with the designated instruction permits the indirect specification of the length, index, mask, immediate-data, register, or extended-op-code field.

3. The fetching of the target instruction is considered to be an instruction fetch for purposes of program-event recording and for purposes of reporting access exceptions.

4. An access or specification exception may be caused by execute-type instructions or by the target instruction, except that EXECUTE RELATIVE LONG cannot cause a specification exception due to a misaligned target operand.

5. When an interruptible instruction is made the target of an execute-type instruction, the program normally should not designate any register updated by the interruptible instruction as the R1, X2, or B2 register for EXECUTE or R1 register for EXECUTE RELATIVE LONG. Otherwise, on resumption of execution after an interruption, or if the instruction is refetched without an interruption, the updated values of these registers will be used in the execution of the execute-type instruction. Similarly, the program should normally not let the destination field in storage of an interruptible instruction include the location of an execute-type instruction, since the new contents of the location may be interpreted when resuming execution.

6. Exception conditions that occur during the execution of EXECUTE or EXECUTE RELATIVE LONG are recognized before exception conditions for the target instruction.

**EXTRACT ACCESS**

<table>
<thead>
<tr>
<th>EAR</th>
<th>R1, R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B24F'</td>
<td>/ / / / / / /</td>
<td>R1</td>
</tr>
<tr>
<td>0</td>
<td>16</td>
<td>24</td>
</tr>
</tbody>
</table>

The contents of access register R2 are placed in bit positions 32-63 of general register R1. Bits 0-31 of general register R1 remain unchanged.

**Condition Code:** The code remains unchanged.

**Program Exceptions:** None.

**EXTRACT CPU ATTRIBUTE**

<table>
<thead>
<tr>
<th>ECAG</th>
<th>R1, R1, D2(B2)</th>
<th>[RSY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB'</td>
<td>R1</td>
<td>R1</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

Information regarding the specified attribute of the storage subsystem is placed into the first-operand location. The first operand is 64 bits.
The second-operand address is not used to address data; rather, the rightmost 24 bits of the address are treated as a code specifying which attribute is returned in general register R1.

The rightmost 24 bits of the second-operand address are defined as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>Reserved</td>
</tr>
<tr>
<td>54</td>
<td>ASI</td>
</tr>
<tr>
<td>56</td>
<td>ASI-Dependent</td>
</tr>
</tbody>
</table>

**Attribute-Set Indication (ASI):** Bit positions 54-55 of the second-operand address contain a 2-bit unsigned binary integer indicating the set of attributes from which an attribute to be extracted is selected. The attribute-set indications are:

0 Cache attributes

All other attribute-set-indication values are reserved. If a reserved attribute-set indication is specified, model-dependent or unpredictable results may occur.

**Cache-Attribute-Set Operation**
The rightmost 24 bits of the second-operand address are defined as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>Reserved</td>
</tr>
<tr>
<td>54</td>
<td>0</td>
</tr>
<tr>
<td>56</td>
<td>0</td>
</tr>
<tr>
<td>60</td>
<td>LI</td>
</tr>
<tr>
<td>63</td>
<td>TI</td>
</tr>
</tbody>
</table>

The attribute, level, and type indications for the cache-attribute set are as follows:

**Attribute Indication (AI):** Bit positions 56-59 of the second-operand address contain a 4-bit unsigned binary integer indicating the cache attribute to be extracted, as follows:

0 Extract topology summary
1 Extract line size of the cache, in bytes
2 Extract total size of the cache, in bytes
3 Extract set-associativity level of the cache
4-15 Reserved

**Level Indication (LI):** Bit positions 60-62 of the second-operand address contain a 3-bit unsigned binary integer indicating the level of the cache for which the cache attribute is to be extracted, with 0 indicating the first-level cache, 1 indicating the second-level cache and so forth. If a cache level is not implemented on a model, its corresponding level indication is reserved.

**Type Indication (TI):** Bit 63 of the second-operand address indicates the type of cache for which the cache attribute is to be extracted, with 0 indicating the data cache and 1 indicating the instruction cache. When a cache level has a unified data and instruction cache, the same result is returned regardless of the type indication.

When the attribute indication is zero, the level indication (LI) and type indication (TI) are ignored.

**Common Operation**
Bits 0-39 of the second-operand address are ignored. Bits 40-53 of the second-operand address are reserved and should contain zeros.

Bits 0-63 of general register R1 are set to ones if any of the following apply:

- A reserved bit position in the second-operand address contains one and is otherwise not specifically designated as ignored.
- A reserved ASI, AI, or, when applicable, LI value is specified and is otherwise not specifically designated as ignored.
- The specified ASI and AI values and, when applicable, the LI value are all valid, but the model does not provide the data.

The contents of general register R3 are ignored, however the R3 field should specify register 0; otherwise, the program may not operate compatibly in the future.

**Cache-Attribute Results (ASI = 0)**
When the cache attribute indication is zero, a summary of each level of cache is returned in general register R1. Each summary field is eight bits, where bits 0-7 of the register contain the summary for the first-level cache, bits 8-15 contain the summary for the second-level cache, and so forth. The contents of an eight-bit summary field are as follows:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-3</td>
<td>Reserved, stored as zeros</td>
</tr>
<tr>
<td>4-5</td>
<td>Cache scope, as follows:</td>
</tr>
<tr>
<td></td>
<td>00    Cache does not exist at this level</td>
</tr>
<tr>
<td></td>
<td>01    Cache is private to the CPU</td>
</tr>
</tbody>
</table>
When the cache attribute indication is one, two, or three, the attribute value is returned in general register $R_1$, as a 64-bit unsigned integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Operation (if the general-instructions-extension facility is not installed)
- Transaction constraint

**Programming Notes:**

1. Knowledge of the cache line size is useful when determining the placement of `PREFETCH DATA` and `PREFETCH DATA RELATIVE LONG` instructions.

2. The value placed in the first-operand location is model dependent and may differ significantly from one model to another. For example, the size of the data cache on one model may be smaller or larger than the size of the data cache on another model. To ensure compatible operation across multiple models, the program should not rely on any particular value being returned in the first-operand location.

3. When the attribute-set indication is 00 binary and the attribute indication is 0000 binary, the summary indications are returned in contiguous 8-bit fields in general register $R_1$. Thus if the program scans the resulting summary-indication fields from left to right and encounters an 8-bit field containing all zeros, no further meaningful fields exist.

4. When the attribute-set indication is 00 binary and the attribute indication is 0000 binary, the summary indications are returned in contiguous 8-bit fields in general register $R_1$. Thus if the program scans the resulting summary-indication fields from left to right and encounters an 8-bit field containing all zeros, no further meaningful fields exist.

5. Cache information returned reflects the depth specified by the level indication and the cache information accessible from the issuing CPU. The total sizes and associativity do not include other, parallel cache structures accessible from other CPUs of the configuration.

**EXTRACT CPU TIME**

```
ECTG D_1(B_1),D_2(B_2),R_3 [SSF]
```

The value of the current CPU timer is subtracted from the first operand, and the difference is placed in general register 0. The second operand is placed unchanged in general register 1. The eight bytes at the third operand location replace the contents of general register $R_3$.

The first and second operands and the results in general registers 0, 1, and $R_3$ are treated as 64-bit unsigned binary integers.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register $R_3$ constitute the address of the third operand, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address. In the access-register mode, the contents of access register $R_3$ are used for accessing the third operand.

All operands are fetched before any general register is modified. If the $R_3$ field designates general register 0, it is unpredictable whether the result placed in the register is the first operand minus the CPU timer or the third operand. If the $R_3$ field designates general register 1, it is unpredictable whether the result would be placed in the third operand.
placed in the register is the second operand or the third operand. The contents of the registers just described are shown in Figure 7-252.

### 24-Bit Addressing Mode

<table>
<thead>
<tr>
<th>R3</th>
<th></th>
<th>Third-Operand Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>/ / / / / / / / / /</td>
<td></td>
</tr>
</tbody>
</table>

### 31-Bit Addressing Mode

<table>
<thead>
<tr>
<th>R3</th>
<th></th>
<th>Third-Operand Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>/ / / / / / / / / /</td>
<td></td>
</tr>
</tbody>
</table>

### 64-Bit Addressing Mode

<table>
<thead>
<tr>
<th>R3</th>
<th></th>
<th>Third-Operand Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>/ / / / / / / / / /</td>
<td></td>
</tr>
</tbody>
</table>

---

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operands 1, 2, and 3)
- Operation (the extract-CPU-time facility is not installed)
- Transaction constraint

---

### EXTRACT PSW

**EPSW**  

<table>
<thead>
<tr>
<th>EPSW</th>
<th>R1, R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B98D'</td>
<td>/ / / /</td>
<td>R1, R2</td>
</tr>
</tbody>
</table>

Bits 0-63 of the current PSW are placed in bit positions 32-63 of the first operand, and bits 0-31 of the operand remain unchanged. Subsequently, bits 32-63 of the current PSW are placed in bit positions 32-63 of the second operand, and bits 0-31 of the operand remain unchanged. The action associated with the second operand is not performed if the R2 field is zero.

---

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Transaction constraint

---

### EXTRACT TRANSACTION NESTING DEPTH

**ETND**  

<table>
<thead>
<tr>
<th>ETND</th>
<th>R1</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B2EC'</td>
<td>/ /</td>
<td>R1</td>
</tr>
</tbody>
</table>

The current transaction nesting depth is placed in bits 48-63 of general register R1. Bits 0-31 of the reg-
ister remain unchanged, and bits 32-47 of the register are set to zero, as illustrated below.

A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Operation (transactional-execution facility not installed)
- Special operation
- Transaction constraint

**Programming Note:** A transaction nesting depth of zero indicates that the CPU is not in the transactional-execution mode.

**FIND LEFTMOST ONE**

FLOGR R1,R2 [RRE]

The byte at the second-operand location is inserted into bit positions 56-63 of general register R1. The remaining bits in the register remain unchanged.

The condition code indicates whether or not a one bit was found in the second operand.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**RESULTING CONDITION CODE:**
- 0 No one bit found
- 1 --
- 2 One bit found
- 3 --

**Program Exceptions:**
- Operation (if the extended-immediate facility is not installed)
- Specification

**Programming Notes:**
1. An example of the use of the FIND LEFTMOST ONE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When the R1 and R2 fields designate the same register, the original contents of general register R2 are replaced by the resulting bit-position value, or 64 if no one bit was found.
3. When the R2 field designates general register R1 + 1, the leftmost one bit (if any) of general register R2 is set to zero; if no one bit is found, the entire register is set to zero.
4. When the R2 field designates neither the even nor the odd registers designated by the R1 field, then general register R2 is not modified.

**INSERT CHARACTER**

IC R1,D2(X2,B2)[RXY-a]

The byte at the second-operand location is inserted into bit positions 56-63 of general register R1. The remaining bits in the register remain unchanged.

The displacement for IC is treated as a 12-bit unsigned binary integer. The displacement for ICY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.
**Program Exceptions:**

- Access (fetch, operand 2)
- Operation (ICY, if the long-displacement facility is not installed)

**INSERT CHARACTERS UNDER MASK**

<table>
<thead>
<tr>
<th>ICM</th>
<th>R₁, M₃, D₂(B₂)</th>
<th>[RS-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>BF</td>
<td>R₁  M₃ B₂ D₂</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ICMY</th>
<th>R₁, M₃, D₂(B₂)</th>
<th>[RSY-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>EB</td>
<td>R₁  M₃ B₂ DL₂ DH₂ '81'</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ICMH</th>
<th>R₁, M₃, D₂(B₂)</th>
<th>[RSY-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>EB</td>
<td>R₁  M₃ B₂ DL₂ DH₂ '80'</td>
<td></td>
</tr>
</tbody>
</table>

Bytes from contiguous locations beginning at the second-operand address are inserted into general register R₁ under control of a mask.

The contents of the M₃ field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R₁. For INSERT CHARACTERS UNDER MASK (ICM, ICMY), the four bytes to which the mask bits correspond are in the low-order half, bit positions 32-63 of general register R₁. For INSERT CHARACTERS UNDER MASK (ICMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The byte positions corresponding to ones in the mask are filled, left to right, with bytes from successive storage locations beginning at the second-operand address. When the mask is not zero, the length of the second operand is equal to the number of ones in the mask. The bytes in the general register corresponding to zeros in the mask remain unchanged. For ICM and ICMY, bits 0-31 of the register remain unchanged, and, for ICMH, bits 32-63 remain unchanged.

The resulting condition code is based on the mask and on the value of the bits inserted. When the mask is zero or when all inserted bits are zeros, the condition code is set to 0. When the inserted bits are not all zeros, the code is set according to the leftmost bit of the storage operand: if this bit is one, the code is set to 1; if this bit is zero, the code is set to 2.

When the mask is not zero, exceptions associated with storage-operand access are recognized only for the number of bytes specified by the mask. When the mask is zero, access exceptions are recognized for one byte at the second-operand address.

The displacement for ICM is treated as a 12-bit unsigned binary integer. The displacement for ICMY and ICMH is treated as a 20-bit signed binary integer.

**Resulting Condition Code:**

0  All inserted bits zeros, or mask bits all zeros
1  Leftmost inserted bit one
2  Leftmost inserted bit zero, and not all inserted bits zeros
3  --

**Program Exceptions:**

- Access (fetch, operand 2)
- Operation (ICMY, if the long-displacement facility is not installed)

**Programming Notes:**

1. Examples of the use of the INSERT CHARACTERS UNDER MASK instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The condition code for INSERT CHARACTERS UNDER MASK (ICM, ICMY only) is defined such that, when the mask is 1111, the instruction causes the same condition code to be set as for LOAD AND TEST (LTR only) Thus, the instruction may be used as a storage-to-register load-and-test operation.

3. INSERT CHARACTERS UNDER MASK (ICM, ICMY) with a mask of 1111 or 0001 performs a function similar to that of a LOAD (L) or INSERT CHARACTER (IC) instruction, respectively, with the exception of the condition-code setting. However, the performance of INSERT CHARACTERS UNDER MASK may be slower.
INSERT IMMEDIATE

IIHF  R1,I2  [RIL-a]

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-31</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

</tbody>
</table>

The second operand is placed in bit positions of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bit positions of the first operand that are loaded with the second operand are as follows:

Condition Code: The code remains unchanged.

Program Exceptions:
- Operation (IIHF and IILF, if the extended-immediate facility is not installed)

INSERT PROGRAM MASK

IPM  R1  [RRE]

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B222'</td>
<td></td>
</tr>
</tbody>
</table>

The condition code and program mask from the current PSW are inserted into bit positions 34 and 35 and 36-39, respectively, of general register R1. Bits 32 and 33 of the register are set to zeros; bits 0-31 and 40-63 are left unchanged.

Condition Code: The code remains unchanged.

Program Exceptions: None.

LOAD

Register-and-register formats:

LR  R1,R2  [RR]

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-15</td>
<td></td>
</tr>
</tbody>
</table>

Register-and-storage formats:

L  R1,D2(X2,B2)  [RX-a]

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-31</td>
<td></td>
</tr>
</tbody>
</table>

LY  R1,D2(X2,B2)  [RXY-a]

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-31</td>
<td></td>
</tr>
</tbody>
</table>

Condition Code: The code remains unchanged.
LOAD IMMEDIATE

The second operand is placed unchanged at the first-operand location, except that, for LOAD (LGFR, LGF), LOAD IMMEDIATE (LGFI), and LOAD RELATIVE LONG (LGRL), it is sign extended.

For LOAD (LR, L, LY) and LOAD RELATIVE LONG (LRL), the operands are 32 bits, and, for LOAD (LGR, LG, LGF), and LOAD RELATIVE LONG (LGRL), the operands are 64 bits. For LOAD (LGFR, LGF), LOAD IMMEDIATE (LGFI), and LOAD RELATIVE LONG (LGFR), the second operand is treated as a 32-bit signed binary integer, and the first operand is treated as a 64-bit signed binary integer.

The displacement for L is treated as a 12-bit unsigned binary integer. The displacement for LY, LG, and LGF is treated as a 20-bit signed binary integer.

For LOAD IMMEDIATE, the contents of the I2 field form the second operand directly.

For LOAD RELATIVE LONG, the contents of the RI2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For LOAD RELATIVE LONG (LRL, LGFRL), the second operand must be aligned on a word boundary, and for LOAD RELATIVE LONG (LGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of L, LY, LG, LGF, LRL, LGRL, and LGFRL only)
- Operation (LY, if the long-displacement facility is not installed; LGFI, if the extended-immediate facility is not installed; LRL, LGRL, LGFRL, if the general-instructions-extension facility is not installed)
- Specification (LRL, LGFRL, LGRL only)

Programming Notes:

1. An example of the use of the LOAD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For LOAD RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.

3. When LOAD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD ACCESS MULTIPLE

The displacement for L is treated as a 12-bit unsigned binary integer. The displacement for LY, LG, and LGF is treated as a 20-bit signed binary integer.
The set of access registers starting with access register \( R_1 \) and ending with access register \( R_3 \) is loaded from the locations designated by the second-operand address.

The storage area from which the contents of the access registers are obtained starts at the location designated by the second-operand address and continues through as many storage words as the number of access registers specified. The access registers are loaded in ascending order of their register numbers, starting with access register \( R_1 \) and continuing up to and including access register \( R_{15} \), with access register 0 following access register 15.

The displacement for LAM is treated as a 12-bit unsigned binary integer. The displacement for LAMY is treated as a 20-bit signed binary integer.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
- Operation (LAMY, if the long-displacement facility is not installed)
- Specification
- Transaction constraint

**LOAD ADDRESS**

\[
\begin{array}{c|ccccc}
\text{LA} & R_1, D_2(X_2, B_2) & [\text{RX-a}] \\
\hline
\text{EB} & R_1 & R_3 & B_2 & DL_2 & DH_2 & 9A' \\
\end{array}
\]

The address specified by the \( X_2, B_2, \) and \( D_2 \) fields is placed in general register \( R_1 \). The address computation follows the rules for address arithmetic.

In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The displacement for LA is treated as a 12-bit unsigned binary integer. The displacement for LAY is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Operation (LAY if the long-displacement facility is not installed)

**Programming Notes:**

1. An example of the use of the LOAD ADDRESS instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. LOAD ADDRESS may be used to increment the rightmost bits of a general register, other than register 0, by the contents of the \( D_2 \) field of the instruction. LOAD ADDRESS (LAY) may also be used to decrement the rightmost bits of a register, other than register 0. The register to be incremented should be designated by \( R_i \) and by either \( X_2 \) (with \( B_2 \) set to zero) or \( B_2 \) (with \( X_2 \) set to zero). The instruction increments 24 bits in the 24-bit addressing mode, 31 bits in the 31-bit addressing mode, and 64 bits in the 64-bit addressing mode.

**LOAD ADDRESS EXTENDED**

\[
\begin{array}{c|ccccc}
\text{LAE} & R_1, D_2(X_2, B_2) & [\text{RX-a}] \\
\hline
\text{E3} & R_1 & X_2 & B_2 & DL_2 & DH_2 & 71' \\
\end{array}
\]

\[
\begin{array}{c|ccccc}
\text{LAey} & R_1, D_2(X_2, B_2) & [\text{RXY-a}] \\
\hline
\text{E3} & R_1 & X_2 & B_2 & DL_2 & DH_2 & 75' \\
\end{array}
\]
The address specified by the \text{X}_2, \text{B}_2, \text{and D}_2 \text{ fields is placed in general register } R_1. \text{ Access register } R_1 \text{ is loaded with a value that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW. If the address-space-control bits are 01 binary, the value placed in the access register also depends on whether the } \text{B}_2 \text{ field is zero or non-zero.}

The address computation follows the rules for address arithmetic. In the 24-bit addressing mode, the address is placed in bit positions 40-63 of general register \text{R}_1, \text{ bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.}

The value placed in access register \text{R}_1 \text{ is as shown in the following table:}

<table>
<thead>
<tr>
<th>PSW Bits 16 and 17</th>
<th>Value Placed in Access Register R_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>00000000 hex (zeros in bit positions 0-31)</td>
</tr>
<tr>
<td>10</td>
<td>00000001 hex (zeros in bit positions 0-30 and one in bit position 31)</td>
</tr>
<tr>
<td>01</td>
<td>If \text{B}_2 \text{ field is zero: 00000000 hex (zeros in bit positions 0-31)} \n</td>
</tr>
<tr>
<td>11</td>
<td>00000002 hex (zeros in bit positions 0-29 and 31, and one in bit position 30)</td>
</tr>
</tbody>
</table>

However, when PSW bits 16 and 17 \text{are 01 binary and the } \text{B}_2 \text{ field is nonzero, bit positions 0-6 of access register } \text{B}_2 \text{ must contain all zeros; otherwise, the results in general register } R_1 \text{ and access register } R_1 \text{ are unpredictable.}

The displacement for LAE \text{is treated as a 12-bit unsigned binary integer. The displacement for LAEY is treated as a 20-bit signed binary integer.}

No storage references for operands take place, and the address is not inspected for access exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Operation (LAEY; if the general-instructions-extension facility is not installed)
- Transaction constraint

**Programming Notes:**

1. When DAT \text{is on, the different values of the address-space-control bits correspond to translation modes as follows:}

<table>
<thead>
<tr>
<th>PSW Bits 16 and 17</th>
<th>Translation Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Primary-space mode</td>
</tr>
<tr>
<td>10</td>
<td>Secondary-space mode</td>
</tr>
<tr>
<td>01</td>
<td>Access-register mode</td>
</tr>
<tr>
<td>11</td>
<td>Home-space mode</td>
</tr>
</tbody>
</table>

2. In the access-register mode, the value 00000000 hex in an access register designates the primary address space, and the value 00000001 hex designates the secondary address space. The value 00000002 hex designates the home address space if the control program assigns entry 2 of the dispatchable-unit access list as designating the home address space and places a zero access-list-entry sequence number (ALESN) in that entry.

**LOAD ADDRESS RELATIVE LONG**

\text{LARL R_1,R_2} [\text{RIL-b}]

The address specified by the \text{R}_2 \text{ field is placed in general register } R_1. \text{ The address computation follows the rules for the branch address of BRANCH RELATIVE ON CONDITION LONG and BRANCH RELATIVE AND SAVE LONG.}

In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The contents of the \text{R}_2 \text{ field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the computed address.}
No storage references for operands take place, and the address is not inspected for access exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:** None.

**Programming Notes:**

1. Only even addresses (halfword addresses) can be generated. If an odd address is desired, LOAD ADDRESS can be used to add one to an address formed by LOAD ADDRESS RELATIVE LONG.

2. When LOAD ADDRESS RELATIVE LONG is the target of an execute-type instruction, the address produced is relative to the location of the LOAD ADDRESS RELATIVE LONG instruction, not of the execute-type instruction. This is consistent with the operation of the relative-branch instructions.

**LOAD AND ADD**

<table>
<thead>
<tr>
<th>LAA</th>
<th>R1, R3, D2(B2)</th>
<th>[RSY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB'</td>
<td>R1</td>
<td>R3</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>LAAG</th>
<th>R1, R3, D2(B2)</th>
<th>[RSY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB'</td>
<td>R1</td>
<td>R3</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

The second operand of LAA must be designated on a word boundary. The second operand of LAAG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Result zero; no overflow  
1  Result less than zero; no overflow  
2  Result greater than zero; no overflow  
3  Overflow

**Program Exceptions:**

- Access (fetch and store, operand 2)  
- Fixed-point overflow  
- Operation (if the interlocked-access facility 1 is not installed)  
- Specification  
- Transaction constraint

**Programming Notes:**

1. Except for the case where the R1 and R3 fields designate the same register, general register R3 is unchanged.

2. The operation of LOAD AND ADD, LOAD AND ADD LOGICAL, LOAD AND AND, LOAD AND EXCLUSIVE OR, and LOAD AND OR may be expressed as follows.

   temp ← operand_2;  
   operand_2 ← temp OP operand_3;  
   operand_1 ← temp;

   OP represents the arithmetic or logical operation being performed by the instruction.

**LOAD AND ADD LOGICAL**

<table>
<thead>
<tr>
<th>LAAL</th>
<th>R1, R3, D2(B2)</th>
<th>[RSY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB'</td>
<td>R1</td>
<td>R3</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>LAALG</th>
<th>R1, R3, D2(B2)</th>
<th>[RSY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB'</td>
<td>R1</td>
<td>R3</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

The second operand of LAAL must be designated on a word boundary. The second operand of LAALG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Result zero; no overflow  
1  Result less than zero; no overflow  
2  Result greater than zero; no overflow  
3  Overflow

**Program Exceptions:**

- Access (fetch and store, operand 2)  
- Fixed-point overflow  
- Operation (if the interlocked-access facility 1 is not installed)  
- Specification  
- Transaction constraint

**Programming Notes:**

1. Except for the case where the R1 and R3 fields designate the same register, general register R3 is unchanged.

2. The operation of LOAD AND ADD, LOAD AND ADD LOGICAL, LOAD AND AND, LOAD AND EXCLUSIVE OR, and LOAD AND OR may be expressed as follows.
ond operand (prior to the addition) are placed unchanged at the first-operand location.

For LAAL, the operands are treated as being 32-bit unsigned binary integers. For LAALG, the operands are treated as being 64-bit unsigned binary integers.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAAL must be designated on a word boundary. The second operand of LAALG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Result zero; no carry
1  Result not zero; no carry
2  Result zero; carry
3  Result not zero; carry

**Program Exceptions:**

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

**Programming Note:** See the programming notes for LOAD AND ADD.

### LOAD AND AND

\[
\text{LAN} \quad R_1, R_2, D_2(B_2) \quad \text{[RSY-a]} \\
\text{'EB'} \quad R_1 \quad R_3 \quad B_2 \quad DL_2 \quad DH_2 \quad 'F4' \\
0 \quad 8 \quad 12 \quad 16 \quad 20 \quad 32 \quad 40 \quad 47
\]

\[
\text{LANG} \quad R_1, R_2, D_2(B_2) \quad \text{[RSY-a]} \\
\text{'EB'} \quad R_1 \quad R_3 \quad B_2 \quad DL_2 \quad DH_2 \quad 'E4' \\
0 \quad 8 \quad 12 \quad 16 \quad 20 \quad 32 \quad 40 \quad 47
\]

The AND of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the AND operation) are placed unchanged at the first-operand location.

For LAN, the operands are 32 bits. For LANG, the operands are 64 bits.

The connective AND is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both operands contain ones; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAN must be designated on a word boundary. The second operand of LANG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Result zero
1  Result not zero
2  --
3  --

**Program Exceptions:**

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

**Programming Note:** See the programming notes for LOAD AND ADD.

### LOAD AND EXCLUSIVE OR

\[
\text{LAX} \quad R_1, R_3, D_2(B_3) \quad \text{[RSY-a]} \\
\text{'EB'} \quad R_1 \quad R_3 \quad B_2 \quad DL_2 \quad DH_2 \quad 'F7' \\
0 \quad 8 \quad 12 \quad 16 \quad 20 \quad 32 \quad 40 \quad 47
\]
The EXCLUSIVE OR of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the EXCLUSIVE OR operation) are placed unchanged at the first-operand location.

For LAX, the operands are 32 bits. For LAXG, the operands are 64 bits.

The connective exclusive OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAX must be designated on a word boundary. The second operand of LAXG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Result zero
1  Result not zero
2  --
3  --

**Program Exceptions:**

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

**Programming Note:** See the programming notes for LOAD AND ADD.

The OR of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the OR operation) are placed unchanged at the first-operand location.

For LAO, the operands are 32 bits. For LAOG, the operands are 64 bits.

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAO must be designated on a word boundary. The second operand of LAOG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Result zero
1  Result not zero
2  --
3  --

**Program Exceptions:**

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
LOAD AND TEST

Register-and-register formats:

LTR  R1,R2  [RR]

LTGR  R1,R2  [RRE]

LTGF  R1,R2  [RRE]

Register-and-storage formats:

LT  R1,D2(X2,B2)  [RXY-a]

LTG  R1,D2(X2,B2)  [RXY-a]

LTGF  R1,D2(X2,B2)  [RXY-a]

The second operand is placed unchanged at the first operand location, except that, for LTGF and LTGFR, it is sign extended. The sign and magnitude of the second operand, treated as a signed binary integer, are indicated in the condition code.

For LT and LTR, the operands are 32 bits, and, for LTG and LTGR, the operands are 64 bits. For LTGF and LTGFR, the second operand is 32 bits, and the first operand is treated as a 64-bit signed binary integer.

**Resulting Condition Code:**

0  Result zero
1  Result less than zero
2  Result greater than zero
3  --

**Program Exceptions:**

- Access (fetch, operand 2 of LT, LTG, and LTGF only)
- Operation (LT and LTG, if the extended-immediate facility is not installed; LTGF, if the general-instructions-extension facility is not installed)

**Programming Note:** For LOAD AND TEST (LTR and LTGR) when the R1 and R2 fields designate the same register, the operation is equivalent to a test without data movement.

LOAD AND TRAP

LAT  R1,D2(X2,B2)  [RXY-a]

LGAT  R1,D2(X2,B2)  [RXY-a]

The second operand is placed unchanged at the first operand location. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

For LAT, the second operand is treated as a 32-bit signed integer and placed in bit positions 32-63 of general register R1, and bit positions 0-31 remain unchanged.

For LGAT, the second operand is treated as a 64-bit signed integer and placed in bit positions 0-63 of general register R1.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data
- Access (fetch, operand 2)
• Operation (if the load-and-trap facility is not installed)

Programming Note: Possible uses of LOAD AND TRAP include checking for pointers containing zero (null pointer).

LOAD AND ZERO RIGHTMOST BYTE

LZRF  \( R_1, D_2(X_2, B_2) \)  \( [RXY-a] \)

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47 \\
\end{array}
\]

\[\text{‘E3’} \quad R_1 \quad X_2 \quad B_2 \quad DL_2 \quad DH_2 \quad \text{‘3B’}\]

LZRG  \( R_1, D_2(X_2, B_2) \)  \( [RXY-a] \)

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47 \\
\end{array}
\]

\[\text{‘E3’} \quad R_1 \quad X_2 \quad B_2 \quad DL_2 \quad DH_2 \quad \text{‘2A’}\]

The second operand, with the rightmost byte set to zero, is placed at the first-operand location. For LZRF, the first and second operands are 32 bits, and for LZRG, the first and second operands are 64 bits.

The displacement is treated as a 20-bit signed binary integer.

It is unpredictable whether an access exception is recognized for the rightmost byte of the second operand.

Condition Code: The code remains unchanged.

Program Exceptions:

• Access (fetch, operand 2 of LB and LGB)
• Operation (LB and LGB, if the long-displacement facility is not installed; LBR and LGBR, if the extended-immediate facility is not installed)

LOAD BYTE

Register-and-register formats:

LBR  \( R_1, R_2 \)  \( [RRE] \)

\[
\begin{array}{cccc}
0 & 16 & 24 & 28 & 31 \\
\end{array}
\]

\[\text{‘B926’} \quad \text{‘/’/’/’/’/’/’/’/’/’} \quad R_1 \quad R_2]\n
LGBR  \( R_1, R_2 \)  \( [RRE] \)

\[
\begin{array}{cccc}
0 & 16 & 24 & 28 & 31 \\
\end{array}
\]

\[\text{‘B906’} \quad \text{‘/’/’/’/’/’/’/’/’/’} \quad R_1 \quad R_2]\n
The second operand is sign extended and placed at the first-operand location. The second operand is one byte in length and is treated as an eight-bit signed binary integer. For LOAD BYTE (LB and LGB), the second operand is a byte in storage. For LOAD BYTE (LBR and LGBR), the second operand is in bits 56-63 of general register \( R_2 \).

For LOAD BYTE (LB and LBR), the first operand is treated as a 32-bit signed binary integer. For LOAD BYTE (LGB and LGBR), the first operand is treated as a 64-bit signed binary integer.

The displacement for LB and LGB is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

• Access (fetch, operand 2 of LB and LGB)
• Operation (LB and LGB, if the long-displacement facility is not installed; LBR and LGBR, if the extended-immediate facility is not installed)

LOAD BYTE HIGH

Register-and-storage formats:

LB  \( R_1, D_2(X_2, B_2) \)  \( [RXY-a] \)

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47 \\
\end{array}
\]

\[\text{‘E3’} \quad R_1 \quad X_2 \quad B_2 \quad DL_2 \quad DH_2 \quad \text{‘76’}\]

LGB  \( R_1, D_2(X_2, B_2) \)  \( [RXY-a] \)

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47 \\
\end{array}
\]

\[\text{‘E3’} \quad R_1 \quad X_2 \quad B_2 \quad DL_2 \quad DH_2 \quad \text{‘77’}\]

The second operand is sign extended and placed at the first-operand location. The second operand is one byte in length and is treated as an eight-bit signed binary integer. For LOAD BYTE (LB and LGB), the second operand is a byte in storage. For LOAD BYTE (LBR and LGBR), the second operand is in bits 56-63 of general register \( R_2 \).

The first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register \( R_1 \); bits 32-63 of the register are unchanged.
The displacement is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

---

**LOAD COMPLEMENT**

- **LCR** \( R_1, R_2 \) \([RR]\)
- **LCGR** \( R_1, R_2 \) \([RRE]\)
- **LCGFR** \( R_1, R_2 \) \([RRE]\)

The two's complement of the second operand is placed at the first-operand location. For LOAD COMPLEMENT (LCR), the second operand and result are treated as 32-bit signed binary integers. For LOAD COMPLEMENT (LCGR), they are treated as 64-bit signed binary integers. For LOAD COMPLEMENT (LCGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

**Resulting Condition Code:**
- 0 Result zero; no overflow
- 1 Result less than zero; no overflow
- 2 Result greater than zero; no overflow
- 3 Overflow

**Program Exceptions:**
- Fixed-point overflow (LCR and LCGR only)

**Programming Note:** The operation complements all numbers. Zero remains unchanged. For LCR or LCGR, the maximum negative 32-bit number or 64-bit number, respectively, remains unchanged, and an overflow condition occurs when the number is complemented. LCGFR complements the maximum negative 32-bit number without recognizing overflow.

---

**LOAD COUNT TO BLOCK BOUNDARY**

- **LCBB** \( R_1, D_2(X_2,B_2), M_3 \) \([RXE]\)

A 32-bit unsigned binary integer containing the number of bytes possible to load from the second operand location without crossing a specified block boundary, with a maximum of sixteen is placed in the first operand. If the number of bytes is greater than sixteen, sixteen is placed in the first operand.

The displacement is treated as a 12-bit unsigned integer.

The second operand address is not used to address data.

The \( M_3 \) field specifies a code that is used to signal the CPU as to the block boundary size to compute the number of possible bytes loaded. If a reserved value is specified then a specification exception is recognized.

<table>
<thead>
<tr>
<th>Code</th>
<th>Boundary</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>64-Byte</td>
</tr>
<tr>
<td>1</td>
<td>128-Byte</td>
</tr>
<tr>
<td>2</td>
<td>256-Byte</td>
</tr>
<tr>
<td>3</td>
<td>512-Byte</td>
</tr>
<tr>
<td>4</td>
<td>1K-Byte</td>
</tr>
<tr>
<td>5</td>
<td>2K-Byte</td>
</tr>
<tr>
<td>6</td>
<td>4K-Byte</td>
</tr>
<tr>
<td>7-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Resulting Condition Code:**
- 0 Operand one is sixteen
1. --
2. --
3. Operand one is less than sixteen

**Program Exceptions:**

- Operation (if the vector facility for z/Architecture is not installed)
- Specification

**Programming Note:** It is expected that LOAD COUNT TO BLOCK BOUNDARY will be used in conjunction with VECTOR LOAD TO BLOCK BOUNDARY to determine the number of bytes that were loaded.

**LOAD HALFWORD**

*Register-and-register formats:*

<table>
<thead>
<tr>
<th>LHRL</th>
<th>R1, Ri2</th>
<th>[RIL-b]</th>
</tr>

<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

**LOAD HALFWORD IMMEDIATE**

<table>
<thead>
<tr>
<th>LHI</th>
<th>R1, I2</th>
<th>[RI-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'A7'</td>
<td>R1</td>
<td>'8'</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

The second operand is sign extended and placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer. For LOAD HALFWORD (LH, LHY, and LGH) and LOAD HALFWORD RELATIVE LONG, the second operand is in storage. For LOAD HALFWORD (LHI and LGHI), the second operand is the immediate field of the instruction. For LOAD HALFWORD (LHR and LGHR), the second operand is in bits 48-63 of general register R2.

For LOAD HALFWORD (LH, LHR, and LHY), LOAD HALFWORD IMMEDIATE (LHI), and LOAD HALFWORD RELATIVE LONG (LHRL), the first operand is treated as a 32-bit signed binary integer. For LOAD HALFWORD (LGH and LGHR), LOAD HALFWORD IMMEDIATE (LGHI), and LOAD HALFWORD RELATIVE LONG (LGHRL), the first operand is treated as a 64-bit signed binary integer.

The displacement for LH is treated as a 12-bit unsigned binary integer. The displacement for LHY and LGH is treated as a 20-bit signed binary integer.

For LOAD HALFWORD RELATIVE LONG, the contents of the Ri2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

**Condition Code:** The code remains unchanged.
Program Exceptions:

- Access (fetch, operand 2 of LH, LHY, LGH, LHRL and LGHRL)
- Operation (LHY, if the long-displacement facility is not installed; LHR and LGHR, if the extended-immediate facility is not installed; LHRL and LGHRL, if the general-instructions-extension facility is not installed)

Programming Notes:

1. An example of the use of the LOAD HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For LOAD HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.
3. When LOAD HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD HALFWORD HIGH

LHH \( R_1, D_2, (X_2, B_2) \) \[ RXY-a \]

The second operand is sign extended and placed at the first-operand location. The second operand is two bytes in length and is treated as an 16-bit signed binary integer.

The first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register \( R_1 \); bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD HALFWORD IMMEDIATE ON CONDITION

LOCHI \( R_1, I_2, M_3 \) \[ RIE-g \]

The second operand is sign extended and placed at the first-operand location if the condition code has one of the values specified by \( M_3 \); otherwise, the first operand remains unchanged.

For LOAD HALFWORD IMMEDIATE ON CONDITION (LOCHI), the first operand is treated as a 32-bit signed binary integer in bits 32-63 of general register \( R_1 \), and bits 0-31 of the register are unchanged. For LOAD HALFWORD HIGH IMMEDIATE ON CONDITION, the first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register \( R_1 \), and bits 32-63 of the register are unchanged. For LOAD HALFWORD IMMEDIATE ON CONDITION (LOCGHI), the first operand is treated as a 64-bit signed binary integer in bits 0-63 of general register \( R_1 \).

The second operand is the two byte \( I_2 \) field of the instruction and is treated as a 16-bit signed binary integer.
The M³ field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

<table>
<thead>
<tr>
<th>Condition Code</th>
<th>Mask Position Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the load is performed. If the mask bit selected is zero, the load is not performed.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Operation (if the load/store-on-condition facility 2 is not installed)

**Programming Notes:** See programming note 4 on page 7-240 for details on extended mnemonics for the instructions of the load/store-on-condition facilities.

### LOAD HIGH

**Register-and-register format:**

\[
\text{LFH} \quad R_1, D_1(X_2, B_2) \quad [RXY-a]
\]

<table>
<thead>
<tr>
<th>'E3'</th>
<th>( R_1 )</th>
<th>X₂</th>
<th>B₂</th>
<th>DL₂</th>
<th>DH₂</th>
<th>'CA'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>47</td>
</tr>
</tbody>
</table>

The second operand is placed unchanged at the first operand location. The second operand is 32 bits, and the first operand is in bits 0-31 of general register \( R_1 \); bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

### LOAD HIGH AND TRAP

**Register-and-register format:**

\[
\text{LFHAT} \quad R_1, D_1(X_2, B_2) \quad [RXY-a]
\]

<table>
<thead>
<tr>
<th>'E3'</th>
<th>( R_1 )</th>
<th>X₂</th>
<th>B₂</th>
<th>DL₂</th>
<th>DH₂</th>
<th>'C8'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>47</td>
</tr>
</tbody>
</table>

The second operand is treated as a 32-bit signed integer and placed unchanged in bit positions 0-31 of general register \( R_1 \), and bit positions 32-63 remain unchanged. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

**Programming Note:** Possible uses of LOAD HIGH AND TRAP include checking for pointers containing zero (null pointer).

### LOAD LOGICAL

**Register-and-register format:**

\[
\text{LLGFR} \quad R_1, R_2 \quad [RRE]
\]

<table>
<thead>
<tr>
<th>'B916'</th>
<th>( ////// // R_1 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8 12 16 20 32 40 47</td>
</tr>
</tbody>
</table>

**Register-and-storage format:**

\[
\text{LLGF} \quad R_1, D_1(X_2, B_2) \quad [RXY-a]
\]

<table>
<thead>
<tr>
<th>'E3'</th>
<th>( R_1 )</th>
<th>X₂</th>
<th>B₂</th>
<th>DL₂</th>
<th>DH₂</th>
<th>'16'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>47</td>
</tr>
</tbody>
</table>

### LOAD LOGICAL RELATIVE LONG

**Register-and-register format:**

\[
\text{LLGFRL} \quad R_1, R_1 \quad [RIL-b]
\]

<table>
<thead>
<tr>
<th>'C4'</th>
<th>( R_1 )</th>
<th>'E'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8 12 16 20 32 40 47</td>
<td></td>
</tr>
</tbody>
</table>

The four-byte second operand is placed in bit positions 32-63 of general register \( R_1 \), and zeros are placed in bit positions 0-31 of general register \( R_1 \).
For LOAD LOGICAL (LLGF), the second operand is in bit positions 32-63 of general register R2.

For LOAD LOGICAL RELATIVE LONG, the contents of the RI2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For LOAD LOGICAL RELATIVE LONG, the second operand must be aligned on a word boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of LLGF and LLGFRL only)
- Operation (LLGFRL, if the general-instructions-extension facility is not installed)
- Specification (LLGFRL only)

**LOAD LOGICAL AND Trap**

\[
\text{LLGFAT} \quad \text{R}_1,\text{D}_2(\text{X}_2,\text{B}_2) [\text{RXY-a}]
\]

The four-byte second operand is placed unchanged in bit positions 32-63 of general register R1, and zeros are placed in bit positions 0-31. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

**Programming Note:** Possible uses of LOAD LOGICAL AND TRAP include checking for pointers containing zero (null pointer).

**LOAD LOGICAL AND ZERO RIGHTMOST BYTE**

\[
\text{LLZRGF} \quad \text{R}_1,\text{D}_2(\text{X}_2,\text{B}_2) [\text{RXY-a}]
\]

The four-byte second operand, with the rightmost byte set to zero, is placed in bit positions 32-63 of general register R1, and zeros are placed in bit positions 0-31 of the register.

The displacement is treated as a 20-bit signed binary integer.

It is unpredictable whether an access exception is recognized for the rightmost byte of the second operand.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Operation (if the load-and-zero-rightmost-byte facility is not installed)

**LOAD LOGICAL CHARACTER**

**Register-and-register formats:**

\[
\text{LLCR} \quad \text{R}_1,\text{R}_2 [\text{RRE}]
\]

\[
\text{LLGCR} \quad \text{R}_1,\text{D}_2(\text{X}_2,\text{B}_2) [\text{RXY-a}]
\]

**Register-and-storage formats:**

\[
\text{LLC} \quad \text{R}_1,\text{D}_2(\text{X}_2,\text{B}_2) [\text{RXY-a}]
\]

\[
\text{LLGC} \quad \text{R}_1,\text{D}_2(\text{X}_2,\text{B}_2) [\text{RXY-a}]
\]
The one-byte second operand is placed in bit positions 56-63 of general register \( R_1 \). For LOAD LOGICAL CHARACTER (LLGC, LLGCR), zeros are placed in bit positions 0-55 of general register \( R_1 \). For LOAD LOGICAL CHARACTER (LLC, LLCR), zeros are placed in bit positions 32-55 of general register \( R_1 \); bit positions 0-31 of general register \( R_1 \) are unchanged.

For LOAD LOGICAL CHARACTER (LLC, LLGC), the second operand is in storage. For LOAD LOGICAL CHARACTER (LLCR, LLGCR), the second operand is in bits 56-63 of general register \( R_2 \).

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of LLC and LLGC)
- Operation (LLC, LLCR, and LLGCR, if the extended-immediate facility is not installed)

### LOAD LOGICAL CHARACTER HIGH

<th>SI</th>
</tr>
</thead>
<tbody>
<tr>
<td>'C4'</td>
<td></td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>
HALFWORD (LLGHR, LLHR), the second operand is in bits 48-63 of general register \( R_2 \).

For LOAD LOGICAL HALFWORD RELATIVE LONG, the contents of the \( R_{i2} \) field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of LLGH, LLH, LLHRL, and LLGHRL)
- Operation (LLGHR, LLH, and LLHR, if the extended-immediate facility is not installed; LLHRL and LLGHRL, if the general-instructions-extension facility is not installed)

**Programming Notes:**

1. For LOAD LOGICAL HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.
2. When LOAD LOGICAL HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

### LOAD LOGICAL HALFWORD HIGH

\[
\text{LLHH} \quad R_{i1}, D_2(X_2, B_2) \quad [\text{RXY-a}]
\]

The two-byte second operand is placed in bit positions 16-31 of general register \( R_1 \); bits positions 32-63 of general register \( R_1 \) are unchanged.

The displacement is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

### LOAD LOGICAL IMMEDIATE

\[
\begin{align*}
\text{LLIHF} & \quad R_{i1}, I_2 \quad [\text{RIL-a}] \\
\text{LLIH} & \quad R_{i1}, I_2 \quad [\text{RIL-a}] \\
\text{LHIL} & \quad R_{i1}, I_2 \quad [\text{RI-a}] \\
\text{LHILF} & \quad R_{i1}, I_2 \quad [\text{RI-a}] \\
\text{LHILF} & \quad R_{i1}, I_2 \quad [\text{RI-a}] \\
\text{LHILF} & \quad R_{i1}, I_2 \quad [\text{RI-a}] \\
\text{LLILF} & \quad R_{i1}, I_2 \quad [\text{RI-a}] \\
\end{align*}
\]

The second operand is placed in bit positions of the first operand. The remainder of the first operand is set to zeros.

For each instruction, the bit positions of the first operand that are loaded with the second operand are as follows:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Bit Positions Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLIHF</td>
<td>0-31</td>
</tr>
</tbody>
</table>
LOAD MULTIPLE

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Bit Positions Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLIHH</td>
<td>0-15</td>
</tr>
<tr>
<td>LLIHL</td>
<td>16-31</td>
</tr>
<tr>
<td>LLILF</td>
<td>32-63</td>
</tr>
<tr>
<td>LLILH</td>
<td>32-47</td>
</tr>
<tr>
<td>LLILL</td>
<td>48-63</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Operation (LLIHF and LLILF, if the extended-immediate facility is not installed)

LOAD LOGICAL THIRTY ONE BITS

**Register-and-register format:**

<table>
<thead>
<tr>
<th>LLGTR R1,R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B917'</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>R1</td>
</tr>
<tr>
<td>16</td>
<td>R2</td>
</tr>
</tbody>
</table>

**Register-and-storage format:**

<table>
<thead>
<tr>
<th>LLGT R1,D2(X2,B2)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E3'</td>
<td>R1, X2, B2, DL2, DH2, '17'</td>
</tr>
</tbody>
</table>

For LLGTR, bits 33-63 of general register R2, with 33 zeros appended on the left, are placed in general register R1. For LLGT, bits 1-31 of the four bytes at the second-operand location, with 33 zeros appended on the left, are placed in general register R1.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)

LOAD LOGICAL THIRTY ONE BITS AND TRAP

<table>
<thead>
<tr>
<th>LLGTAT R1,D2(X2,B2)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E3'</td>
<td>R1, X2, B2, DL2, DH2, '9C'</td>
</tr>
</tbody>
</table>

For LLGTAT, bits 33-63 of general register R2, with 33 zeros appended on the left, are placed unchanged in bit positions 33-63 of general register R1, and zeros are placed in bit positions 0-32. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

**Programming Note:** Possible uses of LOAD LOGICAL THIRTY ONE BITS AND TRAP include checking for pointers containing zero (null pointer).

LOAD MULTIPLE

<table>
<thead>
<tr>
<th>LM R1,R3,D2(B2)</th>
<th>[RS-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'98' R1, R3, B2</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Loaded</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>R1</td>
</tr>
<tr>
<td>8</td>
<td>R3</td>
</tr>
<tr>
<td>12</td>
<td>B2</td>
</tr>
<tr>
<td>16</td>
<td>D2</td>
</tr>
</tbody>
</table>

Bit positions of the set of general registers starting with general register R1 and ending with general register R3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD MULTIPLE (LM, LMY), bit positions 32-63 of the general registers are loaded from successive four-byte fields beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD MULTIPLE (LMG), bit positions 0-63 of the general registers are loaded from successive eight-byte fields beginning at the second-operand address.
The general registers are loaded in the ascending order of their register numbers, starting with general register R1 and continuing up to and including general register R3, with general register 0 following general register 15.

The displacement for LM is treated as a 12-bit unsigned binary integer. The displacement for LMY and LMG is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Operation (LMY, if the long-displacement facility is not installed)

**Programming Note:** All combinations of register numbers specified by R1 and R3 are valid. When the register numbers are equal, only four bytes, for LM or LMY or eight bytes, for LMG, are transmitted. When the number specified by R3 is less than the number specified by R1, the register numbers wrap around from 15 to 0.

**LOAD MULTIPLE DISJOINT**

```
LMD   R1, R3, D2(B2), D4(B4) [SS-e]
```

Bit positions 0-31 of the set of general registers starting with general register R1 and ending with general register R3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed. Bit positions 32-63 of the same registers are similarly loaded from storage beginning at the location designated by the fourth-operand address.

The general registers are loaded in the ascending order of their register numbers, starting with general register R1 and continuing up to and including general register R3, with general register 0 following general register 15.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operands 2 and 4)
- Transaction constraint

**Programming Notes:**
1. All combinations of register numbers specified by R1 and R3 are valid. When the register numbers are equal, only eight bytes are transmitted. When the number specified by R3 is less than the number specified by R1, the register numbers wrap around from 15 to 0.
2. The second-operand and fourth-operand addresses are computed before the contents of any register are changed.
3. The combination of a LOAD MULTIPLE instruction and a LOAD MULTIPLE HIGH instruction provides equal or better performance than a LOAD MULTIPLE DISJOINT instruction for the same register range. LOAD MULTIPLE DISJOINT is for use when the second or fourth operand must be addressed by means of one of the registers loaded.

**LOAD MULTIPLE HIGH**

```
LMH   R1, R3, D2(B2) [RSY-a]
```

The high-order halves, bit positions 0-31, of the set of general registers starting with general register R1 and ending with general register R3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed, that is, bit positions 0-31 are loaded from successive four-byte fields beginning at the second-operand address. Bits 32-63 of the registers remain unchanged.

The general registers are loaded in the ascending order of their register numbers, starting with general register R1 and continuing up to and including general register R3, with general register 0 following general register 15.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
**Programming Note:** All combinations of register numbers specified by \( R_1 \) and \( R_3 \) are valid. When the register numbers are equal, only four bytes are transmitted. When the number specified by \( R_3 \) is less than the number specified by \( R_1 \), the register numbers wrap around from 15 to 0.

**LOAD NEGATIVE**

\[
\text{LNR} \quad R_1, R_2 \quad \text{[RR]}
\]

\[
\begin{array}{c|cccc}
 & \text{‘11’} & R_1 & R_2 \\
\hline
0 & 8 & 12 & 15
\end{array}
\]

\[
\text{LNGR} \quad R_1, R_2 \quad \text{[RRE]}
\]

\[
\begin{array}{c|cccc}
 & \text{‘B901’} & 0 & 16 & 24 \\
\hline
0 & 8 & 12 & 15 & 28 & 31
\end{array}
\]

\[
\text{LNGFR} \quad R_1, R_2 \quad \text{[RRE]}
\]

\[
\begin{array}{c|cccc}
 & \text{‘B911’} & 0 & 16 & 24 \\
\hline
0 & 8 & 12 & 15 & 28 & 31
\end{array}
\]

The two’s complement of the absolute value of the second operand is placed at the first-operand location. For LOAD NEGATIVE (LNR), the second operand and result are treated as 32-bit signed binary integers, and, for LOAD NEGATIVE (LNGR), they are treated as 64-bit signed binary integers. For LOAD NEGATIVE (LNGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

**Resulting Condition Code:**

- 0 Result zero
- 1 Result less than zero
- 2 --
- 3 --

**Program Exceptions:** None.

**Programming Note:** The operation complements positive numbers; negative numbers remain unchanged. The number zero remains unchanged.

**LOAD ON CONDITION**

**Register-and-register formats:**

\[
\text{LOCR} \quad R_1, R_2, M_3 \quad \text{[RRF-c]}
\]

\[
\begin{array}{c|cccc}
\text{‘B9F2’} & M_3 & \ldots & R_1 & R_2 \\
\hline
0 & 16 & 20 & 24 & 28 & 31
\end{array}
\]

\[
\text{LOCGR} \quad R_1, R_2, M_3 \quad \text{[RRF-c]}
\]

\[
\begin{array}{c|cccc}
\text{‘B9E2’} & M_3 & \ldots & R_1 & R_2 \\
\hline
0 & 16 & 20 & 24 & 28 & 31
\end{array}
\]

**Register-and-storage formats:**

\[
\text{LOC} \quad R_1, D_2(B_2), M_3 \quad \text{[RSY-b]}
\]

\[
\begin{array}{c|cccc}
\text{‘EB’} & R_1 & M_3 & B_2 & \ldots \\
\hline
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47
\end{array}
\]

\[
\text{LOCG} \quad R_1, D_2(B_2), M_3 \quad \text{[RSY-b]}
\]

\[
\begin{array}{c|cccc}
\text{‘EB’} & R_1 & M_3 & B_2 & \ldots \\
\hline
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47
\end{array}
\]

**LOAD HIGH ON CONDITION**

**Register-and-register formats:**

\[
\text{LOCFHR} \quad R_1, R_2, M_3 \quad \text{[RRF-c]}
\]

\[
\begin{array}{c|cccc}
\text{‘B9E0’} & M_3 & \ldots & R_1 & R_2 \\
\hline
0 & 16 & 20 & 24 & 28 & 31
\end{array}
\]

\[
\text{LOCFH} \quad R_1, D_2(B_2), M_3 \quad \text{[RSY-b]}
\]

\[
\begin{array}{c|cccc}
\text{‘EB’} & R_1 & M_3 & B_2 & \ldots \\
\hline
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47
\end{array}
\]

The second operand is placed unchanged at the first-operand location if the condition code has one of the values specified by \( M_3 \); otherwise, the first operand remains unchanged.

**Program Exceptions:** None.

**Programming Note:** The operation complements positive numbers; negative numbers remain unchanged. The number zero remains unchanged.

For LOC, LOCFH, LOCFHR, and LOCR, the first and second operands are 32 bits, and for LOCG and LOCGR, the first and second operands are 64 bits.

For LOC and LOCR, the first operand is in bits 32-63 of general register \( R_1 \), and bits 0-31 of the register are unchanged. For LOCFH and LOCFHR, the first operand is in bits 0-31 of general register \( R_1 \), and bits 32-63 of the register are unchanged.

For LOCR, the second operand is in bits 32-63 of general register \( R_2 \), and bits 0-31 of the register are unchanged.
ignored. For LOCFHR, the second operand is in bits 0-31 of general register R2, and bits 32-63 of the register are ignored.

The M3 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

<table>
<thead>
<tr>
<th>Condition Code</th>
<th>Mask Position Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the load is performed. If the mask bit selected is zero, the load is not performed.

The displacement for LOC, LOCFH, and LOCG is treated as a 20-bit signed binary integer.

For LOC, LOCFH, and LOCG, when the condition specified by the M3 field is not met (that is, the load operation is not performed), it is model dependent whether an access exception or a PER zero-address detection event is recognized for the second operand.

**Condition Code**: The code remains unchanged.

**Program Exceptions**:  
- Access (fetch, operand 2 of LOC, LOCFH, and LOCG)
- Operation (LOC, LOCG, LOCGR, LOCIBM, if the load/store-on-condition facility 1 is not installed; LOCFH, LOCFHR, if the load/store-on-condition facility 2 is not installed)

**Programming Notes**:  
1. When the M3 field contain all zeros and no exception condition exists, the instruction acts as a NOP. When the M3 field contains all ones and no exception condition exists, the load operation is always performed. However, these are not the preferred means of implementing a NOP or unconditional load, respectively.

2. For LOC, LOCFH, and LOCG, when the condition specified by the M3 field is not met, it is model dependent whether the second operand is brought into the cache.

3. LOAD ON CONDITION provides a function similar to that of a separate BRANCH ON CONDITION instruction followed by a LOAD instruction, except that LOAD ON CONDITION does not provide an index register. For example, the following two instruction sequences are equivalent.

```
LOC 15,256(7),8 BC 7,SKIP
LG 15,256(0,7)
SKIP DS 0H
```

On models that implement predictive branching, the combination of the BRANCH ON CONDITION and LOAD instructions may perform somewhat better than the LOAD ON CONDITION instruction when the CPU is able to successfully predict the branch condition. However, on models where the CPU is not able to successfully predict the branch condition, such as when the condition is more random, the LOAD ON CONDITION instruction may provide significant performance improvement.

4. The High-Level Assembler (HLASM) provides the following extended-mnemonic suffixes for the load/store-on-condition facilities’ instructions in place of the M3 field.

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
<th>Effective M3 Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>Equal</td>
<td>B’1000’</td>
</tr>
<tr>
<td>L</td>
<td>Low</td>
<td>B’0100’</td>
</tr>
<tr>
<td>H</td>
<td>High</td>
<td>B’0010’</td>
</tr>
<tr>
<td>NE</td>
<td>Not equal</td>
<td>B’0110’</td>
</tr>
<tr>
<td>NL</td>
<td>Not low</td>
<td>B’1011’</td>
</tr>
<tr>
<td>NH</td>
<td>Not high</td>
<td>B’1110’</td>
</tr>
</tbody>
</table>

Later versions of HLASM provide the following extended-mnemonic suffixes for the load/store-
on-condition facilities’ instructions in place of the M₃ field.

When the extended mnemonic is coded, the M₃ field must be omitted.

**LOAD PAIR DISJOINT**

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
<th>Effective M₃ Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Z</td>
<td>Zero</td>
<td>B'1000'</td>
</tr>
<tr>
<td>M</td>
<td>Minus or mixed</td>
<td>B'0100'</td>
</tr>
<tr>
<td>P</td>
<td>Plus</td>
<td>B'0010'</td>
</tr>
<tr>
<td>O</td>
<td>Overflow or ones</td>
<td>B'0001'</td>
</tr>
<tr>
<td>NZ</td>
<td>Not zero</td>
<td>B'0111'</td>
</tr>
<tr>
<td>NM</td>
<td>Not minus or not mixed</td>
<td>B'1011'</td>
</tr>
<tr>
<td>NP</td>
<td>Not plus</td>
<td>B'1101'</td>
</tr>
<tr>
<td>NO</td>
<td>Not overflow or not ones</td>
<td>B'1110'</td>
</tr>
</tbody>
</table>

When the extended mnemonic is coded, the M₃ field must be omitted.

The displacement of the first and second operands is treated as a 12-bit unsigned binary integer.

The first and second operands of LPD must be designated on a word boundary. The first and second operands of LPDG must be designated on a double-word boundary. General register R₃ must designate the even numbered register. Otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Register pair loaded by means of interlocked fetch
1  --
2  --
3  Register pair not loaded by means of interlocked fetch

**Program Exceptions:**

- Access (fetch, operands 1 and 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification

**Programming Notes:**

1. The setting of the condition code is dependent upon storage accesses by other CPUs in the configuration.
2. When the resulting condition code is 3, the program may branch back to reexecute the LOAD PAIR DISJOINT instruction. However, after repeated unsuccessful attempts to attain an interlocked fetch, the program should use an alternate means of serializing access to the storage operands. It is recommended that the program reexecute the LOAD PAIR DISJOINT no more than 10 times before branching to the alternate path.
3. The program should be able to accommodate a situation where condition code 0 is never set.
LOAD PAIR FROM QUADWORD

LOAD PAIR FROM QUADWORD

The quadword second operand is loaded into the first-operand location. The second operand appears to be fetched with quadword concurrency as observed by other CPUs. The left doubleword of the quadword is loaded into general register $R_1$, and the right doubleword is loaded into general register $R_1 + 1$.

The $R_1$ field designates an even-odd pair of general registers and must designate an even-numbered register. The second operand must be designated on a quadword boundary. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
- Specification
- Transaction constraint

**Programming Notes:**

1. The LOAD MULTIPLE (LM or LMG) instruction does not necessarily provide quadword-concurrent access.

2. The performance of LOAD PAIR FROM QUADWORD on some models may be significantly slower than that of LOAD MULTIPLE (LMG). Unless quadword consistency is required, LMG should be used instead of LPQ.

LOAD POSITIVE

LOAD REVERSED

The absolute value of the second operand is placed at the first-operand location. For LOAD POSITIVE (LPR), the second operand and result are treated as 32-bit signed binary integers, and, for LOAD POSITIVE (LPGR), they are treated as 64-bit signed binary integers. For LOAD POSITIVE (LPGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

**Resulting Condition Code:**

- 0 Result zero; no overflow
- 1 --
- 2 Result greater than zero; no overflow
- 3 Overflow

**Program Exceptions:**

- Fixed-point overflow (LPR and LPGR only)

**Programming Note:** The operation complements negative numbers; positive numbers and zero remain unchanged. For LPR or LPGR, an overflow condition occurs when the maximum negative 32-bit number or 64-bit number, respectively, is complemented; the number remains unchanged. LPGFR complements the maximum negative 32-bit number without recognizing overflow.

LOAD REVERSED

Register-and-register formats:
Register-and-storage formats:

<table>
<thead>
<tr>
<th>Register</th>
<th>R1, D1(X2, B2)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>LRH</td>
<td>'E1' R1 X2 B2 DL2 DH2 '1F'</td>
<td></td>
</tr>
<tr>
<td>LRV</td>
<td>'E1' R1 X2 B2 DL2 DH2 '1E'</td>
<td></td>
</tr>
<tr>
<td>LRVG</td>
<td>'E1' R1 X2 B2 DL2 DH2 '0F'</td>
<td></td>
</tr>
</tbody>
</table>

The second operand is placed at the first-operand location with the left-to-right sequence of the bytes reversed.

For LOAD REVERSED (LRVH), the second operand is two bytes, the result is placed in bit positions 48-63 of general register R1, and bits 0-47 of the register remain unchanged.

For LOAD REVERSED (LRVR, LRV), the second operand is four bytes, the result is placed in bit positions 32-63 of general register R1, and bits 0-31 of the register remain unchanged. For LOAD REVERSED (LRVR), the second operand is in bit positions 32-63 of general register R2.

For LOAD REVERSED (LRVGR, LRVG), the second operand is eight bytes.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of LRVH, LRV, LRVG only)

**Programming Notes:**

1. The instruction can be used to convert two, four, or eight bytes from a “little-endian” format to a “big-endian” format, or vice versa. In the big-endian format, the bytes in a left-to-right sequence are in the order most significant to least significant. In the little-endian format, the bytes are in the order least significant to most significant. For example, the bytes ABCD in the big-endian format are DCBA in the little-endian format.

2. LOAD REVERSED (LRVR) can be used with a two-byte value already in a register as shown in the following example. In the example, the two bytes of interest are in bit positions 48-63 of the R1 register.

   LRVR R1,R1
   SRA R1,16

   The LOAD REVERSED instruction places the two bytes of interest in bit positions 32-47 of the register, with the order of the bytes reversed. The SHIFT RIGHT SINGLE (SRA) instruction shifts the two bytes to bit positions 48-63 of the register and extends them on their left, in bit positions 32-47, with their sign bit. The instruction SHIFT RIGHT SINGLE LOGICAL (SRL) should be used, instead, if the two bytes of interest are unsigned.

3. The storage-operand references of LOAD REVERSED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

**MONITOR CALL**

<table>
<thead>
<tr>
<th>MC</th>
<th>D1(B1), I2</th>
<th>[SI]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'AF'</td>
<td>I2 B1 D1</td>
<td></td>
</tr>
</tbody>
</table>
When the monitor-mask bit corresponding to the specified monitor class is one, a monitor event occurs. When the monitor-mask bit corresponding to the specified monitor class is zero, no monitor-event occurs, and the instruction is executed as a no-operation.

When the enhanced-monitor facility is installed, the enhanced-monitor-mask bits are in bit positions 16-31 of control register 8, which correspond to monitor classes 0-15 respectively. When a monitor event occurs and either (a) the enhanced-monitor facility is not installed, or (b) the facility is installed but the enhanced-monitor-mask bit corresponding to the monitor class is zero, then a monitor-event program interruption occurs, as described below. When a monitor event occurs and the enhanced-monitor-mask bit corresponding to the monitor class is one, a monitor-event counting operation is performed.

The first-operand address is not used to address data; instead, the address specified by the B₁ and D₁ fields forms the monitor code. Address computation follows the rules of address arithmetic; in the 24-bit addressing mode, bits 0-39 are set to zeros; in the 31-bit addressing mode, bits 0-32 are set to zeros.

**Monitor-Event Program Interruption**

When a monitor-event program interruption occurs:

- The monitor code formed by the first-operand address is placed in the doubleword at real location 176.
- The contents of the I₂ field are stored at real location 149, with zeros stored at real location 148.
- Bit 9 of the program-interruption code is set to one.

**Monitor-Event Counting Operation**

The monitor-event counting operation is described in “Monitor-Event Counting” on page 5-110.

**Special Conditions**

Bit positions 8-11 of the instruction must contain zeros; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Monitor event
- Specification
- Transaction constraint

**Programming Notes:**

1. The monitor-event program interruption provides the capability for passing control to a monitoring program when selected points are reached in the monitored program. This is accomplished by implanting MONITOR CALL instructions at the desired points in the monitored program. This function may be useful in performing various measurement functions; specifically, tracing information can be generated indicating which programs were executed, counting information can be generated indicating how often particular programs were used, and timing information can be generated indicating the amount of time a particular program required for execution.

2. The monitor masks provide a means of disallowing all monitor events or allowing monitor events for all or selected classes.

3. When used to generate a monitor-event program interruption, the monitor code provides a means of associating descriptive information, in addition to the class number, with each MONITOR CALL.

Without the use of a base register, up to 4,096 distinct monitor codes can be associated with a monitor event. With the base register designated by a nonzero value in the B₁ field, each monitoring interruption can be identified by a 24-bit, 31-bit, or 64-bit code, depending on the addressing mode.

**MOVE**

**Storage-and-storage format:**

<table>
<thead>
<tr>
<th>MVC</th>
<th>D₁(B₁),D₂(B₂)</th>
<th>[SS-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;D2&quot;</td>
<td>L</td>
<td>B₁</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>16</td>
</tr>
</tbody>
</table>

**Storage-and-immediate formats:**

<table>
<thead>
<tr>
<th>MVHHI</th>
<th>D₁(B₁),I₂</th>
<th>[SIL]</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;E544&quot;</td>
<td>B₁</td>
<td>D₁</td>
</tr>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>
MOVE INVERSE

MOVE INVERSE

MVHI D1(B1),I2 [SIL]

MVGHI D1(B1),I2 [SIL]

MVI D1(B1),I2 [SI]

MVIY D1(B1),I2 [SIY]

The second operand is placed at the first-operand location.

For MOVE (MVC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand byte.

For MOVE (MVI, MVIY), the first operand is one byte in length, and only one byte is stored.

For MOVE (MVGHI, MVHHI, and MVHI), the second operand is treated as a 16-bit signed integer, sign-extended as necessary, and placed in the first-operand location. The first operand is two, four, or eight bytes for MVHHI, MVHI, and MVGHI, respectively.

The displacements for MVGHI, MVHHI, MVHI, MVI and both operands of MVC are treated as 12-bit unsigned binary integers. The displacement for MVIY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of MVC; store, operand 1, MVC, MVGHI, MVHHI, MVHI, MVI, and MVIY)
- Operation (MVIY, if the long-displacement facility is not installed; MVGHI, MVHHI, and MVHI, if the general-instructions-extension facility is not installed)

MOVCIN D1(L,B1),D2(B2) [SS-a]

The second operand is placed at the first-operand location with the left-to-right sequence of the bytes inverted.

The first-operand address designates the leftmost byte of the first operand. The second-operand address designates the rightmost byte of the second operand. Both operands have the same length.

The result is obtained as if the second operand were processed from right to left and the first operand from left to right. The second operand may wrap around from location 0 to location $2^{24} - 1$ in the 24-bit addressing mode, to location $2^{31} - 1$ in the 31-bit addressing mode, or to location $2^{64} - 1$ in the 64-bit addressing mode. The first operand may wrap around from location $2^{24} - 1$ to location 0 in the 24-bit addressing mode, from location $2^{31} - 1$ to location 0 in the 31-bit addressing mode, or from location $2^{64} - 1$ to location 0 in the 64-bit addressing mode.

When the operands overlap by more than one byte, the contents of the overlapped portion of the result field are unpredictable.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint
Programming Notes:

1. An example of the use of the MOVE INVERSE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The contents of each byte moved remain unchanged.

3. MOVE INVERSE is the only SS-format instruction for which the second-operand address designates the rightmost, instead of the leftmost, byte of the second operand.

4. The storage-operand references for MOVE INVERSE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123)

MOVE LONG

MVCL R1, R2 [RR]

The second operand is placed at the first-operand location, provided overlapping of operand locations would not affect the final contents of the first-operand location. The remaining rightmost byte positions, if any, of the first-operand location are filled with padding bytes.

The R1 and R2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R1 +1 and R2 +1, respectively. The number of bytes in the first-operand and second-operand locations is specified by unsigned binary integers in bit positions 40-63 of general registers R1 +1 and R2 +1, respectively. Bit positions 32-39 of general register R2 +1 contain the padding byte. The contents of bit positions 0-39 of general register R1 +1 and of bit positions 0-31 of general register R2 +1 are ignored.

The handling of the addresses in general registers R1 and R2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-253 on page 7-247.

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified by bits 40-63 of general register R1 +1 have been moved into the first-operand location. If the second operand is shorter than the first operand, the remaining rightmost bytes of the first-operand location are filled with the padding byte.

As part of the execution of the instruction, the values of the two length fields are compared for the setting of the condition code, and a check is made for destructive overlap of the operands. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it, assuming the inspection for overlap is performed by the use of logical operand addresses. When the operands overlap destructively, no movement takes place, and condition code 3 is set.

Operands do not overlap destructively, and movement is performed, if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location 224 -1 (or 231 -1 or 264 -1) to location 0, operand bytes in locations up to and including 224 -1 (or 231 -1 or 264 -1) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location 224 -1 to location 0; in the 31-bit addressing mode, wraparound is from location 231 -1 to location 0; in the 64-bit addressing mode, wraparound is from location 264 -1 to location 0.

In the access-register mode, the contents of access register R1 and access register R2 are compared. If the R1 or R2 field is zero, 32 zeros are used rather than the contents of access register 0. If all 32 bits of the compared values are equal, then the destructive
overlap test is made. If all 32 bits of the compared values are not equal, destructive overlap is declared not to exist. If, for this case, the operands actually overlap in real storage, it is unpredictable whether the result reflects the overlap condition.

When the length specified by bits 40-63 of general register R₁ + 1 is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the lengths in general registers R₁ + 1 and R₂ + 1 are decremented by the number of bytes moved, and the addresses in general registers R₁ and R₂ are incremented by the same number, so that the instruction, when reexecuted, resumes at the point of interruption. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R₁ and R₂ are set to zeros, and the contents of bit positions 0-31 remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers R₁ + 1 and R₂ + 1 remain unchanged; and the condition code is unpredictable. If the operation is interrupted during padding, the length field in general register R₂ + 1 is 0, the address in general register R₂ is incremented by the original length in general register R₂ + 1, and general registers R₁ and R₁ + 1 reflect the extent of the padding operation.

When the first-operand location includes the location of the instruction or of an execute-type instruction, the instruction may be refetched from storage and reinterpreted even in the absence of an interruption during execution. The exact point in the execution at which such a refetch occurs is unpredictable.
Padding byte values of B0 hex and B8 hex may be used during the nonpadding part of the operation by some models, in certain cases, as an indication of whether the movement should be performed bypassing the cache or using the cache, respectively. Thus, a padding byte of B0 hex indicates no intention to reference the destination area after the move, and a padding byte of B8 hex indicates an intention to reference the destination area.

For the nonpadding part of the operation when the padding byte is not B1 hex, accesses to the operands for MOVE LONG may be multiple-access references, and these accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. When the padding byte is B1 hex, accesses to the operands are single-access references, and these accesses appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding byte is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding byte may cause unpredictable results.

At the completion of the operation, the length in general register R1 + 1 is decremented by the number of bytes stored at the first-operand location, and the address in general register R1 is incremented by the same amount. The length in general register R2 + 1 is decremented by the number of bytes moved out of the second-operand location, and the address in general register R3 is incremented by the same amount. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R1 and R2 are set to zeros, even when one or both of the original length values are zeros or when condition code 3 is set. The contents of bit positions 0-31 of the registers remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers R1 + 1 and R2 + 1 remain unchanged.

When condition code 3 is set, no exceptions associated with operand access are recognized. When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the second operand is longer than the first operand, access exceptions are not recognized for the part of the second-operand field that is in excess of the first-operand field. For operands longer than 2K bytes, access exceptions are not recognized for locations more than 2K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

**Resulting Condition Code:**

0  Operand lengths equal; no destructive overlap
1  First-operand length low; no destructive overlap
2  First-operand length high; no destructive overlap
3  No movement performed because of destructive overlap

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

**Programming Notes:**

1. An example of the use of the MOVE LONG instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE LONG may be used for clearing storage by setting the padding byte to zero and the second-operand length to zero. On most models, this is the fastest instruction for clearing storage areas in excess of 256 bytes. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-123.

3. The program should avoid specification of a length for either operand which would result in an addressing exception. Addressing (and also protection) exceptions may result in termination of the entire operation, not just the current unit of
operation. The termination may be such that the contents of all result fields are unpredictable; in the case of MOVE LONG, this includes the condition code and the two even-odd general-register pairs, as well as the first-operand location in main storage. The following are situations that have actually occurred on one or more models:

a. When a protection exception occurs on a 4K-byte block of a first operand which is several blocks in length, stores to the protected block are suppressed. However, the move continues into the subsequent blocks of the first operand, which are not protected. Similarly, an addressing exception on a block does not necessarily suppress processing of subsequent blocks which are available.

b. Some models may update the general registers only when an external, I/O, repressible machine-check, or restart interruption occurs, or when a program interruption occurs for which it is required to nullify or suppress a unit of operation. Thus, if, after a move into several blocks of the first operand, an addressing or protection exception occurs, the general registers may remain unchanged.

4. When the first-operand length is zero, the operation consists in setting the condition code and, in the 24-bit or 31-bit addressing mode, of setting the leftmost bits in bit positions 32-63 of general registers R1 and R2 to zero.

5. When the contents of the R1 and R2 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by twice the number of bytes moved. Condition code 0 is set.

6. The following is a detailed description of those cases in which movement takes place, that is, where destructive overlap does not exist.

In the access-register mode, the contents of the access registers used are called the effective space designations. When the effective space designations are not equal, destructive overlap is declared not to exist and movement occurs. When the effective space designations are the same or when not in the access-register mode, then the following cases apply.

Depending on whether the second operand wraps around from location $2^{2k} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$, depending on the addressing mode) to location 0, movement takes place in the following cases:

a. When the second operand does not wrap around, movement is performed if the leftmost byte of the first operand coincides with or is to the left of the leftmost byte of the second operand, or if the leftmost byte of the first operand is to the right of the rightmost second-operand byte participating in the operation.

b. When the second operand wraps around, movement is performed if the leftmost byte of the first operand coincides with or is to the left of the leftmost byte of the second operand, and if the leftmost byte of the first operand is to the right of the rightmost second-operand byte participating in the operation.

The rightmost second-operand byte is determined by using the smaller of the first-operand and second-operand lengths.

When the second-operand length is one or zero, destructive overlap cannot exist.

7. Special precautions should be taken if MOVE LONG is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

8. Since the execution of MOVE LONG is interruptible, the instruction cannot be used for situations where the program must rely on uninterrupted execution of the instruction. Similarly, the program should normally not let the first operand of MOVE LONG include the location of the instruction or of an execute-type instruction because the new contents of the location may be interpreted for a resumption after an interruption, or the instruction may be refetched without an interruption.

9. Further programming notes concerning interruptible instructions are included in "Interruptible Instructions" in Chapter 5, "Program Execution."

10. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.
MOVE LONG EXTENDED

All or part of the third operand is placed at the first-operand location. The remaining rightmost byte positions, if any, of the first-operand location are filled with padding bytes. The operation proceeds until the end of the first-operand location is reached or a CPU-determined number of bytes have been placed at the first-operand location, whichever occurs first. The result is indicated in the condition code.

The R1 and R3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R1 and R3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers R1 + 1 and R3 + 1, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the entire contents of general registers R1 + 1 and R3 + 1, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R1 and R3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The second-operand address is not used to address data; instead, the rightmost eight bits of the second-operand address, bits 56-63, are the padding byte. Bits 0-55 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-254 on page 7-251.

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified in general register R1 + 1 have been placed at the first-operand location or when a CPU-determined number of bytes have been placed, whichever occurs first. If the third operand is shorter than the first operand, the remaining rightmost bytes of the first-operand location are filled with the padding byte.

When the operation is completed because the end of the first operand has been reached, the condition code is set to 0 if the two operand lengths are equal, it is set to 1 if the first-operand length is less than the third-operand length, or it is set to 2 if the first-operand length is greater than the third-operand length. When the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the third-operand bytes participating in the operation other than the leftmost byte of the third operand. When an operand wraps around from location 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) to location 0, operand bytes in locations up to and including 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location 2^{24} - 1 to location 0; in the 31-bit addressing mode, wraparound is from location 2^{31} - 1 to location 0; and, in the 64-bit addressing mode, wraparound is from location 2^{64} - 1 to location 0.

When the length specified in general register R1 + 1 is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.
Padding byte values of B0 hex and B8 hex may be used during the nonpadding part of the operation by some models, in certain cases, as an indication of whether the movement should be performed bypassing the cache or using the cache, respectively. Thus, a padding byte of B0 hex indicates no intention to reference the destination area after the move, and a padding byte of B8 hex indicates an intention to reference the destination area.

For the nonpadding part of the operation when the padding byte is not B1 hex, accesses to the operands for MOVE LONG EXTENDED may be multiple-access references, and these accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. When the padding byte is B1 hex, accesses to the operands are single-access references, and these accesses appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. During the nonpadding part of the operation, operands appear to be doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding byte is not necessarily stored into in
a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding byte may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register $R_1$ is incremented by the same amount. The length in general register $R_3 + 1$ is decremented by the number of bytes moved out of the third-operand location, and the address in general register $R_3$ is incremented by the same amount.

If the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes moved, and the addresses in general registers $R_1$ and $R_3$ are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be moved. If the operation is completed during padding, the length field in general register $R_3 + 1$ is zero, the address in general register $R_3$ is incremented by the original length in general register $R_3 + 1$, and general registers $R_1$ and $R_1 + 1$ reflect the extent of the padding operation.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers $R_1$, $R_1 + 1$, $R_3$, and $R_3 + 1$, always remain unchanged.

The padding byte may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by $R_1$ and $R_3$ may be updated multiple times. Therefore, if $B_2$ equals $R_1$, $R_1 + 1$, $R_3$, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed. The maximum amount is approximately 4K bytes of either operand.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers $R_1$ and $R_3$ may be set to zeros or may remain unchanged from their original values, even when one or both of the original length values are zeros.

When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the third operand is longer than the first operand, access exceptions are not recognized for the part of the third-operand field that is in excess of the first-operand field. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the $R_1$ field is odd, PER storage-alteration events are not recognized, and no change bits are set.

**Resulting Condition Code:**

0  All bytes moved, operand lengths equal
1  All bytes moved, first-operand length low
2  All bytes moved, first-operand length high
3  CPU-determined number of bytes moved without reaching end of first operand

**Program Exceptions:**

- Access (fetch, operand 3; store, operand 1)
- Specification
- Transaction constraint

**Programming Notes:**

1. MOVE LONG EXTENDED is intended for use in place of MOVE LONG when the operand lengths are specified as 32-bit or 64-bit binary integers and a test for destructive overlap is not required. MOVE LONG EXTENDED sets condition code 3 in cases in which MOVE LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the movement. The program need not determine the number of bytes that were moved.

3. The function of not processing more than approximately 4K bytes of either operand is intended to permit software polling of a flag that may be set by a program on another CPU during long operations.

4. MOVE LONG EXTENDED may be used for clearing storage by setting the padding byte to
zero and the third-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand and Consistency” on page 5-123.

5. When the contents of the R1 and R3 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by twice the number of bytes moved. The condition code is finally set to 0 after possible settings to 3.

6. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

MOVE LONG UNICODE

```
MVCLU R1,R3,D2(B2) [RSY-a]
```

All or part of the third operand is placed at the first-operand location. The remaining rightmost positions, if any, of the first-operand location are filled with one or more padding bytes, alternating between the even padding byte and the odd padding byte. The operation proceeds until the end of the first-operand location is reached or a CPU-determined number of bytes have been placed at the first-operand location, whichever occurs first. The result is indicated in the condition code.

The R1 and R3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R1 and R3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers R1 + 1 and R3 + 1, respectively, and those contents are treated as 32-bit unsigned binary integers.

On some models, the contents of general registers R1 + 1 and R3 + 1 must specify an even number of bytes; otherwise, a specification exception is recognized.

The handling of the addresses in general registers R1 and R3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the registers constitute the address.

The second-operand address is not used to address data; instead, the rightmost 16 bits of the second-operand address, bits 48-63, are the two padding bytes; bits 48-55 are the even padding byte, and bits 56-63 are the odd padding byte. Bits 0-47 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-255 on page 7-254.

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified by the contents of general register R1 + 1 have been placed at the first-operand location or when a CPU-determined number of bytes have been placed, whichever occurs first.

If the third operand is shorter than the first operand, the remaining rightmost positions of the first-operand location are filled with alternating padding bytes. When the number of bytes remaining in the first-operand location is an even number, the even padding byte is placed first; when the number of bytes remaining in the first-operand location is odd, the odd padding byte is placed first.

When the operation is completed because the end of the first operand has been reached, the condition code is set to 0 if the two operand lengths are equal, it is set to 1 if the first-operand length is less than the third-operand length, or it is set to 2 if the first-oper-
and length is greater than the third-operand length. When the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the third-operand bytes participating in the operation other than the leftmost byte of the third operand. When an operand wraps around from location 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) to location 0, operand bytes in locations up to and including 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location 2^{24} - 1 to location 0; in the 31-bit addressing mode, wraparound is from location 2^{31} - 1 to location

---

**Figure 7-255. Register Contents and Second-Operand Address for MOVE LONG UNICODE**
0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

When the length specified in general register $R_1 + 1$ is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

For the nonpadding part of the operation, accesses to the operands for MOVE LONG UNICODE may be multiple-access references. These accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by channel programs. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding bytes is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding bytes may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register $R_1$ is incremented by the same amount. The length in general register $R_3 + 1$ is decremented by the number of bytes moved out of the third-operand location, and the address in general register $R_3$ is incremented by the same amount.

If the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes moved, and the addresses in general registers $R_1$ and $R_3$ are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be moved. If the operation is completed during padding, the length field in general register $R_3 + 1$ is zero, the address in general register $R_3$ is incremented by the number of bytes moved from operand 3, and general registers $R_1$ and $R_1 + 1$ reflect the extent of the padding operation.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers $R_1$, $R_1 + 1$, $R_2$, and $R_2 + 1$, always remain unchanged.

The padding bytes may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by $R_1$ and $R_3$ may be updated multiple times. Therefore, if $B_2$ equals $R_1$, $R_1 + 1$, $R_3$, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers $R_1$ and $R_3$ may be set to zeros or may remain unchanged from their original values, including the case when one or both of the original length values are zeros.

When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the third operand is longer than the first operand, access exceptions are not recognized for the part of the third-operand field that is in excess of the first-operand field. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the $R_1$ field is odd, PER storage-alteration events are not recognized, and no change bits are set. On models that recognize a specification exception if the length associated with an operand is odd, access exceptions and PER storage-alteration events are not recognized and no change bits are set if the length is odd.

**Resulting Condition Code:**

0  All bytes moved, operand lengths equal
1  All bytes moved, first-operand length low
2  All bytes moved, first-operand length high
3  CPU-determined number of bytes moved without reaching end of first operand

**Program Exceptions:**
• Access (fetch, operand 3; store, operand 1)
• Operation (if the extended-translation facility 2 is not installed)
• Specification
• Transaction constraint

**Programming Notes:**

1. MOVE LONG UNICODE is intended for use in place of MOVE LONG or MOVE LONG EXTENDED when padding with double-byte characters. The character may be a Unicode character or any other double-byte character. MOVE LONG UNICODE may set condition code 3 in cases in which MOVE LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the movement. The program need not determine the number of bytes that were moved.

3. MOVE LONG UNICODE may be used for filling storage with padding bytes by placing the padding bytes in the second-operand address and setting the third-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-123.

4. When the contents of the R_1 and R_3 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by two times the number of bytes moved. The condition code is finally set to 0 after possible settings to 3.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

6. The padding bytes may be represented in the displacement field of the instruction. The following example illustrates padding with a Unicode space character.

   \[ \text{MVCLU} \ 6,8,\text{x'0020'} \]

   When the B_2 field of the instruction designates general register 0, and the long-displacement facility is not installed, the padding bytes are limited to a character whose representation is less than or equal to 0FFF hex.

7. MOVE LONG UNICODE is intended to be used to move and pad pairs of bytes. Although some models allow the first- and third-operand length registers to designate an odd length, without recognizing a specification exception, the program should always be coded to provide an even length. This ensures that the program will operate compatibly in configurations that recognize a specification exception for an odd length value.

**MOVE NUMERICS**

\[
\begin{array}{cccccc}
\text{MVN} & D_1(L,B_1),D_2(B_2) & [\text{SS-a}] \\
D_2 & D_1 & B_2 & B_1 & L & D_1 \\
0 & 8 & 16 & 20 & 32 & 36 & 47
\end{array}
\]

The rightmost four bits of each byte in the second operand are placed in the rightmost bit positions of the corresponding bytes in the first operand. The leftmost four bits of each byte in the first operand remain unchanged.

Each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

• Access (fetch, operand 2; fetch and store, operand 1)
• Transaction constraint

**Programming Notes:**

1. An example of the use of the MOVE NUMERICS instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE NUMERICS moves the numeric portion of a decimal-data field that is in the zoned format. The zoned-decimal format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes.

3. Accesses to the first operand of MOVE NUMERICS consist in fetching the leftmost four bits of
each byte in the first operand and subsequently storing the updated value of the byte. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

**MOVE STRING**

```
MVST R1, R2 [RRE]
```

All or part of the second operand is placed in the first-operand location. The operation proceeds until the end of the second operand is reached or a CPU-determined number of bytes have been moved, whichever occurs first. The CPU-determined number is at least one. The result is indicated in the condition code.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R1 and R2, respectively.

The handling of the addresses in general registers R1 and R2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The end of the second operand is indicated by an ending character in the last byte position of the operand. The ending character to be used to determine the end of the second operand is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right and ends as soon as the second-operand ending character has been moved or a CPU-determined number of second-operand bytes have been moved, whichever occurs first. The CPU-determined number is at least one. When the ending character is in the first byte position of the second operand, only the ending character is moved. When the ending character has been moved, condition code 1 is set. When a CPU-determined number of second-operand bytes not including an ending character have been moved, condition code 3 is set. Destructive overlap is not recognized. If the second operand is used as a source after it has been used as a destination, the results are unpredictable.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R1, and the contents of general register R2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R1 and R2, respectively. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R1 and R2 registers always remain unchanged in the 24-bit or 31-bit mode.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the first and second operands are recognized only for that portion of the operand that is necessarily used in the operation.

The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction, except that destructive overlap is not recognized.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>--</td>
</tr>
<tr>
<td>1</td>
<td>Entire second operand moved; general register R1 updated with address of ending character in first operand; general register R2 unchanged</td>
</tr>
<tr>
<td>2</td>
<td>--</td>
</tr>
<tr>
<td>3</td>
<td>CPU-determined number of bytes moved; general registers R1 and R2 updated with addresses of next bytes</td>
</tr>
</tbody>
</table>
**Program Exceptions:**
- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

**Programming Notes:**

1. An example of the use of the MOVE STRING instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the data movement. The program need not determine the number of bytes that were moved.

3. $R_1$ or $R_2$ may be zero, in which case general register 0 is treated as containing an address and also the ending character.

4. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

5. If the second operand is used as a source after it has been used as a destination, an ending character in the second operand may not be recognized.

**MOVE WITH OFFSET**

<table>
<thead>
<tr>
<th>MOVE</th>
<th>D_{i}(L_{z},B_{z}),D_{j}(L_{z},B_{z})</th>
</tr>
</thead>
<tbody>
<tr>
<td>[SS-b]</td>
<td></td>
</tr>
</tbody>
</table>

The second operand is placed to the left of and adjacent to the rightmost four bits of the first operand.

The rightmost four bits of the first operand are attached as the rightmost bits to the second operand, the second-operand bits are offset by four bit positions, and the result is placed at the first-operand location.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first operand is too short to contain all of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time, as if each result byte were stored immediately after fetching the necessary operand bytes, and as if the left digit of each second-operand byte were to remain available for the next result byte and need not be refetched.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the MOVE WITH OFFSET instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE WITH OFFSET may be used to shift packed decimal data by an odd number of digit positions. The packed-decimal format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes. In many cases, however, SHIFT AND ROUND DECIMAL may be more convenient to use.

3. Access to the rightmost byte of the first operand of MOVE WITH OFFSET consists in fetching the rightmost four bits and subsequently storing the updated value of this byte. These fetch and store accesses to the rightmost byte of the first operand do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

4. The storage-operand references for MOVE WITH OFFSET may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)
MOVE ZONES

MVZ D1(L,B1) D2(B2) [SS-a]

The leftmost four bits of each byte in the second operand are placed in the leftmost four bit positions of the corresponding bytes in the first operand. The rightmost four bits of each byte in the first operand remain unchanged.

Each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte is fetched.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE ZONES instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE ZONES moves the zoned portion of a decimal field in the zoned format. The zoned format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes.

3. Accesses to the first operand of MOVE ZONES consist in fetching the rightmost four bits of each byte in the first operand and subsequently storing the updated value of the byte. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for the OR (OI) instruction in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

MULTIPLY

Register-and-register format:

MR R1,R2 [RR]

Register-and-storage formats:

M R1,D2(X2,B2) [RX-a]

MFY R1,X2 B2 D2 [RXY-a]

The 32-bit first operand (the multiplicand) is multiplied by the 32-bit second-operand (the multiplier), and the 64-bit product is placed at the first-operand location.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Both the multiplicand and multiplier are treated as 32-bit signed binary integers. The multiplicand is in bit positions 32-63 of general register R1 + 1. For MULTIPLY (MR), the multiplier is in bit positions 32-63 of general register R2. The contents of general register R1 and of bit positions 0-31 of general register R1 + 1 and, for MR, of general register R2 are ignored.

The product is a 64-bit signed binary integer. Bits 0-31 of the product replace bits 32-63 of general register R1. Bits 32-63 of the product replace bits 32-63 of general register R1 + 1. Bits 0-31 of general registers R1 and R1 + 1 remain unchanged. An overflow cannot occur.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for M is treated as a 12-bit unsigned binary integer. The displacement for MFY is treated as a 20-bit signed binary integer.
MULTIPLY HALFWORD

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of M and MFY only)
- Operation (MFY; if the general-instructions-extension facility is not installed)
- Specification

**Programming Notes:**
1. An example of the use of the MULTIPLY instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The significant part of the product usually occupies 62 bit positions or fewer. Only when two maximum 32-bit negative numbers are multiplied are 63 significant product bits formed.
3. Care should be taken not to confuse the mnemonic for MULTIPLY UNNORMALIZED (MY) with the mnemonic for MULTIPLY (MFY).

For MULTIPLY HALFWORD and MULTIPLY HALFWORD IMMEDIATE (MHI), the multiplicand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R1, and it is replaced by the rightmost 32 bits of the signed-binary-integer product. The bits to the left of the 32 rightmost bits of the product are not tested for significance; no overflow indication is given. Bits 0-31 of general register R1 are ignored and remain unchanged.

For MULTIPLY HALFWORD IMMEDIATE (MGHI), the multiplicand is treated as a 64-bit signed binary integer in bit positions 0-63 of general register R1, and it is replaced by the rightmost 64 bits of the signed-binary-integer product. The bits to the left of the 64 rightmost bits of the product are not tested for significance; no overflow indication is given.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for MH is treated as a 12-bit unsigned binary integer. The displacement for MHY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of MH and MHY only)
- Operation (MHY; if the general-instructions-extension facility is not installed)

**Programming Notes:**
1. An example of the use of the MULTIPLY HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For MH, MHY, and MHI, the significant part of the product usually occupies 46 bit positions or fewer. Only when two maximum negative numbers are multiplied are 47 significant product bits formed. Since the rightmost 32 bits of the product are placed unchanged at the first-operand location, ignoring all bits to the left, the sign bit of the result may differ from the true sign of the product in the case of overflow. For a negative product, the 32 bits placed in register R1 are the rightmost part of the product in two’s-complement notation. For MGHI, the significant part of
the product usually occupies 78 bit positions or fewer.

MULTIPLY LOGICAL

Register-and-register formats:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MLR</strong> R1,R2</td>
<td>[RRE]</td>
<td><code>E3</code> R1 X2 B2 DL2 DH2 <code>96</code></td>
</tr>
<tr>
<td><strong>MLGR</strong> R1,R2</td>
<td>[RRE]</td>
<td><code>E3</code> R1 X2 B2 DL2 DH2 <code>96</code></td>
</tr>
</tbody>
</table>

Register-and-storage formats:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ML</strong> R1,D2(X2,B2)</td>
<td>[RXY-a]</td>
<td><code>71</code> R1 X2 B2 D2</td>
</tr>
</tbody>
</table>

For MULTIPLY LOGICAL (MLGR, MLG), the multiplicand and the multiplier are treated as 64-bit unsigned binary integers. The multiplicand is in general register R1 + 1. The contents of general register R1 are ignored. The product is a 128-bit unsigned binary integer. Bits 0-63 of the product replace the contents of general register R1, and bits 64-127 of the product replace the contents of general register R1 + 1. An overflow cannot occur.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of ML and MLG only)
- Specification

MULTIPLY SINGLE

Register-and-register formats:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MSR</strong> R1,R2</td>
<td>[RRE]</td>
<td><code>B252</code> R1 R2</td>
</tr>
<tr>
<td><strong>MSGR</strong> R1,R2</td>
<td>[RRE]</td>
<td><code>B90C</code> R1 R2</td>
</tr>
<tr>
<td><strong>MSGFR</strong> R1,R2</td>
<td>[RRE]</td>
<td><code>B91C</code> R1 R2</td>
</tr>
</tbody>
</table>

Register-and-storage formats:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MS</strong> R1,D2(X2,B2)</td>
<td>[RX-a]</td>
<td><code>71</code> R1 X2 B2</td>
</tr>
</tbody>
</table>

For MULTIPLY LOGICAL (MLGR, MLG), the multiplicand and the multiplier are treated as 64-bit unsigned binary integers. The multiplicand is in bit positions 32-63 of general register R1 + 1. For MULTIPLY LOGICAL (MLR), the multiplier is in bit positions 32-63 of general register R2. The contents of general register R1 and of bit positions 0-31 of general register R1 + 1 and, for MLR, of general register R2 are ignored. The product is a 64-bit unsigned binary integer. Bits 0-31 of the product replace bits 32-63 of general register R1, and bits 32-63 of the product replace bits 32-63 of general register R1 + 1. Bits 0-31 of general registers R1 and R1 + 1 remain unchanged. An overflow cannot occur.
MULTIPLY SINGLE IMMEDIATE

\[ \text{MSGF} \quad R_{1}, D_{2}(X_{2} B_{2}) \quad [RXY-a] \]

- The first operand (multiplicand) is multiplied by the second operand (multiplier), and the rightmost 32 or 64 bits of the product are placed at the first-operand location.

- For MULTIPLY SINGLE (MSR, MS, MSY) and for MULTIPLY SINGLE IMMEDIATE (MSFI), the multiplicand, multiplier, and product are treated as 32-bit signed binary integers. The multiplicand is taken from bit positions 32-63 of general register \( R_{1} \) and is replaced by the rightmost 32 bits of the signed-binary-integer product. Bits 0-31 of general register \( R_{1} \) remain unchanged. For MSR, the multiplier is in bit positions 32-63 of general register \( R_{2} \). For MSFI, the multiplier is in the \( I_{2} \) field of the instruction. The bits to the left of the 32 rightmost bits of the product are not tested for significance; no overflow indication is given.

- For MULTIPLY SINGLE (MSG, MSGFR, MSG, MSGF) and for MULTIPLY SINGLE IMMEDIATE (MSGFI), the multiplicand, multiplier, and product are treated as 64-bit signed binary integers, except that, for MSGF, MSGFI, and MSGFR, the multiplier is treated as a 32-bit signed binary integer. The multiplicand is taken from general register \( R_{1} \) and is replaced by the rightmost 64 bits of the signed-binary-integer product. For MSGFR, the multiplier is in bit positions 32-63 of general register \( R_{2} \). For MSGFI, the multiplier is in the \( I_{2} \) field of the instruction. The bits to the left of the 64 rightmost bits of the product are not tested for significance; no overflow indication is given.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for MS is treated as a 12-bit unsigned binary integer. The displacement for MSY, MSG, and MSGF is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 of MS, MSY, MSG, MSGF only)
- Operation (MSY, if the long-displacement facility is not installed; MSFI, MSGFI, if the general-instructions-extension facility is not installed)

NEXT INSTRUCTION ACCESS INTENT

\[ \text{NIAI} \quad I_{1}, I_{2} \quad [IE] \]

Note: In this instruction definition, the term primary-access operand means the lowest numbered storage operand of an instruction. Similarly, the term secondary-access operand means the next-lowest numbered storage operand of the instruction. These terms do not have the same meaning as the terms first operand and second operand, even though there may be some correlation. For example, for the MOVE instruction the first operand is the primary-access operand and the second operand is the secondary-access operand. However, for the LOAD MULTIPLE DISJOINT instruction, the second operand is the primary-access operand and the fourth operand is the secondary-access operand.

Subject to the controls in the \( I_{1} \) and \( I_{2} \) fields, the CPU is signalled the future access intent for either or both the primary-access and secondary-access operands of the next-sequential instruction. The \( I_{1} \) field contains a code to signal the CPU the access intent for the primary-access operand of the next-sequential instruction. The \( I_{2} \) field contains a code to signal the CPU the access intent for the secondary-access operand of the next-sequential instruction. When the next-sequential instruction has only a single storage operand, the \( I_{2} \) field is ignored.
The $I_1$ and the $I_2$ field have the following format:

```
/ / / AI
0 1 2 3
```

**Reserved:** Bits 0-1 of the $I_1$ and $I_2$ fields are reserved and should contain zeros, otherwise the program may not operate compatibly in the future.

**Access Intent (AI):** Bits 2-3 of the $I_1$ and $I_2$ fields contain an unsigned integer that is used as a code to signal the CPU the access intent for the corresponding operand of the next-sequential instruction as follows:

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The corresponding operand of the next-sequential instruction may or may not be accessed as an instruction operand by subsequent instructions.</td>
</tr>
<tr>
<td>1</td>
<td>The corresponding operand of the next-sequential instruction will be accessed by subsequent instructions for operand store access, and may also be accessed for operand fetch access.</td>
</tr>
<tr>
<td>2</td>
<td>The corresponding operand of the next-sequential instruction will be accessed by subsequent instructions for operand fetch access.</td>
</tr>
<tr>
<td>3</td>
<td>The corresponding operand of the next-sequential instruction will not be accessed as an instruction operand by subsequent instructions.</td>
</tr>
</tbody>
</table>

Depending on the model, the CPU may not recognize all of the access intents for an operand. For access intents that are not recognized by the CPU, the instruction acts as a no-operation. If the instruction has more than two storage operands, no access intent is specified for the additional operands.

Depending on the model, the CPU may not recognize access intents for a particular instruction. For such cases, the instruction acts as a no-operation.

The NEXT INSTRUCTION ACCESS INTENT instruction only affects subsequent instruction's operand accesses; it does not affect subsequent instruction fetches.

No references to storage are made.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Operation (if the execution-hint facility is not installed)

**Programming Notes:**

1. NEXT INSTRUCTION ACCESS INTENT signals the CPU of the future access intent for the storage operands of the next-sequential instruction, but it does not guarantee that the CPU will necessarily retain or use this information.

2. Specifying an incorrect access intent or an access intent for a non-existent operand may lead to performance degradation.

3. Caches are managed on a cache-line-size granularity. Therefore, when NEXT INSTRUCTION ACCESS INTENT is used to signal the CPU the intended future use of the specified storage operands, the program is actually signalling the CPU the access intent for the entire cache line of the operand. The cache line size can be determined by executing the EXTRACT CPU ATTRIBUTE instruction.

4. If a specified storage operand crosses a cache-line boundary, it is model dependent whether the CPU is signalled the access intent for one or both of the cache lines.

5. Specifying an access-intent value of three does not signal the CPU to actively release the cache line from the cache for the specified operand. Instead, it signals the CPU that it should not actively try to retain that line in the cache.

6. Specifying an access-intent value of zero to a single operand instruction is not encouraged and not necessary. However, in the case where an instruction has two operands and access intent is known for one operand, but not the other, the access intent value of zero can be used for the operand of unknown intent.

7. If an interruption occurs after the execution of NEXT INSTRUCTION ACCESS INTENT and before the execution of the next-sequential instruction, NEXT INSTRUCTION ACCESS INTENT acts as a no-operation and the specified access intent is ignored.

8. If the next sequential instruction after NEXT INSTRUCTION ACCESS INTENT is a PREFETCH DATA (RELATIVE LONG) instruction, it is unpredictable what the CPU will do with data prefetching.
NONTRANSACTIONAL STORE

The 64-bit first operand is nontransactionally placed unchanged at the second-operand location.

The displacement is treated as a 20-bit signed binary integer.

The second operand must be aligned on a double-word boundary; otherwise, a specification exception is recognized and the operation is suppressed.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, second operand)
- Operation (transactional-execution facility not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. NONTRANSACTIONAL STORE provides a means by which a program executing in the non-constrained transactional-execution mode can perform stores that will be retained, even if the transaction aborts. This may facilitate debugging of the transaction if it is aborted.

2. When the CPU is not in the transactional-execution mode, the operation of NONTRANSACTIONAL STORE is identical to that of STORE (STG), except that the second operand of NONTRANSACTIONAL STORE is required to be on a doubleword boundary (regardless of transactional-execution mode) whereas the second operand of STG has no alignment requirements.

3. Depending on the model, the performance of NONTRANSACTIONAL STORE may be slower than that of STORE (STG).

4. If a CPU makes transactional and non-transactional stores to the same storage location within a transaction, and the transaction then aborts, the content of all storage locations altered by either the transactional or nontransactional store are unpredictable.

**OR**

**Register-and-register formats:**

```
   OR R1, R2 [RR]
   '16'  R1  R2
   0  8 12 15
```

```
   OGR R1, R2 [RRE]
   'B961'
   0  16 24 31
```

```
   ORK R1, R2, R3 [RRF-a]
   'B9F6'
   0  16 24 31
```

```
   OGRK R1, R2, R3 [RRF-a]
   'B9E6'
   0  16 24 31
```

**Register-and-storage formats:**

```
   OR R1, D2(X2, B2) [RXY-a]
   'E3'  R1  X2  B2  DL2  DH2  '56'
   0  8 12 16 20 31 47
```

```
   OY R1, D2(X2, B2) [RXY-a]
   'E3'  R1  X2  B2  DL2  DH2  '56'
   0  8 12 16 20 31 47
```

```
   OG R1, D2(X2, B2) [RRY-a]
   'E3'  R1  X2  B2  DL2  DH2  '81'
   0  8 12 16 20 31 47
```

**Storage-and-immediate formats:**

```
   OI D1(B1), I2 [SI]
   '96'  I2  B1  D1
   0  8 16 20 31
```

```
   OIY D1(B1), I2 [SIY]
   'EB'  I2  B1  DL1  DH1  '56'
   0  8 16 20 31 47
```
**Storage-and-storage format:**

For O, OC, OG, OGR, OI, OIY, OR, and OY, the OR of the first and second operands is placed at the first-operand location. For OGRK and ORK, the OR of the second and third operands is placed at the first-operand location.

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

For OR (OC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

For OR (OI, OIY), the first operand is one byte in length, and only one byte is stored. When the interlocked-access facility 2 is installed, the update of the first operand appears to be an interlocked-update reference as observed by other CPUs and channel programs, and a specific-operand-serialization operation is performed.

For OR (O, OR, ORK, and OY), the operands are 32 bits, and for OR (OG, OGR, and OGRK), they are 64 bits.

The displacements for O, OI, and both operands of OC are treated as 12-bit unsigned binary integers. The displacement for OY, OIY, and OG is treated as a 20-bit signed binary integer.

**Resulting Condition Code:**

0  Result zero
1  Result not zero
2  --
3  --

**Program Exceptions:**

- Operation (OY and OIY, if the long-displacement facility is not installed; OGRK and ORK, if the distinct-operands facility is not installed)
- Transaction constraint (OC)

**Programming Notes:**

1. Examples of the use of the OR instruction are given in Appendix A, "Number Representation and Instruction-Use Examples."

2. OR may be used to set a bit to one.

3. Accesses to the first operand of OR (OC) – and, when the interlocked-access facility 2 is not installed, accesses to the first operand of OR (OI, OIY) – consist in fetching a first-operand byte from storage and subsequently storing the updated value. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown in “Multiprogramming and Multiprocessing Examples” on page A-45.

When the interlocked-access facility 2 is installed, OR (OI, OIY) can be safely used to update a location in storage, even if the possibility exists that another CPU or a channel program may also be updating the location.
The second operand is ORed with bits of the first operand, and the result replaces those bits of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bits of the first operand that are ORed with the second operand and then replaced are as follows:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Bits ORed and Replaced</th>
</tr>
</thead>
<tbody>
<tr>
<td>OIHF</td>
<td>0-31</td>
</tr>
<tr>
<td>OIHH</td>
<td>0-15</td>
</tr>
<tr>
<td>OIHL</td>
<td>16-31</td>
</tr>
<tr>
<td>OILF</td>
<td>32-63</td>
</tr>
<tr>
<td>OILH</td>
<td>32-47</td>
</tr>
<tr>
<td>OILL</td>
<td>48-63</td>
</tr>
</tbody>
</table>

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

**Resulting Condition Code:**

0  Result is zero
1  Result is not zero
2  --
3  --

**Program Exceptions:**

- Operation (OIHF and OILF, if the extended-immediate facility is not installed)

**Programming Note:** The setting of the condition code is based only on the bits that are ORed and replaced.

---

The format of the second operand is changed from zoned to signed-packed-decimal, and the result is placed at the first-operand location. The zoned and signed-packed-decimal formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the zoned format. The numeric bits of each byte are treated as a digit. The zone bits are ignored, except the zone bits in the rightmost byte, which are treated as a sign.

The sign and digits are moved unchanged to the first operand and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if each result byte were stored immediately after fetching the necessary operand bytes. Two second-operand bytes are needed for each result byte, except for the rightmost byte of the result field, which requires only the rightmost second-operand byte.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the PACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. PACK may be used to interchange the two hexadecimal digits in one byte by specifying a zero in the L_1 and L_2 fields and the same address for both operands.

3. To remove the zone bits of all bytes of a field, including the rightmost byte, both operands should be extended on the right with a dummy byte, which subsequently should be ignored in the result field.

4. The storage-operand references for PACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

PACK ASCII

The format of the second operand is changed from ASCII to signed-packed-decimal, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second-operand bytes are treated as containing decimal digits, having the binary encoding 0000-1001 for 0-9, in their rightmost four bit positions. The leftmost four bit positions of a byte are ignored. The second operand is considered to be positive.

The implied positive sign (1100 binary) and the source digits are placed at the first-operand location. The source digits are moved unchanged and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros.

The length of the first operand is 16 bytes.

The length of the second operand is designated by the contents of the L_2 field. The second-operand length must not exceed 32 bytes (L_2 must be less than or equal to 31); otherwise, a specification exception is recognized.

When the length of the second operand is 32 bytes, the leftmost byte is ignored.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first-operand location is not necessarily stored into in any particular order.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. Although PACK ASCII is primarily intended to change the format of ASCII decimal digits, its use is not restricted to ASCII since the leftmost four bits of each byte are ignored.

2. The following example illustrates the use of the instruction to pack ASCII digits:

```
ASDIGITS DS OCL31
DC 'X3132333435'
DC 'X3637383930'
DC 'X3132333435'
DC 'X3637383930'
DC 'X31'
PKDIGITS DS PL16
PKA PKDIGITS,ASDIGITS(31)
```

3. The instruction can also be used to pack EBCDIC digits, which is especially useful when
the length of the second operand is greater than the 16-byte second-operand limit of PACK.

PACK UNICODE

The format of the second operand is changed from Unicode to signed-packed-decimal, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, "Decimal Instructions."

The two-byte second-operand characters are treated as Unicode Basic Latin characters containing decimal digits, having the binary encoding 0000-1001 for 0-9, in their rightmost four bit positions. The leftmost 12 bit positions of a character are ignored. The second operand is considered to be positive.

The implied positive sign (1100 binary) and the source digits are placed at the first-operand location. The source digits are moved unchanged and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros.

As observed by other CPUs and by channel programs, the first-operand location is not necessarily stored into in any particular order.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The following example illustrates the use of PACK UNICODE to pack European numbers:

   UNDIGITS DS 0CL62
   DC X'00310032003300340035'
   DC X'00360037003800390030'
   DC X'00310032003300340035'
   DC X'00360037003800390030'
   DC X'00310032003300340035'
   DC X'00360037003800390030'
   DC X'0031'
   PKDIGITS DS PL16
   :  
   PKU PKDIGITS,UNDIGITS(62)

2. Because the leftmost 12 bits of each character are ignored, those Unicode decimal digits where the digit zero has four rightmost zero bits can
also be packed by the instruction. For example, for Thai digits:

UNDIGITS DS OCL62
DC 'X'0E510E520E530E540E55'
DC 'X'0E560E570E580E590E50'
DC 'X'0E510E520E530E540E55'
DC 'X'0E560E570E580E590E50'
DC 'X'0E510E520E530E540E55'
DC 'X'0E560E570E580E590E50'
PDKIGITS DS PL16
PKU PDKIGITS,UNDIGITS(62)

3. The storage-operand references for PACK UNICODE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

PERFORM CRYPTOGRAPHIC COMPUTATION

PCC [RRE] 01 6 3 1

A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-256 on page 7-269 shows the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for PERFORM CRYPTOGRAPHIC COMPUTATION are as follows.

<table>
<thead>
<tr>

Explanation:

Not applicable

Figure 7-256. Function Codes for PERFORM CRYPTOGRAPHIC COMPUTATION

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions.
Figure 7-257 on page 7-270 shows the contents of general registers 0 and 1.

![Figure 7-257. General Register Assignment for PCC](image)

In the access-register mode, access register 1 specifies the address space containing the parameter block.

As observed by this CPU, other CPUs, and channel programs, reference to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

**Symbols Used in Function Descriptions**

The following symbols are used in the subsequent description of the PERFORM CRYPTOGRAPHIC COMPUTATION functions. Further description of the AES standard may be found in Reference [12.] on page xxviii. The XTS multiplication operation is the same as the GCM (Galois/counter mode) multiplication operation. Further description of the GCM multiplication over GF(2^{128}) may be found in Reference [15.] on page xxviii.

![Figure 7-258. Symbol For Bit-Wise Exclusive OR](image)

![Figure 7-259. Symbol For XTS Multiplication Operation Over GF(2^{128})](image)

![Figure 7-260. Symbol For XTS Power Operation Over GF(2^{128})](image)
PERFORM CRYPTOGRAPHIC COMPUTATION

PCC-Query (Function Code 0)
The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.

The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Symbol</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>K</td>
<td>Key value</td>
</tr>
<tr>
<td>C</td>
<td>Ciphertext</td>
</tr>
<tr>
<td>P</td>
<td>Plaintext</td>
</tr>
</tbody>
</table>

```

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function
codes 0-127, respectively, of the PCC instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the PCC-Query function completes; condition codes 1, 2, and 3 are not applicable to this function.

**PCC-Compute-Last-Block-CMAC-Using-DEA (Function Code 1)**

**PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA (Function Code 9)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-DEA function has the following format:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>

<td>(WKdVP)</td>
</tr>
</tbody>
</table>

Figure 7-267. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, \(K_x\), is derived using the 64-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, \(K_y\), is derived using the 64-bit cryptographic key,
K. The subkey generation algorithm is shown in the following figure.

**Steps:**

1. \( L = \text{CIPH}_k(0) \)
2. If MSB (L) = 0, then \( K_x = L << 1 \); Else, \( K_x = (L << 1) \text{ XOR (R}_{64}) \)
3. If MSB (\( K_x \)) = 0, then \( K_y = K_x << 1 \); Else \( K_y = (K_x << 1) \text{ XOR (R}_{64}) \)

**Explanation:**

- \( \text{CIPH}_k(0) \) Encryption of the value zero using a 64-bit key and the DEA encryption algorithm.
- MSB(A) Most significant (leftmost) bit of A
- \( B<<1 \) The bit string that results from discarding the leftmost bit of B and appending a ‘0’ bit on the right.
- XOR Bit-wise exclusive OR.
- \( R_{64} \) A 64-bit value of 27.

*Figure 7-268. Subkey Generation Algorithm*

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey \( K_x \). The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 64-bit cryptographic key, K, and the DEA encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey \( K_y \). The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 64-bit cryptographic key, K, and the DEA encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-DEA function.

**PCC-Compute-Last-Block-CMAC-Using-TDEA-128 (Function Code 2)**

**PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 (Function Code 10)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function has the following format:

<table>
<thead>
<tr>
<th>0</th>
<th>ML</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Message</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>Initial Chaining Value (ICV)</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td>Cryptographic Key (K)</td>
<td></td>
</tr>
</tbody>
</table>

*Figure 7-269. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-TDEA-128*

For the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-39 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 function has the following format:

<table>
<thead>
<tr>
<th>0</th>
<th>ML</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Message</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>Initial Chaining Value (ICV)</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td>Encrypted Cryptographic Key (WKd(K))</td>
<td></td>
</tr>
<tr>
<td>32</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
<td></td>
</tr>
</tbody>
</table>

*Figure 7-270. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128*

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 function, the contents of byte offsets 40-63 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation
is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-39 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_x, is derived using the 128-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_y, is derived using the 128-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. \( L = \text{CIPH}_K(0) \)
2. If MSB (L) = 0, then \( K_x = L << 1 \); Else, \( K_x = (L << 1) \ XOR (R_{64}) \)
3. If MSB (K_x) = 0, then \( K_y = K_x << 1 \); Else \( K_y = (K_x << 1) \ XOR (R_{64}) \)

Figure 7-271. Subkey Generation Algorithm

Explanation:

- \( \text{CIPH}_K(0) \) Encryption of the value zero using a 128-bit key and the TDEA-128 encryption algorithm.
- MSB(A) Most significant (leftmost) bit of A
- B<<1 The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
- XOR Bit-wise exclusive OR.
- R_{64} A 64-bit value of 27.

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then deciphered using the 128-bit cryptographic key, K, and the TDEA-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then deciphered using the 128-bit cryptographic key, K, and the TDEA-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function.

PCC-Compute-Last-Block-CMAC-Using-TDEA-192 (Function Code 3)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.
The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function has the following format:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ML</td>
</tr>
<tr>
<td>8</td>
<td>Reserved</td>

<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
</tbody>
</table>

*Figure 7-273. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192*

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 function, the contents of byte offsets 48-71 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-47 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-374 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, $K_x$, is derived using the 192-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, $K_y$, is derived using the 192-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

**Steps:**
1. $L = \text{CIPH}_K(0)$
2. If MSB ($L$) = 0, then $K_x = L << 1$;
   Else, $K_x = (L << 1) \text{ XOR } (R_{64})$
3. If MSB ($K_y$) = 0, then $K_y = K_x << 1$;
   Else $K_y = (K_x << 1) \text{ XOR } (R_{64})$

*Figure 7-274. Subkey Generation Algorithm*
When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey $K_x$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then encrypted using the 192-bit cryptographic key, $K$, and the TDEA-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey $K_y$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then encrypted using the 192-bit cryptographic key, $K$, and the TDEA-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function.

**PCC-Compute-Last-Block-CMAC-Using-AES-128 (Function Code 18)**

**PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 (Function Code 26)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.
PERFORM CRYPTOGRAPHIC COMPUTATION

phered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, $K_x$, is derived using the 128-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, $K_y$, is derived using the 128-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

**Steps:**

1. $L = \text{CIPH}_K(0)$
2. If MSB (L) = 0, then $K_x = L << 1$; Else, $K_x = (L << 1) \text{ XOR } (R_{128})$
3. If MSB ($K_x$) = 0, then $K_y = K_x << 1$; Else $K_y = (K_x << 1) \text{ XOR } (R_{128})$

**Explanation:**

- $\text{CIPH}_K(0)$: Encryption of the value zero using a 128-bit key and the AES-128 encryption algorithm.
- MSB(A): Most significant (leftmost) bit of A
- $B << 1$: The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
- $\text{XOR}$: Bit-wise exclusive OR.
- $R_{128}$: A 128-bit value of 135.

**Figure 7-277. Subkey Generation Algorithm (Continued)**

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey $K_x$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the AES-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey $K_y$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the AES-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-128 function.

**PCC-Compute-Last-Block-CMAC-Using-AES-192 (Function Code 19)**

**Figure 7-279. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192**

For the PCC-Compute-Last-Block-CMAC-Using-AES-192 function, the initial chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-63 of the parameter block.

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 function, the contents of byte offsets 40-63 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, \( K_x \), is derived using the 192-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, \( K_y \), is derived using the 192-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

**Figure 7-280. Subkey Generation Algorithm**

**Steps:**

1. \( L = \text{CIPH}_k(0) \)
2. If MSB \( (L) = 0 \), then \( K_x = L \ll 1 \);
   Else, \( K_x = (L \ll 1) \text{ XOR } (R_{128}) \)
3. If MSB \( (K_y) = 0 \), then \( K_y = K_y \ll 1 \);
   Else \( K_y = (K_y \ll 1) \text{ XOR } (R_{128}) \)
When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey $K_x$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, $K$, and the AES-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey $K_y$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, $K_y$, and the AES-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-192 function.

PCC-Compute-Last-Block-CMAC-Using-AES-256 (Function Code 20)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 (Function Code 28)
The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-256 function has the following format:

```
<table>
<thead>
<tr>
<th>ML</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Message</td>
</tr>
<tr>
<td>24</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>40</td>
<td>Cryptographic Key (K)</td>
</tr>
</tbody>
</table>
```

For the PCC-Compute-Last-Block-CMAC-Using-AES-256 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-71 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 function has the following format:

```
<table>
<thead>
<tr>
<th>ML</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Message</td>
</tr>
<tr>
<td>24</td>
<td>Initial Chaining Value (ICV)</td>
</tr>
<tr>
<td>40</td>
<td>Encrypted Cryptographic Key (WK_y(K))</td>
</tr>
<tr>
<td>56</td>
<td>AES Wrapping-Key Verification Pattern (WK_VP)</td>
</tr>
</tbody>
</table>
```

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 function, the contents of byte offsets 72-103 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-
block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block contain the initial chaining value, and the contents of byte offsets 40-71 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, $K_x$, is derived using the 256-bit cryptographic key, $K$. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, $K_y$, is derived using the 256-bit cryptographic key, $K$. The subkey generation algorithm is shown in the following figure.

**Figure 7-283. Subkey Generation Algorithm**

<table>
<thead>
<tr>
<th>Steps</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>$L = \text{CIPH}_K(0)$</td>
</tr>
<tr>
<td>2.</td>
<td>If MSB ($L$) = 0, then $K_x = L &lt;&lt; 1$; Else, $K_x = (L &lt;&lt; 1) \text{ XOR } R_{128}$</td>
</tr>
<tr>
<td>3.</td>
<td>If MSB ($K_x$) = 0, then $K_y = K_x &lt;&lt; 1$; Else $K_y = (K_x &lt;&lt; 1) \text{ XOR } R_{128}$</td>
</tr>
</tbody>
</table>

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey $K_x$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value.

The result of the second exclusive-OR operation is then enciphered using the 256-bit cryptographic key, $K$, and the AES-256 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey $K_y$. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value.

The result of the second exclusive-OR operation is then enciphered using the 256-bit cryptographic key, $K$, and the AES-256 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-256 function.

**PCC-Compute-XTS-Parameter-Using-AES-128 (Function Code 50)**

**PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 (Function Code 58)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.
The parameter block used for the PCC-Compute-XTS-Parameter-Using-AES-128 function has the following format:

For the PCC-Compute-XTS-Parameter-Using-AES-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block; the 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 16-31 and 32-47, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 48-79 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 64-79 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 48-63 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 48-63 are zero, then it is the initial execution of the computation, and the contents of byte offsets 64-79 of the parameter block are ignored; if the contents of byte offsets 48-63 are in the range between 1 and 127, inclusively, then byte offsets 64-79 contain the partial XTS parameter computed by a previous iteration; if byte offsets 48-63 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 function has the following format:

For the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 function, the contents of byte offsets 16-47 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-374 for details.) The 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 48-63 and 64-79, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 80-111 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 96-111 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 80-95 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 80-95 are zero, then it is the initial execution of the computation, and the contents of byte offsets 96-111 of the parameter block are ignored; if the contents of byte offsets 80-95 are in the range between 1 and 127, inclusively, then byte offsets 96-111 contain the partial XTS parameter computed by a previous iteration;
PERFORM CRYPTOGRAPHIC COMPUTATION

if byte offsets 80-95 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The following description applies to both functions.

The 128-bit XTS parameter is the result of multiplying the encrypted tweak value by the value of 2 raised to the power of the block sequential number (j). Both the power and multiplication operations are performed over GF($2^{128}$). The 128-bit tweak value (i) is encrypted using the 128-bit cryptographic key and the AES encryption algorithm. The operation is shown in Figure 7-286.

The value of 2 raised to the power of j is computed as follows: For each bit in j, the value of 2 raised to the power of an exponent, that is a 128-bit unsigned binary integer with a one in that bit and zeros in all other bits, is pre-computed. To obtain the value of 2 raised to the power of j, the pre-computed values that correspond to a bit of one in j are multiplied together. The power and multiplication operations are performed over GF($2^{128}$).

For a nonzero j, bits in j are processed from left to right, with an index of 0 for the leftmost bit and an index of 127 for the rightmost bit. The operation is ended when all bits in j have been processed (called normal completion) or when a CPU-determined number of bits that is less than the total number of bits in j have been processed (called partial completion). The CPU-determined number of bits depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bits is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-128 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 64-79 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-128 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 96-111 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-128 function.

PCC-Compute-XTS-Parameter-Using-AES-256 (Function Code 52)

PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 (Function Code 60)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-257 on page 7-270.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-AES-256 function has the following format:

For the PCC-Compute-XTS-Parameter-Using-AES-256 function, the cryptographic key is in byte offsets 0-31 of the parameter block; the 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 32-47 and 48-63, respectively, of the parameter block. When the block sequential number
is zero, the contents of byte offsets 64-95 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 80-95 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 64-79 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 64-79 are zero, then it is the initial execution of the computation, and the contents of byte offsets 80-95 of the parameter block are ignored; if the contents of byte offsets 64-79 are in the range between 1 and 127, inclusively, then byte offsets 80-95 contain the partial XTS parameter computed by a previous iteration; if byte offsets 64-79 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 function has the following format:

![Parameter Block Diagram](image)

The following description applies to both functions.

The 128-bit XTS parameter is the result of multiplying the encrypted tweak value by the value of 2 raised to the power of the block sequential number (j). Both the power and multiplication operations are performed over GF(2\(^{128}\)). The 128-bit tweak value (i) is encrypted using the 256-bit cryptographic key and the AES encryption algorithm. The operation is shown in Figure 7-289.

![AES Encryption Diagram](image)

The value of 2 raised to the power of j is computed as follows: For each bit in j, the value of 2 raised to the power of an exponent, that is a 128-bit unsigned binary integer with an one in that bit and zeros in all other bits, is pre-computed. To obtain the value of 2 raised to the power of j, the pre-computed values that correspond to a bit of one in j are multiplied together. The power and multiplication operations are performed over GF(2\(^{128}\)).
For a nonzero j, bits in j are processed from left to right, with an index of 0 for the leftmost bit and an index of 127 for the right most bit. The operation is ended when all bits in j have been processed (called normal completion) or when a CPU-determined number of bits that is less than the total number of bits in j have been processed (called partial completion). The CPU-determined number of bits depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bits is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Invalid bit index or message length
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Invalid bit index or message length
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Invalid bit index or message length
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Invalid bit index or message length
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Invalid bit index or message length
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Invalid bit index or message length
3 Partial completion

Program Exceptions:
lock is released. However, as observed by other CPUs: (1) storage operands, including fields in a parameter list that may be used, may be fetched, and may be tested for store-type access exceptions if a store at a tested location is possible, before the lock is obtained, and (2) operands may be stored in the parameter list after the lock has been released. If an operand not in the parameter list is fetched before the lock is obtained, it is fetched again after the lock has been obtained.

The function code can specify any of six operations: compare and load, compare and swap, double compare and swap, compare and swap and store, compare and swap and double store, or compare and swap and triple store.

A test bit in general register 0 specifies, when one, that a lock is not to be obtained and none of the six operations is to be performed but, instead, the validity of the function code is to be tested. This will be useful if additional function codes for additional operations are assigned in the future. This definition is written as if the test bit is zero except when stated otherwise.

If compare and load is specified, the first-operand comparison value and the second operand are compared. If they are equal, the fourth operand is placed in the third-operand location. If the comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value.

If compare and swap is specified, the first-operand comparison value and the second operand are compared. If they are equal, the first-operand replacement value is stored at the second-operand location. If the comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value.

If double compare and swap is specified, the first-operand comparison value and the second operand are compared. If they are equal, the third-operand comparison value and the fourth operand are compared. If both comparisons indicate equality, the first-operand and third-operand replacement values are stored at the second-operand location and fourth-operand location, respectively. If the first comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value. If the first comparison indicates equality but the second does not, the fourth operand is placed in the third-operand-comparison-value location as a new third-operand comparison value.

If compare and swap and store, double store, or triple store is specified, the first-operand comparison value and the second operand are compared. If they are equal, the first-operand replacement value is stored at the second-operand location, and the third operand is stored at the fourth-operand location. Then, if the operation is the double-store or triple-store operation, the fifth operand is stored at the sixth-operand location, and, if it is the triple-store operation, the seventh operand is stored at the eighth-operand location. If the first-operand comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value.

After any of the six operations, the result of the comparison or comparisons is indicated in the condition code.

The function code (FC) is in bit positions 56-63 of general register 0. The function code specifies not only the operation to be performed but also the length of the operands and whether the first-operand comparison and replacement values and the third operand or third-operand comparison and replacement values, which are referred to collectively simply as the first and third operands, are in general registers or a parameter list. The pattern of the function codes is as follows:

- A function code that is a multiple of 4 (including 0) specifies a 32-bit length with the first and third operands in bit positions 32-63 of general registers.
- A function code that is one more than a multiple of 4 specifies a 64-bit length with the first and third operands in a parameter list.
- A function code that is 2 more than a multiple of 4 specifies a 64-bit length with the first and third operands in bit positions 0-63 of general registers.
- A function code that is 3 more than a multiple of 4 specifies a 128-bit length with the first and third operands in a parameter list.

Figure 7-291 on page 7-286 shows the function codes, operation names, and operand lengths, and
also symbols that may be used to refer to the operations in discussions. For example, PLO.DCS may be used to mean PERFORM LOCKED OPERATION with function code 8. In the symbols, the letter “G” indicates a 64-bit operand length, the letter “R” indicates that some or all 64-bit operands are in general registers, and the letter “X” indicates a 128-bit operand length.

The CPU can perform all of the operations specified by the function codes listed in Figure 7-291. Specifying operations that the CPU can perform are called valid. Function codes that have not been assigned to operations or that specify operations that the CPU cannot perform because the operations are not implemented (installed) are called invalid.

Bit 55 of general register 0 is the test bit (T). When bit 55 is zero, the function code in general register 0 must be valid; otherwise, a specification exception is recognized. When bit 55 is one, the condition code is set to 0 if the function code is valid or to 3 if the function code is invalid, and no other operation is performed.

Bits 32-54 of general register 0 must be all zeros; otherwise, a specification exception is recognized. When bit 55 of the register is one, this is the only exception that can be recognized. Bits 0-31 of general register 0 are ignored.

The lock to be used is represented by a program lock token (PLT) whose logical address is specified in general register 1. In the 24-bit addressing mode, the PLT address is bits 40-63 of general register 1, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, the PLT address is bits 33-63 of the register, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, the PLT address is bits 0-63 of the register.

The contents of general registers 0 and 1 described above are shown in Figure 7-292.

For the even-numbered function codes, including 0, the first-operand comparison value is in general register R1. For the even-numbered function codes beginning with 4, the first-operand replacement value is in general register R1 + 1, and R1 designates an even-odd pair of registers and must designate an even-numbered register; otherwise, a specification exception is recognized. For function codes 0 and 2, R1 can be even or odd.

For function codes 0, 2, 12, and 14, the third operand is in general register R3, and R3 can be even or odd.

For function codes 8 and 10, the third-operand comparison value is in general register R3, the third-operand replacement value is in general register R3 + 1, and R3 designates an even-odd pair of registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For all function codes, the B2 and D2 fields of the instruction specify the second-operand address.

For function codes 0, 2, 8, 10, 12, and 14, the B4 and D4 fields of the instruction specify the fourth-operand address.

Figure 7-291. PERFORM LOCKED OPERATION Function Codes and Operations
For function codes 1, 3, 5, 7, 9, 11, 13, 15, and 16-23, the B₄ and D₄ fields of the instruction specify the address of a parameter list that is used by the instruction, and this address is not called the fourth-operand address. The parameter list contains odd-numbered operands, including comparison and replacement values, and addresses of even-numbered operands other than the second operand. In the access-register mode, the parameter list also contains access-list-entry tokens (ALETs) associated with the even-numbered-operand addresses.

In the access-register mode, for function codes that cause use of a parameter list containing an ALET, R₃ must not be zero; otherwise, a specification exception is recognized.

The rules about R₁ and R₃, and the use of the address specified by B₄ and D₄, are summarized in Figure 7-293 on page 7-287.

### Function Codes Operation | R₁ | R₃ | D₄(B₄)
--- | --- | --- | ---
0 and 2 | Compare and load | EO | EO | Op4a
1 and 3 | Compare and load | - | NZ | PLa
4 and 6 | Compare and swap | E | - | -
5 and 7 | Compare and swap | - | - | PLa
8 and 10 | Double compare and swap | E | E | Op4a
9 and 11 | Double compare and swap | - | NZ | PLa
12 and 14 | Compare and swap and store | E | EO | Op4a

Explanation:
- Ignored.
E Must be even.
EO Can be even or odd.
NZ Must be nonzero in the access-register mode. Ignored otherwise.
Op4a D4(B4) is operand-4 address.
PLa D4(B4) is parameter-list address.

Figure 7-293. Register Rules and D₄(B₄) Usage for PERFORM LOCKED OPERATION

Figure 7-294 on page 7-288 shows the locations of the operands (including operand comparison and replacement values), operand addresses, and parameter-list address used by the instruction.

Operand addresses in a parameter list, if used, are in doublewords in the list. In the 24-bit addressing mode, an operand address is bits 40-63 of a doubleword, and bits 0-39 of the doubleword are ignored. In the 31-bit addressing mode, an operand address is bits 33-63 of a doubleword, and bits 0-32 of the doubleword are ignored. In the 64-bit addressing mode, an operand address is bits 0-63 of a doubleword.
In the access-register mode, access register 1 specifies the address space containing the program lock token (PLT), access register B2 specifies the address space containing the second operand, and access register B4 specifies the address space containing a fourth operand or a parameter list as shown in Figure 7-294 on page 7-288. Also, for an operand whose address is in the parameter list, the associated ALET in the parameter list is loaded into access register R3 when the exception or event is recognized. Then, during the resulting program interruption, if a value is due to be stored as the exception access identification at real location 160 or the PER access identification at real location 161, R3 is stored. If the instruction execution is completed without the recognition of an exception or event, the contents of access register R3 are unpredictable. When not in the access-register mode, or when a parameter list containing an ALET is not used, the contents of access register R3 remain unchanged.

Explanation:

1 For function codes that are a multiple of 4 (including 0) or one more than a multiple of 4, operands in general registers are in bit positions 32-63 of the registers, and bits 0-31 of the registers are ignored and remain unchanged. For function codes that are two more than a multiple of 4, operands in general registers are in bit positions 0-63 of the registers.

- Operand, value, or address is not used in the operation.

OpNC Operand-N comparison value.

OpNr Operand-N replacement value.

OpNa Operand-N address.

PL Operand, value, or address is in the parameter list.

PLa Parameter-list address.

Figure 7-294. Operand and Address Locations for PERFORM LOCKED OPERATION
Storage operand 2, and, when present, storage operands 4, 6, and 8 must be designated on an integral boundary, which is a word boundary for function codes that are a multiple of 4, a doubleword boundary for function codes that are one or 2 more than a multiple of 4, or a quadword boundary for function codes that are 3 more than a multiple of 4. A parameter list, if used, must be designated on a doubleword boundary. Otherwise, a specification exception is recognized. The program-lock-token (PLT) address in general register 1 does not have a boundary-alignment requirement.

All unused fields in a parameter list should contain all zeros; otherwise, the program may not operate compatibly in the future.

A serialization function is performed immediately after the lock is obtained and again immediately before it is released. However, values fetched from the parameter list before the lock is obtained are not necessarily refetched. A serialization function is not performed if the test bit, bit 55 of general register 0, is one.

In the following figures showing the parameter lists for the different function codes, the offsets shown on the left are byte values.

**Function Codes 0-3 (Compare and Load)**
The locations of the operands and addresses used by the instruction are as shown in Figure 7-294 on page 7-288.

The parameter list used for function code 1 has the following format:

</table>

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the third operand is replaced by the fourth operand, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

**Function Codes 4-7 (Compare and Swap)**
The locations of the operands and addresses used by the instruction are as shown in Figure 7-294 on page 7-288.

The parameter list used for function code 5 has the following format:

<table>
<thead>
<tr>
<th>Parameter List for Function Code 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>16</td>
</tr>
<tr>
<td>24</td>
</tr>
<tr>

</tr>
<tr>
<td>Operand-1 Replacement Value</td>
</tr>
</tbody>
</table>

In the following figures showing the parameter lists for the different function codes, the offsets shown on the left are byte values.
The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

**Function Codes 8-11 (Double Compare and Swap)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-294 on page 7-288.

The parameter list used for function code 9 has the following format:

<table>
<thead>
<tr>
<th>Parameter List for Function Code 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>16</td>

</tr>
<tr>
<td>32</td>
</tr>
<tr>
<td>40</td>
</tr>
<tr>
<td>48</td>
</tr>
<tr>
<td>56</td>
</tr>
<tr>
<td>64</td>
</tr>
<tr>
<td>72</td>
</tr>
</tbody>
</table>

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the third-operand comparison value is compared to the fourth operand. When the third-operand comparison value is equal to the fourth operand (after the first-operand comparison value has been found equal to the second operand), the first-operand replacement value is stored at the second-operand location, the third-operand replacement value is stored at the fourth-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the third-operand comparison value is not equal to the fourth operand (after the first-operand comparison value has been found equal to the second operand), the third-operand comparison value is replaced by the fourth operand, and condition code 2 is set.

**Function Codes 12-15 (Compare and Swap and Store)**

The locations of the operands and addresses used by the instruction are as shown in Figure 7-294 on page 7-288.

The parameter list used for function code 13 has the following format:
The parameter list used for function code 15 has the following format:

<table>
<thead>
<tr>
<th>Parameter List for Function Code 15</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>16</td>

<tr>
<td>136</td>
</tr>
</tbody>
</table>

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, the third operand is stored at the fourth-operand location, the fifth operand is stored at the sixth-operand location, the seventh operand is stored at the eighth-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

**Locking**

A lock is obtained at the beginning of the operation and released at the end of the operation. The lock obtained is represented by a program lock token (PLT) whose logical address is specified in general register 1 as already described.

A PLT is a value produced by a model-dependent transformation of the PLT logical address. Depending on the model, the PLT may be derived directly from the PLT logical address or, when DAT is on, from the real address that results from transformation of the PLT logical address by DAT. If DAT is used, access-register translation (ART) precedes DAT in the access-register mode.

A PLT selects one of a model-dependent number of locks within the configuration. Programs being executed by different CPUs can be assured of specifying the same lock only by specifying PLT logical addresses that are the same and that can be transformed to the same real address by the different CPUs.

Since a model may or may not use ART and DAT when forming a PLT, access-exception conditions that can be encountered during ART and DAT may or may not be recognized as exceptions. There is no accessing of a location designated by a PLT, but an addressing exception may be recognized for the location. A protection exception is not recognized for any reason during processing of a PLT logical address.

The CPU can hold one lock at a time.

When PERFORM LOCKED OPERATION is executed by this CPU and is to use a lock that is already held by another CPU due to the execution of a PERFORM LOCKED OPERATION instruction by the other CPU, the execution by this CPU is delayed until the lock is no longer held. An excessive delay can be caused only by a machine malfunction and is a machine-check condition.

The order in which multiple requests for the same lock are satisfied is undefined.

A nonrecoverable failure of a CPU while holding a lock may result in a machine check, entry into the check-stop state, or system check stop. The machine check is processing backup if all operands are undamaged or processing damage if register operands are damaged. If a machine check or the check-stop state is the result, either no storage operands have been changed or else all storage operands that were due to be changed have been correctly changed, and, in either case, the lock has been released. If the storage operands are not in either their correct original state or their correct final state, the result is system check stop.

**Storage-Operand References**
The accesses to the even-numbered storage operands appear to be word concurrent, as observed by other CPUs, for function codes that are a multiple of 4 or doubleword concurrent for function codes that are one, 2, or 3 more than a multiple of 4. The accesses to the doublewords in the parameter list appear to be doubleword concurrent, as observed by other CPUs, regardless of the function code.

As observed by other CPUs, all storage operands may be tested for access exceptions before a lock is obtained. (A channel program cannot observe a lock.)

As observed by other CPUs, in all operations except the compare-and-swap operation (which does not have a fourth operand), the fourth operand is accessed while the lock is held only if a comparison of the first-operand comparison value to the second operand while the lock is held has indicated equality. In these operations, the fourth operand is accessed before the lock is held only if a comparison of the first-operand comparison value to the second operand and has indicated equality and only if, when DAT is on, an INVALIDATE PAGE TABLE ENTRY instruction executed by another CPU after the fetch of the second operand will not be the cause of a page-translation exception recognized for the fourth operand, which it will if it sets to one the page-invalid bit in the page-table entry for the fourth operand when this CPU does not have a TLB entry corresponding to that page-table entry. In the compare-and-swap-and-double-store and compare-and-swap-and-triple-store operations, the sixth operand, and also the eighth operand in the triple-store operation, are treated the same as the fourth operand described above. The reason for this specification about INVALIDATE PAGE TABLE ENTRY is given in programming note 7.

Provided that accessing of an operand is not prohibited as described in the preceding paragraph, store-type access exceptions may be recognized for the fourth, sixth, or eighth operands even when a store does not occur because of the results of a comparison. A storage-alteration PER event is recognized, and a change bit is set, only if a store occurs.

When a comparison is made between an operand comparison value and an operand before the lock is obtained and indicates inequality, the lock still is obtained. The condition code is set only as a result of a comparison made while the lock is held. When condition code 1 or 2 is set, the first-operand comparison value or third-operand comparison value is replaced only by means of a fetch of the second operand or fourth operand, respectively, made while the lock is held, as observed by other CPUs.

In those cases when a store is performed to the second-operand location and one or more of the fourth-, sixth-, and eighth-operand locations, the store to the second-operand location is always performed last, as observed by other CPUs and by channel programs.

Stores into the parameter list may be performed while the lock is held or after it has been released.

Access exceptions may be recognized for parameter-list locations even when the locations are not required in the operation. The locations are those beginning at offset 0 and extending up through the last location defined for the function code used.

For the compare-and-load and compare-and-swap operations, the operation is suppressed on all addressing and protection exceptions.

When a nonrecoverable failure of a CPU while holding a lock results in a machine check or entry into the check-stop state, either no storage operands have been changed or else all storage operands that were due to be changed have been correctly changed. The latter may be accomplished by repeating stores that were performed successfully before the failure. Therefore, there may be two single-access store references (possibly the store part of an update reference and then a store reference) to the store-type operands, with the first value stored equal to the second value stored.

**Resulting Condition Code:**

When test bit is zero:

- 0 All comparisons equal; replacement value or values stored or loaded
- 1 First-operand comparison not equal; first-operand comparison value replaced
- 2 -- (all operations except double compare and swap)
- 2 First-operand comparison equal but third-operand comparison not equal; third-operand comparison value replaced (double compare and swap)
- 3 --
When test bit is one:

0  Function code valid
1  --
2  --
3  Function code invalid

Program Exceptions:

- Access (for all function codes, fetch, except addressing and protection for PLT location, program lock token, model-dependent; for function codes 0-3, fetch, operand 2; for function codes 4-23, fetch and store, operand 2; for odd-numbered function codes, fetch and store, parameter list; for function codes 16, 18, 20, and 22, fetch, parameter list; for function codes 0-3, fetch, operand 4; for function codes 8-11, fetch and store, operand 4; for function codes 12-23, store, operand 4; for function codes 16-23, store, operand 6; for function codes 20-23, store, operand 8)
- Specification
- Transaction constraint

Programming Notes:

1. In configurations that support the transactional-execution facility, a transaction may provide benefits over the use of PERFORM LOCKED OPERATION, as follows:
   a. Transactional execution may provide improved performance over an equivalent code path that uses PLO.
   b. Transactional execution does not require the specification of a program lock token in general register 1.
   c. Transactional execution does not require the use of a parameter list for more complex operations.
   d. Transactional execution provides a much broader scope of operations that can be performed, all of which appear to execute in a block-concurrent manner as observed by other CPUs and the channel subsystem.
   e. The use of classic interlocked-access techniques on one CPU can correctly coexist with transactional execution on another CPU. This coexistence is not possible using PLO, as explained in programming note 4, below.

2. An example of the use of the PERFORM LOCKED OPERATION instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

3. When the contents of storage locations are changed by PERFORM LOCKED OPERATION instructions that are executed concurrently by different CPUs and that use the same lock, the changes to operands not in the parameter list will be completed by one of the CPUs before they are begun by the other CPU, depending on which CPU first obtains the lock.

4. The compare-and-swap functions of PERFORM LOCKED OPERATION are not performed by means of interlocked-update references. Concurrent store references by another CPU to the storage operands, even if they are interlocked-update references, will interfere unpredictably, in terms of the resulting register and storage contents, with the intended operation of PERFORM LOCKED OPERATION. All changes to the contents of the storage locations must be made by PERFORM LOCKED OPERATION instructions that use the same lock, if predictable storage results are to be obtained.

5. Because a nonrecoverable failure of a CPU while executing PERFORM LOCKED OPERATION may cause two stores of the same value to a store-type operand, a concurrent store made by another CPU to the same operand but not by executing PERFORM LOCKED OPERATION may be lost.

6. When programs in different address spaces are using the same lock when DAT is on, the programs must ensure that they are using PLT logical addresses that are the same and that will be translated to the same real address regardless of the address space in which a translation occurs. Otherwise, the programs may in fact use different locks.

7. The section “Storage-Operand References” on page 7-294 contains a specification concerning the INVALIDATE PAGE TABLE ENTRY (IPTE) instruction. The need for the specification is
shown by the following example that is possible without the specification.

a. CPU 1 begins to execute a PERFORM LOCKED OPERATION instruction with function code 8, which is referred to as PLO.DCS. Operand 2 is a location, Qtail, containing the address (the first-operand comparison value) of the last element, element X, on a queue, and operand 4 is a location in that element containing the address (0, the third-operand comparison value) of the next (nonexisting) element on the queue. The purpose of the PLO instruction is to enqueue an element by placing the address of the element (the first-operand and third-operand replacement values) in both operand 2 and operand 4. With the lock not held, the PLO instruction fetches operand 2 and compares it, with an equal result, to the first-operand comparison value.

b. CPU 2 completely executes a PLO.DCS instruction to dequeue element X, which is the only element on the queue, from the queue. The PLO instruction stores 0 in Qtail and also in Qhead, which is a location containing the address of the first element on the queue. The program on CPU 2 processes the dequeued element and then invokes the freemain service of the control program to deallocate the storage containing the element. The freemain service uses IPTE to set the page-invalid bit to one in the page-table entry for the page containing element X. The IPTE instruction immediately sets the page-invalid bit to one, and then it waits for the signal that all other CPUs have cleared their TLBs of entries corresponding to the page.

c. CPU 1 attempts to fetch operand 4. CPU 1 does not have a TLB entry for the operand-4 page. CPU 1 signals CPU 2 that the CPU 2 IPTE instruction may proceed.

d. CPU 2 completes its IPTE instruction. The program on CPU 2 sets a software bit in the page-table entry to one to indicate that the page has been freemained and that, therefore, a reference to the page should result in presentation by the control program of an addressing exception to the program making the reference.

e. CPU 1 attempts to do DAT for operand 4 and sees that the page-invalid bit is one. CPU 1 performs a program interruption indicating a page-translation exception. The exception handler sees that the software bit indicating freemained is one, and it presents an addressing exception to the CPU 1 program, which causes an abend of the program.

If CPU 1 had had a TLB entry for the page, its PLO instruction would not have been interrupted, and the comparison of the first-operand comparison value to the second operand while the lock was held would indicate that CPU 2 had changed the second operand. The PLO instruction would set condition code 1. If CPU 1 did not have a TLB entry but IPTE could not set the page-invalid bit to one while CPU 1 was executing an instruction, CPU 1 could successfully translate the operand-4 address and, again, discover while the lock was held that operand 2 had changed. The case when operand 2 points to element X but the freemained bit for the element-X page is one is a programming error.

8. For functions that use a parameter list in the access register mode, the value in the R3 field of the instruction should be different from that of the B2 and B4 fields. Because access register R3 is modified as a result of an access exception, subsequent re-execution of the instruction (for example, following the resolution of a page-translation exception) may yield unpredictable results if the R3 field designates the same access register as that of the second operand or parameter list.
The operation of each assist function, and the registers used by the function are as follows:

**Transaction-Abort Assist:** When the function code in the M3 field is 1, the processor is requested to assist following an aborted nonconstrained transaction. The program is expected to provide an unsigned 32-bit binary integer in bits 32-63 of general register R1, specifying the number of times the nonconstrained transaction has been repeatedly aborted. Depending on the value of this integer, the processor may take escalating actions to increase the likelihood of successful completion of the transaction in a subsequent execution.

---

### PERFORM PROCESSOR ASSIST

**PPA R1 R2 M3 [RRF-c]**

<table>
<thead>
<tr>
<th>PPA</th>
<th>R1</th>
<th>R2</th>
<th>M3</th>
<th>[RRF-c]</th>
</tr>
</thead>
<tbody>

- OpNr Operand-N replacement value.

*Figure 7-295. Summary of PERFORM LOCKED OPERATION Results*
Reserved: Reserved function codes should not be specified; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (processor-assist facility not installed)
- Transaction constraint

Programming Notes:

1. For the transaction-abort-assist function, a larger value in general register R1 does not necessarily guarantee successful completion when the transaction is reexecuted, and it may unnecessarily delay the CPU. Therefore, the program should provide an accurate count of the number of times a transaction has been aborted in the register.

A value of one in bits 32-63 of general register R1 means that the transaction has been aborted once, a value of two means the transaction has been aborted twice, and so forth.

2. An example of the use of PERFORM PROCESSOR ASSIST is shown in programming note 2 on page 5-106.

3. The processor-assist facility is indicated by facility bit 49.

PERFORM PSEUDORANDOM NUMBER OPERATION

PPNO R1 R2 [RRE]

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are reserved and should contain zeros; otherwise, the instruction may not operate compatibly in the future.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-296 shows the assigned function codes for PERFORM PSEUDORANDOM NUMBER OPERATION. All other function codes are unassigned.

Figure 7-296. Function Codes for PERFORM PSEUDORANDOM NUMBER OPERATION

If bits 57-63 of general register 0 designate an unassigned or uninstalled function code, a specification exception is recognized.

The query function provides the means of indicating the availability of the other functions.

For all functions other than the query function, bit 56 of general register 0 is the modifier bit. When the modifier bit is zero, a generate operation is performed, and when the modifier bit is one, a seed operation is performed. The modifier bit is ignored for the query function. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address. In the access-register mode, access register 1 specifies the address space containing the parameter block.

The R1 and R2 fields each designate an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

For the generate operation, the leftmost byte of the first operand is specified by the contents of general register R1, and the length of the first operand is specified in general register R1 + 1. The contents of general register R2 are ignored by a generate operation.
For a seed operation, the leftmost byte of the second operand is specified by the contents of general register \( R_2 \), and the length of the second operand is specified in general register \( R_2 + 1 \). The contents of general register \( R_1 \) are ignored by a seed operation.

Regardless of whether a generate or seed operation is specified, the contents of the even-numbered general register designating the storage operand (\( R_1 \) or \( R_2 \), respectively) are subject to the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of the register constitute the address of the storage operand, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address of the storage operand, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register constitute the address of the storage operand. In the access-register mode, the respective access register (\( R_1 \) or \( R_2 \)) specifies the address space containing the storage operand.

Regardless of whether a generate or seed operation is specified, in both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of the odd-numbered general register (\( R_1 + 1 \) or \( R_2 + 1 \), respectively) form a 32-bit unsigned binary integer which specifies the number of bytes in the storage operand. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register form a 64-bit unsigned binary integer which specifies the number of bytes in the storage operand.

For a generate operation, the first-operand length is updated in general register \( R_1 + 1 \) at the completion of the instruction. In both the 24-bit and the 31-bit addressing modes, the updated value replaces the contents of bit positions 32-63 of general register \( R_1 + 1 \); the contents of bit positions 0-31 of general register \( R_1 + 1 \), always remain unchanged. In the 64-bit addressing mode, the updated value replaces the contents of general register \( R_1 + 1 \).

Figure 7-297 on page 7-300 shows the contents of the general registers just described.

Figure 7-297. General Register Assignment for PPNO (Part 1 of 2)
When the parameter block overlaps any portion of the storage operand, the results are unpredictable.

When the storage-operand length is zero, access exceptions for the storage-operand location are not recognized. However, the parameter block is accessed even when the storage-operand length is zero. For a generate operation when the storage-operand length is zero, general register R1 + 1 is not changed, and condition code 0 is set.

As observed by other CPUs and the I/O subsystem, references to the parameter block and storage operand may be multiple-access references, accesses to these locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

A PER storage-alteration event is recognized only for the portion of the parameter block that is stored. For a generate operation, when a PER storage-alteration event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported. When a PER storage-alteration event is recognized both for the first-operand and location and for the portion of the parameter block that is stored, it is unpredictable which of these two locations is identified in the PAID and AI. Similarly, when a PER zero-address-detection event is recognized for both for the first-operand location and for the parameter block, it is unpredictable which of these two locations is identified in the PAID and AI.

For a generate operation, access exceptions may be reported for a larger portion of the first operand than is processed in a single execution of the instruction. However, access exceptions are not recognized for locations that do not encompass the first operand nor for locations more than 4K bytes from the current location being processed.

For a generate operation, when the operation ends due to normal completion, condition code 0 is set and the resulting value in general register R1 + 1 is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in general register R1 + 1 is nonzero.

**PPNO-Query (PPNO Function Code 0)**
The contents of general registers R1, R1 + 1, R2, and R2 + 1 are ignored by the query function.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-297 on page 7-300.
PERFORM PSEUDORANDOM NUMBER OPERATION

The parameter block used for the function has the following format:

<table>
<thead>
<tr>
<th>0</th>
<th>8</th>
<th>16</th>
<th>232</th>
</tr>
</thead>
</table>
| Status Word | Stream Bytes | Reseed Counter | \_

*Figure 7-298. Parameter Block for PPNO-Query*

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PERFORM PSEUDORANDOM NUMBER OPERATION instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the PPNO-Query function completes; condition code 3 is not applicable to this function.

**PPNO-SHA-512-DRNG (PPNO Function Code 3)**

Depending on the modifier bit, bit 56 of general register 0, the PPNO-SHA-512-DRNG function performs either a deterministic pseudorandom-number generate operation or a deterministic pseudorandom-number seed operation using the 512-bit secure-hash algorithm (SHA-512).

Deterministic pseudorandom-number generation, also known as deterministic random-bit generation, is defined in Reference [16.] on page xxviii; refer to this publication for further description on terms used in this definition. Further description of the secure hash algorithm may be found in Reference [13.] on page xxviii.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-297 on page 7-300.

The same parameter block format is used by both the generate operation and the seed operation (including instantiation and reseeding). A parameter block containing all zeros is considered to be not instantiated. The program should zero the parameter block prior to issuing the seed operation to instantiate the parameter block, and subsequently, the program should not alter the contents of the parameter block except to zero it; otherwise, unpredictable results may be produced by the instruction.

**Reserved:** Bytes 0-3, 16, and 128 of the parameter block are reserved. As observed by other CPUs and the I/O subsystem, the contents of byte 16 may appear to change during the execution of the instruction; however, byte 16 will contain zero when the instruction completes with condition code 0. As observed by other CPUs and the I/O subsystem, the contents of byte 128 may appear to change during the execution of the seed operation, however, byte 128 will contain zero at the completion of the seed operation.

**Reseed Counter:** Bytes 4-7 of the parameter block contain a 32-bit unsigned binary integer indicating the number of times that the instruction has completed with condition code 0 since the parameter block was last instantiated or reseeded.

When the reseed counter contains zero, the parameter block is considered to be not instantiated, and the following applies:

- Execution of the seed operation causes the parameter block to be instantiated with initial val-
ues, including setting the reseed counter to a value of one.

- Execution of the generate operation results in a general-operand data exception being recognized.

When the reseed counter contains a nonzero value, the parameter block is considered to be instantiated, and the following applies:

- Execution of the seed operation causes the parameter block to be reseeded, including resetting the reseed counter to a value of one.
- Execution of a generate operation that results in condition code 0 causes the reseed counter to be incremented by one; any carry out of bit position 0 of the reseed-counter field is ignored.

Stream Bytes: Bytes 8-15 of the parameter block contain a 64-bit unsigned binary integer. The stream-bytes field is set to zero by the execution of the seed operation when instantiating the parameter block (that is, when the reseed counter is zero); the field is not changed by the execution of the seed operation when the parameter block is already instantiated.

Partial or full completion of a generate operation causes the contents of the stream-bytes field to be incremented by the number of bytes stored into the first operand; any carry out of bit position 0 of the stream-bytes field is ignored.

Value (V): Bytes 17-127 of the parameter block contain an 888-bit value indicating the internal state of the random-number generator represented by the parameter block. V is initialized by the execution of the seed operation when instantiating the parameter block. V is updated by either (a) the execution of the seed operation when the reseed counter is nonzero, or (b) the execution of the generate operation that ends in condition code 0.

Constant (C): Bytes 129-239 of the parameter block contain an 888-bit value indicating the internal state of the random-number generator represented by the block. C is initialized by the execution of the seed operation, and inspected by the generate operation.

Seed Operation

The PPNO-SHA-512-DRNG seed operation instantiates or reseeds a deterministic-pseudorandom-number-generation parameter block using the 512-bit secure-hash algorithm.

Depending on whether the reseed counter in bytes 4-7 of the parameter block is zero or nonzero, an instantiation or reseeding operation is performed, respectively.

- For the instantiation operation, the second operand in storage contains entropy input, nonce, and an optional personalization string, used to form seed material.
- For the reseed operation, the second operand in storage contains entropy input and optional additional input, used to form the seed material.

See Reference [16.] on page xxviii for the definition and usage of entropy input, nonce, personalization string, and additional input, and for details on the algorithms used. The length of the second operand in general register \( R_2 + 1 \) must not exceed 512 bytes, otherwise, a specification exception is recognized.

When performing an instantiation operation, seed material is formed using only the second operand. When performing a reseeding operation, seed material is formed from a concatenation of the value 01 hex, the V field of the parameter block, and the second operand. The formation of the seed material is illustrated in Figure 7-300.

Figure 7-300. PPNO-SHA-512-DRNG Seed Operation’s Generation of Seed Material (Part 1 of 2)
For either the instantiation or reseeding operation, a new value field \( (V_{\text{new}}) \) is formed as follows: A one byte counter, four-byte value of 888, the seed material, and padding are used as input to the SHA-512 algorithm. The padding consists of a value of 80 hex, concatenated with 0-127 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte counter, four-byte value of 888, and the seed material). The SHA-512 algorithm is invoked twice to form two 64-bit hashed results; the one-byte counter contains the value 1 for the first invocation of the SHA-512 algorithm, and it contains the value 2 for the second invocation. The two 64-byte hashed results are concatenated together, and the leftmost 111 bytes of the 128-byte concatenation form the new value field \( (V_{\text{new}}) \) in the parameter block. The generation of \( V_{\text{new}} \) is illustrated in Figure 7-301.

**Explanation:**

- \(<b>\) Length of field in bytes
- \( R2+1 \) Length of operand 2 in storage in the range of 0-512 bytes.

*Figure 7-300. PPNO-SHA-512-DRNG Seed Operation’s Generation of Seed Material (Part 2 of 2)*

*Figure 7-301. PPNO-SHA-512-DRNG Seed Operation’s Formation of New Value \( (V_{\text{new}}) \) (Part 1 of 2)*
Similar to the formation of the \( V_{\text{new}} \) field, the new constant field \( (C_{\text{new}}) \) is formed during both the instantiation or reseeding operation. A one byte counter, four-byte value of 888, one byte value of zero, the \( V_{\text{new}} \) field, and padding are concatenated to form input to the SHA-512 algorithm. The padding consists of a value of 80 hex, concatenated with 122 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte counter, four-byte value of 888, one-byte value of zero, and the \( V_{\text{new}} \) field). The SHA-512 algorithm is invoked twice to form two 64-bit hashed results; the one-byte counter contains the value 1 for the first invocation of the SHA-512 algorithm, and it contains the value 2 for the second invocation. The two 64-byte hashed results are concatenated together, and the leftmost 111 bytes of the 128-byte concatenation form the new constant field \( (C_{\text{new}}) \) in the parameter block.

For either the instantiate or reseeding operation, the reseed-counter field in the parameter block is set to a value of one. For the instantiate operation only, the stream-bytes field in the parameter block is set to zeros; the stream-bytes field remains unchanged by a reseeding operation.
The generation of $C_{\text{new}}$ and the initialization of the reseed-counter and stream-bytes fields is illustrated in Figure 7-302.

**Generate Operation**

If the reseed counter in the parameter block is zero, a general-operand data exception is recognized and the operation is suppressed.

General register $R_1$ contains the address of the *leftmost* byte of the first operand. When the first-operand length in general register $R_1 + 1$ is nonzero, the first operand is formed in right-to-left order in units of 64-byte blocks, except that the rightmost block may contain fewer than 64 bytes. The number of blocks to be stored, including any partial rightmost block, is determined by rounding the first-operand length in general register $R_1 + 1$ up to a multiple of 64 and dividing this value by 64. The blocks of the first oper-
and are numbered from left to right as 0 to n–1, where n–1 represents the rightmost block. The following procedure is performed for each block of the first-operand location, beginning with the rightmost (n–1) block and proceeding to the left.

1. The value (V) from the parameter block is added to the block number being processed, with any overflow from the addition ignored.

2. The 111-byte sum of this addition, concatenated with 17 bytes of padding, are used as input to the SHA-512 algorithm, resulting in a 64-byte hashed value. The 17-byte padding provided to the SHA-512 algorithm consists of a value of 80 hex followed by a 16-byte binary integer value of 888 (the length of V in bits).

3. If the first-operand length in general register $R_1 + 1$ is a multiple of 64, then the resulting 64-byte hashed value is stored in the respective block of the first-operand location, and the length in general register $R_1 + 1$ is decremented by 64.

If the first-operand length is not a multiple of 64, then the leftmost $m$ bytes of the resulting 64-byte hashed value is stored in the rightmost partial block of the first operand, where $m$ represents the remainder of the first-operand length divided by 64. In this case, the length in general register $R_1 + 1$ is decremented by $m$.

4. Regardless of whether a full or partial block is stored, the stream-bytes field in bytes 8-15 of the parameter block is incremented by the number of bytes stored into the first-operand location.

The above process is repeated until either the first-operand length in general register $R_1 + 1$ is zero (called normal completion) or a CPU-determined number of blocks has been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The process of generating the deterministic pseudorandom numbers in the first operand is shown in Figure 7-303.
When the first-operand length in general register R1 + 1 is initially zero, normal completion occurs without storing into the first-operand location; however, the parameter block is updated as described below.

When the pseudorandom-number-generation process ends due to normal completion, the parameter block is updated as described below.

1. A one byte value of 03 hex, 111-byte value (V) from the parameter block, and 144 bytes of padding are used as input to the SHA-512 algorithm, resulting in a 64-byte hashed value. The padding consists of a value of 80 hex, concatenated with 127 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte value of 03 hex and the V field). The values of the 4-byte reseed-counter field and the 111-byte value (V) and constant (C) fields in the parameter block, and the 64-byte hashed value (from the above computation) are added. For the purposes of this addition, each value is treated as an unsigned binary integer, extended to the left with zeros as necessary. Any overflow from the addition is ignored, and the resulting 111-byte sum replaces the value field in the parameter block (∆Vnew).

2. The 4-byte reseed-counter field in the parameter block is incremented by one.

3. Condition code 0 is set.

Steps 1 and 2 of the normal completion processing are illustrated in Figure 7-304.

When the pseudorandom-number-generation process ends due to partial completion, the first-operand length in general register R1 + 1 contains a nonzero multiple of 64, the reseed-counter and value (V) fields in the parameter block are not updated, and condition code 3 is set.
Special Conditions

A specification exception is recognized and no other action is taken if any of the following conditions exist:

1. Bits 57-63 of general register 0 specify an unsigned or uninstalled function code.
2. The \( R_1 \) or \( R_2 \) fields designate an odd-numbered register or general register 0.
3. For the seed operation, the length in general register \( R_2 + 1 \) is greater than 512.

A general-operand data exception is recognized for the generate operation if the reseed counter in the parameter block is zero.

| 0 | Normal completion |
| 1 | -- |
| 2 | -- |
| 3 | Partial completion (generate operation only) |

Program Exceptions:

- Access (store, operand 1, generate operation; fetch, operand 2, seed operation; fetch and store, parameter block)
- Data with DXC 0, general operand
- Operation (if the message-security-assist extension 5 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. For the generate operation, when condition code 3 is set, the first operand length in general register \( R_1 + 1 \) is updated such that the program can simply branch back to the instruction to continue the operation.
2. The PPNO-SHA-512-DRNG seed operation (instantiation and reseeding) and generate operation correspond to the following algorithm specifications in Reference [16.] on page xxviii:
   - Section 10.1.1.2: Instantiation of Hash_DRBG
   - Section 10.1.1.3: Reseeding a Hash_DRBG Instantiation
   - Section 10.1.1.4: Generating Pseudorandom Bits Using Hash_DRBG (steps 3–7)
3. If a carry out of bit position 0 of the reseed-counter field occurs during a generate operation, then the counter wraps around to zero; in this case, the parameter block is considered not to be instantiated. Unless a seed operation is performed to reinstantiate the parameter block, a subsequent generate operation will result in a general-operand data exception being recognized.
4. The PERFORM PSEUDORANDOM NUMBER OPERATION instruction does not implement the testing and uninstantiation functions described in Reference [16.] on page xxviii. As the parameter block exists in program storage, the program can effect the testing function by directly inspecting the parameter block; similarly, the program can effect the uninitialization function by zeroing the parameter block.
5. The program is responsible for reseeding the parameter block depending on policy and pseudorandom-number-generation state. For example, reseeding may be required after each generate operation if prediction resistance is required. Reseeding may be appropriate after a preset number of stream bytes is produced. See Reference [16.] on page xxviii for further explanation.
6. Even though the generate operation processes the blocks of the first operand in right to left order, it is the address of the leftmost byte of the operand in general register \( R_1 \) that is used for PER zero-address detection. If the first-operand address is nonzero, and length of the operand is such that the operand wraps around to location zero, stores to the first-operand location – including stores to location zero – will not result in the recognition of a PER zero-address-detection event.
7. For the PPNO-SHA-512-DRNG function, the length in bits of the input to the SHA-512 algorithm is implicitly determined by the instruction; this length is described as occupying the rightmost 16 bytes of the padding field. This differs from the KLMD-SHA-512 function of the COMPUTE LAST MESSAGE DIGEST instruction where the message-bit length (\( mbl \)) is explicitly specified in the parameter block, and the padding (\( p \)) and \( mbl \) are described separately.
8. The initial chaining value (ICV) used by the PPNO-SHA-512-DRNG function is described as the initial-hash value (IHV) in Reference [16.] on page xxviii.
9. The program may issue a seed operation with the second-operand length in general register \( R_2 + 1 \) set to zero. However, the results in this case will always be deterministic.

10. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

### POPULATION COUNT

**POPCTN R1,R2 [RRE]**

A count of the number of one bits in each of the eight bytes of general register \( R_2 \) is placed into the corresponding byte of general register \( R_1 \). Each byte of general register \( R_1 \) is an 8-bit binary integer in the range of 0-8.

**Resulting Condition Code:**

- 0: Result zero
- 1: Result not zero
- 2: --
- 3: --

**Program Exceptions:**

- Operation (if the population-count facility is not installed)

**Programming Notes:**

1. The condition code is set based on all 64 bits of general register \( R_1 \).

2. The total number of one bits in a general register can be computed as shown below. In this example, general register 15 contains the bits to be counted; the result containing the total number of one bits in general register 15 is placed in general register 8. (General register 9 is used as a work register and contains residual values on completion.)

3. Using techniques similar to that shown in programming note 2, the number of one bits in a word, halfword, or discontiguous bytes of the second operand may be determined.

### PREFETCH DATA

**PFD M1,D2(X2,B2) [RXY-b]**

**PFDRL M1,RI2 [RIL-c]**

Note: In this instruction definition, the name "PREFETCH DATA (RELATIVE LONG)" refers to both the PREFETCH DATA instruction and the PREFETCH DATA RELATIVE LONG instruction.

Subject to the controls specified in the \( M_1 \) field, the CPU is signalled to perform one of the following operations:

- Prefetch the second operand into a cache line.
- Release a cache line containing the second operand.

The second operand designates a logical address. The \( M_1 \) field contains a 4-bit unsigned binary integer that is used as a code to signal the CPU as to the
intended use of the second operand. The codes are as follows:

<table>
<thead>
<tr>
<th>Code</th>
<th>Function Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Prefetch the data at the second-operand address into a cache line for fetch access.</td>
</tr>
<tr>
<td>2</td>
<td>Prefetch the data at the second-operand address into a cache line for store access.</td>
</tr>
<tr>
<td>6</td>
<td>Release the cache line containing the second operand from store access; retain the data in the cache line for fetch access.</td>
</tr>
<tr>
<td>7</td>
<td>Release the cache line containing the second operand from all accesses.</td>
</tr>
</tbody>
</table>

All other codes are reserved. Depending on the model, the CPU may not implement all of the prefetch functions. For functions that are not implemented by the CPU, and for reserved functions, the instruction acts as a no-op. Code 0 always acts as a no-op.

No access exceptions or PER storage-alteration events are recognized for the second operand.

Code 2 has no effect on the change bit for the second operand. For all codes, it is model dependent whether any TLB entry is formed for the data that is prefetched.

For PREFETCH DATA, the displacement is treated as a 20-bit signed binary integer.

For PREFETCH DATA RELATIVE LONG, the contents of the RI2 field are signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

When PREFETCH DATA (RELATIVE LONG) is attempted in a nonconstrained transaction, and the code in the M1 field is 6 or 7, the transaction may be aborted due to abort code 16. When PREFETCH DATA (RELATIVE LONG) is attempted in a constrained transaction, a transaction-constraint program interruption is recognized, and the transaction is aborted with abort code 4.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Operation (if the general-instructions-extension facility is not installed)
- Transaction constraint

**Programming Notes:**

1. PREFETCH DATA (RELATIVE LONG) signals the CPU to perform the specified operation, but it does not guarantee that the CPU will necessarily honor the request.

2. There is no guarantee that storage location will still be in the cache when a subsequent instruction references the location. Likewise, there is no guarantee that when a cache line is released, that the CPU will not subsequently refetch it (independent of any prefetching operations). Rather, PREFETCH DATA (RELATIVE LONG) simply provides hints as to the program's anticipated use of storage areas.

3. If an exception condition would otherwise be recognized when accessing the second operand, PREFETCH DATA (RELATIVE LONG) is completed with no indication of the exception provided to the program, however, the performance of PREFETCH DATA (RELATIVE LONG) may be significantly slower than if the exception condition did not exist.

4. A significant delay may be experienced if a storage location has been prefetched and then released, and then a subsequent instruction references the same storage location. Similarly, a delay may be experienced if a storage location has been prefetched for fetch access, and then a subsequent instruction references the same location for storing.

5. On models that implement a unified data and instruction cache, the function performed may affect both subsequent operand accesses and instruction fetches from the second-operand location. On such models, a significant delay may be experienced if the code 7 is used to release data in a cache line from which an instruction is subsequently fetched.

6. On models that implement separate data and instruction caches, codes 1 and 2 cause the second operand to be prefetched into the data cache. Similarly, on such models, codes 6 and 7 cause the second operand to be released from
the data cache. However, on certain models with separate data and instruction caches, code 7 may also cause the second operand to be released from the instruction cache, in addition to being released from the data cache.

7. On models that implement separate data and instruction caches, the use of code 2 to prefetch (for storing) a cache line from which instructions will subsequently be fetched may cause significant delays. Similar delays may be experienced for any store operation into a cache line from which instructions are subsequently fetched.

8. The use of PREFETCH DATA (RELATIVE LONG) to prefetch operands that are frequently updated in a multiprocessing environment may actually degrade performance by causing unnecessary contention for the cache line.

9. A prefetch operation consists of fetching a cache line on an integral boundary. The cache line size (and corresponding integral boundary) may be determined by executing EXTRACT CPU ATTRIBUTE.

10. The second operand is fetched into the cache line in model-dependent units, on an integral boundary, the minimum size of which is a double-word. Thus, at least the rightmost three bits of the second-operand address are assumed to contain zeros, regardless of what is specified by the program.

11. On most models, the unit directly addressed by the second-operand address is prefetched first. The order in which the remaining units of the cache line are prefetched is also model dependent.

12. When PREFETCH DATA RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

### ROTATE LEFT SINGLE LOGICAL

<table>
<thead>
<tr>
<th>RLL</th>
<th>R1, R2, D2(B2) [RSYa]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘EB’</td>
<td>R1</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

The 32-bit or 64-bit third operand is rotated left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R1 and R3 fields designate the same register, the third operand remains unchanged in general register R3. For ROTATE LEFT SINGLE LOGICAL (RLL), bits 0-31 of general registers R1 and R3 remain unchanged.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be rotated. The remainder of the address is ignored.

For RLL, the first and third operands are in bit positions 32-63 of general registers R1 and R3, respectively. For RLLG, the operands are in bit positions 0-63 of the registers.

All 32 or 64 bits of the third operand participate in a left shift. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand.

**Condition Code:** The code remains unchanged.

**Program Exceptions:** None.

### ROTATE THEN AND SELECTED BITS

<table>
<thead>
<tr>
<th>RNSBG</th>
<th>R1, R2, I3, I4, [I5] [RIE-f]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘EC’</td>
<td>R1</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

### ROTATE THEN EXCLUSIVE OR SELECTED BITS

<table>
<thead>
<tr>
<th>RXSBG</th>
<th>R1, R2, I3, I4, [I5] [RIE-f]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘EC’</td>
<td>R1</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>
The second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. Depending on the instruction, the selected bits of the rotated second operand are logically ANDed, exclusive ORed, or ORed with the corresponding bits of the first operand, and the results of the logical operation may replace the selected bits of the first operand. The result is indicated by the condition code.

The second operand remains unchanged in general register R2.

Bits 2-7 of the I3 field (bits 18-23 of the instruction) contain an unsigned binary integer specifying the starting bit position of the selected range of bits in the first operand and in the second operand after rotation. Bits 2-7 of the I4 field (bits 26-31 of the instruction) contain an unsigned binary integer specifying the ending bit position (inclusive) of the selected range of bits. When the ending bit position is less than the starting bit position, the range of bits wraps around from bit 63 to bit 0.

Bits 2-7 of the I5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I3 field (bit 16 of the instruction) contains the test-results control (T). When the T bit is zero, the results of the logical operation replace the selected bits of the first operand, and the remaining bits of the first operand are unchanged. When the T bit is one, the entire first operand is unchanged.

The condition code is set based on the results of the logical operation, regardless of the setting of the T bit. Only the selected range of bits is used to determine the condition code.

Bit 1 of the I3 field and bits 0-1 of the I4 field (bits 17 and 24-25 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I5 field (bits 32-33 of the instruction) are ignored.

**Resulting Condition Code:**

0  Result is zero
1  Result is not zero
2  --
3  --

**Program Exceptions:**

- Operation (if the general-instructions-extension facility is not installed)

**Programming Notes:**

1. Although the bits 2-7 of the I5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. The first operand is always used in its unrotated form. When the R1 and R2 fields designate the same register, the contents of the register are first rotated, and then the selected bits of the rotated value logically operate upon the corresponding bits of the unrotated register contents.

3. Examples of the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS, and ROTATE THEN OR SELECTED BITS are given in “Number Representation and Instruction-Use Examples” on page A-1.

4. In the assembler syntax, the I5 operand containing the rotate amount is considered to be optional. When the I5 field is not coded, a rotate amount of zero is implied.

5. The I3 field contains both the test-results control (in bit 0) and the starting bit position value (in bits 2-7). For example, to AND bits 40-43 of register 5 with the corresponding bits of register 7 (no rota-
The X'80' represents the test-results control which is added to the starting-bit position to form the $I_3$ field.

The high-level assembler (HLASM) provides alternative mnemonics for the test versions of these instructions, as shown below:

\[
\text{RNSBG} \quad R_5, R_7, X'80'+40, 43, 0
\]

The "T" suffix to the mnemonic indicates that the specified $I_3$ field is ORed with a value of X'80' when generating the object code. The T mnemonic suffix also applies to ROSBG and RXSBG.

The High-Level Assembler implements various high-word logical operations by providing extended-mnemonics for the RNSBG, ROSBG, and RXSBG instructions, as shown in Figure 7-305.

<table>

</tr>
</tbody>
</table>

Bits 2-7 of the $I_3$ field (bits 18-23 of the instruction) contain an unsigned binary integer specifying the starting bit position of the selected range of bits in the first operand and in the second operand after rotation. Bits 2-7 of the $I_4$ field (bits 26-31 of the instruction) contain an unsigned binary integer specifying the ending bit position (inclusive) of the selected range of bits. When the ending bit position is less than the starting bit position, the range of bits wraps around from bit 63 to bit 0.

Bits 2-7 of the $I_5$ field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the $I_4$ field (bit 24 of the instruction) contains the zero-remaining-bits control (Z). The Z bit controls how the remaining bits of the first operand are set (that is, those bits, if any, that are outside of the specified range). When the Z bit is zero, the remaining bits of the first operand are unchanged. When the Z bit is one, the remaining bits of the first operand are set to zeros.
The immediate fields just described are as follows:

<table>
<thead>
<tr>
<th>I3 Field</th>
<th>I4 Field</th>
<th>I5 Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>/</td>
<td>/</td>
</tr>
<tr>
<td>0 2 7</td>
<td>0 2 7</td>
<td>0 2 7</td>
</tr>
</tbody>
</table>

Bits 0-1 of the I3 field and bit 1 of the I4 field (bits 16-17 and 25 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I5 field (bits 32-33 of the instruction) are ignored.

For the purposes of setting the condition code for RISBG, the result in general register R1 is treated as being a 64-bit signed binary integer.

**Resulting Condition Code:**

For RISBG, the condition code is set as follows:

- 0: Result is zero
- 1: Result is less than zero
- 2: Result is greater than zero
- 3: --

For RISBGN, the condition code remains unchanged.

**Program Exceptions:**

- Operation (RISBG, if the general-instructions-extension facility is not installed; RISBGN, if the miscellaneous-instruction-extensions facility is not installed)

**Programming Notes:**

1. Although the bits 2-7 of the I3 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. When used with the zero-remaining-bits control, ROTATE THEN INSERT SELECTED BITS provides a means of effecting a shift operation.

3. When the R1 and R2 fields designate the same register and the Z bit is one, ROTATE THEN INSERT SELECTED BITS may be used to zero a selected range of bits in a register. Note, this technique cannot be used to zero all 64 bits of the register.

4. The first operand is always used in its unrotated form. When the R1 and R2 fields designate the same register, the contents of the register are first rotated, and then the selected bits of the rotated value are inserted into the corresponding bits of the unrotated register contents.

5. Examples of the use of ROTATE THEN INSERT SELECTED BITS are given in “Number Representation and Instruction-Use Examples” on page A-1.

6. In the assembler syntax, the I5 operand containing the rotate amount is considered to be optional. When the I5 field is not coded, a rotate amount of zero is implied.

7. The I4 field contains both the zero-remaining-bits control (in bit 0) and the ending bit position value (in bits 2-7). For example, to insert bits 40-43 of register 7 into the corresponding bits of register 5 (no rotation) and zero the remaining bits in register 5, the programmer might code:

```
RISBG R5,R7,40,X’80’+43,0
RISBGN R5,R7,40,X’80’+43,0
```

The ‘X’80’ represents the zero-remaining-bits control which is added to the ending-bit position to form the I4 field.

The high-level assembler (HLASM) provides an alternative mnemonic for the zero-remaining-bits versions of the instruction, as shown below:

```
RISBGZ R5,R7,40,43,0
RISBGNZ R5,R7,40,43,0
```

The “Z” suffix to the mnemonic indicates that the specified I4 field is ORed with a value of X’80’ when generating the object code.

**ROTATE THEN INSERT SELECTED BITS HIGH**

<table>
<thead>
<tr>
<th>RISBHGs</th>
<th>R1,R2,I3,I4[,I5][ RIE-f]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘EC’</td>
<td>R1</td>
</tr>
<tr>
<td>0 8 12 16 24 32 40 47</td>
<td></td>
</tr>
</tbody>
</table>
ROTATE THEN INSERT SELECTED BITS LOW

The 64-bit second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. The selected bits of the rotated second operand replace the contents of the corresponding bit positions of the first operand.

For ROTATE THEN INSERT SELECTED BITS HIGH, the first operand is in bits 0-31 of general register R1, and bits 32-63 of the register are unchanged. For ROTATE THEN INSERT SELECTED BITS LOW, the first operand is in bits 32-63 of general register R1, and bits 0-31 of the register are unchanged.

The second operand remains unchanged in general register R2.

For ROTATE THEN INSERT SELECTED BITS HIGH, bits 3-7 of the I3 and I4 fields (bits 19-23 and 27-31 of the instruction, respectively), with a binary zero appended on the left of each, form six-bit unsigned binary integers specifying the starting and ending bit positions (inclusive) of the selected range of bits in the first operand and in the second operand after rotation. When the ending bit position is less than the starting bit position, the range of selected bits wraps around from bit 31 to bit 0. Thus, the starting and ending bit positions of the selected range of bits are always between 0 and 31.

For ROTATE THEN INSERT SELECTED BITS LOW, bits 3-7 of the I3 and I4 fields, with a binary one appended on the left of each, form six-bit unsigned binary integers specifying the starting and ending bit positions (inclusive) of the selected range of bits in the first operand and in the second operand after rotation. When the ending bit position is less than the starting bit position, the range of selected bits wraps around from bit 63 to bit 32. Thus, the starting and ending bit positions of the selected range of bits are always between 32 and 63.

Bits 2-7 of the I5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I4 field (bit 24 of the instruction) contains the zero-remaining-bits control (Z). The Z bit controls how the remaining bits of the first operand are set (that is, those bits, if any, that are outside of the specified range). When the Z bit is zero, the remaining bits of the first operand are unchanged. When the Z bit is one, the remaining bits of the first operand are set to zeros.

The immediate fields just described are as follows:

```
<table>
<thead>
<tr>
<th>I3 Field</th>
<th>I4 Field</th>
<th>I5 Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ / / Starting Bit Position</td>
<td>Z / / Ending Bit Position</td>
<td>0 2 Rotate Amount</td>
</tr>
</tbody>
</table>
```

Bits 0-2 of the I3 field and bits 1-2 of the I4 field (bits 16-19 and 25-26 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I5 field (bits 32-33 of the instruction) are ignored.

Condition Code: The code remains unchanged

Program Exceptions:
- Operation (if the high-word facility is not installed)

Programming Notes:
1. Although the bits 2-7 of the I5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.
2. The first operand is always used in its unrotated form. When the R1 and R2 fields designate the same register, the value contained in the register is first rotated, and then the selected bits of the rotated value are inserted into the corresponding bits of the unrotated register contents.
3. In the assembler syntax, the I5 operand containing the rotate amount is considered to be optional. When the I5 field is not coded, a rotate amount of zero is implied.
4. The I4 field contains both the zero-remaining-bits control (in bit 0) and the ending bit position value (in bits 2-7). For example, to insert bits 40-43 of
register 7 into the corresponding bits of register 5 (no rotation) and zero the remaining bits in the right half of register 5, the programmer might code:

RISBLG R5,R7,40,X'80'+43,0

The X'80' represents the zero-remaining-bits control which is added to the ending-bit position to form the I4 field.

The High-Level Assembler (HLASM) provides alternative mnemonics for the zero-remaining-bits versions of RISBHG and RISBLG in the form of RISBHGZ and RISBLGZ, respectively. The "Z" suffix to the mnemonic indicates that the specified I4 field is ORed with a value of X'80' when generating the object code.

An equivalent to the example shown above using the Z-suffixed mnemonic is as follows:

RISBLGZ R5,R7,40,43,0

5. On some models, improved performance of RISBHG and RISBLG may be realized by setting the zero-remaining-bits control to one (or using the Z mnemonic suffix).

6. Unlike ROTATE THEN INSERT SELECTED BITS which sets the condition code, ROTATE THEN INSERT SELECTED BITS HIGH and ROTATE THEN INSERT SELECTED BITS LOW do not set the condition code.

7. The High-Level Assembler implements various high-word logical operations by providing extended-mnemonics for the RISBHG and RISBLG instructions, as shown in Figure 7-306.

</table>

Figure 7-306. Extended Mnemonics Formed Using RISBHG and RISBLG

The second operand is searched until a specified character is found, the end of the second operand is reached, or a CPU-determined number of bytes have been searched, whichever occurs first. The CPU-determined number is at least 256. The result is indicated in the condition code.

The location of the first byte of the second operand is designated by the contents of general register R1. The location of the first byte after the second operand is designated by the contents of general register R2.

The handling of the addresses in general registers R1 and R2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

In the access-register mode, the address space containing the second operand is specified only by means of access register R2. The contents of access register R1 are ignored.

The character for which the search occurs is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all
zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right and ends as soon as the specified character has been found in the second operand, the address of the next second-operand byte to be examined equals the address in general register R1, or a CPU-determined number of second-operand bytes have been examined, whichever occurs first. The CPU-determined number is at least 256. When the specified character is found, condition code 1 is set. When the address of the next second-operand byte to be examined equals the address in general register R1, condition code 2 is set. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set. When the CPU-determined number of second-operand bytes have been examined and the address of the next second-operand byte is in general register R1, it is unpredictable whether condition code 2 or 3 is set.

When condition code 1 is set, the address of the specified character found in the second operand is placed in general register R1, and the contents of general register R2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R2, and the contents of general registers R1 and R2 remain unchanged. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R1 and R2 registers always remain unchanged in the 24-bit or 31-bit mode.

When the address in general register R1 equals the address in general register R2, condition code 2 is set immediately, and access exceptions are not recognized. When the address in general register R1 is less than the address in general register R2, condition code 2 can be set only if the operand wraps around from the top of storage to location 0.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the second operand are recognized only for that portion of the operand that is necessarily examined.

The storage-operand-consistency rules are described in the section “Storage-Operand Consistency” on page 5-123.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Condition Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>--</td>
</tr>
<tr>
<td>1</td>
<td>Specified character found; general register R1 updated with address of character; general register R2 unchanged</td>
</tr>
<tr>
<td>2</td>
<td>Specified character not found in entire second operand; general registers R1 and R2 unchanged</td>
</tr>
<tr>
<td>3</td>
<td>CPU-determined number of bytes searched; general register R1 unchanged; general register R2 updated with address of next byte</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Access (fetch, operand 2)
- Specification
- Transaction constraint

**Programming Notes:**

1. Examples of the use of the SEARCH STRING instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the search. The program need not determine the number of bytes that were searched.

3. The R1 or R2 fields may designate general register 0, in which case general register 0 is treated as containing an address and also the specified character.

However, if the program branches back to the SEARCH STRING instruction following condition code 3, specifying R2 as register 0 is impractical. This is because bits 32-55 of the register will have been altered to a nonzero value, thus resulting in a specification exception on the subsequent execution. The search character in bit positions 56-63 of the register also may have been altered.

4. When it is desired to search a string of unknown length for its ending character, and assuming that the specified character in general register 0
need not be preserved, then the $R_1$ field can designate general register 0 in order to have SEARCH STRING use only two general registers instead of three. In this case, the rightmost portion of general register 0 containing the required zeros and the 8-bit search character is also used to form the address of the first byte after the second operand.

5. If the program branches back to the SEARCH STRING instruction when condition code 3 is set, and a subsequent execution results in condition code 1 or 2, general register $R_2$ will have changed from its initial value, even though the definition states that the register is unchanged when the character is found.

6. If the length of the string (as determined by the difference between the addresses in general registers $R_1$ and $R_2$) is 255 characters or less, condition code 3 will never be set, and branching on that condition is not necessary. However, if the length of the string is 256 or more characters, condition code 3 may be set – even if condition code 2 also applies.

**SEARCH STRING UNICODE**

<table>
<thead>
<tr>
<th>SRSTU</th>
<th>$R_1$, $R_2$</th>
<th>[RRE]</th>
</tr>
</thead>
</table>

The second operand is searched until a specified two-byte character is found, the end of the second operand is reached, or a CPU-determined number of two-byte characters have been searched, whichever occurs first. The CPU-determined number is at least 256 two-byte characters. The result is indicated in the condition code.

The location of the first two-byte character of the second operand is designated by the contents of general register $R_2$. When the contents of bit position 63 of general registers $R_1$ and $R_2$ are identical (that is, when both addresses are even or both addresses are odd), the location of the first two-byte character after the second operand is designated by the contents of general register $R_1$. When the contents of bit position 63 of general registers $R_1$ and $R_2$ differ (that is, when one address is even and the other is odd), the location of the first two-byte character after the second operand is one more than the contents of general register $R_1$.

The handling of the addresses in general registers $R_1$ and $R_2$ is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers $R_1$ and $R_2$ constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

In the access-register mode, the address space containing the second operand is specified only by means of access register $R_2$. The contents of access register $R_1$ are ignored.

The two-byte character for which the search occurs is specified in bit positions 48-63 of general register 0. Bit positions 32-47 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

Except for the case when the address in general register $R_1$ equals the address in general register $R_2$, the operation proceeds from left to right in steps of two bytes and ends as soon as the specified two-byte character has been found in the second operand, the address of the next second-operand two-byte character to be examined (excluding the first two-byte character) is equal to the address of the first two-byte character after the second operand (as designated by general register $R_1$), or a CPU-determined number of second-operand two-byte characters have been examined, whichever occurs first. The CPU-determined number is at least 256. When the specified two-byte character is found, condition code 1 is set. When the address of the next second-operand two-byte character to be examined (excluding the first two-byte character) is equal to the address of the first two-byte character after the second operand, condition code 2 is set. When a CPU-determined number of second-operand two-byte characters have been examined, condition code 3 is set, except that condition code 2 is set if the conditions for setting it also apply.

When condition code 1 is set, the address of the specified two-byte character found in the second operand is placed in general register $R_1$, and the contents of general register $R_2$ remain unchanged. When condition code 3 is set, the address of the next two-byte character to be processed in the second operand is placed in general register $R_2$, and the contents
of general register R1 remain unchanged. When condition code 2 is set, the contents of general registers R1 and R2 remain unchanged. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R1 and R2 registers always remain unchanged in the 24-bit or 31-bit mode.

When the address in general register R1 equals the address in general register R2, condition code 2 is set immediately, and access exceptions are not recognized. When the address in general register R1 is less than the address in general register R2, condition code 2 can be set only if the operand wraps around from the top of storage to location 0.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the second operand are recognized only for that portion of the operand that is necessarily examined.

The storage-operand-consistency rules are described in the section “Storage-Operand Consistency” on page 5-123.

**Resulting Condition Code:**

0  --
1  Specified two-byte character found; general register R1 updated with address of character; general register R2 unchanged
2  Specified two-byte character not found in entire second operand; general registers R1 and R2 unchanged
3  CPU-determined number of two-byte characters searched; general register R1 unchanged; general register R2 updated with address of next two-byte character

**Program Exceptions:**

- Access (fetch, operand 2)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the search. The program need not determine the number of two-byte characters that were searched.
2. The R1 or R2 fields may designate general register 0, in which case general register 0 is treated as containing an address and also the specified character.

However, if the program branches back to the SEARCH STRING UNICODE instruction following condition code 3, specifying R2 as register 0 is impractical. This is because bits 32-47 of the register may have been altered to a nonzero value, thus resulting in a specification exception on the subsequent execution. The search character in bit positions 48-63 of the register also may have been altered.

3. When it is desired to search a string of unknown length for its ending two-byte character, and assuming that the specified two-byte character in general register 0 need not be preserved, then the R1 field can designate general register 0 in order to have SEARCH STRING UNICODE use only two general registers instead of three. In this case, the rightmost portion of general register 0 containing the required zeros and the 16-bit search character is also used to form the address of the first byte after the second operand.

4. If the program branches back to the SEARCH STRING UNICODE instruction when condition code 3 is set, and a subsequent execution results in condition code 1 or 2, general register R2 will have changed from its initial value, even though the definition states that the register is unchanged when the two-byte character is found.

5. If the length of the string (as determined by the difference between the addresses in general registers R1 and R2) is 256 two-byte characters or less, condition code 3 will never be set, and branching on that condition is not necessary. However, if the length of the string is 257 or more two-byte characters, condition code 3 may be set.
SET ACCESS

SAR R1, R2 [RRE]

The contents of bit positions 32-63 of general register R2 are placed in access register R1.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Transaction constraint

SET ADDRESSING MODE

SAM24 [E]

0 15

0 15

SAM31 [E]

0 15

0 15

SAM64 [E]

0 15

The addressing mode is set by setting the extended-addressing-mode bit, bit 31 of the current PSW, and the basic-addressing-mode bit, bit 32 of the current PSW, as follows:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>PSW Bit 31</th>
<th>PSW Bit 32</th>
<th>Resulting Addressing Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAM24</td>
<td>0</td>
<td>0</td>
<td>24-bit</td>
</tr>
<tr>
<td>SAM31</td>
<td>0</td>
<td>1</td>
<td>31-bit</td>
</tr>
<tr>
<td>SAM64</td>
<td>1</td>
<td>1</td>
<td>64-bit</td>
</tr>
</tbody>
</table>

The instruction address in the PSW is updated under the control of the new addressing mode, as follows. The value 2 (the instruction length) is added to the contents of bit positions 64-127 of the PSW, or the value 4 is added if the instruction is the target of EXECUTE, or the value 6 is added if the instruction is the target of EXECUTE RELATIVE LONG. In any case, a carry out of bit position 0 is ignored. Then bits 64-103 of the PSW are set to zeros if the new addressing mode is the 24-bit mode, or bits 64-96 are set to zeros if the new addressing mode is the 31-bit mode.

The instruction is completed only if the new addressing mode and the unupdated instruction address in the PSW are a valid combination. When the new addressing mode is to be the 24-bit mode, bits 64-103 of the unupdated PSW must be all zeros, or, when the new addressing mode is to be the 31-bit mode, bits 64-96 of the unupdated PSW must be all zeros; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Specification (SAM24 and SAM31 only)
- Trace
- Transaction constraint

**Programming Note:** Checking the unupdated instruction address prevents completion in two major cases: the instruction is located at address $2^{24}$ or above and the new addressing mode is to be the 24-bit mode, or the instruction is located at address $2^{31}$ or above and the new addressing mode is to be the 24-bit or 31-bit mode. In these cases, if the instruction were completed, the updating of the instruction address under the control of the new addressing mode would cause one or more leftmost bits of the address to be set to zeros, which would cause the next instruction to be fetched from other than the next sequential location. This action is sometimes called a "wild branch." A wild branch still can occur if the instruction is located at $2^{24} - 2$ or $2^{31} - 2$, or at $2^{24} - 4$ or $2^{31} - 4$ if EXECUTE or EXECUTE RELATIVE LONG is used, or at $2^{24} - 6$ or $2^{31} - 6$ if EXECUTE RELATIVE LONG is used.

SET PROGRAM MASK

SPM R1 [RR]

The first operand is used to set the condition code and the program mask of the current PSW.

Bits 34 and 35 of general register R1 replace the condition code, and bits 36-39 replace the program
SHIFT LEFT DOUBLE

SLDA R1,D2(B2)

The 63-bit numeric part of the signed first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R1 followed on the right by bits 32-63 of general register R1 + 1.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

The first operand is treated as a 64-bit signed binary integer. The sign bit of the first operand, bit 32 of the even-numbered register, remains unchanged. Bit position 32 of the odd-numbered register contains a numeric bit, which participates in the shift in the same manner as the other numeric bits. Zeros are supplied to the vacated bit positions on the right. Bits 0-31 of general registers R1 and R1 + 1 remain unchanged.

If one or more bits unlike the sign bit are shifted out of bit position 33 of the even-numbered register, an overflow occurs, and condition code 3 is set. If the fixed-point-overflow mask bit is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0  Result zero; no overflow
1  Result less than zero; no overflow
2  Result greater than zero; no overflow
3  Overflow

Program Exceptions:
- Fixed-point overflow
- Specification

Programming Notes:
1. An example of the use of the SHIFT LEFT DOUBLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The eight shift instructions that are in both ESA/390 and z/Architecture provide the following three pairs of alternatives for 32 bits in one general register or, for double, in each of two general registers: left or right, single or double, and signed or logical. The four additional shift instructions in z/Architecture provide left or right, signed or logical shifts of 64 bits in one general register. The signed shifts differ from the logical shifts in that, in the signed shifts, overflow is recognized, the condition code is set, and the leftmost bit participates as a sign.
3. A zero shift amount in the two signed double-shift operations provides a double-length sign and magnitude test.
4. The base register participating in the generation of the second-operand address permits indirect specification of the shift amount by means of placement of the shift amount in the base regis-
A zero in the $B_2$ field indicates the absence of indirect shift specification.

**SHIFT LEFT DOUBLE LOGICAL**

<table>

<td></td>
</tr>
</tbody>
</table>

The 64-bit first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register $R_1$ followed on the right by bits 32-63 of general register $R_1 + 1$.

The $R_1$ field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

All 64 bits of the first operand participate in the shift. Bits shifted out of bit position 32 of the even-numbered register are not inspected and are lost. Zeros are supplied to the vacated bit positions on the right. Bits 0-31 of general registers $R_1$ and $R_1 + 1$ remain unchanged.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Specification

**SHIFT LEFT SINGLE**

<table>
<thead>
<tr>
<th>SLA</th>
<th>$R_1, D_2(B_2)$</th>
<th>[RS-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'8B'</td>
<td>$R_1$ $B_2$ $D_2$</td>
<td></td>
</tr>
</tbody>
</table>

SLA, the 31-bit numeric part of the signed first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register $R_1$ remain unchanged.

For SLA, the first operand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register $R_1$. The sign of the first operand remains unchanged. All 31 numeric bits of the operand participate in the left shift.

For SLAK, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers $R_1$ and $R_3$, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the left shift.

For SLAG, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers $R_1$ and $R_3$, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the left shift.
For SLA, SLAG, or SLAK, zeros are supplied to the vacated bit positions on the right.

If one or more bits unlike the sign bit are shifted out of bit position 33, for SLA or SLAK, or 1, for SLAG, an overflow occurs, and condition code 3 is set. If the fixed-point-overflow mask bit is one, a program interruption for fixed-point overflow occurs.

**Resulting Condition Code:**

0 Result zero; no overflow  
1 Result less than zero; no overflow  
2 Result greater than zero; no overflow  
3 Overflow

**Program Exceptions:**

- Fixed-point overflow  
- Operation (SLAK, if the distinct-operands facility is not installed)

**Programming Notes:**

1. An example of the use of the SHIF T LEFT SINGLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For SHIF T LEFT SINGLE (SLA and SLAK), for numbers with a value greater than or equal to -2^30 and less than 2^30, a left shift of one bit position is equivalent to multiplying the number by 2. For SHIF T LEFT SINGLE (SLAG), the comparable values are -2^62 and 2^62.

3. For SHIF T LEFT SINGLE (SLA and SLAK), shift amounts from 31 to 63 cause the entire numeric part to be shifted out of the register, leaving a result of the maximum negative number or zero, depending on whether or not the initial contents were negative. For SHIF T LEFT SINGLE (SLAG), a shift amount of 63 causes the same effect.

**SHIFT LEFT SINGLE LOGICAL**

<table>
<thead>
<tr>
<th>SLL</th>
<th>R_i, D_j (B_j)</th>

<td>DL_j DH_j '0D'</td>
</tr>
</tbody>
</table>

For SLL, the 32-bit first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_i remain unchanged.

For SLLK, the 32-bit third operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_i remain unchanged. Except for when the R_i and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SLLG, the 64-bit third operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_i and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SLL, the first operand is in bit positions 32-63 of general register R_i. All 32 bits of the operand participate in the left shift.

For SLLK, the first and third operands are in bit positions 32-63 of general registers R_i and R_3, respectively. All 32 bits of the third operand participate in the left shift.

For SLLG, the first and third operands are in bit positions 0-63 of general registers R_i and R_3, respectively. All 64 bits of the third operand participate in the left shift.

For SLL, SLLG, or SLLK, zeros are supplied to the vacated bit positions on the right.

**Condition Code:** The code remains unchanged.
Program Exceptions:

- Operation (SLLK, if the distinct-operands facility is not installed)

Programming Note: The rightmost six bits of the second-operand address are treated as a 6-bit unsigned binary integer specifying the number of bit positions to be shifted to the left. Thus, the number of bit positions to be shifted is the value of the second-operand address, modulo 64.

When the number of bit positions to be shifted is between 32 and 63, SLL and SLLK can be used to zero the rightmost 32 bits of the result in general register R1. However, because of the modulo 64 behavior, it is not true that any second-operand-address value greater than 32 produces a result of zero.

Because the number of shifted bit positions is limited to 63, SLLG cannot be used to zero all 64 bits of the result.

SHIFT RIGHT DOUBLE

0 8 12 16 20 31

The 64-bit first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R1 followed on the right by bits 32-63 of general register R1 + 1.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

All 64 bits of the first operand participate in the shift. Bits shifted out of bit position 63 of the odd-numbered register are not inspected and are lost. Zeros are supplied to the vacated bit positions on the left. Bits 0-31 of general registers R1 and R1 + 1 remain unchanged.

Condition Code: The code remains unchanged.

Program Exceptions:

- Specification
SHIFT RIGHT SINGLE

For SRA, the first and third operands are treated as 32-bit signed binary integers in bit positions 32-63 of general registers R1 and R3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 31 numeric bits of the third operand participate in the right shift.

For SRAK, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers R1 and R3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the right shift.

For SRAG, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers R1 and R3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the right shift.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SRA, the first operand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R1. The sign of the first operand remains unchanged. All 31 numeric bits of the operand participate in the right shift.

Resulting Condition Code:

0  Result zero
1  Result less than zero
2  Result greater than zero
3  --

Program Exceptions:

- Operation (SRAK, if the distinct-operands facility is not installed)

Programming Notes:

1. A right shift of one bit position is equivalent to division by 2 with rounding downward. When an even number is shifted right one position, the result is equivalent to dividing the number by 2. When an odd number is shifted right one position, the result is equivalent to dividing the next lower number by 2. For example, +5 shifted right by one bit position yields +2, whereas -5 yields -3.

2. For SRA and SRAK, shift amounts from 31 to 63 cause the entire numeric part to be shifted out of the register, leaving a result of -1 or zero, depending on whether or not the initial contents were negative. For SHIFT RIGHT SINGLE (SRAG), a shift amount of 63 causes the same effect.
SHIFT RIGHT SINGLE LOGICAL

For SRL, the 32-bit first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R1 remain unchanged.

For SRLK, the 32-bit third operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R1 remain unchanged. Except for when the R1 and R3 fields designate the same register, the third operand remains unchanged in general register R3.

For SRLG, the 64-bit third operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R1 and R3 fields designate the same register, the third operand remains unchanged in general register R3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted to the right. Thus, the number of bit positions to be shifted is the value of the second-operand address, modulo 64.

When the number of bit positions to be shifted is between 32 and 63, SRL and SRLK can be used to zero the rightmost 32 bits of the result in general register R1. However, because of the modulo 64 behavior, it is not true that any second-operand-address value greater than 32 produces a result of zero.

Because the number of shifted bit positions is limited to 63, SRLG cannot be used to zero all 64 bits of the result.

STOR E

STORE

ST R1,D2(X2,B2) [RX-a]

STY R1,D2(X2,B2) [RXY-a]

STG R1,D2(X2,B2) [RXY-a]
STORE RELATIVE LONG

STRL  R1,RI2  [RIL-b]

The first operand is placed unchanged at the second-operand location.

For STORE (ST, STY) and STORE RELATIVE LONG (STRL), the operands are 32 bits, and, for STORE (STG) and STORE RELATIVE LONG (STGRL), the operands are 64 bits.

The displacement for ST is treated as a 12-bit unsigned binary integer. The displacement for STY and STG is treated as a 20-bit signed binary integer.

For STORE RELATIVE LONG, the contents of the RI2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For STORE RELATIVE LONG (STRL), the second operand must be aligned on a word boundary, and for STORE RELATIVE LONG (STGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code:  The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STY, if the long-displacement facility is not installed; STRL and STGRL, if the general-instructions-extension facility is not installed)
- Specification (STRL, STGRL only)

Programming Notes:

1. For STORE RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.
2. When STORE RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.
3. Significant delay may be incurred if the program stores into the same cache line as that containing the storing instruction or into the cache line from which a subsequent instruction may be fetched. The EXTRACT CPU ATTRIBUTE instruction may be used to determine the cache-line size.

STORE ACCESS MULTIPLE

STAM  R1,R3,D2(B2) [RS-a]
           '9B'  R1  R3  B2  D2
    0  8  12  16  20  31

STAMY  R1,R3,D2(B2) [RSY-a]
          'EB'  R1  R3  B2  DL2  DH2  '9B'
   0  8  12  16  20  22  32  40  47

The contents of the set of access registers starting with access register R1 and ending with access register R3 are stored at the locations designated by the second-operand address.

The storage area where the contents of the access registers are placed starts at the location designated by the second-operand address and continues through as many storage words as the number of access registers specified. The contents of the access registers are stored in ascending order of their register numbers, starting with access register R1, and continuing up to and including access register R3, with access register 0 following access register 15. The contents of the access registers remain unchanged.

The displacement for STAM is treated as a 12-bit unsigned binary integer. The displacement for STAMY is treated as a 20-bit signed binary integer.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.
**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Operation (STAMY, if the long-displacement facility is not installed)
- Specification

**STORE CHARACTER**

<table>
<thead>
<tr>
<th>STC</th>
<th>R₁,D₉(X₂,B₂)</th>
<th>[RX-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'42' R₁ X₂ B₂ D₂</td>
<td></td>

</tbody>
</table>

<table>
<thead>
<tr>
<th>STCY</th>
<th>R₁,D₉(X₂,B₂)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E3' R₁ X₂ B₂ DL₂ DH₂ '72'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 56-63 of general register R₁ are placed unchanged at the second-operand location. The second operand is one byte in length.

The displacement for STC is treated as a 12-bit unsigned binary integer. The displacement for STCY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Operation (STCY, if the long-displacement facility is not installed)

**STORE CHARACTER HIGH**

<table>
<thead>
<tr>
<th>STCH</th>
<th>R₁,D₉(X₂,B₂)</th>
<th>[RXY-a]</th>

<tbody>
<tr>
<td>'E3' R₁ X₂ B₂ DL₂ DH₂ 'C3'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 24-31 of general register R₁ are placed unchanged at the second-operand location. The second operand is one byte in length.

The displacement is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**STOR CHARACTER UNDER MASK**

**STORE CHARACTERS UNDER MASK**

<table>
<thead>
<tr>
<th>STCM</th>
<th>R₁,M₃,D₉(B₂)</th>
<th>[RS-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'BE' R₁ M₃ B₂ D₂</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>STCMY</th>
<th>R₁,M₃,D₉(B₂)</th>
<th>[RSY-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB' R₁ M₃ B₂ DL₂ DH₂ '2D'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>STCMH</th>
<th>R₁,M₃,D₉(B₂)</th>
<th>[RSY-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB' R₁ M₃ B₂ DL₂ DH₂ '2C'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bytes selected from general register R₁ under control of a mask are placed at contiguous byte locations beginning at the second-operand address.

The contents of the M₃ field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R₁. For STORE CHARACTERS UNDER MASK (STCM, STCMY), the four bytes to which the mask bits correspond are in bit positions 32-63 of general register R₁. For STORE CHARACTERS UNDER MASK (STCMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The bytes corresponding to ones in the mask are placed in the same order at successive and contiguous storage locations beginning at the second-operand address. When the mask is not zero, the length of the second operand is equal to the number of ones in the mask. The contents of the general register remain unchanged.

When the mask is not zero, exceptions associated with storage-operand accesses are recognized only for the number of bytes specified by the mask.

When the mask is zero, the single byte designated by the second-operand address remains unchanged. However, on some models, an access exception may be recognized for the location. If accessible, (a) a PER zero-address-detection event may be recognized for the location, and (b) the contents may be
fetched and subsequently stored back unchanged at the same storage location; this update appears to be an interlocked-update reference as observed by other CPUs.

The displacement for STCM is treated as a 12-bit unsigned binary integer. The displacement for STCMY and STCMH is treated as a 20-bit signed binary integer.

When STORE CHARACTERS UNDER MASK (STCMH) is attempted in a nonconstrained transaction, the M₃ field is 0, and the code in the R₁ field is 6 or 7, the transaction may be aborted due to abort code 16. When STORE CHARACTER UNDER MASK (STCMH) is attempted in a constrained transaction, the M₃ field is 0, and the code in the R₁ field is 6 or 7, a transaction-constraint program interruption is recognized, and the transaction is aborted with abort code 4.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STCMY, if the long-displacement facility is not installed)
- Transaction constraint (STCMH)

Programming Notes:

1. An example of the use of the STORE CHARACTERS UNDER MASK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. STORE CHARACTERS UNDER MASK (STCM, STCMY), with a mask of 0111 binary may be used to store a three-byte address, for example, in modifying the address in a format-0 CCW.

3. STORE CHARACTERS UNDER MASK (STCM, STCMY) with a mask of 1111, 0011, or 0001 binary performs the same function as STORE (ST), STORE HALFWORD, or STORE CHARACTER, respectively.

4. Using STORE CHARACTERS UNDER MASK with a zero mask may cause any of the following to occur for the byte designated by the second-operand address: a PER storage-alteration event may be recognized; access exceptions may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

5. On certain models, STORE CHARACTERS UNDER MASK with mask field that specifies discontiguous bytes may perform slower than when the mask specifies contiguous bytes.

### STORE CLOCK

<table>
<thead>
<tr>
<th>D₂(B₂)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘B205’</td>
<td>B₂</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
</tr>
<tr>
<td>20</td>
<td>31</td>
</tr>
</tbody>
</table>

### STORE CLOCK FAST

<table>
<thead>
<tr>
<th>D₂(B₂)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘B27C’</td>
<td>B₂</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
</tr>
<tr>
<td>20</td>
<td>31</td>
</tr>
</tbody>
</table>

The current value of bits 0-63 of the TOD clock is stored in the eight-byte field designated by the second-operand address, provided the clock is in the set, stopped, or not-set state.

When the clock is stopped, zeros are stored in positions to the right of the rightmost bit position that is incremented when the clock is running. For STORE CLOCK, when the value of a running clock is stored, nonzero values may be stored in positions to the right of the rightmost incremented bit; this is to ensure that a unique value is stored. For STORE CLOCK FAST, when the value of a running clock is stored, bits to the right of the rightmost bit that is incremented are stored as zeros.

Zeros are stored at the operand location when the clock is in the error state or the not-operational state.

The quality of the clock value stored by the instruction is indicated by the resultant condition-code setting.

For STORE CLOCK, a serialization function is performed before the value of the clock is fetched and again after the value is placed in storage.
Resulting Condition Code:

0 Clock in set state
1 Clock in not-set state
2 Clock in error state
3 Clock in stopped state or not-operational state

Program Exceptions:

- Access (store, operand 2)
- Operation (STCKF, if the store-clock-fast facility is not installed)
- Transaction constraint

Programming Notes:

1. Bit position 31 of the clock is incremented every 1.048576 seconds; hence, for timing applications involving human responses, the leftmost clock word may provide sufficient resolution.

2. Condition code 0 normally indicates that the clock has been set by the control program. Accordingly, the value may be used in elapsed-time measurements and as a valid time-of-day and calendar indication. Condition code 1 indicates that the clock value is the elapsed time since the power for the clock was turned on. In this case, the value may be used in elapsed-time measurements but is not a valid time-of-day indication. Condition codes 2 and 3 mean that the value provided by STORE CLOCK cannot be used for time measurement or indication.

3. Condition code 3 indicates that the clock is in either the stopped state or the not-operational state. These two states can normally be distinguished because an all-zero value is stored when the clock is in the not-operational state.

4. If a problem program written for z/Architecture is to be executed also on a system in the System/370 mode, then the program should take into account that, in the System/370 mode, the value stored when the condition code is 2 is not necessarily zero.

5. Two executions of STORE CLOCK FAST, or an execution of STORE CLOCK FAST and STORE CLOCK, either on the same or different CPUs, do not necessarily return different values of the clock if the clock is running. Similarly, an execution of STORE CLOCK FAST and STORE CLOCK EXTENDED, either on the same or different CPUs, do not necessarily return different values of TOD clock bits 0-63 if the clock is running.

6. When the TOD-clock-steering facility is installed, and assuming a valid operating system, then, for the problem program, the TOD clock is always in the set state and there is no need to test the condition code after issuing STORE CLOCK or STORE CLOCK FAST.

STORE CLOCK EXTENDED

\[
\text{STCKE} \quad D_i(B_2) \quad [S]
\]

<table>
<thead>
<tr>
<th>B278</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>

The current value of bits 0-103 of the TOD clock is stored in byte positions 1-13 of the sixteen-byte field designated by the second-operand address, provided the clock is in the set, stopped, or not-set state. Zeros are stored in byte position 0. The TOD programmable field, bits 16-31 of the TOD programmable register, is stored in byte positions 14 and 15.

The operand just described has the following format:

<table>
<thead>
<tr>
<th>Zeros</th>
<th>TOD Clock</th>
<th>Programmable Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>112</td>
</tr>
<tr>
<td></td>
<td>120</td>
<td>127</td>
</tr>
</tbody>
</table>

When the clock is stopped, zeros are stored in the clock value in positions to the right of the rightmost bit position that is incremented when the clock is running. The programmable field still is stored.

When the value of a running clock is stored, the value in bit positions 64-103 of the clock (bit positions 72-111 of the storage operand) is always nonzero; this ensures that values stored by STORE CLOCK EXTENDED are unique when compared with values stored by STORE CLOCK and extended with zeros.

Zeros are stored at the operand location when the clock is in the error state or the not-operational state.
The quality of the clock value stored by the instruction is indicated by the resultant condition-code setting.

A serialization function is performed before the value of the clock is fetched and again after the value is placed in storage.

**Resulting Condition Code:**

0  Clock in set state
1  Clock in not-set state
2  Clock in error state
3  Clock in stopped state or not-operational state

**Program Exceptions:**

- Access (store, operand 2)
- Transaction constraint

1. Condition code 0 normally indicates that the clock has been set by the control program. Accordingly, the value may be used in elapsed-time measurements and as a valid time-of-day and calendar indication. Condition code 1 indicates that the clock value is the elapsed time since the power for the clock was turned on. In this case, the value may be used in elapsed-time measurements but is not a valid time-of-day indication. Condition codes 2 and 3 mean that the value provided by STORE CLOCK EXTENDED cannot be used for time measurement or indication.

2. When the TOD-clock-steering facility is installed, and assuming a valid operating system, then, for the problem program, the TOD clock is always in the set state and there is no need to test the condition code after issuing STORE CLOCK EXTENDED.

3. Programming notes beginning on page 4-45 show hex values related to the value of the TOD clock as it is stored by the STORE CLOCK instruction. Notes 4-6, below, are repetitions of those notes except with the text and hex values adjusted so they apply to bits 0-71 of the value stored by STORE CLOCK EXTENDED.

4. The following chart shows the time interval between instants at which various bits of the TOD-clock value stored by STORE CLOCK EXTENDED are stepped. This time value may also be considered as the weighted time value that the bit, when one, represents. The bit numbers are those of the STORE CLOCK EXTENDED operand.

<table>

The stepping value of TOD-clock bit position 63, if implemented, is $2^{-12}$ microseconds, or approximately 244 picoseconds. This value is called a clock unit.

The following chart shows various time intervals in clock units expressed in hexadecimal notation. The chart shows the values stored in bit positions 0-71 of the STORE CLOCK EXTENDED operand. Bit 71 of the operand represents a clock unit.

<table>

</tr>
</tbody>
</table>

* Number of days in four years, including a leap year. Note that the year 1900 was not a leap year. Thus, the four-year span starting in 1900 has only 1,460 days.

For the leftmost doublewords in which facility bits are assigned, the reserved bits are stored as zeros. Doublewords to the right of the doubleword in which the highest-numbered facility bit is assigned for a model may or may not be stored. Access exceptions and PER events are not recognized for doublewords that are not stored.

The size of the second operand, in doublewords, is one more than the value specified in bits 56-63 of general register 0. The remaining bits of general register 0 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

When the size of the second operand is large enough to contain all of the facility bits assigned for a model, then the complete facility list is stored in the second operand location, bits 56-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the facility bits assigned for the model, and condition code 0 is set.

When the size of the second operand is not large enough to contain all of the facility bits assigned for a model, then only the number of doublewords specified by the second-operand size are stored, bits 56-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the facility bits assigned for the model, and condition code 3 is set.

Figure 4-24, “Assigned Facility Bits” on page 4-76 shows the meanings of the assigned facility bits.

### Special Conditions

The second operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Complete facility list stored
- 1 --
- 2 --
- 3 Incomplete facility list stored

### Program Exceptions:

- Access (store, second operand)
- Operation (if the store-facility-list-extended facility is not installed)
- Specification
• Transaction constraint

Programming Notes:

1. The performance of STORE FACILITY LIST EXTENDED may be significantly slower than that of simply testing a byte in storage. Programs that need to frequently test for the presence of a facility — for example, dual-path code in which the facility is used in one path but not another — should execute the STORE FACILITY LIST EXTENDED instruction once during initialization. Subsequently, the program may test for the presence of the facility by examining the stored result, using an instruction such as TEST UNDER MASK.

2. When condition code 0 is set, bits 56-63 of general register 0 are updated to contain a value that is one less than the number of doublewords stored. If the program chooses to ignore the results in general register 0, then it should ensure that the entire second operand in storage is set to zero prior to executing STORE FACILITY LIST EXTENDED.

STORE HALFWORD

STH $R_1, D_2(X_2, B_2)$ [RX-a]

For STORE HALFWORD RELATIVE LONG, the contents of the $R_{I_2}$ field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

Access (store, operand 2)

Operation (STHY if the long-displacement facility is not installed; STHRL, if the general-instructions-extension facility is not installed.)

Programming Notes:

1. For STORE HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand's size.

2. When STORE HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

3. Significant delay may be incurred if the program stores into the same cache line as that containing the storing instruction. The EXTRACT CPU ATTRIBUTE instruction may be used to determine the cache-line size.

STORE HALFWORD HIGH

STHH $R_1, D_2(X_2, B_2)$

Bits 48-63 of general register $R_1$ are placed unchanged at the second-operand location. The second operand is two bytes in length.

The displacement for STH is treated as a 12-bit unsigned binary integer. The displacement for STHY is treated as a 20-bit signed binary integer.

STORE HALFWORD RELATIVE LONG

STHRL $R_1, R_{I_2}$ [RIL-b]

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.
Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE HIGH

```
STFH R1,D2(X2,B2) [RXY-a]

'E3' R1 X2 B2 DL2 DH2 'CB'
0 8 12 16 20 32 40 47
```

The first operand is placed unchanged at the second-operand location. The first operand is in bits 0-31 of general register R1, and the second operand is 32 bits in storage.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE MULTIPLE

```
STM R1,R3,D2(B2) [RS-a]

'90' R1 R3 B2 D2
0 8 12 16 20 31
```

```
STMY R1,R3,D2(B2) [RSY-a]

'EB' R1 R3 B2 DL2 DH2 '90'
0 8 12 16 20 32 40 47
```

```
STMG R1,R3,D2(B2) [RSY-a]

'EB' R1 R3 B2 DL2 DH2 '24'
0 8 12 16 20 32 40 47
```

The contents of bit positions of the set of general registers starting with general register R1 and ending with general register R3 are placed in the storage area beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For STORE MULTIPLE (STM, STMY), the contents of bit positions 32-63 of the general registers are stored in successive four-byte fields beginning at the second-operand address. For STORE MULTIPLE (STMG), the contents of bit positions 0-63 of the general registers are stored in successive eight-byte fields beginning at the second-operand address.

The general registers are stored in the ascending order of their register numbers, starting with general register R1, and continuing up to and including general register R3, with general register 0 following general register 15.

The displacement for STM is treated as a 12-bit unsigned binary integer. The displacement for STMY and STMG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STMY, if the long-displacement facility is not installed)

Programming Note: An example of the use of the STORE MULTIPLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

STORE MULTIPLE HIGH

```
STMH R1,R3,D2(B2) [RSY-a]

'EB' R1 R3 B2 DL2 DH2 '26'
0 8 12 16 20 32 40 47
```

The contents of the high-order halves, bit positions 0-31, of the set of general registers starting with general register R1 and ending with general register R3 are placed in the storage area beginning at the location designated by the second-operand address and continuing through as many locations as needed, that is, the contents of bit positions 0-31 are stored in successive four-byte fields beginning at the second-operand address. Bits 32-63 of the registers are ignored.

The general registers are stored in the ascending order of their register numbers, starting with general register R1, and continuing up to and including general register R15, with general register 0 following general register 15.
**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)

**Programming Note:** All combinations of register numbers specified by \( R_1 \) and \( R_3 \) are valid. When the register numbers are equal, only four bytes are transmitted. When the number specified by \( R_3 \) is less than the number specified by \( R_1 \), the register numbers wrap around from 15 to 0.

---

**STORE ON CONDITION**

\[
\text{STOC} \quad R_1, D_2(B_2), M_3 \quad [\text{RSY-b}]
\]

The first operand is placed unchanged at the second-operand location if the condition code has one of the values specified by \( M_3 \); otherwise, the second operand remains unchanged.

For STOC and STOCFH, the first and second operands are 32 bits, and for STOCG, the first and second operands are 64 bits. For STOC, the first operand is in bits 32-63 of general register \( R_1 \), and bits 0-31 of the register are ignored. For STOCFH, the first operand is in bits 0-31 of general register \( R_1 \), and bits 32-63 of the register are ignored.

The M₃ field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

<table>
<thead>
<tr>
<th>Condition Code</th>
<th>Mask Position Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the store is performed. If the mask bit selected is zero, the store is not performed.

The displacement is treated as a 20-bit signed binary integer.

When the condition specified by the M₃ field is not met (that is, store operation is not performed), it is model dependent whether any or all of the following occur for the second operand: (a) an access exception is recognized, (b) the change bit is set, or (c) a PER storage-alteration or zero-address-detection event is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)
- Operation (if the load/store-on-condition facility 1 is not installed; STOCFH, if the load/store-on-condition facility 2 is not installed)

**Programming Notes:**

1. When the M₃ field contain all zeros and no exception condition exists, the instruction acts as a NOP. When the M₃ field contains all ones and no exception condition exists, the store operation is always performed. However, these are not the preferred means of implementing a NOP or unconditional store, respectively.

2. When the condition specified by the M₃ field is not met, it is model dependent whether the second operand is brought into the cache.

3. STORE ON CONDITION provides a function similar to that of a separate BRANCH ON CONDITION instruction followed by a STORE instruc-
tion, except that STORE ON CONDITION does not provide an index register. For example, assuming the storage location is accessible, the following two instruction sequences are equivalent.

<table>
<thead>
<tr>
<th>STORE REVERSED</th>
<th>BC</th>
<th>SKIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>STOCG 15,256(7,8)</td>
<td>STG 15,256(0,7)</td>
<td>SKIP DS 0H</td>
</tr>
</tbody>
</table>

On models that implement predictive branching, the combination of the BRANCH ON CONDITION and STORE instructions may perform somewhat better than the STORE ON CONDITION instruction when the CPU is able to successfully predict the branch condition. However, on models where the CPU is not able to successfully predict the branch condition, such as when the condition is more random, the STORE ON CONDITION instruction may provide significant performance improvement.

4. See programming note 4 on page 7-240 for details on extended mnemonics for the instructions of the load/store-on-condition facilities.

**STORE PAIR TO QUADWORD**

<table>
<thead>
<tr>
<th>STORE PAIR TO QUADWORD</th>
<th>STPQ R1,D2(X2,B2)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘E3’</td>
<td>R1</td>
<td>X2</td>
</tr>
</tbody>
</table>

The quadword first operand is stored at the second-operand location. The store at the second-operand location appears to be quadword concurrent as observed by other CPUs. The left doubleword of the first operand is in general register R1, and the right doubleword is in general register R1 + 1.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register. The second operand must be designated on a quadword boundary. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)
- Specification
- Transaction constraint

**Programming Notes:**

1. The STORE MULTIPLE (STM or STMG) instruction does not necessarily provide quadword-concurrent access.

2. The performance of STORE PAIR TO QUADWORD on some models may be significantly slower than that of STORE MULTIPLE (STMG). Unless quadword consistency is required, STMG should be used instead of STPQ.

**STORE REVERSED**

<table>
<thead>
<tr>
<th>STORE REVERSED</th>
<th>STRVH R1,D2(X2,B2)</th>
<th>STG R1,D2(X2,B2)</th>
<th>STVG R1,D2(X2,B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘E3’</td>
<td>R1</td>
<td>X2</td>
<td>B2</td>
</tr>
<tr>
<td>‘E3’</td>
<td>R1</td>
<td>X2</td>
<td>B2</td>
</tr>
<tr>
<td>‘E3’</td>
<td>R1</td>
<td>X2</td>
<td>B2</td>
</tr>
</tbody>
</table>

The first operand is placed at the second-operand location with the left-to-right sequence of the bytes reversed.

For STORE REVERSED (STRVH), the first operand is two bytes in bit positions 48-63 of general register R1. For STORE REVERSED (STRV), the first operand is four bytes in bit positions 32-63 of general register R1. For STORE REVERSED (STRVG), the first operand is eight bytes in bit positions 0-63 of general register R1.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)

**Programming Notes:**

1. The instruction can be used to convert two, four, or eight bytes from a “little-endian” format to a “big-endian” format, or vice versa. In the big-endian format, the bytes in a left-to-right sequence are in the order most significant to
least significant. In the little-endian format, the bytes are in the order least significant to most significant. For example, the bytes ABCD in the big-endian format are DCBA in the little-endian format.

2. The storage-operand references of STORE REVERSED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

**SUBTRACT**

*Register-and-register formats:*

SR \( R_1, R_2 \) \([RR]\)

\[
1'B' \ R_1 \ R_2
\]

SGR \( R_1, R_2 \) \([RRE]\)

\[
'B909' \ R_1 \ R_2
\]

SGFR \( R_1, R_2 \) \([RRE]\)

\[
'B919' \ R_1 \ R_2
\]

SRK \( R_1, R_2, R_3 \) \([RRF-a]\)

\[
'B9F9' \ R_3 \ R_1 \ R_2
\]

SGRK \( R_1, R_2, R_3 \) \([RRF-a]\)

\[
'B9E9' \ R_3 \ R_1 \ R_2
\]

*Register-and-storage formats:*

S \( R_1, D_2(X_2, B_2) \) \([RX-a]\)

\[
5'B' \ R_1 \ X_2 \ B_2 \ D_2
\]

SY \( R_1, D_2(X_2, B_2) \) \([RXY-a]\)

\[
'E3' \ R_1 \ X_2 \ B_2 \ DL_2 \ DH_2 \ '5B'
\]

SG \( R_1, D_2(X_2, B_2) \) \([RXY-a]\)

\[
'E3' \ R_1 \ X_2 \ B_2 \ DL_2 \ DH_2 \ '09'
\]

For S, SG, SGF, SGFR, SGR, SR, and SY, the second operand is subtracted from the first operand, and the difference is placed at the first-operand location. For SGRK and SRK, the third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

For S, SR, SRK, and SY, the operands and the difference are treated as 32-bit signed binary integers. For SG, SGR, and SGRK, they are treated as 64-bit signed binary integers. For SGFR and SGF, the second operand is treated as a 32-bit signed binary integer, and the first operand and the difference are treated as 64-bit signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

The displacement for S is treated as a 12-bit unsigned binary integer. The displacement for SY, SG, and SGF is treated as a 20-bit signed binary integer.

**Resulting Condition Code:**

0  Result zero; no overflow
1  Result less than zero; no overflow
2  Result greater than zero; no overflow
3  Overflow

**Program Exceptions:**

- Access (fetch, operand 2 of S, SY, SG, and SGF only)
- Fixed-point overflow
- Operation (SY, if the long-displacement facility is not installed; SRK, SGRK, if the distinct-operands facility is not installed)

**Programming Notes:**

1. For SR and SGR, when \( R_1 \) and \( R_2 \) designate the same register, subtracting is equivalent to clearing the register.
2. Subtracting a maximum negative number from itself gives a zero result and no overflow.

**SUBTRACT HALFWORD**

The second operand is subtracted from the first operand, and the difference is placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer. The first operand and the difference are treated as 32-bit signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

The displacement for SH is treated as a 12-bit unsigned binary integer. The displacement for SHY is treated as a 20-bit signed binary integer.

**Resulting Condition Code:**

0 Result zero; no overflow  
1 Result less than zero; no overflow  
2 Result greater than zero; no overflow  
3 Overflow

**Program Exceptions:**

- Access (fetch, operand 2)  
- Fixed-point overflow  
- Operation (SHY, if the long-displacement facility is not installed)

**Programming Note:** The function of a SUBTRACT HALFWORD IMMEDIATE instruction, which is an instruction not provided, can be obtained by using an ADD HALFWORD IMMEDIATE instruction with a negative I_2 field.

---

**SUBTRACT HIGH**

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location. The operands and the difference are treated as 32-bit signed binary integers.

The first and second operands are in bits 0-31 of general registers R_1 and R_2, respectively; bits 32-63 of general register R_1 are unchanged, and bits 32-63 of general register R_2 are ignored. For SHHHR, the third operand is in bits 0-31 of general register R_3; bits 32-63 of the register are ignored. For SHHLR, the third operand is in bits 32-63 of general register R_3; bits 0-31 of the register are ignored.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

**Resulting Condition Code:**

0 Result zero; no overflow  
1 Result less than zero; no overflow  
2 Result greater than zero; no overflow  
3 Overflow

**Program Exceptions:**

- Fixed-point overflow  
- Operation (if the high-word facility is not installed)

---

**SUBTRACT LOGICAL**

Register-and-register formats:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Registers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SLR R_1 R_2</td>
<td>[RR]</td>
<td>SUBTRACT LOGICAL</td>
</tr>
</tbody>
</table>
For SUBTRACT LOGICAL (SL, SLR, SLRK, and SLY) and for SUBTRACT LOGICAL IMMEDIATE (SLFI), the operands and the difference are treated as 32-bit unsigned binary integers. For SUBTRACT LOGICAL (SLG, SLGR, and SLGRK), they are treated as 64-bit unsigned binary integers. For SUBTRACT LOGICAL (SLGFR, SLGF) and for SUBTRACT LOGICAL IMMEDIATE (SLGFI), the second operand is treated as a 32-bit unsigned binary integer, and the first operand and the difference are treated as 64-bit unsigned binary integers.

The displacement for SL is treated as a 12-bit unsigned binary integer. The displacement for SLY, SLG, and SLGF is treated as a 20-bit signed binary integer.

**Resulting Condition Code:**

- 0 --
- 1 Result not zero; borrow
- 2 Result zero; no borrow
- 3 Result not zero; no borrow

**Program Exceptions:**

- Access (fetch, operand 2 of SL, SLY, SLG, and SLGF only)
- Operation (SLY, if the long-displacement facility is not installed; SLFI and SLGFI, if the extended-immediate facility is not installed; SLRK and SLGRK, if the distinct-operands facility is not installed)

**Programming Notes:**

1. Logical subtraction is performed by adding the one’s complement of the second operand and a value of one to the first operand. The use of the one’s complement and the value of one instead of the two’s complement of the second operand results in a carry when the second operand is zero.

2. SUBTRACT LOGICAL differs from SUBTRACT only in the meaning of the condition code and in the absence of the interruption for overflow.
3. A zero difference is always accompanied by a carry out of bit position 0 for 64-bit results or bit position 32 for 32-bit results, and, therefore, no borrow.

4. The condition-code setting for SUBTRACT LOGICAL can also be interpreted as indicating the presence or absence of a carry, as follows:

   1. Result not zero; no carry
   2. Result zero; carry
   3. Result not zero; carry

**SUBTRACT LOGICAL HIGH**

<table>
<thead>
<tr>
<th>SLHHHR</th>
<th>R1,R2,R3</th>
<th>[RRF-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B9CB'</td>
<td>R3 /// R1 R2</td>
<td></td>
</tr>
<tr>
<td>0 16 20 24 28 31</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SLHHLR</th>
<th>R1,R2,R3</th>
<th>[RRF-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B9DB'</td>
<td>R3 /// R1 R2</td>
<td></td>
</tr>
<tr>
<td>0 16 20 24 28 31</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location. The operands and the difference are treated as 32-bit unsigned binary integers.

The first and second operands are in bits 0-31 of general registers R1 and R2, respectively; bits 32-63 of general register R1 are unchanged, and bits 32-63 of general register R2 are ignored. For SLHHHR, the third operand is in bits 0-31 of general register R3; bits 32-63 of the register are ignored. For SLHHLR, the third operand is in bits 32-63 of general register R3; bits 0-31 of the register are ignored.

**Resulting Condition Code:**

0  --
1  Result not zero; borrow
2  Result zero; no borrow
3  Result not zero; no borrow

**Program Exceptions:**

- Operation (if the high-word facility is not installed)

**SUBTRACT LOGICAL WITH BORROW**

**Register-and-register formats:**

<table>
<thead>
<tr>
<th>SLBR</th>
<th>R1,R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B999'</td>
<td>R1,R2</td>
<td></td>
</tr>
<tr>
<td>0 16 20 24 28 31</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SLBGR</th>
<th>R1,R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B999'</td>
<td>R1,R2</td>
<td></td>
</tr>
<tr>
<td>0 16 20 24 28 31</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Register-and-storage formats:**

<table>
<thead>
<tr>
<th>SLB</th>
<th>R1,D(X2,B2)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E3'</td>
<td>R1 X2 B2 DL2 DH2 '99'</td>
<td></td>
</tr>
<tr>
<td>0 8 12 16 20 32 40 47</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SLBG</th>
<th>R1,D(X2,B2)</th>
<th>[RXY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E3'</td>
<td>R1 X2 B2 DL2 DH2 '89'</td>
<td></td>
</tr>
<tr>
<td>0 8 12 16 20 32 40 47</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The second operand and the borrow are subtracted from the first operand, and the difference is placed at the first-operand location. For SUBTRACT LOGICAL WITH BORROW (SLBR, SLB), the operands, the borrow, and the difference are treated as 32-bit unsigned binary integers. For SUBTRACT LOGICAL WITH BORROW (SLBGR, SLBG), they are treated as 64-bit unsigned binary integers.

**Resulting Condition Code:**

0  Result zero; borrow
1  Result not zero; borrow
2  Result zero; no borrow
3  Result not zero; no borrow

**Program Exceptions:**

- Access (fetch, operand 2 of SLB and SLBG only)

**Programming Notes:**

1. A borrow is represented by a zero value of bit 18 of the current PSW. Bit 18 is the leftmost bit of the two-bit condition code in the PSW. Bit 18 is set to zero by an execution of a SUBTRACT LOGICAL or SUBTRACT LOGICAL WITH BOR-
ROW instruction that produces a borrow into the leftmost bit position of the 32-bit or 64-bit result.

2. Logical subtraction with borrow is performed by adding the one's complement of the second operand and bit 18 of the current PSW to the first operand. Therefore, when bit 18 is one, indicating no borrow, the addition is the same as for SUBTRACT LOGICAL.

3. Condition code zero is set for SUBTRACT LOGICAL WITH BORROW (SLBR, SLB), when the maximum 32-bit unsigned binary integer, \(2^{32} - 1\), is subtracted from zero when PSW bit 18 indicates a borrow. For SUBTRACT LOGICAL WITH BORROW (SLBGR, SLBG) condition code zero is set when the maximum 64-bit unsigned binary integer, \(2^{64} - 1\), is subtracted from zero when PSW bit 18 indicates a borrow.

4. SUBTRACT and SUBTRACT LOGICAL may provide better performance than SUBTRACT LOGICAL WITH BORROW, depending on the model.

**SUPERVISOR CALL**

SVC I [I]

<table>
<thead>
<tr>
<th>0A</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

The instruction causes a supervisor-call interruption, with the I field of the instruction providing the rightmost byte of the interruption code.

Bits 8-15 of the instruction, with eight zeros appended on the left, are placed in the supervisor-call interruption code that is stored in the course of the interruption. See “Supervisor-Call Interruption” on page 6-54.

A serialization and checkpoint-synchronization function is performed.

**Condition Code:** The code remains unchanged and is saved as part of the old PSW. A new condition code is loaded as part of the supervisor-call interruption.

**Program Exceptions:**
- Transaction constraint

**TEST ADDRESSING MODE**

TAM [E]

<table>
<thead>
<tr>
<th>010B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 15</td>
</tr>
</tbody>
</table>

The extended-addressing-mode bit and basic-addressing-mode bit, bits 31 and 32 of the current PSW, respectively, are tested, and the result is indicated in the condition code.

**Resulting Condition Code:**

| 0 | PSW bits 31 and 32 zeros (indicating 24-bit addressing mode) |
| 1 | PSW bit 31 zero and bit 32 one (indicating 31-bit addressing mode) |
| 2 | -- |
| 3 | PSW bits 31 and 32 ones (indicating 64-bit addressing mode) |

**Program Exceptions:**
- Transaction constraint

**Programming Note:** The case when PSW bit 31 is one and bit 32 is zero causes an early PSW specification exception to be recognized.

**TEST AND SET**

TS D2(B2) [S]

<table>
<thead>
<tr>
<th>'93'</th>
<th>/ / / / / / / /</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 16 20 31</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The leftmost bit (bit position 0) of the byte located at the second-operand address is used to set the condition code, and then the byte is set to all ones.

Bits 8-15 of the instruction are ignored.

The byte in storage is set to all ones as it is fetched for the testing of bit 0. This update appears to be an interlocked-update reference as observed by other CPUs.

A serialization function is performed before the byte is fetched and again after the storing of all ones.
**Resulting Condition Code:**

0  Leftmost bit zero  
1  Leftmost bit one  
2  --  
3  --  

**Program Exceptions:**

- Access (fetch and store, operand 2)  
- Transaction constraint

**Programming Notes:**

1. TEST AND SET may be used for controlled sharing of a common storage area by programs operating on different CPUs. This instruction is provided primarily for compatibility with programs written for System/360. The instructions COMPARE AND SWAP and COMPARE DOUBLE AND SWAP provide functions which are more suitable for sharing among programs on a single CPU or for programs that may be interrupted. See the description of these instructions and the associated programming notes for details.

2. TEST AND SET does not interlock against storage accesses by channel programs. Therefore, the instruction should not be used to update a location into which a channel program may store, since the channel-program data may be lost.

**TEST UNDER MASK (TEST UNDER MASK HIGH, TEST UNDER MASK LOW)**

<table>
<thead>
<tr>
<th>TM</th>
<th>D_{i}(B_{1}), I_{2} [SI]</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'91'</td>
<td>I_{2} B_{1} D_{1}</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TMY</th>
<th>D_{i}(B_{1}), I_{2} [SI/Y]</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'EB'</td>
<td>I_{2} B_{1} DL_{1} DH_{1} '51'</td>
<td></td>
</tr>
</tbody>
</table>

A mask is used to select bits of the first operand, and the result is indicated in the condition code.

TEST UNDER MASK is a new name of, and TMLH and TMLL are new mnemonics for, the ESA/390 instructions TEST UNDER MASK HIGH (TMH) and TEST UNDER MASK LOW (TML), respectively.

In TEST UNDER MASK (TM, TMY), the byte of immediate data, I_{2}, is used as an eight-bit mask. The bits of the mask are made to correspond one for one with the bits of the byte in storage designated by the first-operand address.

A mask bit of one indicates that the storage bit is to be tested. When the mask bit is zero, the storage bit is ignored. When all storage bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are all ones, condition code 3 is set; otherwise, condition code 1 is set.

Access exceptions associated with the storage operand are recognized for one byte even when the mask is all zeros.

In TEST UNDER MASK (TMHH, TMHL, TMLH, TMLL), The contents of the I_{2} field are used as a 16-bit mask. For each instruction, the bits of the
A mask bit of one indicates that the first-operand bit is to be tested. When the mask bit is zero, the first-operand bit is ignored. When all first-operand bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are mixed zeros and ones, condition code 1 is set if the leftmost selected bit is zero, or condition code 2 is set if the leftmost selected bit is one. When the selected bits are all ones, condition code 3 is set.

The displacement for TM is treated as a 12-bit unsigned binary integer. The displacement for TMY is treated as a 20-bit signed binary integer.

**Resulting Condition Code:**

0  Selected bits all zeros; or mask bits all zeros
1  Selected bits mixed zeros and ones (TM and TMY only)
1  Selected bits mixed zeros and ones, and leftmost is zero (TMHH, TMHL, TMLH, TMLL)
2  -- (TM and TMY only)
2  Selected bits mixed zeros and ones, and leftmost is one (TMHH, TMHL, TMLH, TMLL)
3  Selected bits all ones

**Program Exceptions:**

- Access (fetch, operand 1, TM and TMY only)
- Operation (TMY, if the long-displacement facility is not installed)

**Programming Notes:**

1. An example of the use of the TEST UNDER MASK (TM) instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When the mask for TMHH, TMHL, TMLH, or TMLL selects exactly two bits, the two selected bits effectively are loaded into the condition code.

**TRANSACTION ABORT**

**Instruction Bits Tested**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Bits Tested</th>
</tr>
</thead>
<tbody>
<tr>
<td>TMHH</td>
<td>0-15</td>
</tr>
<tr>
<td>TMHL</td>
<td>16-31</td>
</tr>
<tr>
<td>TMLH (or TMH)</td>
<td>32-47</td>
</tr>
<tr>
<td>TMLL (or TML)</td>
<td>48-63</td>
</tr>
</tbody>
</table>

If the CPU is in the nonconstrained transactional-execution mode, the transaction is aborted.

The second-operand address is not used to address data; instead, the address specified by the $B_2$ and $D_2$ fields forms the transaction abort code which is placed in the transaction diagnostic block during abort processing. Address computation for the second-operand address follows the rules of address arithmetic; in the 24-bit addressing mode, bits 0-39 are set to zeros; in the 31-bit addressing mode, bits 0-32 are set to zeros.

Aborting of a transaction by the TABORT instruction consists of performing steps 1-7 of the section “Transaction Abort Processing” on page 5-103. The condition code in the transaction-abort PSW is set to either 2 or 3, depending on whether bit 63 of the second-operand address is zero or one, respectively.

A serialization function is implicitly performed by the abort processing.

When TRANSACTION ABORT is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

A specification exception is recognized and the operation is suppressed if the second-operand address is between 0 and 255.

A special-operation exception is recognized and the operation is suppressed if the CPU is not in the transactional-execution mode at the beginning of the instruction.

If the CPU is in the constrained transactional-execution mode, a transaction-constraint program exception condition is recognized.

**Condition Code:** The code remains unchanged. However, the condition code of the transaction-abort PSW will be set by the subsequent transaction-abort processing.
Program Exceptions:

- Execute
- Operation (transactional-execution facility not installed)
- Special-operation
- Specification
- Transaction constraint

Programming Notes:

1. If the transactional-execution control, bit 8 of control register 0, is zero, the CPU cannot be in the transactional-execution mode; Attempted execution of a TRANSACTION ABORT in this case results in a special-operation exception.

2. Abort codes 0-255 are reserved for transactions that are implicitly aborted by the CPU. See “Transaction Abort Conditions” on page 5-100 for details.

3. Program interruptions are subject to the effective program-interruption filtering control.

4. Execution of TABORT may result in significant performance degradation, potentially causing high contention which, in turn, can lead to other abort conditions.

5. Following the TABORT instruction, program execution continues at the instruction designated by the transaction-abort PSW.

 TRANSACTION BEGIN (TBEGIN)

<table>
<thead>
<tr>
<th>TBEGIN</th>
<th>D1(B1)</th>
<th>I2</th>
<th>[SIL]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E560'</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Execution of the TRANSACTION BEGIN (TBEGIN) instruction causes the CPU either to enter or to remain in the nonconstrained transactional-execution mode.

When the B1 field is nonzero, the following applies:

- When the transaction nesting depth is initially zero, the first-operand address designates the location of the 256-byte transaction diagnostic block, called the TBEGIN-specified TDB, into which various diagnostic information may be stored if the transaction is aborted (see “Transaction Diagnostic Block (TDB)” on page 5-94). When the CPU is in the primary-space mode or access-register mode, the first-operand address designates a location in the primary address space. When the CPU is in the secondary-space or home-space mode, the first-operand address designates a location in the secondary or home address space, respectively. When DAT is off, the TDBA designates a location in real storage.

- Store accessibility to the first operand is determined. If accessible, the logical address of the operand is placed into the transaction-diagnostic-block address (TDBA), and the TDBA is valid.

When the B1 field is zero, no access exceptions are detected for the first operand, and, for the outermost TBEGIN instruction, the TDBA is invalid.

The I2 field contains various controls for the instruction and has the following format:

```
GRSM / / / A FC PI
```

The bits of the I2 field are defined as follows:

**General Register Save Mask (GRSM):** Bits 0-7 of the I2 field contain the general register save mask (GRSM). Each bit of the GRSM represents an even-odd pair of general registers, where bit 0 represents registers 0 and 1, bit 1 represents registers 2 and 3, and so forth. When a bit in the GRSM of the outermost TBEGIN instruction is zero, the corresponding register pair is not saved. When a bit in the GRSM of the outermost TBEGIN instruction is one, the corresponding register pair is saved in a model-dependent location that is not directly accessible by the program.

If the transaction aborts, saved register pairs are restored to their contents when the outermost TBEGIN instruction was executed. The contents of all other (unsaved) general registers are not restored when a transaction aborts.

The general register save mask is ignored on all TBEGINs except for the outermost one.
**Allow AR Modification (A):** The A control, bit 12 of the I₂ field, controls whether the transaction is allowed to modify an access register. The effective allow-AR-modification control is the logical AND of the A control in the TBEGIN instruction for the current nesting level and for all outer levels.

If the effective A control is zero, the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to modify any access register. If the effective A control is one, the transaction will not be aborted if an access register is modified (absent of any other abort condition).

**Allow Floating-Point Operation (F):** The F control, bit 13 of the I₂ field, controls whether the transaction is allowed to execute any floating-point instruction (that is, any instruction defined in Chapters 9, 18, 19, or 20) or any vector instruction (that is, any instruction defined in Chapters 21, 22, 23, or 24). The effective allow-floating-point-operation control is the logical AND of the F control in the TBEGIN instruction for the current nesting level and for all outer levels.

If the effective F control is zero, then (a) the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to execute a floating-point or vector instruction, and (b) the data-exception code (DXC) in byte 2 of the floating-point control register (FPCR) will not be set by any data-exception program-exception condition. If the effective F control is one, then (a) the transaction will not be aborted if an attempt is made to execute a floating-point or vector instruction (absent any other abort condition), and (b) the DXC or VXC in the FPCR may be set by a data-exception or vector-exception program-exception condition.

**Program-Interuption-Filtering Control (PIFC):**

Bits 14-15 of the I₂ field are the program-interuption-filtering control (PIFC). The PIFC controls whether certain classes of program-exception conditions that occur while the CPU is in the transactional-execution mode result in an interruption. See “Program-Interuption Filtering on a Transaction Abort” on page 5-104 for a description of these classes.

The effective PIFC is the highest value of the PIFC in the TBEGIN instruction for the current nesting level and for all outer levels. When the effective PIFC is zero, all program-exception conditions result in an interruption. When the effective PIFC is one, program-exception conditions having a transactional-execution class of 1 and 2 result in an interruption. When the effective PIFC is two, program-exception conditions having a transactional-execution class of 1 result in an interruption. A PIFC of 3 is reserved.

Bits 8-11 of the I₂ field (bits 40-43 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

**TRANSACTION BEGIN (TBEGIN) Processing**

Execution of the TRANSACTION BEGIN (TBEGIN) instruction consists of the following steps: Note, exception checking does not necessarily need to occur in the order listed below. See Figure 7-307 on page 7-348 for the precise ordering requirements for exception checking.

1. A serialization function is performed.
2. A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.
3. A specification exception is recognized and the operation is suppressed if either of the following is true.
   a. The program-interuption-filtering control, bits 14-15 of I₂ field of the instruction, contains the value 3.
   b. The first-operand address does not designate a doubleword boundary. It is model dependent whether a specification exception is recognized when the first-operand address does not designate a doubleword boundary if either the B₁ field is zero or the transaction-nesting depth is nonzero.
4. If the CPU is in the constrained transactional-execution mode, then a transaction-constraint-exception program exception is recognized and the operation is suppressed.
5. When the B₁ field is nonzero, the following applies:
   - If the CPU is not in the transactional-execution mode (that is, the transaction nesting depth is zero), then the following occurs:
     - Store accessibility to the first operand is determined. If the first operand cannot
be accessed for stores, then an access exception is recognized and the operation is either nullified, suppressed, or terminated, depending on the specific access-exception condition.

- Any PER storage-alteration or zero-address-detection event for the first operand is recognized.

- If the CPU is already in the transactional-execution mode, it is unpredictable whether (a) store accessibility to the first operand is determined, and (b) PER storage-alteration or zero-address-detection events are detected for the first operand.

If the B₁ field is zero, then the first operand is not accessed.

6. If the transaction nesting depth, when incremented by one, would exceed a model-dependent maximum transaction nesting depth, the transaction is aborted with abort code 13. See “Transaction Abort Processing” on page 5-103 for details on the handling of a transaction abort.

7. If the CPU is not in the transactional-execution mode, the following occurs:

   a. If the B₁ field is nonzero, the first-operand address is placed in the transaction-diagnostic-block address, and the transaction-diagnostic-block address is valid. If the B₁ field is zero, the transaction-diagnostic-block address is invalid.

   b. The transaction-abort PSW is set from the contents of the current PSW. The instruction address of the transaction-abort PSW designates the next-sequential instruction (that is, the instruction following the outermost TBEGIN).

8. An effective value of the allow-AR-modification (A) control, bit 12 of the I₂ field of the instruction, is determined. The effective A control is the logical AND of the A control in the TBEGIN instruction for the current level and for all outer levels.

9. An effective value of the allow-floating-point-operation (F) control, bit 13 of the I₂ field of the instruction, is determined. The effective F control is the logical AND of the F control in the TBEGIN instruction for the current level and for all outer levels.

10. An effective value of the program-interruption-filtering control (PIFC), bits 14-15 of the I₂ field of the instruction, is determined. The effective PIFC value is highest value in the TBEGIN instruction for the current level and for all outer levels.

11. If the CPU is not in the transactional-execution mode, the contents of the general register pairs designated by the general-register save mask are saved in a model-dependent location that is not directly accessible by the program.

12. A value of one is added to the transaction nesting depth, and the instruction completes by setting condition code 0. If the transaction nesting depth transitions from zero to one, the CPU enters the nonconstrained transactional-execution mode; otherwise, the CPU remains in the nonconstrained transactional-execution mode.

When TBEGIN is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

See “Event-Suppression Control (ES)” on page 4-25 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION BEGIN.

**Resulting Condition Code:**

0 Transaction initiation successful
1 – (see programming notes 3 and 4)
2 – (see programming notes 3 and 4)
3 – (see programming notes 3 and 4)

**Program Exceptions:**

- Access (store, first operand)
- Execute
- Operation (transactional-execution facility not installed)
- Special operation
- Specification
- Transaction constraint
Programming Notes:

1. When the $B_1$ field is nonzero, the following applies:
   
   • An accessible transaction diagnostic block (TDB) must be provided when an outermost transaction is initiated — even if the transaction never aborts.
   
   • Since it is unpredictable whether accessibility of the TDB is tested for nested transactions, an accessible TDB should be provided for any nested TBEGIN instruction.
   
   • The performance of any TBEGIN in which the $B_1$ field is nonzero, and the performance of any abort processing that occurs for a transaction that was initiated by an outermost TBEGIN in which the $B_1$ field is nonzero, may be slower than when the $B_1$ field is zero.

2. Registers designated to be saved by the general register save mask are only restored if the transaction aborts, not when the transaction ends normally by means of TRANSACTION END. Only the registers designated by the GRSM of the outermost TRANSACTION BEGIN instruction are restored on abort.

   The $I_2$ field should designate all register pairs that provide input values that are changed by the transaction. Thus, if the transaction is aborted, the input register values will be restored to their original contents when the abort handler is entered.

3. The TRANSACTION BEGIN (TBEGIN) instruction is expected to be followed by a conditional branch instruction that will determine whether the transaction was successfully initiated. See programming note 3 on page 5-103 for a complete explanation of each condition code.

4. If a transaction is aborted due to conditions that do not result in an interruption, the instruction designated by the transaction-abort PSW receives control (that is, the instruction following the outermost TRANSACTION BEGIN (TBEGIN)). In addition to the condition code set by the TRANSACTION BEGIN (TBEGIN) instruction, condition codes 1-3 are also set when a transaction aborts.

   Therefore, the instruction sequence following the outermost TRANSACTION BEGIN (TBEGIN) instruction should be able to accommodate all four condition codes, even though the TBEGIN instruction only sets code 0. See the explanation of abort condition codes in programming note 3 on page 5-103.

5. On most models, improved performance may be realized, both on TRANSACTION BEGIN and when a transaction aborts, by specifying the minimum number of registers needed to be saved and restored in the general-register save mask.

6. While in the nonconstrained transactional-execution mode, a program may call a service function which may alter access registers, floating-point registers (including the floating-point control register), or vector registers. Although such a service routine may save the altered registers on entry and restore them at exit, the transaction may be aborted prior to normal exit of the routine. If the calling program makes no provision for preserving these registers while the CPU is in the nonconstrained transactional-execution mode, it may not be able to tolerate the service function’s alteration of the registers.

To prevent inadvertent alteration of access registers while in the nonconstrained transactional-execution mode, the program can set the allow-AR-modification control, bit 12 of the $I_2$ field of the TRANSACTION BEGIN instruction, to zero. Similarly, to prevent the inadvertent alteration of the floating-point registers or vector registers, the program can set the allow-floating-point-opera-
tion control, bit 13 of the $I_2$ field of the TBEGIN instruction, to zero.

7. Program-interruption conditions recognized during the execution of TRANSACTION BEGIN (TBEGIN) instruction are subject to the effective program-interruption filtering control set by any outer TBEGIN instructions. Program-interruption conditions recognized during the execution of the outermost TBEGIN instruction are not subject to filtering.

8. In order to update multiple storage locations in a serialized manner, conventional code sequences may employ a lock word (semaphore). If (a) transactional execution is used to implement updates of multiple storage locations, (b) the program also provides a “fall-back” path to be invoked if the transaction aborts, and (c) the fall-back path employs a lock word, then the transactional-execution path should also test for the availability of the lock, and, if the lock is unavailable, end the transaction by means of the TRANSACTION END instruction and branch to the fall-back path. This ensures consistent access to the serialized resources, regardless of whether they are updated transactionally.

Alternatively, the program could abort if the lock is unavailable, however the abort processing may be significantly slower than simply ending the transaction via TEND.

9. If the effective program-interruption filtering control (PIFC) is greater than zero, the CPU filters most data-exception program interruptions. If the effective allow-floating-point-operation (F) control is zero, the data-exception code (DXC) will not be set in the floating-point control register as a result of an abort due to a data-exception program-exception condition. In this scenario (filtering applies and the effective F control is zero), the only location in which the DXC can be inspected is in the TBEGIN-specified TDB. If the program’s abort handler needs to inspect the DXC in such a situation, general register $B_1$ should be nonzero, such that a valid transaction-diagnostic-block address (TDBA) is set.

10. If a PER storage-alteration or zero-address-detection condition exists for the TBEGIN-specified TDB of the outermost TBEGIN instruction, and PER event suppression does not apply, the PER event will be recognized during the execution of the instruction, thus causing the transac-

**TRANSACTION BEGIN (TBEGINC)**

<table>
<thead>
<tr>
<th>$E561'$</th>

<th>$D_1$</th>
<th>$I_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
<td>32</td>
</tr>
</tbody>
</table>

Execution of the TRANSACTION BEGIN (TBEGINC) instruction causes the CPU to enter the constrained transactional-execution mode or remain in the non-constrained transactional-execution mode.

The first-operand address is not used to access storage. The $B_1$ field, bits 16-19 of the instruction, must contain zeros; otherwise, a specification exception is recognized.

The $I_2$ field contains various controls for the instruction and has the following format:

The bits of the $I_2$ field are defined as follows:

**General Register Save Mask (GRSM):** Bits 0-7 of the $I_2$ field contain the general register save mask (GRSM). Each bit of the GRSM represents an even-odd pair of general registers, where bit 0 represents registers 0 and 1, bit 1 represents registers 2 and 3, and so forth. When a bit in the GRSM is zero, the corresponding register pair is not saved. When a bit in the GRSM is one, the corresponding register pair is saved in a model-dependent location that is not directly accessible by the program.

If the transaction aborts, saved register pairs are restored to their contents when the outermost TRANSACTION BEGIN instruction was executed. The contents of all other (unsaved) general registers are not restored when a constrained transaction aborts.

When TBEGINC is used to continue execution in the nonconstrained transactional-execution mode, the general register save mask is ignored.

**Allow AR Modification (A):** The A control, bit 12 of the $I_2$ field, controls whether the transaction is allowed to modify an access register. The effective...
allow-AR-modification control is the logical AND of the A control in the TBEGINC instruction for the current nesting level and for any outer TRANSACTION BEGIN or TBEGINC instructions.

If the effective A control is zero, the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to modify any access register. If the effective A control is one, the transaction will not be aborted if an access register is modified (absent of any other abort condition).

Bits 8-11 and 13-15 of the I2 field (bits 40-43 and 45-47 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

 TRANSACTION BEGIN (TBEGINC) Processing

Execution of the TRANSACTION BEGIN (TBEGINC) instruction consists of the following steps: Note, exception checking does not necessarily need to occur in the order listed below. See Figure 7-308 on page 7-351 for the precise ordering requirements for exception checking.

1. A serialization function is performed.
2. A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.
3. A specification exception is recognized and the operation is suppressed if the B1 field, bits 16-19 of the instruction, is nonzero.
4. If the CPU is already in the constrained transactional-execution mode, then a transaction-constraint-exception program exception is recognized and the operation is suppressed.
5. If the transaction nesting depth, when incremented by one, would exceed a model-dependent maximum transaction nesting depth, the transaction is aborted with abort code 13. See “Transaction Abort Processing” on page 5-103 for details on the handling of a transaction abort.
6. If the transaction nesting depth is zero, then the following is performed:
   a. The transaction-diagnostic-block address is considered to be invalid.
   b. The transaction-abort PSW is set from the contents of the current PSW, except that the instruction address of the transaction-abort PSW designates the TBEGINC instruction (rather than the next-sequential instruction).
   c. The contents of the general register pairs designated by the general-register save mask are saved in a model-dependent location that is not directly accessible by the program.
7. An effective value of the allow-AR-modification (A) control, bit 12 of the I2 field of the instruction, is determined. The effective A control is the logical AND of the A control in the TBEGINC instruction for the current level and for any outer TRANSACTION BEGIN instructions.
8. If the transaction nesting depth is zero, then it is set to one, and the CPU enters the constrained transactional-execution mode. The effective allow-floating-point-operation and program-interruption-filtering controls (F and PIFC, respectively) are set to zero.
   If the transaction nesting depth is nonzero, then it is incremented by one, and the CPU remains in the nonconstrained transactional-execution mode. In this case, the effective value of the allow-floating-point-operation control is set to zero, and the effective value of the program-interruption-filtering control is unchanged. See “Allow Floating-Point Operation (F)” on page 7-346 and “Program-Interruption-Filtering Control (PIFC)” on page 7-346 for a description of these controls.
9. The instruction completes by setting condition code 0.

When TBEGINC is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

See “Event-Suppression Control (ES)” on page 4-25 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION BEGIN.

Resulting Condition Code:

0  Transaction initiation successful
1  –
2  –
3  –
Program Exceptions:

- Execute
- Operation (constrained transactional-execution facility not installed)
- Special operation
- Specification
- Transaction constraint

1.-7 Exceptions with the same priority as the priority of program-interruption conditions for the general case.

8.A Specification exception due to the B_1 field containing a nonzero value.

8.B Abort due to exceeding transaction nesting depth.

9 Condition code 0 due to normal completion.

Programming Notes:

1. Registers designated to be saved by the general register save mask are only restored if the transaction aborts, not when the transaction ends normally by means of TRANSACTION END. Only the registers designated by the GRSM of the outermost TRANSACTION BEGIN instruction are restored on abort.

   The I_2 field should designate all register pairs that provide input values that are changed by a constrained transaction. Thus, if the transaction is aborted, the input register values will be restored to their original contents when constrained transaction is reexecuted.

2. On most models, improved performance may be realized, both on TRANSACTION BEGIN and when a transaction aborts, by specifying the minimum number of registers needed to be saved and restored in the general-register save mask.

3. Figure 7-309 on page 7-351 illustrates the results of the TRANSACTION BEGIN instruction (both TBEGIN and TBEGINC) based on the current transaction nesting depth and, when the TND is nonzero, whether the CPU is in the non-constrained or constrained transactional-execution mode.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>TND = 0</th>
<th>TND &gt; 0</th>

</tr>
</tbody>
</table>

   If the CPU is in the transactional-execution mode, the transaction nesting depth is decremented. If the transactional nesting depth is zero following the decrementing, all store accesses made by the transaction are committed, the CPU leaves the transactional-execution mode, and the instruction completes.

   The effective allow-floating-point-operation (F) control, allow-AR-modification (A) control, and program-interruption-filtering control (PIFC) are reset to their respective values prior to TRANSACTION BEGIN instruction that initiated the level being ended.

   If the CPU is in the transactional-execution mode at the beginning the operation, the condition code is set to 0; otherwise, the condition code is set to 2.

   A serialization function is performed at the completion of the operation.
When TRANSACTION END is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.

**Resulting Condition Code:**

- 0 CPU in the transactional-execution mode at the beginning of the operation
- 1–2 CPU not in the transactional-execution mode at the beginning of the operation
- 3–

**Program Exceptions:**

- Execute
- Operation (transactional-execution facility not installed)
- Special operation

**Programming Notes:**

1. If the transactional-execution control, bit 8 of control register 0, is zero, the CPU cannot be in the transactional-execution mode. Attempted execution of a TRANSACTION END in this case results in a special-operation exception.

2. PER instruction-fetching and transaction-end events that are recognized at the completion of the outermost TRANSACTION END instruction do not result in the transaction being aborted. See “Event-Suppression Control (ES)” on page 4-25 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION END.

<tbody>
<tr>
<td>'DC'</td>
<td>L</td>
<td>B1</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>16</td>
</tr>
</tbody>
</table>

The bytes of the first operand are used as eight-bit arguments to reference a list designated by the second-operand address. Each function byte selected from the list replaces the corresponding argument in the first operand.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding left to right. Each argument byte is added to the initial second-operand address. The addition is performed following the rules for address arithmetic, with the argument byte treated as an eight-bit unsigned binary integer and extended with zeros on the left. The sum is used as the address of the function byte, which then replaces the original argument byte.

The operation proceeds until the first-operand field is exhausted. The list is not altered unless an overlap occurs.

When the operands overlap, the result is obtained as if each result byte were stored immediately after fetching the corresponding function byte.

Access exceptions are recognized only for those bytes in the second operand which are actually required.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the TRANSLATE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. TRANSLATE may be used to convert data from one code to another code.

3. The instruction may also be used to rearrange data. This may be accomplished by placing a pattern in the destination area, by designating the pattern as the first operand of TRANSLATE, and by designating the data that is to be rearranged as the second operand. Each byte of the pattern contains an eight-bit number specifying the byte destined for this position. Thus, when the instruction is executed, the pattern selects the bytes of the second operand in the desired order.
4. Because each eight-bit argument byte is added to the initial second-operand address to obtain the address of a function byte, the list may contain 256 bytes. In cases where it is known that not all eight-bit argument values will occur, it is possible to reduce the size of the list.

5. Significant performance degradation is possible when the second-operand address of TRANSLATE designates a location that is less than 256 bytes to the left of a 4K-byte boundary. This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary.

6. The fetch and subsequent store accesses to a particular byte in the first-operand field do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

7. The storage-operand references of TRANSLATE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

**TRANSLATE AND TEST**

<table>
<thead>
<tr>
<th>TRT</th>
<th>D1(L,B1)</th>
<th>D2(B2)</th>
<th>[SS-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DD'</td>
<td>L</td>
<td>B1</td>
<td>D1</td>
</tr>
</tbody>
</table>

The bytes of the first operand are used as eight-bit arguments to select function bytes from a list designated by the second-operand address. The first nonzero function byte is inserted in general register 2, and the related argument address in general register 1.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding left to right. The first operand remains unchanged in storage. Calculation of the address of the function byte is performed as in the TRANSLATE instruction. The function byte retrieved from the list is inspected for a value of zero.

When the function byte is zero, the operation proceeds with the next byte of the first operand. When the first-operand field is exhausted before a nonzero function byte is encountered, the operation is completed by setting condition code 0. The contents of general registers 1 and 2 remain unchanged.

When the function byte is nonzero, the operation is completed by inserting the function byte in general register 2 and the related argument address in general register 1. This address points to the argument byte last translated. The function byte replaces bits 56-63 of general register 2, and bits 0-55 of this register remain unchanged. In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of this register remain unchanged. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of this register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

When the function byte is nonzero, either condition code 1 or 2 is set, depending on whether the argument byte is the rightmost byte of the first operand. Condition code 1 is set if one or more argument bytes remain to be translated. Condition code 2 is set if no more argument bytes remain.

The contents of access register 1 always remain unchanged.

Access exceptions are recognized only for those bytes in the second operand which are actually required. Access exceptions are not recognized for those bytes in the first operand which are to the right of the first byte for which a nonzero function byte is obtained.

**Resulting Condition Code:**

0 All function bytes zero
1 Nonzero function byte; first-operand field not exhausted
2 Nonzero function byte; first-operand field exhausted
3 --

**Program Exceptions:**

- Access (fetch, operands 1 and 2)
- Transaction constraint
Programming Notes:

1. An example of the use of the TRANSLATE AND TEST instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. TRANSLATE AND TEST may be used to scan the first operand for characters with special meaning. The second operand, or list, is set up with all-zero function bytes for those characters to be skipped over and with nonzero function bytes for the characters to be detected.

**TRANSLATE AND TEST EXTENDED**

```
TRTE R1(R2),M3 [RRF-c]
```

The argument characters of the first operand are used to select function codes from a function-code table designated by general register 1. For TRANSLATE AND TEST EXTENDED, the argument characters are processed in a left-to-right direction; for TRANSLATE AND TEST REVERSE EXTENDED, the argument characters are processed in a right-to-left direction. When a nonzero function code is selected, it is inserted in general register R2, the related argument address is placed in general register R1, and the first-operand length in general register R1 + 1 is decremented by the number of bytes processed. The operation proceeds until a nonzero function code is encountered, the end of the first operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first. The result is indicated in the condition code.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

General register R1 + 1 contains the length of the first operand in bytes.

Operation of the instruction is subject to controls specified in the M3 field, bits 16-19 of the instruction. The M3 field has the following format:

```
AFL
```

The bits of the M field are defined as follows:

- **Argument-Character Control (A):** The A bit, bit 0 of the M3 field, controls the size of the argument characters in the first operand. When the A bit is zero, the argument characters are one byte in length. When the A bit is one, the argument characters are two bytes in length.

When the A bit is one, the first-operand length in general register R1 + 1 must specify an even number of bytes; otherwise, a specification exception is recognized.

- **Function-Code Control (F):** The F bit, bit 1 of the M3 field, controls the size of the function codes in the function-code table designated by general register 1. When the F bit is zero, a function code is one byte in length. When the F bit is one, a function code is two bytes in length.

- **Argument-Character Limit (L):** The L bit, bit 2 of the M3 field, controls whether argument characters with a value greater than 255 are used to select function codes. When the L bit is zero, argument character values are unlimited. When the L bit is one, an argument character with a value greater than 255 is not used to select a function code; rather, the function code is assumed to contain zeros.

When the A bit of the M3 field is zero, the L bit is ignored.

- **Unassigned:** Bit 3 of the M3 field is unassigned and should contain zero; otherwise, the program may not operate compatibly in the future.

Figure 7-310 summarizes the size of the function-code table based on the A, F, and L bits.

The location of the first argument character in the first operand is designated by the contents of general register R1. The location of the leftmost byte of the function-code table is designated by the contents of
The argument characters of the first operand are selected one by one for processing, proceeding in a left-to-right direction for TRANSLATE AND TEST EXTENDED, or in a right-to-left direction for TRANSLATE AND TEST REVERSE EXTENDED. Depending on the A bit of the M3 field, the argument characters are treated as either eight-bit or sixteen-bit unsigned binary integers, extended with zeros on the left.

When the F bit of the M3 field is zero, the argument character is added to the function-code-table address in general register 1 to form the address of the selected 8-bit function code. When the F bit is one, the argument character, extended on the right with a binary 0, is added to the function-code-table address in general register 1 to form the address of the selected 16-bit function code. These additions follow the rules for address arithmetic.

When both the A and L bits are one, and the value of the argument character is greater than 255, then the function code table is not accessed. The function code is assumed to contain zero in this case.

When the selected function code contains zero, or when the function code is assumed to contain zero, processing continues with the next argument character in the first operand. The operation proceeds until a nonzero function code is selected, the first-operand location is exhausted, or a CPU-determined number of first-operand bytes have been processed.

When the first-operand location is exhausted without having selected a nonzero function code, general register R1 is either incremented or decremented by the first operand length in general register R1 + 1; general register R1 + 1 is set to zero; general register R2 is set as though a function code of zero was selected; and condition code 0 is set. For TRANSLATE AND TEST EXTENDED, general register R1 is incremented by the first operand length; for TRANSLATE AND TEST REVERSE EXTENDED, general register R1 is decremented by the first operand length. In the 24-bit or 31-bit addressing mode, bits

Figure 7-310. Function-Code Table Size

general register 1. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand location is specified by the contents of bit positions 32-63 of general register R1 + 1, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the first-operand location is specified by the entire contents of general register R1 + 1, and those contents are treated as a 64-bit unsigned binary integer.

The handling of the argument-character address in general register 1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of the register constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The function-code table is treated as being on a doubleword boundary. The handling of the function-code-table address in general register 1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-60 of the register constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 constitute the address.

When a nonzero function code is selected, it is inserted into either bits 56-63 or bits 48-63 of general register R2, depending on whether the F bit of the M3 field is zero or one, respectively. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R2 are unchanged, and bits 32-55 (F=0) or 32-47 (F=1) of the register are set to zero. In the 64-bit addressing mode, bits 0-55 (F=0) or 0-47 (F=1) are set to zero.

The contents of the registers just described are shown in Figure 7-311.
0-31 of general register $R_2$ are unchanged, and bits 32-63 of the register are set to zeros; in the 64-bit addressing mode, bits 0-63 of general register $R_2$ are set to zeros.

When a nonzero function code is selected, the function code replaces bits 56-63 or bits 48-63 of general register $R_2$, depending on whether the F bit is zero or one, respectively; depending on the addressing mode, the remaining bits in general register $R_2$ are set to zeros; the address of the argument character used to select the nonzero function code is placed in general register $R_1$; general register $R_1 + 1$ is decremented by the number of first-operand bytes processed prior to selecting the nonzero function byte; and condition code 1 is set. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register $R_2$ are unchanged, and bits 32-55 ($F=0$) or 32-47 ($F=1$) are set to zero; in the 64-bit addressing mode, bits 0-55 ($F=0$) or 0-47 ($F=1$) are set to zeros.

When a CPU-determined number of bytes have been processed, general register $R_1$ is either incremented or decremented by the number of bytes in the first operand that were processed, general register $R_1 + 1$ is decremented by this number, and condition code 3 is set. For TRANSLATE AND TEST EXTENDED, general register $R_1$ is incremented by the number of bytes processed; for TRANSLATE AND TEST REVERSE EXTENDED, general register $R_1$ is decre-
mented by the number of bytes processed. Condition code 3 may be set even when the first-operand location is exhausted or when the next argument character to be processed selects a nonzero function byte. In these cases, condition code 0 or 1 will be set when the instruction is executed again.

When the R₂ field designates the same register as register R₁, the updated first-operand address is placed in the register. When the R₂ field designates the same register as register R₁+1, the updated first-operand length is placed in the register.

When general register R₁ is updated in the 24-bit or 31-bit addressing mode, bits 32-39, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged from their original values.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R₁, R₁ + 1, and R₂ always remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the portion of the first operand beyond the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed. When the length of the first operand is zero, no access exceptions for the first operand are recognized.

Access exceptions for any byte of the function-code table specified by general register 1 may be recognized, even if not all bytes are used.

Special Conditions

A specification exception is recognized for any of the following conditions:

1. The R₁ field designates an odd-numbered register.

2. The A bit of the M₃ field is one and the first operand length in general register R₁ + 1 is odd.

Resulting Condition Code:

0 Entire first operand processed without selecting a nonzero function code
1 Nonzero function code selected
2 --
3 CPU-determined number of bytes processed

Program Exceptions:

- Access (fetch, operand 1 and the function-code table)
- Operation (if the parsing-enhancement facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue processing. The program need not determine the number of bytes that were processed.

2. The storage-operand references of TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The following example illustrates the use of TRANSLATE AND TEST EXTENDED to parse a buffer of 16-bit Unicode argument characters for delimiters such as those used in common markup languages. Because the Unicode representation of such delimiters is in the range of 0000 - 00FF hex, a limited function-code table is used (the L bit of the M₃ field is one).

In this example, the variable BUFFER is used to hold the 16-bit characters to be parsed. If a delimiting character is not found, control passes to the label NOTFND. If a delimiting character is found, the function code placed in general register R₂ is used as an index to the branch table that
TRANSLATE AND TEST REVERSE

The bytes of the first operand are used as eight-bit arguments to select function bytes from a list designated by the second-operand address. The first-operand address designates the rightmost byte of the first operand. The first nonzero function byte is inserted in general register 2, and the related argument address in general register 1.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding from right to left. The first operand remains unchanged in storage. Calculation of the address of the function byte is performed as in the TRANSLATE instruction. The function byte retrieved from the list is inspected for a value of zero.

When the function byte is zero, the operation proceeds with the preceding byte of the first operand. When the first-operand field is exhausted before a nonzero function byte is encountered, the operation is completed by setting condition code 0. The contents of general registers 1 and 2 remain unchanged.

When the function byte is nonzero, the operation is completed by inserting the function byte in general register 2 and the related argument address in general register 1. This address points to the argument byte last translated. The function byte replaces bits 56-63 of general register 2, and bits 0-55 of this register remain unchanged. In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of this register remain unchanged. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, and bits 0-32 of this register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

When the function byte is nonzero, either condition code 1 or 2 is set, depending on whether the argument byte is the leftmost byte of the first operand. Condition code 1 is set if one or more argument bytes remain to be translated. Condition code 2 is set if no more argument bytes remain.

Note, the branch to label NOT_FND does not result from a function-code-table entry of zeros. Rather, the branch is taken when the first operand is exhausted without selecting a nonzero function-code-table entry.

As an alternative to treating the selected function-code value as a table index (as shown in programming note 3, above), the function-code value may be used directly as a branch offset.

The performance of TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED may be significantly slower if the program modifies the function-code table prior to execution of the instruction.

In the assembler syntax, the M₃ operand is considered to be optional. When the M₃ field is not coded, it is considered to contain zeros by the assembler.
The contents of access register 1 always remain unchanged.

Access exceptions can be recognized for any byte in either the first or in the second operand.

**Resulting Condition Code:**

0  All function bytes zero
1  Nonzero function byte; first-operand field not exhausted
2  Nonzero function byte; first-operand field exhausted
3  --

**Program Exceptions:**

- Access (fetch, operands 1 and 2)
- Operation (if the extended-translation facility 3 is not installed)
- Transaction constraint

**Programming Note:**

TRANSLATE AND TEST REVERSE may be used to scan the first operand for characters with special meaning. The second operand, or list, is set up with all-zero function bytes for those characters to be skipped over and with nonzero function bytes for the characters to be detected.

**TRANSLATE EXTENDED**

The bytes of the first operand are compared to a test byte in general register 0 and, unless an equal comparison occurs, are used as eight-bit arguments to reference a 256-byte translation table designated by the second-operand address. Each function byte selected from the second operand replaces the corresponding argument in the first operand. The operation proceeds until a first-operand byte equal to the test byte is encountered, the end of the first operand is reached, or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The \(R_1\) field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers \(R_1\) and \(R_2\), respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand location is specified by the contents of bit positions 32-63 of general register \(R_1 + 1\), and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the first-operand location is specified by the entire contents of general register \(R_1 + 1\), and those contents are treated as a 64-bit unsigned binary integer.

The handling of the addresses in general registers \(R_1\) and \(R_2\) is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers \(R_1\) and \(R_2\) constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The test byte is in bit positions 56-63 of general register 0, and the contents of bit positions 0-55 of this register are ignored.

The contents of the registers just described are shown in Figure 7-312.

The bytes of the first operand are selected one by one for translation, proceeding left to right. Each argument byte is first compared to the test byte in general register 0. If the result is an equal comparison, the operation is completed. If the argument byte is not equal to the test byte, the argument byte is added to the initial second-operand address. The addition is performed following the rules for address arithmetic, with the argument byte treated as an eight-bit unsigned binary integer and extended with zeros on the left. The sum is used as the address of the function byte, which then replaces the original argument byte. The second operand is not altered unless an overlap occurs.

The operation proceeds until a first-operand byte equal to the test byte is encountered, the first-operand location is exhausted, or a CPU-determined number of first-operand bytes have been processed.
When the first-operand location is exhausted without finding a byte equal to the test byte, condition code 0 is set. When a first-operand byte equal to the test byte is encountered, condition code 1 is set. When a CPU-determined number of bytes have been processed, condition code 3 is set. Condition code 3 may be set even when the first-operand location is exhausted or when the next byte to be processed is equal to the test byte. In these cases, condition code 0 or 1, respectively, will be set when the instruction is executed again.

If the operation is completed with condition code 0, the contents of general register \( R_1 \) are incremented by the contents of general register \( R_1 + 1 \), and then the contents of general register \( R_1 + 1 \) are set to zero. If the operation is completed with condition code 1, the contents of general register \( R_1 + 1 \) are decremented by the number of bytes processed before the first-operand byte equal to the test byte was encountered, and the contents of general register \( R_1 \) are incremented by the same number, so that general register \( R_1 \) contains the address of the equal byte. If the operation is completed with condition code 3, the contents of general register \( R_1 + 1 \) are decremented by the number of bytes processed, and the contents of general register \( R_1 \) are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be processed. When general register \( R_1 \) is updated in the 24-bit or 31-bit addressing mode, bits 32-39 of it, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged from their original values.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers \( R_1 \) and \( R_1 + 1 \) always remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.
When the $R_2$ register is the same register as the $R_1$ or $R_1 + 1$ register, the results are unpredictable.

When $R_1$ or $R_2$ is zero, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portion of the first operand to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

Access exceptions for all 256 bytes of the second operand may be recognized, even if not all bytes are used.

Access exceptions are not recognized if the $R_1$ field is odd. When the length of the first operand is zero, no access exceptions for the first operand are recognized.

**Resulting Condition Code:**

0  Entire first operand processed without finding a byte equal to the test byte
1  First-operand byte is equal to the test byte
2  --
3  CPU-determined number of bytes processed

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

**Programming Notes:**

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of bytes that were translated.

2. The instruction can improve performance by being used in place of a TRANSLATE AND TEST instruction that locates an escape character, followed by a TRANSLATE instruction that translates the bytes preceding the escape character.

3. The storage-operand references of TRANSLATE EXTENDED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)
reached, or a CPU-determined number of characters have been processed, whichever occurs first.

The result is indicated in the condition code.

When the ETF2-enhancement facility is installed, the M3 field has the following format:

```
/ / / C
0 1 2
```

The bits of the M3 field are defined as follows:

- **Unassigned**: Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

- **Test-Character-Comparison Control (C)**: The C bit, bit 3 of the M3 field, controls test-character comparison. When the C bit is zero, test-character comparison is performed. When the C bit is one, test-character comparison is not performed.

When the ETF2-enhancement facility is not installed, the M3 field is ignored.

The lengths of the operand and test characters are as follows:

- For TRANSLATE ONE TO ONE, the second-operand, first-operand, and test characters are single bytes.
- For TRANSLATE ONE TO TWO, the second-operand characters are single bytes, and the first-operand and test characters are double bytes.
- For TRANSLATE TWO TO ONE, the second-operand characters are double bytes, and the first-operand and test characters are single bytes.
- For TRANSLATE TWO TO TWO, the second-operand, first-operand, and test characters are double bytes.

For TRANSLATE ONE TO ONE and TRANSLATE TWO TO TWO, the test character is in bit positions 56-63 of general register 0. For TRANSLATE ONE TO TWO and TRANSLATE TWO TO TWO, the test character is in bit positions 48-63 of general register 0.

The R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R1 and R2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the second-operand location is specified by the contents of bit positions 32-63 of general register R1 + 1, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the second-operand location is specified by the contents of bit positions 0-63 of general register R1 + 1, and those contents are treated as a 64-bit unsigned binary integer. The length of the first-operand location is considered to be the same as that of the second operand for TRANSLATE ONE TO ONE and TRANSLATE TWO TO TWO, twice that for TRANSLATE ONE TO TWO, and one half that for TRANSLATE TWO TO ONE.

For TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO, the length in general register R1 + 1 must be an even number of bytes; otherwise, a specification exception is recognized.

The translation table is treated as being on a double-word boundary for TRANSLATE ONE TO ONE and TRANSLATE ONE TO TWO. For TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO, the translation table is treated as follows:

- When the ETF2-enhancement facility is not installed, the translation table is treated as being on a 4K-byte boundary.
- When the ETF2-enhancement facility is installed, the translation table is treated as being on a doubleword boundary.

The rightmost bits of the register that are not used to form the address, which are bits 61-63 in the doubleword case and bits 52-63 in the 4K-byte case, are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

The handling of the addresses in general registers R1, R2, and 1 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R1 and R2 and 40-60 or 40-51 of 1 constitute the address, and the
contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of registers \( R_1 \) and \( R_2 \) and 33-60 or 33-51 of 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of registers \( R_1 \) and \( R_2 \) and 0-60 or 0-51 of 1 constitute the address.

The contents of the registers just described are shown in Figure 7-313 on page 7-364.

In the access-register mode, the contents of access registers \( R_1 \), \( R_2 \), and 1 are used for accessing the first operand, second operand, and translation table, respectively.

The length of the translation table designated by the address contained in general register 1 is as follows:

- For TRANSLATE ONE TO ONE, the translation-table length is 256 bytes; each of the 256 function characters is a single byte.
- For TRANSLATE ONE TO TWO, the translation-table length is 512 bytes; each of the 256 function characters is a double byte.
- For TRANSLATE TWO TO ONE, the translation-table length is 65,536 (64K) bytes; each of the 64K function characters is a single byte.
- For TRANSLATE TWO TO TWO, the translation-table length is 131,072 (128K) bytes; each of the 64K function characters is a double byte.

The characters of the second operand are selected one by one for translation, proceeding left to right. Each argument character is added to the initial translation-table address. The addition is performed following the rules for address arithmetic, with the argument character treated as follows:

- For TRANSLATE ONE TO ONE, the argument character is treated as an eight-bit unsigned binary integer extended on the left with 56 zeros.
- For TRANSLATE ONE TO TWO, the argument character is treated as an eight-bit unsigned binary integer extended on the right with a zero and on the left with 55 zeros.
- For TRANSLATE TWO TO ONE, the argument character is treated as a 16-bit unsigned binary integer extended on the left with 48 zeros.
- For TRANSLATE TWO TO TWO, the argument character is treated as a 16-bit unsigned binary integer extended on the right with a zero and on the left with 47 zeros.

The rightmost bits of the translation-table address that are ignored (61-63 or 52-63) are treated as zeros during this addition.

The sum is used as the address of the function character.

When the ETF2-enhancement facility is not installed, or when the test-character-comparison control is zero, processing is as follows. Each function character selected as described above is first compared to the test character in general register 0. If the result is an equal comparison, the operation is completed. If the function character is not equal to the test character, the function character is placed in the next available character position in the first operand, that is, the first function character is placed at the beginning of the first-operand location, and each successive function character is placed immediately to the right of the preceding character. The second operand and the translation table are not altered unless an overlap occurs.

The operation proceeds until a selected function character equal to the test character is encountered, the second-operand location is exhausted, or a CPU-determined number of second-operand characters have been processed.

When the ETF2-enhancement facility is installed and the test-character-comparison control is one, processing is as described above, except that no test-character comparison is performed.

When a selected function character equal to the test character is encountered, condition code 1 is set. When the second-operand location is exhausted without finding a selected function character equal to the test character, condition code 0 is set. When a CPU-determined number of characters have been processed, condition code 3 is set. Condition code 3 may be set even when the next character to be processed results in a function character equal to the test character or when the second-operand location is exhausted. In these cases, condition code 1 or 0, respectively, will be set when the instruction is executed again. When the ETF2-enhancement facility is installed and the test-character-comparison control is one, condition code 1 does not apply.
If the operation is completed with condition code 0, the contents of general register $R_2$ are incremented by the contents of general register $R_1 + 1$, and the contents of general register $R_1$ are incremented as follows:

**Explanation:**

1. When the ETF2-enhancement facility is not installed, or when the C bit, bit 3 of the M3 field, is zero, test-character comparison is performed. When the ETF2-enhancement facility is installed and the C bit is one, test-character comparison is not performed, and general register 0 is ignored.

2. When the ETF2-enhancement facility is not installed, $N$ is 61 for TRANSLATE ONE TO ONE and TRANSLATE ONE TO TWO, and $N$ is 52 for TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO. When the ETF2-enhancement facility is installed, $N$ is 61.

**Figure 7-313. Register Contents for TRANSLATE ONE TO ONE, TRANSLATE ONE TO TWO, TRANSLATE TWO TO ONE, and TRANSLATE TWO TO TWO**
• For TRANSFORM ONE TO ONE and TRANSFORM TWO TO TWO, the same as for general register R2.
• For TRANSFORM ONE TO TWO, by twice the amount for general register R2.
• For TRANSFORM TWO TO ONE, by one half the amount for general register R2.

The contents of general register R1 + 1 are then set to zero.

If the operation is completed with condition code 1, the contents of general register R1 + 1 are decremented by the number of second-operand bytes processed before the character that selected a function character equal to the test character was encountered, and the contents of general register R2 are incremented by the same number, so that general register R2 contains the address of the character that selected a function character equal to the test character. The contents of general register R1 are incremented by the same, twice, or one half the number, as described above for condition code 0.

If the operation is completed with condition code 3, the contents of general register R1 + 1 are decremented by the number of second-operand bytes processed, and the contents of general register R2 are incremented by the same number, so that the instruction, when reexecuted, contains the address of the next character to be processed. The contents of general register R1 are incremented by the same, twice, or one half the number, as described above for condition code 0.

When general registers R1 and R2 are updated in the 24-bit or 31-bit addressing mode, the bits in bit positions 32-39 of them that are not part of the address may be set to zeros or may remain unchanged from their original values. In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R1, R1 + 1, and R2 always remain unchanged.

The contents of general registers 0 and 1 remain unchanged.

When any of the following conditions are true, the results are unpredictable:

• Either the R1 or R1 + 1 registers are the same register as the R2 register.
• The R1 register is register 0.
• The R2 register is register 0, and either the ETF2-enhancement facility is not installed, or the facility is installed and the C bit is zero.
• The R2 register is register 1.
• Any of the first and second operands and the translation table overlaps another of them.

Access exceptions for the portion of the first or second operand to the right of the last character processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last character processed.

Access exceptions for all characters of the translation table may be recognized even if not all characters are used.

Access exceptions are not recognized if the R1 field is odd. When the length of the second operand is zero, no access exceptions for the first or second operand are recognized, and access exceptions for the translation table may or may not be recognized.

Resulting Condition Code:

0: Entire second operand processed; if test-character comparison was performed, no resulting function character was equal to the test character
1: Second-operand character found resulting in a function character equal to the test character (applicable only when test-character comparison is performed)
2: --
3: CPU-determined number of characters processed

Program Exceptions:

• Access (fetch, operand 2 and translation table; store, operand 1)
• Operation (if the extended-translation facility 2 is not installed)
• Specification
• Transaction constraint
Programming Notes:

1. These instructions differ from the TRANSLATE EXTENDED instruction by having the following attributes:
   • Depending on the instruction used, the sets of argument characters and function characters each can contain single-byte or double-byte characters.
   • The test character is compared to a resulting function character instead of to an argument character.
   • The argument (source) and function (destination) operands are different operands.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of characters that were translated.

3. The storage operand references of these instructions may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

UNPACK

\[ \text{UNPK} \quad D_{1}(L_{1},B_{1}),D_{2}(L_{2},B_{2}) \quad \text{[SS-b]} \]

The format of the second operand is changed from signed-packed-decimal to zoned, and the result is placed at the first-operand location. The signed-packed-decimal and zoned formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits and sign are placed unchanged in the first-operand location, using the zoned format. Zone bits with coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the second operand. The sign and digits are not checked for valid codes.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first-operand field is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time and as if the first result byte were stored immediately after fetching the first operand byte. The entire rightmost second-operand byte is used in forming the first result byte. For the remainder of the field, information for two result bytes is obtained from a single second-operand byte, and execution proceeds as if the leftmost four bits of the byte were to remain available for the next result byte and need not be refetched. Thus, the result is as if two result bytes were to be stored immediately after fetching a single operand byte.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the UNPACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. A field that is to be unpacked can be destroyed by improper overlapping. To save storage space for unpacking by overlapping the operands, the rightmost byte of the first operand must be to the right of the rightmost byte of the second operand by the number of bytes in the second operand minus 2. If only one or two bytes are to be unpacked, the rightmost bytes of the two operands may coincide.

3. The storage-operand references of UNPACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)
UNPACK ASCII

The format of the second operand is changed from signed-packed-decimal to ASCII, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to ASCII characters by extending them on the left with 0011 binary, and the ASCII characters are then placed at the first operand location. The digits are not checked for valid codes.

The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost byte position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes. The second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L1 field. The first-operand length must not exceed 32 bytes (L1 must be less than or equal to 31); otherwise, a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 bytes, the leftmost byte is set to ASCII zero, 30 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

Resulting Condition Code:

0  Sign is plus
1  Sign is minus
2  --
3  Sign is invalid

Program Exceptions:

• Access (fetch, operand 2; store, operand 1)
• Operation (if the extended-translation facility 2 is not installed)
• Specification
• Transaction constraint

Programming Note:

1. The following example illustrates the use of the instruction to unpack to ASCII digits:

   ASDIGITS DS CL31
   PKDIGITS DS 0PL16
   DC X'1234567890'
   DC X'1234567890'
   DC X'1234567890'
   DC X'1C'
   UNPKA ASDIGITS(31), PKDIGITS

2. The storage-operand references of UNPACK ASCII may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

UNPACK UNICODE

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

Resulting Condition Code:

0  Sign is plus
1  Sign is minus
2  --
3  Sign is invalid

Program Exceptions:

• Access (fetch, operand 2; store, operand 1)
• Operation (if the extended-translation facility 2 is not installed)
• Specification
• Transaction constraint

Programming Note:

1. The following example illustrates the use of the instruction to unpack to ASCII digits:

   ASDIGITS DS CL31
   PKDIGITS DS 0PL16
   DC X'1234567890'
   DC X'1234567890'
   DC X'1234567890'
   DC X'1C'
   UNPKA ASDIGITS(31), PKDIGITS

2. The storage-operand references of UNPACK ASCII may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.
The format of the second operand is changed from signed-packed-decimal to Unicode Basic Latin, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to two-byte Unicode characters by extending them on the left with 000000000011 binary (003 hex), and the Unicode characters are then placed at the first operand location. The digits are not checked for valid codes. The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost character position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes; the second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L1 field. The first-operand length must not exceed 32 characters or 64 bytes (L1 must be less than or equal to 63 and must be odd); otherwise a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 characters, the leftmost character is set to Unicode Basic Latin zero, 0030 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Code</th>

</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sign is plus</td>
</tr>
<tr>
<td>1</td>
<td>Sign is minus</td>
</tr>
<tr>
<td>2</td>
<td>--</td>
</tr>
<tr>
<td>3</td>
<td>Sign is invalid</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. The following example illustrates the use of the instruction to unpack to European numbers:

   ```asm
   UNDIGITS DS CL62
   PKDIGITS DS 0PL16
   DC 'X'1234567890'
   DC 'X'1234567890'
   DC 'X'1234567890'
   DC 'X'1C'
   UNPKU UNDIGITS(62),PKDIGITS
   UNDIGITS UNPKU UNDIGITS(62),PKDIGITS
   UNPACK ASCII UNPACK UNICODE
   ```

2. The storage-operand references of UNPACK UNICODE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

**UPDATE TREE**

```
  | E |
  0 102
```

The nodes of a tree in storage are examined successively on a path toward the base of the tree, and contents of general register 0, conceptually followed on the right by contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in gen-
eral register 0. The first half of a node and general register 0 contain a codeword, which is for use in sort/merge algorithms.

If the codeword in general register 0 equals the codeword in a node, the contents of the node are placed in general registers 2 and 3.

General register 4 contains the base address of the tree, and general register 5 contains the index of a node whose parent node will be examined first.

In the access-register mode, access register 4 specifies the address space containing the tree.

This instruction may be interrupted between units of operation. The condition code is unpredictable if the instruction is interrupted.

The size of a node, the size of a codeword, and the participation of bits 0-31 of general registers 1-5 in the operation depend on the addressing mode. In the 24-bit or 31-bit addressing mode, a node is eight bytes, a codeword is four bytes, and bits 0-31 are ignored and remain unchanged. In the 64-bit addressing mode, a node is 16 bytes, a codeword is eight bytes, and bits 0-31 are used in and may be changed by the operation.

Operation in the 24-Bit or 31-Bit Addressing Mode

In the 24-bit or 31-bit addressing mode, the double-word nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of bit positions 32-63 of general register 0, conceptually followed on the right by the contents of bit positions 32-63 of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in bit positions 32-63 of general register 0.

Bit positions 32-63 of general register 4 contain the base address of the tree, and bit positions 32-63 of general register 5 contain the index of a node whose parent node will be examined first. The base address is eight less than the address of the root node of the tree. The initial contents of bit positions 32-63 of general registers 4 and 5 must be a multiple of 8; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of bit positions 32-63 of general register 5 right logically one position and then setting bit 61 to zero. However, bits 32-63 of general register 5 remain unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 61 to zero, bits 32-63 of general register 5 are all zeros, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 32 of general register 0 is tested. If bit 32 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 32 of general register 0 is zero, the sum of bits 32-63 of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

Bits 32-63 of general register 0 are logically compared with the contents of the first word of the currently addressed node. If the register operand is low, the contents of bit positions 32-63 of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, bit positions 32-63 of general register 2, conceptually followed on the right by bit positions 32-63 of general register 3, are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first word of the node is less than or equal to the value in bit positions 32-63 of the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

Operation in the 64-Bit Addressing Mode

In the 64-bit addressing mode, the quadword nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of general register 0, conceptually followed on the right by the contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0.

General register 4 contains the base address of the tree, and general register 5 contain the index of a node whose parent node will be examined first. The base address is 16 less than the address of the root node of the tree. The initial contents of general regis-
A unit of operation begins by shifting the contents of general register 5 right logically one position and then setting bit 60 to zero. However, general register 5 remains unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 60 to zero, the contents of general register 5 are zero, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 0 of general register 0 is tested. If bit 0 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 0 of general register 0 is zero, the sum of the contents of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

The contents of general register 0 are logically compared with the contents of the first doubleword of the currently addressed node. If the register operand is low, the contents of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, general registers 2 and 3 are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first doubleword of the node is less than or equal to the value in the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

Specifications Independent of Addressing Mode

Access exceptions are recognized only for one node at a time. Access exceptions, change-bit action, and PER storage alteration do not occur for subsequent nodes until the previous node has been successfully compared and updated, and they also do not occur if a specification-exception condition exists.

Resulting Condition Code:

0  Equal compare values at currently addressed node
1  No equal compare values found on path, or no comparison made
2  --
3  In 24-bit or 31-bit mode, bits 32-63 of general register 5 nonzero and bits 32-63 of general register 0 negative; in 64-bit mode, general register 5 nonzero and general register 0 negative

Program Exceptions:
- Access (fetch and store, nodes of tree)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of UPDATE TREE is given in “Sorting Instructions” in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For use in sorting in the 24-bit or 31-bit addressing mode, when equal compare values have been found, the contents of bit positions 32-63 of general registers 1 and 3 can be appropriate (depending on the contents of the tree) for the subsequent execution of COMPARE AND FORM CODEWORD. The contents of bit positions 32-63 of general register 2, shifted right 16 bit positions, can be similarly appropriate, and they can provide for minimal recomparison of partially equal keys. The same applies in the 64-bit addressing mode except to the contents of bit positions 0-63 of the registers and with the contents of bit positions 0-63 of general register 2 shifted right 48 bit positions. Refer to “Sorting Instructions” on page A-53 for a discussion of trees and their use in sorting.

3. The program should avoid placing a nonzero value in bit positions 32-38 of general register 5 when in the 24-bit addressing mode. If any bit in bit positions 32-38 is a one, the nodes of the tree will not be examined successively.

4. When bits 32-63 of general register 0 are negative in the 24-bit or 31-bit addressing mode, or when bits 0-63 are negative in the 64-bit mode, and provided that the tree has been updated properly previously, the node represented by general registers 0 and 1 either is the node or is equal to the node (equal keys) that would be
selected if the unit of operation continued. In this case, ending the unit of operation and setting condition code 3 is a faster means of selecting an appropriate node because it does not require further examination and updating of the tree.

5. Setting condition code 3 provides improved performance when the replacement record is equal to the old winner and, more importantly (since the first case can be detected by means of the condition code of CFC), when the update path contains a negative codeword, indicating equality with the old winner.

6. In those cases when the codeword in the node is less than or equal to the codeword in general register 0, depending on the model, the contents of the node may be fetched and subsequently stored back. As a result, any of the following may occur for the storage location containing the node: a PER storage-alteration event may be recognized; a protection exception for storing may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

7. Special precautions should be taken when UPDATE TREE is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

8. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

9. The storage-operand references for UPDATE TREE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

10. Figure 7-314 on page 7-372 is a summary of the operation of UPDATE TREE in the 24-bit or 31-bit addressing mode, and Figure 7-315 on page 7-373 is a summary of the operation in the 64-bit addressing mode.
Figure 7-314. Execution of UPDATE TREE in the 24-Bit or 31-Bit Addressing Mode
Figure 7-315. Execution of UPDATE TREE in the 64-Bit Addressing Mode
Protection of Cryptographic Keys

When the message-security-assist-extension-3 facility is installed, two wrapping-key registers and two wrapping-key-verification-pattern registers are provided for each configuration. The two wrapping-key registers consist of a 192-bit DES wrapping-key (WKd) register and a 256-bit AES wrapping-key (WKa) register. The two wrapping-key-verification-pattern registers consist of a 192-bit DES wrapping-key-verification-pattern (WKdVP) register and a 256-bit AES wrapping-key-verification-pattern (WKaVP) register.

WKd is used to protect user DES or TDES keys, and WKdVP is used to verify the value of WKd. WKa is used to protect user AES keys, and WKaVP is used to verify the value of WKa. Whenever the contents of the WKd or WKa register are changed, the contents of the corresponding verification-pattern register are also changed.

Each time a clear reset is performed, a new set of wrapping keys and their associated verification patterns are generated. The contents of the two wrapping-key registers are kept internal to the model so that no program, including the operating system, can directly observe their clear value.

The following instructions provide functions supporting encrypted cryptographic keys:

- CIPHER MESSAGE
- CIPHER MESSAGE WITH CHAINING
- CIPHER MESSAGE WITH CIPHER FEEDBACK
- CIPHER MESSAGE WITH COUNTER
- CIPHER MESSAGE WITH OUTPUT FEEDBACK
- COMPUTE MESSAGE AUTHENTICATION CODE
- PERFORM CRYPTOGRAPHIC COMPUTATION

For each of these instructions, a program-specified DES or AES wrapping-key-verification-pattern in the parameter block is compared with the respective wrapping-key-verification-pattern register. the instruction completes with condition code 1 if the two do not match.

The program may also inspect the value of the DES or AES wrapping-key verification patterns in the parameter block stored by PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION.

Programming Notes:

1. Upon condition code 1, the program should re-import the cryptographic key for encrypting it under the appropriate wrapping key before the operation is resumed.

2. Even though the architecture defines that a new set of wrapping keys are generated upon a clear reset, condition code 1 could occur at any time for message-security-assist functions using an encrypted key because the application may be relocated to another system with a different set of wrapping keys.

Symbols Used in Subsequent Descriptions

The following symbols are used in the subsequent description. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [11.] on page xxviii. Further description of the AES standard may be found in Reference [12.] on page xxviii.
Protection of DES Keys

When the message-security-assist-extension-3 facility is installed, user DEA or TDEA keys may be protected under the 192-bit DEA wrapping key.

Figure 7-320 on page 7-375 describes encryption of a 64-bit DEA key, a 128-bit TDEA key, and a 192-bit TDEA key using the 192-bit DEA wrapping key.

Figure 7-321 on page 7-376 describes decryption of an encrypted 64-bit DEA key, an encrypted 128-bit TDEA key, and an encrypted 192-bit TDEA key using the 192-bit DEA wrapping key.
Protection of AES Keys

When the message-security-assist-extension-3 facility is installed, user AES keys may be protected under the 256-bit AES wrapping key.

Figure 7-322 on page 7-376 describes encryption of a 128-bit AES key using the 256-bit AES wrapping key. Figure 7-323 on page 7-376 describes decryption of an encrypted 128-bit AES key using the 256-bit AES wrapping key.

Figure 7-324 on page 7-377 describes encryption of a 192-bit AES key using the 256-bit AES wrapping key. Figure 7-325 on page 7-377 describes decryption of an encrypted 192-bit AES key using the 256-bit AES wrapping key.

Figure 7-326 on page 7-377 describes encryption of a 256-bit AES key using the 256-bit AES wrapping key. Figure 7-327 on page 7-377 describes decryption of an encrypted 256-bit AES key using the 256-bit AES wrapping key.
**Explanation:**

K = K1 || K2; a user 192-bit AES key.

WK_a(K) = C1 || C2; K is encrypted under WK_a using AES-256 encryption.

Pad is a 64-bit value of zero.

  ZERO AND ADD .......................... 8-14

The decimal instructions of this chapter perform arithmetic and editing operations on decimal data. Additional operations on decimal data are provided by several of the instructions in Chapter 7, “General Instructions.” Also, several instructions in Chapter 20, “Decimal-Floating-Point Instructions” operate on decimal numbers in the packed-decimal format. Except for decimal-floating-point instructions, decimal operands always reside in storage, and most decimal instructions use the SS instruction format. Decimal operands occupy storage fields that can start on any byte boundary. For decimal-floating-point instructions, the packed-decimal operands are fixed length and occupy a general register, or general register pair.

Decimal-Number Formats

Decimal numbers may be represented in several formats, including zoned, signed-packed-decimal and unsigned-packed-decimal. These formats are of variable length; most instructions used to operate on these formats specify the length of their operands and results. Each byte of a format consists of a pair of four-bit codes; the four-bit codes include decimal-digit codes, sign codes, and a zone code.

Zoned Format

\[ Z \bar{Z} N \bar{Z} N \bar{Z} N \bar{Z}/S N \]

In the zoned format, the rightmost four bits of a byte are called the numeric bits (N) and normally consist of a code representing a decimal digit. The leftmost four bits of a byte are called the zone bits (Z), except for the rightmost byte of a decimal operand, where these bits may be treated either as a zone or as a sign (S).

Decimal digits in the zoned format may be part of a larger character set, which includes also alphabetic and special characters. The zoned format is, therefore, suitable for input, editing, and output of numeric data in human-readable form. There are no decimal-arithmetic instructions which operate directly on decimal numbers in the zoned format; such numbers must first be converted to the signed-packed-decimal format or one of the DFP formats.

The editing instructions produce a result of up to 256 bytes; each byte may be a decimal digit in the zoned format, a message byte, or a fill byte.

Packed-Decimal Formats

There are two packed-decimal formats, signed-packed, and unsigned-packed.

Signed-Packed-Decimal Format

\[ D \bar{D} D \bar{D}/D D D S \]

In the signed-packed-decimal format, each byte contains two decimal digits (D), except for the rightmost byte, which contains a sign (S) to the right of a decimal digit. Decimal arithmetic is performed with operands in the signed-packed-decimal format and
generates results in the signed-packed-decimal format.

The signed-packed-decimal operands and results of decimal-arithmetic instructions may be up to 16 bytes (31 digits and sign), except that the maximum length of a multiplier or divisor is eight bytes (15 digits and sign). In division, the sum of the lengths of the quotient and remainder may be from two to 16 bytes. The editing instructions can fetch as many as 256 decimal digits from one or more decimal numbers of variable length, each in the signed-packed-decimal format. CONVERT FROM PACKED and CONVERT TO PACKED may have signed-packed-decimal operands up to 18 bytes (34 digits and sign).

**Unsigned-Packed-Decimal Format**

\[
\begin{array}{cccc}
D & D & D & D \\
/ & D & D & D \\
\end{array}
\]

In the unsigned-packed-decimal format, each byte contains two decimal digits (D) and there is no sign. The unsigned-packed-decimal format can be used as the source operand of the editing instructions, as the second operand of MOVE WITH OFFSET, and is also used by the decimal floating-point (DFP) instructions CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT TO PACKED, and CONVERT TO UNSIGNED PACKED.

**Decimal Codes**

The decimal digits 0-9 have the binary encoding 0000-1001.

The preferred sign codes are 1100 for plus and 1101 for minus. These are the sign codes generated for the results of the decimal-arithmetic instructions and the CONVERT TO DECIMAL instruction. The instructions PACK ASCII and PACK UNICODE supply an implied positive sign (1100 binary). The DFP instructions CONVERT TO PACKED, CONVERT TO SIGNED PACKED, and CONVERT TO ZONED include a plus sign-code selection bit. The plus sign can be encoded as either 1100 or 1111.

Alternate sign codes are also recognized as valid in the sign position: 1010, 1110, and 1111 are alternate codes for plus, and 1011 is an alternate code for minus. Alternate sign codes are accepted for any decimal source operand, but are not generated in the completed result of a decimal-arithmetic instruction or CONVERT TO DECIMAL. This is true even when an operand remains otherwise unchanged, such as when adding zero to a number. An alternate sign code is, however, left unchanged by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, and UNPACK.

When an invalid sign or digit code is detected, a general-operand data exception is recognized. For the decimal-arithmetic instructions and CONVERT TO BINARY, and the decimal floating-point instructions CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT FROM UNSIGNED PACKED, and CONVERT FROM ZONED, the operation is suppressed.

For the editing instructions EDIT and EDIT AND MARK, an invalid sign code is not recognized. It is model dependent whether the operation is suppressed or terminated for a general-operand data exception due to an invalid digit code. No validity checking is performed by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, PACK ASCII, PACK UNICODE, and UNPACK. The instructions UNPACK ASCII and UNPACK UNICODE do not check for invalid digit codes; invalid sign codes are recognized, but are not reported as a general-operand data exception, instead condition code 3 is set.

The zone code 1111 is generated in the left four bit positions of each byte representing a zone and a decimal digit in zoned-format results. Zoned-format results are produced by EDIT, EDIT AND MARK, and UNPACK. For EDIT and EDIT AND MARK, each result byte representing a zoned-format decimal digit contains the zone code 1111 in the left four bit positions and the decimal-digit code in the right four bit positions. For UNPACK, zone bits with a coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign.

The zone code 0011 is generated in the leftmost four bit positions of each byte representing a zone for a decimal digit in ASCII format. ASCII formats are produced by CONVERT TO ZONED when the zone-control bit is one and by UNPACK ASCII.
The meaning of the decimal codes is summarized in Figure 8-1.

Explanation:

* The zone code 0011 binary is generated in the leftmost four bit positions of each byte representing a decimal digit in the ASCII format.

Figure 8-1. Summary of Digit and Sign Codes

**Programming Note:** Since 1111 is both the zone code and an alternate code for plus, unsigned (positive) decimal numbers may be represented in the zoned format with 1111 zone codes in all byte positions. The result of the PACK instruction converting such a number to the signed-packed-decimal format may be used directly as an operand for decimal instructions.

---

**Decimal Operations**

The decimal instructions in this chapter consist of two classes, the decimal-arithmetic instructions and the editing instructions.

**Decimal-Arithmetic Instructions**

The decimal-arithmetic instructions perform addition, subtraction, multiplication, division, comparison, and shifting.

Operands of the decimal-arithmetic instructions are in the signed-packed-decimal format and are treated as signed decimal integers. A decimal integer is represented in true form as an absolute value with a separate plus or minus sign. It contains an odd number of decimal digits, from one to 31, and the sign; this corresponds to an operand length of one to 16 bytes.

A decimal zero normally has a plus sign, but multiplication, division, and overflow may produce a zero value with a minus sign. Such a negative zero is a valid operand and is treated as equal to a positive zero by COMPARE DECIMAL.

The lengths of the two operands specified in the instruction need not be the same. If necessary, the shorter operand is considered to be extended with zeros on the left. Results, however, cannot exceed the first-operand length as specified in the instruction.

When a carry or leftmost nonzero digits of the result are lost because the first-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

The operands of decimal-arithmetic instructions should not overlap at all or should have coincident rightmost bytes. In ZERO AND ADD, the operands may also overlap in such a manner that the rightmost byte of the first operand (which becomes the result) is to the right of the rightmost byte of the second operand. For these cases of proper overlap, the result is obtained as if operands were processed right to left. Because the codes for digits and signs are verified during the performance of the arithmetic, improperly overlapping operands are recognized as general-operand data exceptions. However, in ZERO AND ADD when the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, the entire second operand may be fetched, depending on the model, before any storing occurs, which will cause a general-operand data exception not to be recognized. See “Interlocks within a Single Instruction” on page 5-114 for how overlap is detected in the access-register mode.

**Programming Note:** A signed-packed-decimal number in storage may be designated as both the first and second operand of ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL,
SUBTRACT DECIMAL, or ZERO AND ADD. Thus, a decimal number may be added to itself, compared with itself, and so forth; SUBTRACT DECIMAL may be used to set a decimal field in storage to zero; and, for MULTIPLY DECIMAL, a decimal number may be squared in place. In these cases, the lengths of the two operands are not necessarily equal and may, depending on the instruction, be prohibited from being equal.

**Editing Instructions**

The editing instructions are EDIT and EDIT AND MARK. For these instructions, only the first operand (the pattern) has an explicitly specified length. The second operand (the source) is considered to have as many digits as necessary for the completion of the operation.

Overlapping operands for the editing instructions yield unpredictable results.

**Execution of Decimal Instructions**

During the execution of a decimal instruction, all bytes of the operands are not necessarily accessed concurrently, and the fetch and store accesses to a single location do not necessarily occur one immediately after the other. Furthermore, for decimal instructions, data in source fields may be accessed more than once, and intermediate values may be placed in the result field that may differ from the original operand and final result values. (See “Storage-Operand Consistency” on page 5-123.) Thus, in a multiprocessing configuration, an instruction such as ADD DECIMAL cannot be safely used to update a shared storage location when the possibility exists that another CPU may also be updating that location.

**Other Instructions for Decimal Operands**

In addition to the decimal-arithmetic instructions in this chapter, (which operate on decimal numbers in the signed-packed-decimal format) several other instructions are provided for operating on decimal data in the zoned, signed-packed-decimal, or unsigned-packed-decimal format.

The editing instructions (described in this chapter) convert decimal numbers in either the signed-packed-decimal or unsigned-packed-decimal format to the zoned format. Zoned results of up to 256 bytes in length can be produced.

CONVERT TO DECIMAL and CONVERT TO BINARY (described in Chapter 7) provide conversion between signed-binary-integer formats and decimal numbers in the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO SIGNED PACKED and CONVERT FROM SIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO UNSIGNED PACKED and CONVERT FROM UNSIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the unsigned-packed-decimal format. Unsigned-packed-decimal operands of up to 16 bytes in length (32 digits) can be processed.

MOVE WITH OFFSET (described in Chapter 7) operates on data in the packed format. (The first operand is treated as signed-packed decimal and the second operand as unsigned-packed decimal.) Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

PACK, UNPACK, PACK ASCII, UNPACK ASCII, PACK UNICODE, and UNPACK UNICODE provide conversion between zoned or character data and signed-packed-decimal data. Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

MOVE NUMERICS and MOVE ZONES (described in Chapter 7) operate on data in the zoned format. Operands are not checked for valid codes. Zoned operands of up to 256 bytes in length can be processed.

**General-Operand Data Exception**

A general-operand data exception is recognized when any of the following is true:
1. The sign or digit codes are invalid in the operands of the decimal instructions or in CONVERT TO BINARY (described in Chapter 7, “General Instructions’); or in CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT FROM UNSIGNED PACKED, and CONVERT FROM ZONED (described in Chapter 20, “Decimal-Floating-Point Instructions”).

2. The operand fields in ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, and SUBTRACT DECIMAL overlap in a way other than with coincident rightmost bytes; or operand fields in ZERO AND ADD overlap, and the rightmost byte of the second operand is to the right of the rightmost byte of the first operand. On some models, the improper overlap of operands for ZERO AND ADD is not recognized as a general-operand data exception; instead, the operation is performed as if the entire second operand were fetched before any byte of the result is stored.

3. The multiplicand in MULTIPLY DECIMAL has an insufficient number of leftmost zeros.

4. COMPRESSION CALL encounters errors in its dictionaries.

5. The reseed counter is zero for a PERFORM PSEUDORANDOM NUMBER OPERATION generate operation.

A general-operand data exception causes the operation to be suppressed, except that, for EDIT and EDIT AND MARK, and COMPRESSION CALL, the operation may be suppressed or terminated. In the case of EDIT and EDIT AND MARK, and COMPRESSION CALL, an invalid sign code cannot occur.

**Note:** In earlier versions of the architecture, the general-operand data exception was known as the decimal-operand data exception.

### Instructions

The decimal instructions and their mnemonics, formats, and operation codes are listed in Figure 8-2 on page 8-6. The figure also indicates when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For ADD DECIMAL, for example, AP is the mnemonic and D1(L1,B1),D2(L2,B2) the operand designation.

**Programming Note:** The decimal instruction TEST DECIMAL is available when the extended-translation facility 2 is installed.
The second operand is added to the first operand, and the resulting sum is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

Addition is algebraic, taking into account the signs and all digits of both operands. All sign and digit codes are checked for validity.

If the first operand is too short to contain all leftmost nonzero digits of the sum, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

The sign of the sum is determined by the rules of algebra. In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given either a positive or negative sign, as determined by what the sign of the correct sum would have been.

**Resulting Condition Code:**

- 0 Result zero; no overflow
- 1 Result less than zero; no overflow
- 2 Result greater than zero; no overflow
- 3 Overflow

**Program Exceptions:**

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint
**Programming Note:** An example of the use of the ADD DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

## COMPARE DECIMAL

The first operand is compared with the second operand, and the result is indicated in the condition code. The operands are in the signed-packed-decimal format.

Comparison is algebraic and follows the procedure for decimal subtraction, except that both operands remain unchanged. When the difference is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

Overflow cannot occur because the difference is discarded.

All sign and digit codes are checked for validity.

### Resulting Condition Code:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Operands equal</td>
</tr>
<tr>
<td>1</td>
<td>First operand low</td>
</tr>
<tr>
<td>2</td>
<td>First operand high</td>
</tr>
<tr>
<td>3</td>
<td>--</td>
</tr>
</tbody>
</table>

### Program Exceptions:

- Access (fetch, operands 1 and 2)
- Data with DXC 0, general operand
- Transaction constraint

### Programming Notes:

1. An example of the use of the COMPARE DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The preferred and alternate sign codes for a particular sign are treated as equivalent for comparison purposes.

3. A negative zero and a positive zero compare equal.

## DIVIDE DECIMAL

The first operand (the dividend) is divided by the second operand (the divisor). The resulting quotient and remainder are placed at the first-operand location. The operands and results are in the signed-packed-decimal format.

The quotient is placed leftmost in the first-operand location. The number of bytes in the quotient field is equal to the difference between the dividend and divisor lengths (L1 - L2). The remainder is placed rightmost in the first-operand location and has a length equal to the divisor length. Together, the quotient and remainder fields occupy the entire first operand; therefore, the address of the quotient is the address of the first operand.

The divisor length cannot exceed 15 digits and sign (L2 not greater than seven) and must be less than the dividend length (L2 less than L1); otherwise, a specification exception is recognized.

The dividend, divisor, quotient, and remainder are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the dividend and divisor are checked for validity.

The sign of the quotient is determined by the rules of algebra from the dividend and divisor signs. The sign of the remainder has the same value as the dividend sign. These rules hold even when the quotient or remainder is zero.

Overflow cannot occur. If the divisor is zero or the quotient is too large to be represented by the number of digits specified, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The decimal-divide exception is indicated only if the sign codes of both the dividend and divisor are valid, and only if the digit or digits used in establishing the exception are valid.

### Condition Code:

The code remains unchanged.

### Program Exceptions:
- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal divide
- Specification
- Transaction constraint

**Programming Notes:**

1. An example of the use of the DIVIDE DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The dividend cannot exceed 31 digits and sign. Since the remainder cannot be shorter than one digit and sign, the quotient cannot exceed 29 digits and sign.

3. The condition for a decimal-divide exception can be determined by a trial comparison. The leftmost digit of the divisor is aligned one digit to the right of the leftmost dividend digit, with rightmost zeros appended up to the length of the dividend. When the divisor, so aligned, is less than or equal to the dividend, ignoring signs, a divide exception is indicated.

4. If a general-operand data exception does not exist, a decimal-divide exception occurs when the leftmost dividend digit is not zero.

**EDIT**

```
ED D1(L,B1),D2(B2) [SS-a]
```

The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The edited result replaces the first operand.

The length field specifies the length of the first operand, which may contain bytes of any value.

The length of the source is determined by the operation according to the contents of the pattern. The source normally consists of one or more decimal numbers, each in the signed-packed-decimal or unsigned-packed-decimal format. The leftmost four bits of each source byte must specify a decimal-digit code (0000-1001); a sign code (1010-1111) is recognized as a general-operand data exception. The rightmost four bits may specify either a sign code or a decimal-digit code. Access and data exceptions and PER zero-address-detection events are recognized only for those bytes in the second operand which are actually required.

The result is obtained as if both operands were processed left to right one byte at a time. Overlapping pattern and source fields give unpredictable results.

During the editing process, each byte of the pattern is affected in one of three ways:

1. It is left unchanged.
2. It is replaced by a source digit expanded to the zoned format.
3. It is replaced by the first byte in the pattern, called the fill byte.

Which of the three actions takes place is determined by one or more of the following: the type of the pattern byte, the state of the significance indicator, and whether the source digit examined is zero.

**Pattern Bytes:** There are four types of pattern bytes: digit selector, significance starter, field separator, and message byte. Their coding is as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Code (Binary)</th>
<th>Code (Hex)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digit Selector</td>
<td>0010 0000</td>
<td>20</td>
</tr>
<tr>
<td>Significance starter</td>
<td>0010 0001</td>
<td>21</td>
</tr>
<tr>
<td>Field separator</td>
<td>0010 0010</td>
<td>22</td>
</tr>
<tr>
<td>Message byte</td>
<td>Any other</td>
<td>Any other</td>
</tr>
</tbody>
</table>

The detection of either a digit selector or a significance starter in the pattern causes an examination to be made of the significance indicator and of a source digit. As a result, either the expanded source digit or the fill byte, as appropriate, is selected to replace the pattern byte. Additionally, encountering a digit selector or a significance starter may cause the significance indicator to be changed.

The field separator identifies individual fields in a multiple-field editing operation. It is always replaced in the result by the fill byte, and the significance indicator is always off after the field separator is encountered.
Message bytes in the pattern are either replaced by the fill byte or remain unchanged in the result, depending on the state of the significance indicator. They may thus be used for padding, punctuation, or text in the significant portion of a field or for the insertion of sign-dependent symbols.

**Fill Byte:** The first byte of the pattern is used as the fill byte. The fill byte can have any code and may concurrently specify a control function. If this byte is a digit selector or significance starter, the indicated editing action is taken after the code has been assigned to the fill byte.

**Source Digits:** Each time a digit selector or significance starter is encountered in the pattern, a new source digit is examined for placement in the pattern field. Either the source digit is disregarded, or it is expanded to the zoned format, by appending the zone code 1111 on the left, and stored in place of the pattern byte.

Execution is as if the source digits were selected one byte at a time. The leftmost four bits of each byte are examined first, and the rightmost four bits, when they represent a decimal-digit code, remain available for the next pattern byte that calls for a digit examination. When the leftmost four bits contain an invalid digit code, a general-operand data exception is recognized, and the operation is either suppressed or terminated.

At the time the left digit of a source byte is examined, the rightmost four bits are checked for the existence of a sign code. When a sign code is encountered in the rightmost four bit positions, these bits are not treated as a decimal-digit code, and a new source byte is fetched from storage when the next pattern byte calls for a source-digit examination.

When the pattern contains no digit selector or significance starter, no source bytes are fetched and examined.

**Significance Indicator:** The significance indicator is turned on or off to indicate the significance or non-significance, respectively, of subsequent source digits or message bytes. Significant source digits replace their corresponding digit selectors or significance starters in the result. Significant message bytes remain unchanged in the result.

The significance indicator, by its on or off state, indicates also the negative or positive value, respectively, of a completed source field and is used as one factor in the setting of the condition code.

The significance indicator is set to off at the start of the editing operation, after a field separator is encountered, or after a source byte is examined that has a plus code in the rightmost four bit positions.

The significance indicator is set to on when a significance starter is encountered whose source digit is a valid decimal digit, or when a digit selector is encountered whose source digit is a nonzero decimal digit, provided that in both instances the source byte does not have a plus code in the rightmost four bit positions.

In all other situations, the significance indicator is not changed. A minus sign code has no effect on the significance indicator.

**Result Bytes:** The result of an editing operation replaces and is equal in length to the pattern. It is composed of pattern bytes, fill bytes, and zoned source digits.

If the pattern byte is a message byte and the significance indicator is on, the message byte remains unchanged in the result. If the pattern byte is a field separator or if the significance indicator is off when a message byte is encountered in the pattern, the fill byte replaces the pattern byte in the result.

If the digit selector or significance starter is encountered in the pattern with the significance indicator off and the source digit zero, the source digit is considered nonsignificant, and the fill byte replaces the pattern byte. If the digit selector or significance starter is encountered either with the significance indicator on or with a nonzero decimal source digit, then the source digit (a) is considered significant, (b) is changed to the zoned format, and (c) replaces the pattern byte in the result. Examination of the significance indicator occurs prior to the processing of the source digit (which might change the significance indicator).

**Condition Code:** The sign and magnitude of the last field edited are used to set the condition code. The term “last field” refers to those source digits, if any, in the second operand selected by digit selectors or significance starters after the last field separator; if the pattern contains no field separator, there is only one field, which is considered to be the last field.
If no such source digits are selected, the last field is considered to be of zero length.

Condition code 0 is set when the last field edited is zero or of zero length.

Condition code 1 is set when the last field edited is nonzero and the significance indicator is on. (This indicates a result less than zero if the last source byte examined contained a sign code in the rightmost four bits.)

Condition code 2 is set when the last field edited is nonzero and the significance indicator is off. (This indicates a result greater than zero if the last source byte examined contained a sign code in the rightmost four bits.)

For the purposes of setting condition codes 2 or 3, the significance indicator is examined after the processing of the last source digit.

Figure 8-3 on page 8-10 summarizes the functions of the EDIT and EDIT AND MARK operations. The leftmost four columns list all the significant combinations of the four conditions that can be encountered in the execution of an editing operation. The rightmost two columns list the action taken for each case — the type of byte placed in the result field and the new setting of the significance indicator.

Explanation:
* No effect on result byte or on new state of significance indicator.
** Not applicable because source is not examined.
# For EDIT AND MARK only, the address of the rightmost such result byte is placed in general register 1.

Figure 8-3. Summary of Editing Functions

**Resulting Condition Code:**

0 Last field zero or zero length
1 Last field less than zero
2 Last field greater than zero
3 --

**Program Exceptions:**

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Transaction constraint

**Programming Notes:**

1. Examples of the use of the EDIT instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. Editing includes sign and punctuation control, and the suppression of leading zeros by replacing them with blanks, or the protection of leading zeros from malicious alteration by replacing them with asterisks or other characters. It also facilitates programmed blanking of all-zero fields. Several fields may be edited in one operation, and numeric information may be combined with text.

3. In most cases, the source is shorter than the pattern because each four-bit source digit produces an eight-bit byte in the result.

4. The total number of digit selectors and significance starters in the pattern always equals the number of source digits edited.

5. If the fill byte is a blank, if no significance starter exists in the pattern, and if the source digit examined for each digit selector is zero, the editing operation blanks the result field.

6. The resulting condition code indicates whether or not the last field is all zeros and, if nonzero, reflects the state of the significance indicator. The significance indicator reflects the sign of the source field only if the last source byte examined contains a sign code in the rightmost four bits. For multiple-field editing operations, the condition code reflects the sign and value only of the field following the last field separator.

7. Significant performance degradation is possible when the second-operand address of an EDIT instruction designates a location that is closer to the left of an access boundary than the length of the first operand of that instruction (for the purposes of this discussion, an access boundary is 4 K-bytes, except when fetch-protection override applies in which case it is 2 K-bytes). This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary. The second operand of EDIT, while normally shorter than the first operand, can in the extreme case have the same length as the first.

**EDIT AND MARK**

<table>
<thead>
<tr>
<th>EDMK</th>
<th>D1(L,B1),D2(B2)</th>
<th>[SS-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DF'</td>
<td>L</td>
<td>B1</td>
</tr>
</tbody>
</table>

0 8 16 20 32 36 47

The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The address of the first significant result byte of the rightmost (or only) field is inserted in general register 1. The edited result replaces the pattern.

EDIT AND MARK is identical to EDIT, except for the additional function of inserting the address of the result byte in general register 1 if the result byte is a zoned source digit and the significance indicator was off before the examination of the source bytes. If no result byte meets the criteria, general register 1 remains unchanged; if more than one result byte meets the criteria, the address of the rightmost such result byte is inserted.

In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of the register are not changed. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of the register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

The contents of access register 1 remain unchanged.

See Figure 8-3 on page 8-10 for a summary of the EDIT and EDIT AND MARK operations.

**Resulting Condition Code:**

0 Last field zero or zero length
1 Last field less than zero
2 Last field greater than zero
3 --

**Program Exceptions:**

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Transaction constraint

**Programming Notes:**

1. Examples of the use of the EDIT AND MARK instruction are given Appendix A, “Number Representation and Instruction-Use Examples.”
2. EDIT AND MARK facilitates the programming of floating currency-symbol insertion. Using appropriate source and pattern data, the address inserted in general register 1 is one greater than the address where a floating currency-sign would be inserted.

3. No address is inserted in general register 1 when the significance indicator is turned on as a result of encountering a significance starter with the corresponding source digit zero. To ensure that general register 1 contains a proper address when this occurs, the address of the pattern byte that immediately follows the appropriate significance starter could be placed in the register beforehand.

4. When multiple fields are edited with one execution of the EDIT AND MARK instruction, the address, if any, inserted in general register 1 applies to the rightmost field edited for which the criteria were met.

5. See also the programming note under EDIT regarding performance degradation due to a possible trial execution.

MULTIPLY DECIMAL

The product of the first operand (the multiplicand) and the second operand (the multiplier) is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

The multiplier length cannot exceed 15 digits and sign (L2 not greater than seven) and must be less than the multiplicand length (L2 less than L1); otherwise, a specification exception is recognized.

The multiplicand must have at least as many bytes of leftmost zeros as the number of bytes in the multiplier; otherwise, a general-operand data exception is recognized. This restriction ensures that no product overflow occurs.

The multiplicand, multiplier, and product are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the multiplicand and multiplier are checked for validity. The sign of the product is determined by the rules of algebra from the multiplier and multiplicand signs, even if one or both operands are zeros.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Specification
- Transaction constraint

**Programming Notes:**
1. An example of the use of the MULTIPLY DECIMAL instruction is given Appendix A, “Number Representation and Instruction-Use Examples.”
2. The product cannot exceed 31 digits and sign. The leftmost digit of the product is always zero.

SHIFT AND ROUND DECIMAL

The first operand is shifted in the direction and for the number of decimal-digit positions specified by the second-operand address, and, when shifting to the right is specified, the absolute value of the first operand is rounded by the rounding digit, I3. The first operand and the result are in the signed-packed-decimal format.

The first operand is considered to be in the signed-packed-decimal format. Only its digit portion is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result replaces the first operand. Nothing is stored outside of the specified first-operand location.

The second-operand address, specified by the \( B_2 \) and \( D_2 \) fields, is not used to address data; bits 58-63 of that address are the shift value, and the leftmost bits of the address are ignored.
The shift value is a six-bit signed binary integer, indicating the direction and the number of decimal-digit positions to be shifted. Positive shift values specify shifting to the left. Negative shift values, which are represented in two's complement notation, specify shifting to the right. The following are examples of the interpretation of shift values:

<table>
<thead>
<tr>
<th>Shift Value (Binary)</th>
<th>Amount and Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>011111</td>
<td>31 digits to the left</td>
</tr>
<tr>
<td>000001</td>
<td>One digit to the left</td>
</tr>
<tr>
<td>000000</td>
<td>No shift</td>
</tr>
<tr>
<td>111111</td>
<td>One digit to the right</td>
</tr>
<tr>
<td>100000</td>
<td>32 digits to the right</td>
</tr>
</tbody>
</table>

For a right shift, the I3 field, bits 12-15 of the instruction, is used as a decimal rounding digit. The first operand, which is treated as positive by ignoring the sign, is rounded by decimally adding the rounding digit to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The result of this addition is then shifted right. Except for validity checking and the participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs. Overflow cannot occur for a right shift, with or without rounding, or when no shifting is specified.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, the sign of the result is the same as the original sign but with the preferred sign code.

A general-operand data exception is recognized when the first operand does not have valid sign and digit codes or when the rounding digit is not a valid digit code. The validity of the first-operand codes is checked even when no shift is specified, and the validity of the rounding digit is checked even when no addition for rounding takes place.

**Resulting Condition Code:**

0  Result zero; no overflow  
1  Result less than zero; no overflow  
2  Result greater than zero; no overflow

**Program Exceptions:**

- Access (fetch and store, operand 1)  
- Data with DXC 0, general operand  
- Decimal overflow  
- Transaction constraint

**Programming Notes:**

1. Examples of the use of the SHIFT AND ROUND DECIMAL instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. SHIFT AND ROUND DECIMAL can be used for shifting up to 31 digit positions left and up to 32 digit positions right. This is sufficient to clear all digits of any decimal number even with rounding.

3. For right shifts, the rounding digit 5 provides conventional rounding of the result. The rounding digit 0 specifies truncation without rounding.

4. When the B2 field is zero, the six-bit shift value is obtained directly from bits 42-47 of the instruction.

**SUBTRACT DECIMAL**

The second operand is subtracted from the first operand, and the resulting difference is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

**SUBTRACT DECIMAL**

```
SP  D1(L1,B1),D2(L2,B2) [SS-b]
```

The second operand is subtracted from the first operand, and the resulting difference is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

**SUBTRACT DECIMAL**

```
SP  D1(L1,B1),D2(L2,B2) [SS-b]
```

The second operand is subtracted from the first operand, and the resulting difference is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

**Resulting Condition Code:**

0  Result zero; no overflow  
1  Result less than zero; no overflow  
2  Result greater than zero; no overlap  
3  Overflow

**Program Exceptions:**
• Access (fetch, operand 2; fetch and store, operand 1)
• Data with DXC 0, general operand
• Decimal overflow
• Transaction constraint

TEST DECIMAL

The first operand is tested for valid decimal digits and a valid sign code, and the result is indicated in the condition code. The operand is in the signed-packed-decimal format.

Resulting Condition Code:
0   All digit codes and the sign valid
1   Sign invalid
2   At least one digit code invalid
3   Sign invalid and at least one digit code invalid

Program Exceptions:
• Access (fetch, operand 1)
• Operation (if the extended-translation facility 2 is not installed)
• Transaction constraint

ZERO AND ADD

The second operand is placed at the first-operand location. The operation is equivalent to an addition to zero. The operand and result are in the signed-packed-decimal format.

Only the second operand is checked for valid sign and digit codes. Extra zeros are supplied on the left for the shorter operand if needed.

If the first operand is too short to contain all leftmost nonzero digits of the second operand, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given the sign of the second operand but with the preferred sign code.

The two operands may overlap, provided the rightmost byte of the first operand is coincident with or to the right of the rightmost byte of the second operand. In this case, the result is obtained as if the operands were processed right to left. When the operands overlap and the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, then, depending on the model, either a general-operand data exception is recognized or the result is obtained as if the entire second operand were fetched before any byte of the result is stored.

Resulting Condition Code:
0   Result zero; no overflow
1   Result less than zero; no overflow
2   Result greater than zero; no overflow
3   Overflow

Program Exceptions:
• Access (fetch, operand 2; store, operand 1)
• Data with DXC 0, general operand
• Decimal overflow
• Transaction constraint

Programming Note: An example of the use of the ZERO AND ADD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

Floating-point instructions are used to perform calculations on operands having a wide range of magnitude and to obtain results scaled to preserve precision.

Floating-point operands have formats based on three radices: 2, 10, or 16. These radix values lead to the terminology “binary,” “decimal,” and “hexadecimal” floating point (BFP, DFP, and HFP), respectively. The formats are also based on three operand lengths: short (32 bits), long (64 bits), and extended (128 bits). Short operands require less storage than long or extended operands. On the other hand, long and extended operands permit greater precision in computation.

Sign Bit
All floating-point data have a sign bit. The sign bit is zero for plus and one for minus.

Finite Floating-Point Numbers
A finite floating-point number has three components: a sign bit, an exponent, and a significand. The magnitude (an unsigned value) of the number is the product of the significand and the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The significand consists of a string of digits, where each digit is an integral value from zero to one less than the radix (2, 10, or 16). (Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The number of digit positions in the significand is called the precision of the floating-point number. The significand has an implied radix point, which, depending on the view, may be considered to be on the left, to the right of the leftmost digit, on the right, or elsewhere.

The exponent, a signed value, is represented as an unsigned binary value by adding a bias; the result, for BFP and DFP, is called the biased exponent; for HFP, it is called the characteristic. The value of the bias depends on the view. In the fraction view, the radix point is considered to be the left of the significand. In the left-units view, the radix point is considered to be to the right of the leftmost digit. In the right-units view, the radix point is considered to be on the right of the significand. By choosing the appropriate bias, any finite floating-point number can be considered in any of these views, or even in another view. For the first three of these views, the bias is called the fraction-view bias, left-units-view bias, and right-units-view bias, respectively. Except where otherwise indicated, HFP is defined in terms of the fraction view, BFP terms of the left-units view, and DFP in terms of the right-units view.

For HFP, the significand is considered to be a fraction with the implied radix point on the left. In this view, the significand is referred to as the fraction. For BFP, the significand consists of an implicit unit digit to the left of an implied radix point and an explicit fraction field to the right. For DFP, the significand is considered to be an integer with the implied radix point on the right.

Infinities
BFP and DFP data include an infinite numeric datum, called infinity. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. An infinity has a sign bit. In comparisons, infinities of the same sign compare equal, \(+\infty\) compares greater than any finite number, and \(-\infty\) compares less than any finite number.

Not-A-Number (NaN)
BFP and DFP data types include a nonnumeric datum, called not-a-number (or NaN). A NaN is produced in place of a numeric result after an invalid operation when there is no IEEE trap action. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area. A NaN has a sign bit, a NaN-type bit, and a payload.

Signaling and Quiet NaNs
There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the NaN-type bit.

For BFP, the NaN-type bit is the leftmost bit of the fraction field, and is called the QNaN bit: a BFP NaN is an SNaN, or a QNaN, depending on whether the QNaN bit is zero, or one, respectively. For DFP, the
NaN-type bit is in bit position 6 in all three formats, and is called the SNaN bit: a DFP NaN is a QNaN, or an SNaN, depending on whether the SNaN bit is zero, or one, respectively.

Payload
NaNs include diagnostic information called the payload. For BFP, the payload has two fewer bits than the precision and is considered to be a left-aligned bit-reversed binary integer. For DFP, the payload has one fewer digit than the precision and is considered to be a right-aligned decimal integer.

For both BFP and DFP the payload of a NaN is considered to be an unsigned integer. Let \( p \) represent the precision, in digits, of a particular format. For DFP, bit 6 of the format is called the SNaN bit and the \( p-1 \) digits in the trailing significand field are the numeric value of the payload. For BFP, the leftmost bit in the fraction field is called the QNaN bit and the remaining \( p-2 \) bits of the fraction field are the numeric value of the payload.

The numeric value of the BFP NaN payload is bit-reversed. That is, the first bit to the right of the QNaN bit is considered to have a value of one, the next bit a value of two, and so on, with each bit having a value of twice the value of the bit to its left.

Propagation of NaNs
Normally, QNaNs are just propagated during computations so that they will remain visible at the end; while an SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by inverting the NaN-type bit, and setting the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

Default QNaN
A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a payload of zeros.

Programming Notes:
1. The program can generate and assign values to the payload of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format truncates digits from the payload. For BFP, bits are truncated on the right; for DFP, digits are truncated on the left. For the PFPO-convert-floating-point-radix operation, payloads are preserved, except that payloads larger than the capacity of the target format are replaced by the default QNaN (payload zero).

2. Depending on the application, the program may or may not desire that an SNaN signal the IEEE invalid-operation exception. The sign-handling instructions LOAD COMPLEMENT, LOAD NEGATIVE, and LOAD POSITIVE do not signal the invalid-operation exception but, instead, treat SNaNs like any other data. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option.

3. The instructions LOAD LENGTHENED and LOAD ROUNDED change the precision of a floating-point datum. The BFP versions of these instructions signal the invalid-operation exception when the operand is an SNaN. The DFP instructions have a modifier bit to control whether the exception is signaled.

Floating-Point Number Representations

Hexadecimal-Floating-Point (HFP)

Hexadecimal-floating-point (HFP) operands have formats which provide for exponents that specify powers of the radix 16 and significands that are hexadecimal numbers. The exponent range is the same for the short, long, and extended formats.

The results of most operations on HFP data are truncated to fit into the target format, but there are instructions available to round the result when converting to a narrower format. Additionally, the PERFORM FLOATING POINT OPERATION instruction provides rounding methods when converting to an HFP format from BFP or DFP.

For HFP operands, the implicit unit digit of the significand is always zero. Since the value of the significand and fraction are the same, HFP operations are
described in terms of the fraction, and the term significand is not used.

Either normalized or unnormalized numbers may be used as operands for any HFP or DFP operation, where, for HFP, a normalized number is one having a nonzero leftmost fraction digit, or, for DFP, a normalized number is one having a nonzero leftmost significand digit. Most HFP instructions generate normalized results for greatest precision. HFP add and subtract instructions that generate unnormalized results are also available.

**Binary Floating-Point (BFP)**

Binary-floating-point (BFP) operands have formats which provide for exponents that specify powers of the radix 2 and significands that are binary numbers. The exponent range differs for different formats, the range being greater for the longer formats. In the long and extended formats, the exponent range is significantly greater for BFP data than for HFP data.

The results of operations performed on BFP data are rounded automatically to fit into the target format. The manner of rounding is determined by a program-settable BFP rounding mode; however, explicit rounding modes may be specified in various BFP instructions.

There are no unnormalized operands for BFP operations. For normal BFP numbers, the implicit unit digit of the significand is one. For values too small in magnitude to be represented in normalized form, the implicit unit digit is zero. These numbers are called subnormal numbers. Unlike the HFP and DFP formats, where the same value can have multiple representations in a given format because of the possibility of unnormalized numbers, the BFP format does not allow such redundancy.

**Decimal Floating-Point (DFP)**

Decimal-floating-point (DFP) operands have formats which provide for exponents that specify powers of the radix 10 and significands that are decimal numbers. The exponent range differs for different formats, the range being greater for the longer formats. The exponent range is greater for DFP data than for BFP data.

The results of operations performed on DFP data are rounded automatically to fit into the target format. The manner of rounding is determined by a program-settable DFP rounding mode; however, explicit rounding modes may be specified in various DFP instructions.

Like HFP, DFP numbers can be normalized or unnormalized. Either normalized or unnormalized numbers may be used as operands for any DFP operation. For DFP, a normalized number is one having a nonzero leftmost significand digit. Because of the possibility of unnormalized numbers, the same value can have multiple representations in a given DFP format. The representations having the same value are called members of a cohort. Unlike HFP, DFP instructions generate normalized results for greater precision only when the result is inexact. When the result is exact, most DFP instructions produce a value in the form that preserves information called the quantum.

**Canonical DFP Data**

A canonical DFP number has only canonical declets, that is, the digits in the trailing-significand field are encoded using only the preferred DPD codes. A canonical DFP infinity has bit 6 and all bits to the right of this in the format set to zeros. A canonical DFP NaN has zeros in all bits to the right of the NaN-type bit in the combination field and only canonical declets in the trailing significand field.

Noncanonical DFP numbers, infinities, and NaNs are accepted as source operands, but all DFP results are canonical.

---

1. Subnormal numbers were previously called denormalized numbers.
Comparison of Floating-Point Number Representations

Explanation:
- **Dmin**: Smallest (in magnitude) representable subnormal (BFP or DFP) or nonzero unnormalized (HFP) number.
- **Nmax**: Largest (in magnitude) representable number.
- **Nmin**: Smallest (in magnitude) representable normal (BFP or DFP) or normalized (HFP) number.

Values are decimal approximations for all of the HFP, BFP, and DFP formats.

Figure 9-1. Decimal Approximations of Number Ranges for HFP, BFP, and DFP Formats

Equivalent Floating-Point Number Representations
The exponent of an HFP number is represented in the format as an unsigned seven-bit binary integer called the characteristic. The characteristic is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63.

The exponent of a BFP or DFP datum is represented in the format as an unsigned binary integer called the biased exponent. The biased exponent is obtained by adding a bias to the exponent value. The number of bit positions containing the biased exponent, the value of the bias, and the exponent range depend on the data format (short, long, or extended) and are shown for the three formats in Figure 19-4 on page 19-3 and the three DFP formats in Figure 20-3 on page 20-6. Biased exponents are similar to the characteristics of the HFP format, except that, for BFP, special meanings are attached to biased exponents of all zeros and all ones. This is discussed in the section “Classes of BFP Data” on page 19-4.

In each of the three BFP or HFP formats, the binary or hexadecimal point of a number, respectively, is considered to be to the left of the leftmost fraction digit. To the left of the point there is an implied unit digit, which is considered to be zero for HFP numbers or, for BFP numbers, one for normal numbers and zero for zeros and subnormal numbers.

Figure 9-2 on page 9-6 and Figure 9-3 on page 9-7 give examples of the closest representation of the same numbers in the BFP, DFP, and HFP formats, with BFP and DFP values being rounded to nearest and HFP values being truncated.

The figures do not necessarily show the results of conversions exactly. Rounding errors may make a small difference. Also, Figure 9-2 on page 9-6 shows corresponding rounded short-format numbers, not the long HFP results of conversion from short BFP operands.

Figure 9-2. Examples of Floating-Point Numbers in Short Format
The resolution of a floating-point format may be described in terms of the spacing between adjacent representable numbers in the format. This is called an ulp (unit in the last place). Thus, for example, when rounding to nearest, the maximum error is 1/2 ulp. The magnitude of an ulp is directly related to the precision of the format. Another way to measure the resolution of the format in the vicinity of a particular value is in terms of relative spacing, which is simply the value of an ulp divided by the value of the number. Relative spacing may be converted to a form called effective width, which is very similar to precision. The effective width ($W_x$) for any particular normalized floating-point value, $v$, is defined as:

$$W_x(v) = \log_x(v/u)$$

</tr>
</tbody>
</table>

The distance between points Va and Vb (Vb-Va) represents a resolution of one part in a thousand; whereas, the distance between points Vb and Vc (Vc-Vb) represents a resolution of one part in a hundred. In the first case, the effective width is three digits; in the second case, it is only two digits. For other values in the format, the effective width lies between these two extremes.

**Floating-Point Data in Storage**

All floating-point data formats appear in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also the section “Storage Addressing” on page 3-2.)

Most of the floating-point instructions are defined in detail in this publication in Chapter 18, “Hexadecimal-Floating-Point Instructions,” Chapter 19, “Binary-Floating-Point Instructions,” and Chapter 20, “Decimal-Floating-Point Instructions.” This chapter, Chapter 9, defines in detail instructions called floating-point-support (FPS) instructions. The FPS instructions either have operands that may be in any floating-point format or have the function of converting between formats. This chapter also provides summary information about all of the floating-point instructions.

**Registers And Controls**

**Floating-Point Registers**

All floating-point instructions (FPS, BFP, DFP, and HFP) use the same 16 floating-point registers. The floating-point registers are identified by the numbers 0-15 and are designated by a four-bit R field in float-
Floating-point instructions. Each floating-point register is 64 bits long and can contain either a short (32-bit) or a long (64-bit) floating-point operand.

A short floating-point datum requires only the leftmost 32 bit positions of a floating-point register. The rightmost 32 bit positions of the register are ignored when the register is the source of an operand in the short format, and they remain unchanged when a short result is placed in the register.

A datum in the extended (128-bit) format occupies a register pair. Register pairs are formed by coupling the 16 registers as follows: 0 and 2, 4 and 6, 8 and 10, 12 and 14, 1 and 3, 5 and 7, 9 and 11, and 13 and 15.

Each of the eight pairs is referred to by the number of the lower-numbered register of the pair.

Additional Floating-Point (AFP) Registers
Floating-point registers 0, 2, 4, and 6 are ones that were originally available on ESA/390 models. The remaining 12 floating-point registers (1, 3, 5, and 7-15) were added to ESA/390 and are referred to as the additional floating-point (AFP) registers. The AFP registers can be used only if bit 45 of control register 0, the AFP-register-control bit, is one. Attempting to use an AFP register when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1).

Valid Floating-Point-Register Designations
Any installed register may be designated by an instruction to specify the register location of a short or long floating-point operand.

An instruction specifying a floating-point operand in the extended format must designate register 0, 1, 4, 5, 8, 9, 12, or 13; otherwise, a specification exception is recognized.

Floating-Point-Control (FPC) Register
The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. An overview of the FPC register is shown in Figure 9-5.

Details are shown in Figure 9-6 and in Figure 9-8. (In Figure 9-6, the abbreviations “IM” and “SF” are based on the terms “interruption mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

Figure 9-5. FPC Register Overview

Figure 9-6. FPC-Register Bit Assignments
When the floating-point extension facility is installed, the FPC register contains six IEEE mask bits and six IEEE flag bits that each correspond to one of the six IEEE exceptions that may be recognized when an IEEE computational instruction is executed. When the floating-point extension facility is not installed, the quantum exception is not recognized; the mask bit FPC 0.5 and the status flag bit FPC 1.5 corresponding to the quantum exception are unsupported and are zeros.

The mask bits, when one, in the FPC register cause an interruption to occur if an exception is recognized. If the mask bit for an exception is zero, the recognition of the exception causes the corresponding flag bit to be set to one. Thus, a flag bit indicates whether the corresponding exception has been recognized at least once since the program last set the flag bit to zero. Except for PFPO, the mask bits are ignored, and the flag bits remain unchanged, when exceptions are recognized for floating-point-support (FPS) and HFP instructions.

The IEEE flag bits in the FPC register are set to zero only by explicit program action, initial CPU reset, clear reset, or power-on reset.

Note: The quantum exception is not part of the IEEE Standard 754-2008 (see Reference [17.] on page xxviii). However, since this data exception with its mask and status flag in the FPC is handled very much like the five IEEE exceptions, this architecture lists the quantum exception among the IEEE exceptions.

**FPC DXC Byte**

Byte 2 of the FPC register contains the data-exception code (DXC), which is an eight-bit code indicating the specific cause of a data exception. When the AFP-register-control bit, bit 45 of control register 0, is one and a program interruption causes the DXC to be placed at real location 147, the DXC is also placed in the DXC field of the FPC register. The DXC field in the FPC register remains unchanged when the AFP-register-control bit is zero or when any other program exception is reported. The DXC is described in "Data-Exception Code (DXC)" on page 6-16.

The DXC is a code, meaning it should be treated as an integer rather than as individual bits. However, when bits 6 and 7 are zero, bits 0-5 are bit significant; bits 0-4 (i, z, o, u, and x) are trap flags and correspond to the same bits in bytes 0 and 1 of the FPC register (IEEE masks and IEEE flags), and bit 5 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

When the floating-point extension facility is installed, DXC bit 5 (q) is also the quantum-exception trap flag. The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit.

**Operations on the FPC Register**

The following unprivileged instructions allow problem-state programs to operate on the FPC register:

```
EXTRACT FPC (DXC 2)
LOAD FPC (DXC 2)
```
LOAD FPC AND SIGNAL (DXC 3)
SET BFP ROUNDDING MODE (DXC 2)
SET DFP ROUNDDING MODE (DXC 3)
SET FPC (DXC 2)
SET FPC AND SIGNAL (DXC 3)
STORE FPC (DXC 2)

These instructions are subject to the AFP-register-control bit, bit 45 of control register 0. An attempt to execute any of the above instructions when the AFP-register-control bit is zero results in a data exception. The term (DXC 2) or (DXC 3) after the name indicates the type of exception: that is, BFP-instruction data exception, (DXC 2), or DFP-instruction data exception, (DXC 3), respectively.

Programming Note: The use of DXC 2 and DXC 3 for these floating-point-support (FPS) instructions is rather arbitrary, but assuming a valid operating system, these exceptions are never reported to the user, as the operating system will set bit 45 of control register 0 to one and re-issue the instruction.

AFP-Register-Control Bit

Bit 45 of control register 0 is the AFP-register-control bit. The AFP registers, the BFP instructions, the DFP instructions, and PFPO can be used successfully only when the AFP-register-control bit is one. Attempting to use one of the 12 additional floating-point registers or executing PFPO when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1). Attempting to execute any BFP instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception (DXC 2). Attempting to execute any DFP instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception (DXC 3).

DXC 2 and 3 are mutually exclusive and are of higher priority than any other DXC. Thus, for example, DXC 2 (BFP instruction) takes precedence over any IEEE exception; and DXC 3 (DFP instruction) takes precedence over any IEEE exception. As another example, if the conditions for both DXC 3 (DFP instruction) and DXC 1 (AFP register) exist, DXC 3 is reported.

If the conditions for both a data exception and a specification exception exist, it is unpredictable which exception is reported.

The initial value of the AFP-register-control bit is zero.

IEEE Computational Operations

Note: The following section primarily discusses the BFP and DFP formats, however the topics on rounding also discuss the HFP format, as indicated in the text.

Instructions which operate on BFP or DFP source operands or produce BFP or DFP results and recognize IEEE exceptions are called IEEE computational operations, and the associated operands and results are sometimes referred to as IEEE operands and IEEE results, respectively.

Execution of IEEE computational operations normally follows a certain pattern. Source operands are first tested for special cases and then processed to form a result. The priority for testing of special cases is SNaN, QNaN, infinity, and then finite number.

If a source operand is an SNaN, an IEEE-invalid-operation exception is recognized; and, in the non-trap case, the result is set to the corresponding QNaN.

In the absence of a source SNaN, if a source operand is a QNaN the result is set to that QNaN.

Handling of the case when more than one source operand is a NaN is covered in the individual instruction descriptions.

In the absence of a NaN, if an operand is an infinity, special “infinity arithmetic” rules are followed to produce the result.

Programming Note: PERFORM FLOATING-POINT OPERATION is an IEEE computational operation.

Intermediate Values

In the normal case (when all source operands are finite numbers), first, a precise intermediate value is produced, then a rounded intermediate value. In the absence of trapped overflow and trapped underflow, the rounded intermediate value is used as the delivered value. For trapped overflow and trapped underflow, the rounded intermediate value is divided by a scale factor to produce a scaled value, which is used as the delivered value. Finally, the delivered value is placed in the target location. For DFP, since the
cohort for the delivered value may have multiple members, one member from the cohort must be selected. Selection is performed by choosing the member having a quantum closest to the preferred quantum (or for trapped overflow and trapped underflow, a scaled preferred quantum).

Precise Intermediate Value
Every IEEE computational operation producing a numeric result computes a value called the precise intermediate value. This is the value that would have been computed were both the precision and exponent range unbounded.

Precision-Rounded Value
Except when otherwise specified, the precise intermediate value is rounded to the precision of the target format, but with unbounded exponent range. This process is called target-precision-constrained rounding, and the value selected by this type of rounding is called the precision-rounded value.

Denormalized Value
For IEEE targets, when the IEEE-underflow trap is disabled and the tininess condition exists, the precise intermediate value is rounded to fit in the destination format (that is, with both precision and exponent range of the target format). This process is called denormalization rounding and the value selected by this type of rounding is called the denormalized value.

Functionally-Rounded Value
The instructions CONVERT TO FIXED, LOAD FP INTEGER, QUANTIZE, and REROUND, as an integral part of the function, take a source operand and modify it to fit in a subset of the destination format. This process is called functionally-constrained rounding and the value selected by this type of rounding is called the functionally-rounded value.

Rounded Intermediate Value
In any particular instance, only one of the three rounding processes is performed and the value selected (precision-rounded value, denormalized value, or functionally-rounded value) is generically referred to as the rounded intermediate value.

Scaled Value
For both overflow and underflow when the associated trap is enabled, the precision-rounded value is scaled to bring it into the representable exponent range of the target. This is called the scaled value and is derived as explained in the next section.

Scale Factor ($\Psi$)
IEEE-overflow trap action and IEEE-underflow trap action produce a scaled value using a scale factor. The scaled value ($z$) is computed from the precision-rounded value ($g$) using the scale factor ($\Psi$) as follows:

$$z = g \times \Psi$$

Unsigned Scaling Exponent ($\alpha$)
For BFP and DFP instructions, the scale factor ($\Psi$) is computed using the unsigned scaling exponent ($\alpha$) and different formulas are used for overflow and underflow.

For overflow:
$$\Psi = b^\alpha$$

For underflow:
$$\Psi = b^{-\alpha}$$

where $b$ is the radix of the target (2 for BFP and 10 for DFP). The unsigned scaling exponent ($\alpha$) depends on the type of operation and operand format.

For all BFP operations except LOAD ROUNDED, $\alpha$ depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For BFP LOAD ROUNDED, $\alpha$ depends on the source format, and is 512 for long and 8192 for extended.

For all DFP operations except LOAD ROUNDED, $\alpha$ depends on the target format and is 576 for long and 9216 for extended. For DFP LOAD ROUNDED, $\alpha$ depends on the source format, and is 192 for long and 3072 for extended.

Signed Scaling Exponent ($\Omega$)
For PFPO convert floating-point radix, the scale factor ($\Psi$) is computed using the signed scaling exponent ($\Omega$) and the formula for the scale factor ($\Psi$) is the same for overflow and underflow:

$$\Psi = b^\Omega$$

Where $b$ is the radix (2, 10, and 16) for BFP, DFP and HFP, respectively. Thus, for overflow, the signed scaling exponent ($\Omega$) is a positive value, and for underflow it is a negative value.
IEEE Rounding

Rounding takes an input value, and, using the effective rounding method, selects a value from a permissible set. The input value, considered to be infinitely-precise, may be an operand of an instruction or the numeric output from an arithmetic operation. The effective rounding method may be the current rounding method specified in the BFP-rounding-mode or DFP-rounding-mode field of the FPC register; or, for some instructions, an explicit rounding method is specified by a modifier field. For the PFPO-convert-floating-point-radix operation, rounding is specified by a field in an implicit register.

For target-precision-constrained rounding and denormalization rounding, the input is the precise intermediate value. For functionally-constrained rounding, the input is a source operand.

Permissible Set
Rounding selects a value from the permissible set. A permissible set is a set of values, and not representations; thus, for DFP, the selection of a member from the cohort is considered to be performed after rounding. A permissible set differs from the values representable in a particular format in the following ways:

1. A permissible set does not include infinity. Infinity is handled as a special case.
2. For target-precision-constrained rounding, the permissible set is considered to have an unbounded exponent range.
3. For denormalization rounding, the permissible set is limited to the values representable in a particular format.
4. For LOAD FP INTEGER, the permissible set contains only integral values.
5. For QUANTIZE, the permissible set is similar to LOAD FP INTEGER, containing only those values which are integral multiples of the requested quantum.
6. For REROUND, the permissible set contains only those values which can be represented within the requested precision.

Selection of Candidates
If a member of the permissible set is equal in value to the input value, then that member is selected; otherwise, two adjacent candidates with the same sign as the input value are chosen from the permissible set. One candidate, called TZ (toward zero), is the member of the permissible set nearest to and smaller in magnitude than the input value; the other candidate, called AZ (away from zero), is the member of the permissible set nearest to and larger in magnitude than the input value. Which of the two candidates is selected depends on the rounding method.

Ties
Three rounding methods depend on a condition called a “tie.” This condition exists when the two candidates are equidistant from the input value.

Voting Digit and Common-Rounding-Point View
Two rounding methods depend on the value of the voting digit of each candidate. (Each “digit” is an integral value from zero to one less than the radix. Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The voting digit is the units digit of the significand when considered in the common-rounding-point view.

Without changing the value of a floating-point number, the significand may be viewed with the implied radix point in different positions, provided a corresponding adjustment is made to the exponent. In the common-rounding-point view, an implied radix point (called the common rounding point) and an associated exponent are selected for the input value and the two candidates, TZ and AZ. The common-rounding point is selected to satisfy the following requirements:

1. The input value and the two candidates all have the same exponent.
2. The significand of TZ is equal to the significand of the input value truncated at the rounding point.
3. The significand of AZ is one greater in magnitude than the significand of TZ.

Rounding Methods
Figure 9-8 and Figure 9-7 on page 9-10 show the implicit rounding methods available for BFP and DFP operations respectively. The section “Explicit Rounding Methods” on page 9-16 describes rounding methods that may be explicitly specified in an instruction, overriding the implicit rounding method. The rounding methods are as follows:
**Round to nearest with ties to even:** The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one whose voting digit has an even value.

**Round toward 0:** The candidate that is smaller in magnitude is selected.

**Round toward +∞:** The candidate that is algebraically greater is selected.

**Round toward −∞:** The candidate that is algebraically less is selected.

**Round to nearest with ties away from 0:** The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is larger in magnitude.

**Round to nearest with ties toward 0:** The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is smaller in magnitude.

**Round away from 0:** The candidate that is greater in magnitude is selected.

**Round to prepare for shorter precision:** For a BFP or HFP permissible set, the candidate selected is the one whose voting digit has an odd value. For a DFP permissible set, the candidate that is smaller in magnitude is selected, unless its voting digit has a value of either 0 or 5; in that case, the candidate that is greater in magnitude is selected.

**Programming Notes:**

1. The two candidates are defined as: “nearest to and smaller” and “nearest to and larger”. Note that the simpler definition, “the two closest values,” is incorrect, as it is possible that the two closest values to the input value can be on the same side (toward zero). To illustrate this, Figure 9-9 on page 9-15 gives an example of rounding the integer value 10,000,003 to DFP short. Several members in the permissible set near this value are shown in three views: left-units view, right-units view, and integer view. The fourth column shows the distance of each member from the input value. In this example, the four closest members are all smaller in magnitude than the input value. Although the example is shown using DFP, corresponding examples can be shown for both BFP and HFP. In the extreme case, the number of members in the permissible set which are closer than candidate AZ, is 2, 10, and 16, for BFP, DFP, and HFP, respectively.

2. Except for rounding methods using the voting digit, rounding can normally be considered to be performed using values independent of the representation and the view. Figure 9-10 on page 9-15 is an example, using the instruction LOAD FP INTEGER, to illustrate the concepts of different representations, views, rounding point, common-rounding-point view, and voting digit. In the example, the input value (source operand) is 29.5 and the two candidates are 29 and 30. The figure shows all three of these values using the left-units, right-units, and common-rounding-point views in both decimal and binary representations. Note that as shown in the left-units and right-units view columns, the rightmost digit is odd for both TZ and AZ. (But as represented in all BFP formats, these values would have an even rightmost digit; and as represented in DFP formats, these values could have an even or odd rightmost digit, depending on the quantum.) The voting digit can be identified in the common-rounding-point view as the digit to the immediate left of the rounding point. In both the decimal and binary representations, candidate TZ has an odd voting digit and candidate AZ has an even voting digit.

LOAD FP INTEGER produces consistent results between decimal and binary for five of the six rounding methods currently supported by the BFP instruction; for the round-to-prepare-for-shorter-precision rounding method, this is not always the case. Figure 9-11 on page 9-16 shows results of LOAD FP INTEGER for several input values for all eight rounding methods. Only in the round-to-prepare-for-shorter-precision method are the results different for decimal and binary.

3. An example of LOAD ROUNDED (long to short DFP) is shown in Figure 9-12 on page 9-16. In this example, the integer 99,999,995 is rounded from DFP long to DFP short. The cohort for candidate TZ in this case, has only one member and is odd. The cohort of candidate AZ has seven members, one of which is odd and the other six are even. The common-rounding-point view makes it clear that in this case, candidate AZ should be considered to be even.
4. The rightmost digit and the voting digit of a candidate are not necessarily the same digit. Figure 9-13 on page 9-16 and Figure 9-14 on page 9-16 give two examples using the instruction REROUND (long DFP). In both examples, the requested significance is one (Result Digits=1). The input value is 95 in the first example and 150 in the second example. Note that candidate AZ in the first example is the same value as candidate TZ in the second example. In the first example, this member is considered to be even, and in the second example it is considered to be odd.

Figure 9-10. LOAD FP INTEGER - Decimal and Binary
Explicit Rounding Methods

The floating-point-support instruction CONVERT HFP TO BFP includes an M3 modifier field which can specify any of six rounding methods. One HFP instruction (CONVERT TO FIXED); three BFP instructions (CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER); and five DFP instructions (CONVERT TO FIXED, LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND) also include either an M3 modifier field or a similar M4 modifier field. When the floating-point extension facility is installed, four more BFP instructions (CONVERT FROM FIXED, CONVERT FROM LOGICAL, CONVERT TO LOGICAL, and LOAD ROUNDED) and seven more DFP instructions (ADD, CONVERT FROM FIXED, CONVERT FROM LOGICAL, CONVERT TO LOGICAL, DIVIDE, MULTIPLY, and SUBTRACT) also include an M3 or M4 modifier field.

The handling of an M3 or M4 value of zero depends on the type of instruction. For BFP instructions, an M3 or M4 value of zero causes rounding to be performed according to the current BFP rounding mode specified in the FPC register. For DFP instructions, an M3 or M4 value of zero causes rounding to be performed according to the current DFP rounding mode speci-

fied in the FPC register. The floating-point-support instruction CONVERT HFP TO BFP and the HFP instruction CONVERT TO FIXED treat an M3 value of zero the same as five; that is, round toward zero.

For PERFORM FLOATING POINT OPERATION (PFPO), any of the rounding methods described in this section may be explicitly specified, or the program may specify the current BFP or DFP rounding method (in the floating-point-control register). The program-specified rounding method is used by PFPO regardless of whether the target-operand format is BFP, DFP or HFP.

**Summary of Rounding Action**

Figure 9-15 on page 9-17 summarizes the rounding action for floating-point-support (FPS), BFP, DFP, and HFP instructions.

**Explanation:**

- **CBRM** Rounded according to current BFP rounding mode.
- **E** Result is exact, no rounding is required.
- **GD** Round using a guard digit; see the instruction definition. This is almost, but not quite, round toward 0.
- **M** Rounding is specified by a modifier field in the instruction. Five rounding methods are supported.
- **MA** Rounding is specified by a modifier field in the instruction. Six rounding methods are supported; current BFP rounding mode can also be specified.
- **MB** Rounding is specified by a modifier field in the instruction. When the floating-point extension facility is not installed, five rounding methods are supported; when the floating-point extension facility is installed, six rounding methods are supported; current BFP rounding mode can also be specified.
- **MBB** When the floating-point extension facility is not installed, rounding is specified by the current BFP rounding mode; four rounding modes are supported. When the floating-point extension facility is installed, rounding is specified by a modifier field in the instruction; six rounding modes are supported; current BFP rounding mode can also be specified.
- **MBD** Rounding is specified by a field in general register 0. Eight rounding methods are supported; current BFP rounding mode and current DFP rounding mode can also be specified.
- **MC** Rounding is specified by a modifier field in the instruction. When the floating-point extension facility is not installed, five rounding methods are supported; when the floating-point extension facility is installed, six rounding methods are supported; current BFP rounding mode cannot be specified.
- **MD** Rounding is specified by a modifier field in the instruction. Eight rounding methods are supported; current DFP rounding mode can also be specified.

*Figure 9-15. Comparison of Rounding Action (Part 2 of 3)*
This section defines handling of IEEE exceptions for most IEEE computational operations. For some instructions the action may differ from the general rules; including, for example, a special controls to suppress recognition of certain IEEE exceptions. These differences are described in the individual instruction descriptions.

The action taken for each IEEE exception is controlled by a mask bit in the FPC register. When an IEEE exception is recognized, one of two actions is taken:

- If the corresponding mask bit in the FPC register is zero, a default action, called IEEE nontrap action, is taken, as specified for each condition, and the corresponding flag bit in the FPC register is set to one. Program execution then continues normally.

- If the corresponding mask bit in the FPC register is one, an action, called IEEE trap action, is taken for that exception, a program interruption for a data exception occurs, and the operation is suppressed or completed, depending on the exception, and the data-exception code (DXC) assigned for that exception is provided. For PFPO, a control bit in GR0 can select alternate exception handling, where overflow or underflow can be reflected by completion with a distinguished condition code, avoiding the interruption.

### Concurrent IEEE Exceptions
IEEE-overflow or IEEE-underflow exception, IEEE-inexact exception, and quantum exception can coincide concurrently.

### IEEE Invalid Operation
An IEEE-invalid-operation exception is recognized when, in the execution of an IEEE computational operation, any of the following occurs:

1. An SNaN is encountered in an IEEE computational operation.
2. A QNaN is encountered in an unordered-signaling comparison (COMPARE AND SIGNAL with a QNaN operand).
3. An IEEE difference is undefined (addition of infinities of opposite sign, or subtraction of infinities of like sign).
4. An IEEE product is undefined (zero times infinity).
5. An IEEE quotient is undefined (DIVIDE instruction with both operands zero or both operands infinity).
6. A BFP remainder is undefined (DIVIDE TO INTEGER with a dividend of infinity or a divisor of zero).
7. A BFP square root is undefined (negative non-zero operand).
8. Any other IEEE computational operation whose result is either undefined or not representable in the target format.

Even though an invalid-operation condition exists, the exception is not recognized if recognition of the exception is suppressed by means of an IEEE-invalid-operation-exception control (XiC).

**IEEE-Invalid-Operation Nontrap Action:** IEEE-invalid-operation nontrap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed and the IEEE-invalid-operation flag bit in the FPC register is set to one. The result of the operation depends on the type of operation and the operands.

If the instruction performs a comparison, the comparison result is *unordered*.

If the instruction is one that produces an IEEE result and none of the operands is a NaN, the result is the default QNaN.

If the instruction is one that produces an IEEE result and one of the operands is a NaN, that operand becomes the result unchanged, except that an SNaN is first converted to the corresponding QNaN and, for DFP, NaNs are canonicalized.

**IEEE-Invalid-Operation Trap Action:** IEEE-invalid-operation trap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

**IEEE Division-By-Zero**

An IEEE-division-by-zero exception is recognized when in IEEE division the divisor is zero and the dividend is a nonzero finite number.

**IEEE-Division-By-Zero Nontrap Action:** IEEE-division-by-zero nontrap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is zero. The operation is completed and the IEEE-division-by-zero flag bit in the FPC register is set to one. The result is set to an infinity with a sign that is the exclusive or of the dividend and divisor signs.

**IEEE-Division-By-Zero Trap Action:** IEEE-division-by-zero trap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 40 hex.

**IEEE Overflow**

An IEEE-overflow exception is recognized for an IEEE target when the precision-rounded value of an IEEE computational operation is greater in magnitude than the largest finite number (Nmax) representable in the target format.

**IEEE-Overflow Nontrap Action:** IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero. The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. The result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward $+\infty$, the result is $+\infty$, if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.
4. For round toward $-\infty$, the result is the largest positive finite number if the sign is plus or $-\infty$ if the sign is minus.

**IEEE-Overflow Trap Action:** IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero. The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.
The result of the operation is derived from the precision-rounded value, the scale factor, and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The delivered value is equal to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

**IEEE Underflow**

An IEEE-underflow exception is recognized for an IEEE target when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the denormalized value is inex-act, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The denormalized value is inexact if it is not equal to the precise intermediate value.

**IEEE-Underflow Nontrap Action:** IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one. The result is set to the denormalized value. For DFP targets, the cohort member with the smallest quantum is selected.

**IEEE-Underflow Trap Action:** IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 10, 18, or 1C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The result is set to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

**IEEE Inexact**

An IEEE-inexact exception is recognized when, for an IEEE computational operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

In the absence of an IEEE-invalid-operation condition, an inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs. When the inexact condition exists, the delivered value and the result are said to be inexact.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if recognition of the exception is suppressed by means of an IEEE-inexact-exception control (XxC) or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

**IEEE-Inexact Nontrap Action:** IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, except for QUANTIZE and REROUND, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and another IEEE nontrap action coincide, the operation is com-
pleted using the result specified for the other exception and the flag bits for both exceptions are set to one.

**IEEE-Inexact Trap Action:** IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

**Quantum Exception**
A quantum exception is recognized when floating-point extension facility is installed and when, for an IEEE computational operation, a quantum-exception condition exists, recognition of the exception is not suppressed, and none of IEEE-overflow trap action, IEEE-underflow trap action, and IEEE-inexact trap action occurs.

For computational operations except DIVIDE, LOAD FP INTEGER, PERFORM FLOATING-POINT OPERATION, QUANTIZE, and REROUND, a quantum-exception condition exists when the delivered DFP result is inexact, or when the delivered DFP result is exact and finite, but the delivered quantum is different from the preferred quantum.

For DIVIDE, a quantum-exception condition exists (1) when the delivered DFP result is inexact, or (2) when the dividend is a finite number and the divisor is an infinity, or (3) when the delivered DFP result is exact and is a finite number, the delivered quantum is the maximum quantum and is not the preferred quantum, and the rightmost significand digit is zero, or (4) when the delivered DFP result is exact and is a finite number, the delivered quantum is the minimum quantum and is greater than the preferred quantum. Note that the maximum quantum is the value of $1 \times 10^{Q_{\text{max}}}$ and the minimum quantum is the value of $1 \times 10^{Q_{\text{min}}}$, where $Q_{\text{max}}$ and $Q_{\text{min}}$ are the maximum and minimum right-units-view exponents, respectively.

For LOAD FP INTEGER, QUANTIZE, and REROUND, a quantum-exception condition exists when the delivered DFP result is a finite number, but the delivered quantum is different from the quantum of the source operand (the second operand for LOAD FP INTEGER, and the third operand for QUANTIZE and REROUND).

For PERFORM FLOATING-POINT OPERATION, a quantum-exception condition exists when the delivered quantum exceeds the preferred quantum of 1.

When floating-point extension facility is not installed, no quantum exception is recognized by executing any instruction.

Even though a quantum-exception condition exists, the exception is not recognized if recognition of the exception is suppressed or if IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action occurs. When a quantum-exception condition exists and the conditions for an IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action also apply, the trap action takes precedence and the quantum-exception condition is not reported.

**Quantum-Exception Nontrap Action:** Quantum-exception nontrap action occurs when the quantum exception is recognized and the quantum-exception flag bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the quantum-exception flag bit in the FPC register is set to one. The delivered result, if it is a finite number, is the cohort member with the quantum closest to the preferred quantum.

When a quantum-exception nontrap action and other concurrent IEEE nontrap actions coincide, the operation is completed using the result specified for the other exceptions and the flag bits for all exceptions are set to one.

**Quantum-Exception Trap Action:** Quantum-exception trap action occurs when the quantum-exception is recognized and the quantum-exception mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 04 hex.
In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value, and the delivered result, if it is a finite number, is the cohort member with the quantum closest to the preferred quantum.

When the quantum-exception trap action coincides with other IEEE nontrap actions, the operation is completed using the result specified for the other IEEE nontrap actions, the flag bits for the other IEEE nontrap exceptions are set to one, and the quantum-exception trap action takes place.

Programming Notes:

1. IEEE traps are reported by means of a program interruption for a data exception with a data-exception code. The use of data exception provides the application program with a convenient interface since this exception is one of the original 15 exceptions in the System/360 architecture and is supported by most control programs that support the z/Architecture.

2. ANSI/IEEE Standard 754-2008 includes recommendations for the trap handler (see Reference [17.] on page xxviii). When a system traps, the trap handler should be able to determine:
   a. Which exception(s) were recognized on this operation.
   b. The kind of operation that was being performed.
   c. The destination's format.
   d. For overflow, underflow, and inexact exceptions, the correctly rounded result, including information that might not fit in the destination's format.
   e. For invalid-operation and divide-by-zero exceptions, the operand values.

   Items a and d are supplied as part of the interruption action. Items b, c, and e can be obtained starting with the instruction address in the old PSW and from this finding the instruction (which indicates the operation and format) and then the operands.

3. The description of underflow is one of the most difficult parts of the standard to understand. This is because:

   a. The condition is described as two “correlated events” — “tininess” and “loss of accuracy”.
   b. For tininess, ANSI/IEEE Standard 754-2008 provides two options for detection: “after rounding” or “before rounding”.
   c. For loss of accuracy, ANSI/IEEE Standard 754-2008 provides two options for detection: “denormalization loss” or “inexact result”.
   d. Implementation of the trap is optional.
   e. The conditions to signal underflow are different depending on whether or not the trap is taken.

Each of the above items is discussed below.

a. Tininess refers to a nonzero number strictly between \( \pm N_{\text{min}} \). (All subnormal numbers are in this range.) Loss of accuracy means that the result cannot be represented exactly.

b. Detection of tininess after or before rounding differs only for the case when “rounding” would increase the magnitude of the result to exactly \( \pm N_{\text{min}} \). It must be noted, however, that the action which ANSI/IEEE Standard 754-2008 here calls “rounding” is not the rounding to produce the delivered result but rounding to compute an intermediate value having the precision of the result but “as though the exponent range were unbounded”. In fact, it is possible that the delivered result may not be tiny even though the intermediate value “after rounding” is tiny.

The option selected in the z/Architecture (and the Power architecture) is to detect tininess before rounding.

c. The difference between detection of loss of accuracy as a denormalization loss or as an inexact result can best be understood by considering three intermediate values: (1) the precise intermediate value, which has unbounded precision and unbounded exponent range, (2) the precision-rounded value, which is obtained by rounding the precise intermediate value to the precision of the target format but with unbounded exponent range, and (3) the denormalized value, which is obtained by rounding the precise intermediate value to the precision and expo-
nent range of the target format. An inexact condition is said to exist when the denormalized value (3) differs from the precise intermediate value (1). A denormalization loss is said to exist when the denormalized value (3) differs from the precision-rounded value (2). The two options differ in the case when the denormalized value (3) is equal to the precision-rounded value (2) but these are not equal to the precise intermediate value (1). Although ANSI/IEEE Standard 754-2008 uses the term “denormalization loss”, this condition includes a case in which the delivered result is normal.

The option selected in the z/Architecture (and the Power architecture) is to detect “loss of accuracy” as an inexact result.

d. Although ANSI/IEEE Standard 754-2008 does not require traps to be implemented for underflow or the other IEEE exceptions, it does state that “with each exception should be associated a trap under user control”. Since it also defines “should” as “that which is strongly recommended as being in keeping with the intent of the standard”, the z/Architecture provides traps by means of program interruptions.

e. When the underflow trap is enabled, underflow is to be signaled when tininess is detected regardless of loss of accuracy. When the underflow trap is not enabled, the underflow flag bit is to be set only when both tininess and loss of accuracy have been detected. Add and subtract can result in tiny or inexact results, but not both. Thus, when underflow is disabled, add and subtract never set the underflow flag bit.

Suppression of Certain IEEE Exceptions

For IEEE-invalid-operation exception, IEEE-inexact exception, and quantum exception, a special control may be provided for an IEEE computational operation to control whether recognition of the exception is suppressed. These controls are called IEEE-invalid-operation-exception control (XIC), IEEE-inexact-exception control (XxC), and quantum-exception control (XqC), respectively.

When a special control is zero, recognition of the designated exception is not suppressed, and normal handling of the exception is performed. And, when the exception is recognized, it further depends on the mask bit in the FPC register to determine if a trap action occurs.

When a special control is one, recognition of the designated exception is suppressed, and no trap or non-trap action for the exception occurs. This suppression affects only recognition of the exception for setting the status flag or for causing the trap action. For example, the IEEE-inexact-exception control (XxC) has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition. Also, it has no effect on recognition of a quantum exception, which may depend on the actual inexact condition regardless of the setting of IEEE-inexact-exception control.

Multiple exception controls may be provided to a single IEEE computational operation. In this case, the effect and setting of each control is independent of other controls. The specific exception controls that are provided are described in the individual instruction descriptions.

IEEE Same-Radix Format Conversion

The instructions LOAD LENGTHENED and LOAD ROUNDED perform conversions of data between the short, long, and extended formats, where the source and target operands are in the same radix. (For mixed-radix conversions, see PFPO.) For BFP and DFP formats, same-radix conversion involves adjustments to both the significand and the biased exponent. Conversion to a narrower format requires rounding of the significand and an IEEE-inexact exception may result.

When converting to a narrower format, adjustment of the biased exponent causes IEEE underflow if the resultant left-units-view (LUV) exponent would be less than the minimum LUV exponent (Emin), or IEEE overflow if the resultant LUV exponent would be greater than the maximum LUV exponent (Emax) for the new format.
Programming Notes:

1. When a NaN is converted to a narrower format, for BFP the appropriate number of payload bits on the right (or for DFP, the appropriate number of payload digits on the left) are simply dropped with no indication. This is unlike the conversion of nonzero numbers, where the loss of nonzero significand digits causes an IEEE-inexact exception. Thus, programs which encode NaN payloads for specific purposes must ensure that the distinguishing bits (or digits) are placed in the left part of the payload for BFP and in the right part of the payload for DFP.

2. For BFP, converting a NaN to a narrower format cannot turn the NaN into an infinity because an SNaN either causes an interruption or turns into a QNaN, and all QNaNs have a leftmost fraction bit of one.

IEEE Comparison

Comparisons are always exact and cannot cause IEEE-overflow or IEEE-underflow exceptions.

Comparison ignores the sign of zero, that is, +0 equals -0.

Infinities with like sign compare equal, that is, +∞ equals +∞, and -∞ equals -∞.

A NaN compares as unordered with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Two sets of instructions are provided: COMPARE and COMPARE AND SIGNAL. In the absence of QNaNs, these instructions work the same. These instructions work differently only when both of the following are true:

- Neither operand of the instruction is an SNaN
- At least one operand of the instruction is a QNaN

In this case, COMPARE simply sets condition code 3, but COMPARE AND SIGNAL recognizes the IEEE-invalid-operation exception. If any operand is an SNaN, both instructions recognize the IEEE-invalid-operation exception.

The action when the IEEE-invalid-operation exception is recognized depends on the IEEE-invalid-operation mask bit in the FPC register. If the mask bit is zero, then the instruction execution is completed by setting condition code 3, and the IEEE-invalid-operation flag in the FPC register is set to one. If the mask bit is one, then the exception is reported as a program interruption for a data exception with DXC 80 hex (IEEE invalid operation).

Programming Note: A compiler can select either COMPARE or COMPARE AND SIGNAL for a comparison, depending on whether it is desired that a QNaN to be recognized as an exception.

Condition Codes for IEEE Instructions

For those operations which set the condition code to indicate the value of an IEEE result, condition codes 0, 1, and 2 are set to indicate that the result is a zero of either sign, less than zero, or greater than zero, respectively. The condition-code setting depends only on an inspection of the rounded result. For comparison operations, condition codes 0, 1, and 2 indicate equal, low, or high, respectively. These settings are the same as for the HFP instructions.

Condition code 3 can also be set. After an arithmetic operation, condition code 3 indicates a NaN result of either sign. After a comparison, it indicates that a NaN was involved in the comparison (the unordered condition). See Figure 9-16.

Figure 9-16. Condition Codes

Instructions

The floating-point-support instructions and their mnemonics and operation codes are listed in Figure 9-17 on page 9-26. The figure indicates, in the column labeled “Characteristics”, the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.
All floating-point-support instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the floating-point instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for floating-point instructions to represent operand-format length, as follows:

D Long
E Short
X Extended

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using LOAD (short), for example, LER is the mnemonic and R1,R2 the operand designation.

Programming Notes:

1. The following additional floating-point-support instruction is available when the decimal-floating-point facility is installed:
   - SET DFP ROUNDED MODE (SRNMT)

2. The following additional floating-point-support instructions are available when the floating-point-support-sign-handling facility is installed:
   - COPY SIGN (CPNSR)
   - LOAD COMPLEMENT (LCDFR)
   - LOAD NEGATIVE (LNEFR)
   - LOAD POSITIVE (LPNSR)

3. The following additional floating-point-support instructions are available when the FPR-GR-transfer facility is installed:
   - LOAD FPR FROM GR (LDGR)
   - LOAD GR FROM FPR (LGDR)

4. The following additional floating-point-support instructions are available when the IEEE-exception-simulation facility is installed:
   - LOAD FPC AND SIGNAL (LFAS)
   - SET FPC AND SIGNAL (SFASR)

5. The following additional floating-point-support instructions are available when the long-displacement facility is installed:
   - LOAD (LDY, LEY)
   - STORE (STDY, STEY)

6. The following additional floating-point-support instruction is available when the PFPO facility is installed:
   - PERFORM FLOATING POINT OPERATION (PFPO)

7. The following additional floating-point-support instruction and features are available when the floating-point extension facility is installed:
   - A new floating-point-support instruction, SET BFP ROUNDED MODE (SRNMB), is added.
   - A new exception, the quantum exception, is defined for some computational operations.
   - Bit 5 of the floating-point-control (FPC) register is assigned to the quantum-exception mask.
   - Bit 13 of the FPC register is assigned to the quantum-exception flag.
   - Data-exception code (DXC) 04 (hex) is assigned to the quantum exception.
   - DXC 07 (hex) is assigned to the simulated quantum exception.
   - The BFP-rounding-mode field in the FPC register is changed to 3 bits to support one additional BFP rounding mode, round to prepare for shorter precision.
   - One new value of the effective rounding method field is assigned to support the round to prepare for shorter precision rounding method for CONVERT HFP TO BFP.
   - For PFPO with a DFP result, bit 58 of general register 0 is assigned to be the DFP quantum-permission control.

Explanation:

- g^7: Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
- g^6: May be restricted from transactional execution depending on machine conditions.
- g^5: Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
- A: Access exceptions for logical addresses.
- B2: B2 field designates an access register in the access-register mode.
- C: Condition code is set.
- Da: AFP-register data exception.
- Dt: DFP-instruction data exception.
- F: Floating-point extension facility.
- FG: FPR-GR-transfer facility.
- FS: Floating-point-support-sign-handling facility.

Figure 9-17. Summary of Floating-Point-Support Instructions
CONVERT BFP TO HFP

The second operand (the source operand) is converted from the binary-floating-point (BFP) format to the hexadecimal-floating-point (HFP) format, and the normalized result is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

For numeric operands, the sign of the result is the sign of the source operand. If the source operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

When, for THDR, the characteristic of the hexadecimal intermediate result is too large to fit into the target format, the result is set to all ones (that is, the largest-in-magnitude representable finite number) but with the same sign as that of the source operand, and condition code 3 is set.

See Figure 9-18 for a detailed description of the results of this instruction.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Transaction constraint

**Programming Notes:**
1. The BFP-to-HFP conversion instructions are summarized in Figure 9-19.
2. CONVERT BFP TO HFP (THDER) converts BFP operands in the short format to HFP operands in the long format, rather than converting short to short, to retain full precision. Using this long HFP result subsequently as a short operand requires no extra conversion steps.

Explanation:

1. Condition code 1 is set to indicate the source was less than zero.
2. Condition code 2 is set to indicate the source was greater than zero.
ccn Condition code is set to n.
r The value derived when the BFP source value a is converted to the HFP format. This result is always exact.
Hmax Largest (in magnitude) representable number in the target HFP format.
Hmin Smallest (in magnitude) representable normalized number in the target HFP format.
$T(x)$ The value x is placed at the target operand location.

Figure 9-19. Summary of BFP-to/from-HFP Conversion Instructions

CONVERT HFP TO BFP

The second operand (the source operand) is converted from the hexadecimal-floating-point (HFP) for-
mat to the binary-floating-point (BFP) format, and the result rounded according to the rounding method specified by the $M_3$ field is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

The $M_3$ field contains a modifier specifying a rounding method, as follows:

$M_3$ Effective Rounding Method

- Round toward 0
- Round to nearest with ties away from 0
- Round to prepare for shorter precision
- Round to nearest with ties to even
- Round toward 0
- Round toward $+\infty$
- Round toward $-\infty$

A modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an $M_3$ modifier of 3 is also invalid.

The sign of the result is the sign of the second operand. If the second operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

See Figure 9-20 on page 9-29 for a detailed description of the results of this instruction.

If the $M_3$ field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the $M_3$ field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

Resulting Condition Code:

- Source was zero
- Source was less than zero
- Source was greater than zero

Overflow

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification
- Transaction constraint

Programming Notes:

1. The HFP-to-BFP conversion instructions are summarized in Figure 9-19 on page 9-28.

2. Conversion to short BFP data requires HFP operands in the long format; a short HFP operand should be extended to long by ensuring that the right half of the register is cleared. Thus, the entire register should be cleared before loading a short HFP operand into it for conversion to BFP. This avoids unrepeatable rounding errors in the BFP result due to data left over from previous use.

1. The second operand is placed at the first-operand location with the sign bit set to the sign of the third operand. The first, second, and third operands are each in a 64-bit floating-point register. The sign bit of the second operand and bits 1-63 of the third operand are ignored.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

**Programming Notes:**
1. COPY SIGN is radix independent and can be used to operate on HFP, BFP, or DFP operands or even to copy the sign between operands having different radices.

2. Since the sign is in the same bit position (the leftmost bit) in all widths for all radices, the third operand can be a short, long, or extended format.

3. COPY SIGN can be used in conjunction with LOAD (LDR) to copy the sign of an operand in the extended format.

---

**EXTRACT FPC**

EFPC  \( R_1 \)  \([\text{RRE}]\)

The contents of the FPC (floating-point-control) register are placed in bit positions 32-63 of the general register designated by \( R_1 \). Bit positions 0-31 of the general register remain unchanged.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 2, BFP instruction
- Transaction constraint
LOAD

Mnemonic1 R1,R2 [RR]

Op Code R1 R2
0  8 12 15

Mnemonic1 Op Code Operands
LER '38' Short
LDR '28' Long

Mnemonic2 R1,R2 [RRE]

Op Code R1 R2
0  16 24 28 31

Mnemonic2 Op Code Operands
LXR 'B365' Extended

Mnemonic3 R1,D2(X2,B2) [RX-a]

Op Code R1 X2 B2 D2
0  8 12 16 20 31

Mnemonic3 Op Code Operands
LE '78' Short
LD '68' Long

Mnemonic4 R1,D2(X2,B2) [RXY-a]

0  8 12 16 20 32 36 40 47

Mnemonic4 Op Code Operands
LEY 'ED64' Short
LDY 'ED65' Long

The second operand is placed unchanged at the first-operand location.

The operation is performed without inspecting the contents of the second operand; no arithmetic exceptions are recognized.

For LXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

The displacement for LE and LD is treated as a 12-bit unsigned binary integer. The displacement for LEY and LDY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Operation (LEY and LDY, if the long-displacement facility is not installed)
- Specification (LXR only)
- Transaction constraint

LOAD COMPLEMENT

Mnemonic4 R1,R2 [RR]

Op Code R1 R2
0  16 24 28 31

Mnemonic4 Op Code Operands
LCDFR 'B373' [RRE]

The second operand is placed at the first-operand location with the sign bit inverted. Both the first and second operands are each in a 64-bit floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

**Programming Notes:**

1. LOAD COMPLEMENT (LCDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.

2. LOAD COMPLEMENT (LCDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD FPC

Mnemonic4 D2(B2) [S]

Op Code B2 D2
0  16 20 31

The four-byte second operand in storage is loaded into the FPC (floating-point-control) register.

Bits corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility
which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Access (fetch, operand 2)
- Data with DXC 2, BFP instruction
- Specification
- Transaction constraint

**Programming Notes:**
1. When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.
2. When the floating-point extension facility is installed, bits 29-31 of the second operand must specify a valid BFP rounding mode and bits 6-7, 14-15, 24, and 28 must be zero; otherwise, a specification exception is recognized.
3. When the floating-point extension facility is not installed, bits 5-7, 13-15, 24, and 28-29 are unassigned and must be zero; otherwise, a specification exception is recognized.

**LOAD FPC AND SIGNAL**

<table>
<thead>
<tr>
<th>LOAD FPC AND SIGNAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>LFAS</td>
</tr>
<tr>
<td>D2(B2)</td>
</tr>
<tr>
<td>[S]</td>
</tr>
<tr>
<td>'B2BD'</td>

<tr>
<td>B3</td>
</tr>
<tr>
<td>D2</td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>16</td>
</tr>
<tr>
<td>20</td>
</tr>
<tr>
<td>31</td>
</tr>
</tbody>
</table>

First, flags of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is the second operand in storage.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Data with DXC 3, DFP instruction
- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification
- Transaction constraint
Programming Notes:

1. When the floating-point extension facility is installed, bits 29-31 of the second operand must specify a valid BFP rounding mode and bits 6-7, 14-15, 24, and 28 must be zero; otherwise, a specification exception is recognized.

2. When the floating-point extension facility is not installed, bits 5-7, 13-15, 24, and 28-29 are unassigned and must be zero; otherwise, a specification exception is recognized.

3. The IEEE-exception-simulation instructions (LOAD FPC AND SIGNAL and SET FPC AND SIGNAL) are provided to facilitate program simulation of IEEE operations not provided directly in the machine. These instructions permit the simulation routine to restore the caller's masks, flags, and rounding modes; and, when appropriate, to simulate IEEE exceptions, including traps when enabled.

4. On entry, the simulation routine should first save the FPC register contents (containing the caller's masks, flags, and rounding modes), disable all traps, clear all flags, establish appropriate rounding modes, and then perform the necessary floating-point operations. Finally, the routine should set the current flags (called signaling flags) appropriately, and invoke either LOAD FPC AND SIGNAL or SET FPC AND SIGNAL.

5. When a program interruption for a data exception occurs, and both bit 6 and 7 of the DXC are ones, it indicates to the trap handler that the interruption was caused by a simulated-IEEE-exception trap action. The remaining bits of the DXC indicate the type of IEEE exception. Additional information required by the trap handler can be determined by the contents of a trap-information block, located by convention, at a fixed offset from the location where the instruction causing the trap resides.

The following shows an example of this scheme. The block and the code below are inserted at an appropriate place where a trap can occur. In this example, the LOAD FPC AND SIGNAL instruction is used, and the caller’s FPC register contents are at the location, SAVEDFPC.

The trap information block can contain the designation of floating-point registers and general registers containing the information (or addresses of the information) for the following types of items:

a. The operation being simulated
b. Format and values of source operands
c. Format and value of the result
d. Any additional information useful to the trap handler.

**LOAD FPR FROM GR**

**LDGR**

R1,R2 [RRE]

'B3C1' 0 16 24 28 31

The second operand is placed at the first-operand location. The second operand is in a general register, and the first operand is in a floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)
- Transaction constraint

**LOAD GR FROM FPR**

**LGDR**

R1,R2 [RRE]

'B3CD' 0 16 24 28 31

The second operand is placed at the first-operand location. The second operand is in a floating-point register, and the first operand is in a general register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)
- Transaction constraint

**LOAD NEGATIVE**

**LNDFR**

R1,R2 [RRE]

'B371' 0 16 24 28 31

The second operand is placed at the first-operand location with the sign bit set to one. Both the first and second operands are each in a 64-bit floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

**Programming Notes:**

1. LOAD NEGATIVE (LNDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
2. LOAD NEGATIVE (LNDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

**LOAD POSITIVE**

**LPDFR**

R1,R2 [RRE]

'B370' 0 16 24 28 31

The second operand is placed at the first-operand location with the sign bit set to zero. Both the first and second operands are each in a 64-bit floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

**Programming Notes:**

1. LOAD POSITIVE (LPDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
2. LOAD POSITIVE (LPDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.
LOAD ZERO

Mnemonic R 1 [RRE]

<table>
<thead>
<tr>

</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

Mnemonic Op Code Operands
LZER 'B374' Short
LZDR 'B375' Long
LZXR 'B376' Extended

All bits of the first operand are set to zeros.

For LZXR, the R 1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Specification (LZXR only)
- Transaction constraint

**Programming Note:** LOAD ZERO sets all bits of a register to zeros, which produces a positive zero value in the BFP, DFP, and HFP formats. For DFP, addition of an all-zero value to any normal value, X, normalizes X.

PERFORM FLOATING-POINT OPERATION

PFPO [E]

<table>
<thead>
<tr>
<th>'010A'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

The operation specified by the function code in general register 0 is performed and the condition code is set to indicate the result. When there are no exceptional conditions, condition code 0 is set. When an IEEE nontrap exception is recognized, condition code 1 is set. When an IEEE trap exception with alternate action is recognized, condition code 2 is set. In the absence of suppression, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The PERFORM FLOATING-POINT OPERATION (PFPO) instruction is subject to the AFP-register-control bit, bit 45 of control register 0. For PFPO to be executed successfully, the AFP-register-control bit must be one; otherwise, an AFP-register data exception, DXC 1, is recognized.

Bit 32 of general register 0 is the test bit. When bit 32 is zero, the function specified by bits 33-63 of general register 0 is performed; each field in bits 33-63 must be valid and the combination must be a valid and installed function; otherwise a specification exception is recognized. When bit 32 is one, the function specified by bits 33-63 is not performed; rather, the condition code is set to indicate whether these bits specify a valid and installed function; the condition code is set to 0 if the function is valid and installed, or to 3 if the function is invalid or not installed. This definition is written as if the test bit is zero except when stated otherwise.

Bits 33-39 of GR0 specify the operation type. Only one operation type is currently defined: 01, hex, is the PFPO-convert-floating-point-radix operation.

For the PFPO-convert-floating-point-radix operation, other fields in general register 0 include first-operand format, second operand format, control flags, and rounding method. The second operand is converted to the format of the first operand and placed at the first-operand location, a return code is placed in bits 32-63 of general register 1, and the condition code is set to indicate whether an exceptional condition was recognized. Alternatively, an exceptional condition may be indicated by the recognition of a data exception resulting in either completion or suppression.

The first and second operands are in implicit floating-point registers. The first operand is in floating-point register 0 (paired with floating-point register 2 for extended). The second operand is in floating-point register 4 (paired with floating-point register 6 for extended).
PERFORM FLOATING-POINT OPERATION

Da AFP-register data exception.
SP Specification exception due to invalid PFPO rounding method; for BFP target, specification exception due to nonzero target-radix-dependent controls; for DFP target, specification exception due to nonzero DFP-quantum-permission control when the floating-point-extension facility is not installed.
Xi IEEE-invalid-operation exception.
Xo IEEE-overflow exception.
Xq Quantum exception, if the floating-point-extension facility is installed.
Xu IEEE-underflow exception.
Xx IEEE-inexact exception.

In the detailed descriptions that follow there are many references to quantum exceptions. Those apply only when the floating-point-extension facility is installed, and bit 58 of general register 0 is one.

**Inexact-Suppression Control:** Bit 56 of general register 0 is the inexact-suppression control. When the inexact-suppression control is zero, IEEE-inexact exceptions are recognized and reported in the normal manner. When the inexact-suppression control is one, IEEE-inexact exceptions are not recognized, and no trap or nontrap action for the exceptions
PERFORM FLOATING-POINT OPERATION

occurs. The inexact-suppression control has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition.

Alternate-Exception-Action Control: Bit 57 of general register 0 is the alternate-exception-action control. The setting of this control affects the action taken for IEEE-overflow and IEEE-underflow trap exceptions.

When the alternate-exception-action control is zero, IEEE-overflow and IEEE-underflow trap exceptions are reported in the normal manner. That is, the appropriate data exception code (DXC) is placed in byte 2 of the floating-point control register, the operation is completed, and a program interruption for a data exception occurs. (As part of the program interruption, the DXC is stored at location 147.) This is called an IEEE trap exception with normal action.

When the alternate-exception-action control is one, the DXC is placed in byte 2 of the floating-point control register, the operation is completed, condition code 2 is set, and program execution continues with the next sequential instruction. (There is no program interruption and the DXC is not stored at location 147.) This is called an IEEE trap exception with alternate action.

Target-Radix-Dependent Controls: Bits 58 and 59 comprise controls for a target (first) operand having either the HFP or DFP format, as described below. When the operand-format control for the first operand designates the BFP format, both bits 58 and 59 must contain zeros; otherwise, a specification exception is recognized (when the test bit is zero) or condition code 3 is set (when the test bit is one).

HFP-Overflow Control: Bit 58 of general register 0 is the HFP-overflow control. When the HFP-overflow control is zero, an HFP-overflow condition is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask. When the HFP-overflow control is one, an HFP-overflow condition is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask.

HFP-Underflow Control: For HFP targets, bit 59 of general register 0 is the HFP alternate underflow control. When the HFP-underflow control is zero, HFP underflow causes the result to be set to a true zero with the same sign as the source and underflow is not reported. (The result in this case is inexact and subject to the inexact-suppression control.) When the HFP-underflow control is one, the condition is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask.

DFP Quantum-Permission Control (DQPC): When the floating-point extension facility is installed, for DFP targets, bit 58 of general register 0 is the DFP quantum-permission control (DQPC). If this control is zero, recognition of the quantum exception is suppressed so that no trap or nontrap action for the exception occurs; if the control is one, recognition of the quantum exception is not suppressed.

DFP Preferred Quantum Control (DPQC): For DFP targets, bit 59 of general register 0 is the DFP preferred quantum control (DPQC). For radix conversion with DFP targets, if the delivered value is inexact, the cohort member with the smallest quantum is selected; if the delivered value is exact, selection depends on the value of bit 59 of general register 0, the DFP preferred quantum control (DPQC). When the delivered value is exact and the DQPC bit is zero, the cohort member with the largest quantum is selected. When the delivered value is exact and the DPQC bit is one, the preferred quantum is one and the cohort member with the quantum closest to one is selected.

Return Code
Regardless of what condition code is set, and independent of whether the test bit is one, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged. A return code is also placed in general register 1 when a program interruption occurs for an IEEE trap exception that completes; general register 1 is not updated when a program interruption occurs for an IEEE trap exception that suppresses. Thus, general register 1 is updated on a program interruption for IEEE-overflow, IEEE-underflow, IEEE-inexact, and quantum-exception trap exceptions, but is not updated on a program interruption for an IEEE-invalid-operation trap exception.

Except where otherwise specified, the return code is a value of zero.

Sign Preservation
For PFPO convert floating-point radix, the sign of the result is the same as the sign of the source. The only exception to this is when the source is a NaN and the
target is HFP; in this case, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.

**Preferred Quantum**
For radix conversion with DFP targets, the handling of the quantum is described in “DFP Preferred Quantum Control (DPQC)” on page 9-38.

**NaN Conversion**
When converting between DFP and BFP, the sign of the NaN is always preserved, and the value of the payload is preserved, when possible. If the value of the source payload exceeds the maximum value of the target payload, the target is set to the default QNaN, but with the same sign as the source.

When traps are disabled, an SNaN is converted to the corresponding QNaN, and the payload is preserved, when possible; that is, SNaN(x) is converted to QNaN(x), where x is the value of the payload. See the section “Propagation of NaNs” on page 9-3 for additional details.

For DFP, both QNaN(0) and SNaN(0) can be represented; but in BFP, there is a representation for QNaN(0), but not for SNaN(0).

**Scaled Value and Signed Scaling Exponent (Ω) for PFPO**
When, for the PFPO-convert-floating-point-radix operation, IEEE-overflow trap action or IEEE-underflow trap action occurs, the scaled value is computed using the following steps:

\[
\Psi = b^\Omega \\
z = g \times \Psi
\]

Where \( \Omega \) is the signed scaling exponent, \( b \) is the target radix (2, 10, or 16), \( \Psi \) is the scale factor, \( g \) is the precision-rounded value, and \( z \) is the scaled value.

The signed scaling exponent (Ω) is selected to make the magnitude of the value of the scaled result (z) lie in the range:

\[1 \leq |z| < b.\]

The value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer, is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The scaled value is used as the delivered value and is placed in the result location. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected. (But it should be noted that for all currently supported conversions where scaling is required, the result is always inexact, so the cohort member with the smallest quantum is selected.) For BFP targets, there are no redundant representations, there is only one member in a cohort. For HFP targets, the result is normalized.

**HFP Values**
Unnormalized HFP values are accepted on input, but all HFP results are normalized. If an HFP result would be less than the smallest (in magnitude) representable normalized number, an HFP underflow condition exists.

**HFP Zero Result**
For PFPO-convert-BFP-to-HFP or PFPO-convert-DFP-to-HFP functions, if the source operand is zero, the result has the same sign as that of the source operand, and has all zeros in fraction and characteristic.

**HFP Overflow and Underflow for PFPO**
For an HFP target of a PFPO-convert-floating-point-radix operation, the handling of overflow and underflow conditions is controlled by the HFP-overflow control and the HFP-underflow control, respectively.

**HFP Overflow:** An HFP-overflow condition exists when an HFP target precision's largest number (Hmax) is exceeded in magnitude by the precision-rounded value. That is, when the characteristic of a normalized HFP result would exceed 127 and the fraction is not zero.

When the HFP-overflow control is zero, HFP-overflow is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask in the FPC register. This is called an **HFP-overflow-as-IEEE-invalid-operation condition**.

When the HFP-overflow control is one, HFP overflow is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask in the FPC register. This is called an **HFP-overflow-as-IEEE-overflow condition**.

**HFP Underflow:** An HFP-underflow condition exists when the precision-rounded value is nonzero and less in magnitude than the HFP target preci-
PERFORM FLOATING-POINT OPERATION

...sion's smallest normalized number, \( H_{\text{min}} \). That is, when the characteristic of a normalized HFP result would be less than zero and the fraction is not zero. Reporting of the HFP-underflow condition is subject to the HFP-underflow control. The result in this case, however, is inexact and is subject to the controls for that condition.

When the HFP-underflow control is zero, the HFP-underflow condition is not reported. The result is set to a true zero with the same sign as the source.

When the HFP-underflow control is one, HFP underflow is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask (IMu) in the FPC register. This is called an HFP-underflow-as-IEEE-underflow condition. When IMu is zero, the result is set to a true zero with the same sign as the source, and the return code in general register 1 is zero; when IMu is one, the result is set to a scaled value, and the return code is nonzero.

**IEEE Exceptions for PFPO**

Except where otherwise stated, the following sections on IEEE exceptions apply to both BFP and DFP.

**IEEE Invalid Operation:** An IEEE-invalid-operation exception is recognized when any of the following occurs:

1. An SNaN is encountered in an IEEE source.
2. In an IEEE-to-HFP conversion, a NaN (QNaN or SNaN) or an infinity is encountered in the IEEE source.

IEEE-invalid-operation exceptions are recognized as either IEEE-invalid-operation nontrap exceptions or IEEE-invalid-operation trap exceptions.

**IEEE-Invalid-Operation Nontrap Action:** IEEE-invalid-operation nontrap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. For IEEE targets, the result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward \(+\infty\), the result is \(+\infty\) if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.

**IEEE-Invalid-Operation Trap Action:** IEEE-invalid-operation trap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

**IEEE Overflow:** For IEEE targets, an IEEE-overflow exception is recognized when the precision-rounded value is greater in magnitude than the largest finite number (Nmax) representable in the target format. For HFP targets, an IEEE-overflow exception is recognized when the HFP-overflow condition exists and the HFP-overflow control is one.

**IEEE-Overflow Nontrap Action:** IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. For IEEE targets, the result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward \(+\infty\), the result is \(+\infty\) if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.
4. For round toward \(-\infty\), the result is the largest positive finite number if the sign is plus or \(-\infty\) if the sign is minus.

For HFP targets, the result is set to the largest representable number in the target HFP format (Hmax) with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception or a quantum exception.

When IEEE-overflow nontrap action occurs, and neither IEEE-inexact exception nor quantum exception has been recognized, the IEEE-overflow flag bit in the FPC register is set to one and condition code 1 is set.

When an IEEE-overflow nontrap action occurs together with an IEEE-inexact nontrap action, or with a quantum-exception nontrap action, or with nontrap actions for both IEEE-inexact and quantum-exception, the IEEE flag bits in the FPC register for all the recognized exceptions are set to ones and condition code 1 is set.

When IEEE-overflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the IEEE-inexact exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively.

When IEEE-overflow nontrap action and quantum-exception trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the quantum exception is reported as a program interruption for a data exception with DXC 04 hex. When in addition an IEEE-inexact nontrap action occurs, the IEEE-inexact flag bit in the FPC register is set to one.

**IEEE-Overflow Trap Action:** IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent (\(\Omega\)), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated (rounded toward zero), or inexact and incremented, respectively. When the precise intermediate result is rounded to an infinity, it is considered to be an incremented result.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

**IEEE Underflow:** For IEEE targets, an IEEE-underflow exception is recognized when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the denormalized value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The denormalized value is inexact if it is not equal to the precise intermediate value.

For HFP targets, an IEEE-underflow exception is recognized when the HFP-underflow condition exists and the HFP-underflow control is one.

**IEEE-Underflow Nontrap Action:** IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one.

For IEEE targets, the result is set to the denormalized value. For DFP targets, the cohort member with the smallest quantum is selected.
For HFP targets, the result is set to a true zero with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception or a quantum exception.

When IEEE-underflow nontrap action occurs, and neither IEEE-inexact exception nor quantum exception has been recognized, the IEEE-underflow flag bit in the FPC register is set to one and condition code 1 is set.

When an IEEE-underflow nontrap action occurs together with an IEEE-inexact nontrap action, or with a quantum-exception nontrap action, or with nontrap actions for both IEEE-inexact and quantum-exception, the IEEE flag bits in the FPC register for all the recognized exceptions are set to ones and condition code 1 is set.

When IEEE-underflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-underflow flag bit in the FPC register is set to one, and the IEEE-inexact trap exception is reported as a program interruption for a data exception with DXC 10, 18, or 1C hex, depending on whether the result is exact and truncated (rounded toward zero) or inexact and incremented, respectively.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

**IEEE Inexact:** An IEEE-inexact exception is recognized when, for a PFPO-convert-floating-point-radix operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

In the absence of an IEEE-invalid-operation condition, an inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow trap action occurs.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if the inexact-suppression control is one or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

**IEEE-Inexact Nontrap Action:** IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

IEEE-Inexact Nontrap Action: IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent (\( \hat{\ell} \)), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 10, 18, or 1C hex, depending on whether the result is exact, inexact and truncated (rounded toward zero), or inexact and incremented, respectively.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and an IEEE-overflow or IEEE-underflow nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both
exceptions are set to one, and condition code 1 is set. When in addition, a quantum-exception nontrap action occurs, the quantum-exception flag bit in the FPC register is also set to one.

**IEEE-Inexact Trap Action:** IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively. When the precise intermediate result is rounded to an infinity, it is considered to be an incremented result.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

**Quantum Exception:** A quantum exception is recognized when the floating-point extension facility is installed, and when a quantum-exception condition exists, recognition of the exception is not suppressed (DQPC = 1), and none of IEEE-overflow trap action, IEEE-underflow trap action, and IEEE-inexact trap action occurs.

For a PFPO-convert-floating-point-radix operation with DFP result, a quantum-exception condition exists when the delivered DFP result is inexact, or when the delivered DFP result is exact and finite, but the delivered quantum exceeds the preferred quantum of 1. (See programming note 6.)

When the floating-point extension facility is not installed, no quantum exception is recognized.

Even though a quantum-exception condition exists, the quantum exception is not recognized if recognition of the exception is suppressed (DQPC = 0), or if IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action occurs. When a quantum-exception condition exists, and the conditions for an IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action also apply, the trap action takes precedence and the quantum exception is not reported in status flag or DXC.

**Quantum-Exception Nontrap Action:** Quantum-exception nontrap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the quantum-exception flag bit in the FPC register is set to one.

When a quantum-exception nontrap action and another one or two IEEE nontrap actions coincide, the operation is completed using the result specified for the other exceptions and the flag bits for all two or three exceptions are set to one, and condition code 1 is set.

**Quantum-Exception Trap Action:** Quantum-exception trap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 04 hex.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value.

When the quantum-exception trap action coincides with other IEEE nontrap actions, the operation is completed using the result specified for the other IEEE nontrap actions, the flag bits for the nontrap exceptions are set to one, and the quantum-exception trap action takes place.

**Resulting Condition Code (when test bit is zero):**

- 0 Normal result
- 1 Nontrap exception
- 2 Trap exception with alternate action
- 3 --

**Resulting Condition Code (when test bit is one):**

- 0 Function is valid
- 1 --
- 2 --
- 3 Function is invalid

**IEEE Exceptions:**
- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**

- Data with DXC 1, AFP register
- Data with DXC for IEEE exception
- Operation (if the PFPO facility is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. The PFPO-convert-floating-point-radix operation performs “correct rounding”; that is, the result is accurately obtained from the precise intermediate value using the effective rounding method. This is in contrast to some radix conversion programs, which may produce results with larger rounding errors.

2. Note that a value of zero in the rounding-method field (GR0 bits 60-63) specifies rounding according to the current DFP rounding mode (FPC 3.1-3) regardless of whether the target is DFP, BFP, or HFP. Similarly, a value of one in the rounding-method field specifies rounding according to the current BFP rounding mode (FPC 3.5-7), regardless of the target format.

3. If the program does not supply a default QNaN (payload = zero) as a source, then its presence as a result indicates that the machine either created a new QNaN or the program attempted to convert a payload which was too large for this format.

4. If the program restricts payloads to values within the smallest payload capacity of any first-oper-and format, then payloads are preserved across radix conversions.

5. To display a value in scientific notation, many programming languages, calculators, and spreadsheet use the letter e (or E) to separate the significand from the exponent. This is referred to as e-form notation. In this document, e-form notation, along with other forms of conventional numeric notation, is used to represent a value without regard to quantum. To indicate that both value and quantum are being represented, a variation of e-form notation, called q-form notation, is used. In q-form notation, the letter q replaces the letter e and the value shown after q is the right-units-view exponent, that is, the base 10 logarithm of the quantum. Thus, for example, the seven members of the cohort for the value 1e6 in the DFP short format are: 1q6, 10q5, 100q4, 1000q3, 10000q2, 100000q1, and 1000000q0.

As an example of the distinction between e-form and q-form notation, consider the representation of the members of the cohort of zero. The DFP short format, for example, can represent 198 exact powers of 10, ranging in value from 1e-101 to 1e96; but can represent only 192 values for a quantum, ranging from 1e-101 to 1e90. Thus, the 192 members of the cohort for zero range from 0q-101 to 0q90.

The effect of the DFP preferred quantum control is shown in Figure 9-29.

*Figure 9-29. Effect of DPOQ on DFP Short Results*
6. When the floating-point extension facility is installed, for a PFPO-convert-floating-point-radix operation with DFP result, if DPQC is zero and the DFP result is finite and exact, no quantum exception is recognized. This is because the operation always delivers the DFP result with the preferred quantum in this case.

7. The test bit (bit 32 of general register 0) provides a means of determining whether any future extensions to the operation-type code, operand-format code, target-radix-dependent controls, rounding method, and various combinations thereof are supported by the CPU.

**PFPO Actions**

Figure 9-30 summarizes the actions performed by the PFPO-convert-floating-point-radix operation for various target formats.

### Explanation:
- **Caa**: Alternate-exception-action control (GR0.57)
- **Cho**: HFP-overflow control (GR0.58 for HFP targets)
- **Csa**: Inexact-suppression control (GR0.56)
- **DQPC**: DFP quantum-permission control (GR0.58 for DFP targets)
- **DXC**: Data-Exception Code (shown in binary)
- **Hmax**: The largest (in magnitude) representable number in this HFP format with the same sign as the source.
- **+Hmax**: Hmax with a plus sign
- **Ho**: HFP-overflow condition
- **Hu**: HFP-underflow condition
- **IMi**: IEEE-invalid-operation mask (FPC.0)
- **IMo**: IEEE-overflow mask (FPC.2)
- **IMq**: Quantum-exception mask (FPC.5)
- **IMu**: IEEE-underflow mask (FPC.3)
- **IMx**: IEEE-inexact mask (FPC.4)
- **N**: No
- **N'**: No (true by virtue of other conditions in this row)
- **Pi**: Program interruption
- **Rx**: Inexact-result condition
- **SFi**: IEEE-invalid-operation flag (FPC.8)
- **SFo**: IEEE-overflow flag (FPC.10)
- **SFq**: Quantum-exception flag (FPC.13)
- **SFu**: IEEE-underflow flag (FPC.11)
- **SFx**: IEEE-inexact flag (FPC.12)
- **x**: Inexact result (bit 4 of the DXC)
- **X**: IEEE-invalid-operation exception
- **Xi**: IEEE-overflow exception
- **Xo**: IEEE-underflow exception
- **Y**: Inexact result was incremented in magnitude (bit 5 of the DXC)
- **Y': Yes (true by virtue of other conditions in this row)

Figure 9-30. Actions for Various PERFORM FLOATING POINT Conditions (Part 2 of 2)
SET BFP ROUNDING MODE

Mnemonic | D2(B2) [S]
---|---
Op Code | B2
---|---
0 | 16
---|---
20 | 31

Mnemonic | Op Code | Operands
---|---|---
SRNMT | 'B2B9' | 2-bit BFP rounding mode
SRNMB | 'B2B8' | 3-bit BFP rounding mode

The BFP rounding-mode bits in the FPC register are set from the second-operand address.

For SRNM, the second-operand address is not used to address data; instead, bits 30-31 of the FPC register are set to bits 62 and 63, respectively, of the address. Bits other than 62 and 63 of the second-operand address are ignored. When the floating-point extension facility is installed, bit 29 of the FPC register is set to zero.

For SRNMB, the second-operand address is not used to address data; instead, bits 29-31 of the FPC register are set to bits 61-63, respectively, of the address. Bits 0-55 of the second-operand address are ignored, bits 56-60 must be zero, and bits 61-63 must designate a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the decimal-floating-point-rounding facility is not installed)
- Transaction constraint

SET FPC

SFPC | R1 | [RRE]
---|---|---
'B2B9' | 24 | 28

The contents of bit positions 32-63 of the general register designated by R1 are placed in the FPC (floating-point-control) register.

All of bits 32-63 corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration. Bits 0-31 of the general register are ignored.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
SET FPC AND SIGNAL

First, bits 0-4 of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is in bits 32-63 of the general register designated by R1; bits 0-31 of the general register are ignored.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21 on page 9-33.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 on page 9-33 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. See also the programming notes under LOAD FPC AND SIGNAL.

2. Bits 0-31 of the general register designated by the R1 field are reserved for future extension and should be set to zeros.

The contents of the FPC (floating-point-control) register are placed in storage at the second-operand location.

The operand is four bytes in length. All 32 bits of the FPC register are stored.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Access (store, operand 2)
- Data with DXC 2, BFP instruction
- Transaction constraint

---

**Summary of All Floating-Point Instructions**

Figures 9-31 through 9-37 on the following pages show mnemonics for all floating-point instructions (except for PFPO) arranged in various categories of operand format and type of operation. Figure 9-31 shows those instructions which operate on the FPC register. Figure 9-32 on page 9-50 shows the floating-point instructions which have all operands in the same format (same radix and same length), including those FPS (floating-point support) instructions which operate on floating-point operands in a radix-independent manner. Figure 9-33 on page 9-51 and Figure 9-34 on page 9-51 show the floating-point instructions in which all operands are in the same radix but not all of the same length. Figure 9-35 on page 9-51 and Figure 9-36 on page 9-52 show the floating-point instructions in which the source or the result is in a general register. Figure 9-37 on page 9-52 shows the floating-point instructions other than PFPO which perform radix conversion.

**Explanation:**

- Mnemonics in **bold** indicate a register-and-storage operation.
- **BFP** The instruction is considered to be part of the BFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception, DXC 2.
- **DFP** The instruction is considered to be part of the DFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception, DXC 3.

**Figure 9-35. Floating-Point Instructions: General Register Source**
Impacts on ESA/390

When the decimal-floating-point facility or the floating-point extension facility is installed in the z/Architecture architectural mode, the behavior of some instructions in the ESA/390 mode is deviated from the definition in the ESA/390 architecture.

The following summarizes the different behavior of affected ESA/390 instructions caused by those two facilities in the z/Architecture architectural mode.

### Impacts of the Decimal-Floating-Point Facility

When the decimal-floating-point facility is installed in the z/Architecture architectural mode, it causes the following deviations from the ESA/390 architecture.

- For LOAD FPC (LFPC) and SET FPC (SFPC), if bits 25-27 of the source operand contain a nonzero value, it is unpredictable whether a specification exception is recognized or the corresponding bits in the FPC register are set to this nonzero value.
Impacts of the Floating-Point
Extension Facility

When the floating-point extension facility is installed in the z/Architectural architecture mode, it causes the following deviations from the ESA/390 architecture.

1. For LOAD FPC (LFPC) and SET FPC (SFPC), if bit 5 of the source operand is one, it is unpredictable whether a specification exception is recognized or the corresponding bit in the FPC register is set to one; if bits 29-31 of the source operand contain all ones, is unpredictable whether a specification exception is recognized or the corresponding bits in the FPC register are set to all ones.

2. For CONVERT HFP TO BFP (TBEDR, TBDR), if the M3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed.

3. For BFP CONVERT TO FIXED (CFEBR, CFDBR, CFXBR), if the M3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

4. For BFP CONVERT FROM FIXED (CEFBR, CDFBR, CXFBR), if bits 16-19 of the instruction contain a nonzero value, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

5. For BFP DIVIDE TO INTEGER (DIEBR, DIDBR), if the M3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed.

6. For BFP LOAD FP INTEGER (FIEBR, FIDBR, FIXBR), if the M3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

7. For BFP LOAD ROUNDED (LEDBR, LDXBR, LEXBR), if bits 16-19 of the instruction contain a nonzero value, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.
This chapter includes all privileged and semiprivileged instructions described in this publication, except the input/output instructions, which are described in “I/O Instructions” on page 14-1.

Privileged instructions may be executed only when the CPU is in the supervisor state. An attempt to execute a privileged instruction in the problem state generates a privileged-operation exception.
The semiprivileged instructions are those instructions that can be executed in the problem state when certain authority requirements are met. An attempt to execute a semiprivileged instruction in the problem state when the authority requirements are not met generates a privileged-operation exception or some other program-interruption condition depending on the particular requirement which is violated. Those requirements which cause a privileged-operation exception to be generated in the problem state are not enforced when execution is attempted in the supervisor state.

The control instructions and their mnemonics, formats, and operation codes are listed in Figure 10-1 on page 10-3. The figure also indicates which instructions are new in z/Architecture as compared to ESA/390, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

The instructions that are new in z/Architecture are indicated in Figure 10-1 by "N."

When the operands of an instruction are 32-bit operands, the mnemonic for the instruction does not include a letter indicating the operand length. If there is an instruction with the same name but with 64-bit operands, its mnemonic includes the letter “G.” In Figure 10-1, when there is an instruction with 32-bit operands and another instruction with the same name but with “G” added in its mnemonic, the first instruction has “(32)” after its name, and the other instruction has “(64)” after its name.

For those control instructions which have special rules regarding the handling of exceptional situations, a section called “Special Conditions” is included. This section indicates the type of ending (suppression, nullification, or completion) only for those exceptions for which the ending may vary.

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For LOAD PSW, for example, LPSW is the mnemonic and D_2(B_2) the operand designation.

**Programming Notes:**

1. The following additional control instructions are available when the DAT-enhancement facility is installed:
   - COMPARE AND SWAP AND PURGE (CSPG)
   - INVALIDATE DAT TABLE ENTRY

   CSPG operates on a doubleword in storage, in contrast to the previously existing instruction COMPARE AND SWAP AND PURGE (CSP), which operates on a word in storage.

2. The long-displacement facility uses new instruction formats, named RSY, RXY, and SIY, to provide 20-bit signed displacements. In connection with the long-displacement facility, all previously existing control instructions of the RSE or RXE format are changed to be of format RSY or RXY, respectively, where the new formats differ from the old by using a previously unused byte, now named DH, in the instructions. When the long-displacement facility is installed, the displacement for an instruction operand address is formed by appending DH on the left of the previous displacement field, now named DL, of the instruction. When the long-displacement facility is not installed, eight zero bits are appended on the left of DL, and DH is ignored.

   The following additional control instruction is available when the long-displacement facility is installed:
   - LOAD REAL ADDRESS (LRAY)

3. The following additional control instructions are available when the ASN-and-LX-reuse facility is installed:
   - EXTRACT PRIMARY ASN AND INSTANCE
   - EXTRACT SECONDARY ASN AND INSTANCE
   - PROGRAM TRANSFER WITH INSTANCE
   - SET SECONDARY ASN WITH INSTANCE

4. The LOAD PAGE TABLE ENTRY ADDRESS control instruction is available when the DAT-enhancement facility 2 is installed.

5. The PERFORM TIMING FACILITY FUNCTION control instruction is available when the TOD-clock-steering facility is installed.
6. The **MOVE WITH OPTIONAL SPECIFICATIONS** control instruction is available when the move-with-optional-specifications facility is installed.

7. The **PERFORM TOPOLOGY FUNCTION** control instruction is available when the configuration-topology facility is installed.

8. The **PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION** control instruction is available when the message-security-assist extension 3 is installed.

9. The **RESET REFERENCE BITS MULTIPLE** control instruction is available when the reset-reference-bits-multiple facility is installed.

10. The **COMPARE AND REPLACE DAT TABLE ENTRY** instruction is available when the enhanced-DAT facility 2 is installed.

Figure 10-1. Summary of Control Instructions (Part 4 of 4)
If the dispatchable unit is in the base-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in the dispatchable-unit control table (DUCT); the PSW-key mask (PKM), PSW key, and problem-state bit also are saved in the DUCT; the PKM and PSW key are replaced using the contents of general register R1; the problem-state bit is set to one; bits 32 and 97-127 of the PSW are replaced using the contents of general register R2; and the dispatchable unit is placed in the reduced-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in the DUCT and replaced from general register R2, and bit 32 of the PSW is neither saved nor replaced.

If the dispatchable unit is in the reduced-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW are saved in general register R1 if R1 is not zero; bits 32 and 97-127 of the PSW and the PKM, PSW key, and problem-state bit are replaced by values saved in the DUCT; and the dispatchable unit is placed in the base-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in general register R1 if R1 is not zero, those bits in the PSW are replaced from the DUCT, and bit 32 of the PSW is neither saved nor replaced.

Words 5, 8, and 9 of the DUCT are used by this instruction. The contents of those words are as follows:

<table>
<thead>
<tr>
<th>Word 5</th>
<th>Word 8</th>
<th>Word 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSW-Key Mask</td>
<td>All Zeros</td>
<td>Bits 33-63 of Return Address</td>
</tr>
<tr>
<td>PSW Key</td>
<td>RA</td>
<td>P</td>
</tr>
<tr>
<td>Bits 0-16</td>
<td>Bits 0-31 of Return Address</td>
<td>Bits 32-63 of Return Address</td>
</tr>
</tbody>
</table>

In the 24-Bit or 31-Bit Addressing Mode

In the 64-Bit Addressing Mode

The fields in words 5, 8, and 9 of the DUCT are allocated as follows:

**PSW-Key Mask:** Bit positions 0-15 of word 5 contain the PSW-key mask (PKM), bits 32-47 of control register 3, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PKM is restored to control register 3 by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**PSW Key:** Bit positions 24-27 of word 5 contain the PSW key, bits 8-11 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PSW key is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Reduced Authority (RA):** Bit 28 of word 5 indicates, when zero, that the dispatchable unit associated with the DUCT is in the base-authority state or, when one, that the dispatchable unit is in the reduced-authority state. Bit 28 is set to one by BRANCH AND SET AUTHORITY executed in the base-authority state, and it is set to zero by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Problem State (P):** Bit position 31 of word 5 contains the problem-state bit, bit 15 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The problem-state bit is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Basic Addressing Mode (BA):** In the 24-bit or 31-bit addressing mode, bit position 0 of word 9 contains the basic-addressing-mode bit, bit 32 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The basic-addressing-mode bit is restored to the PSW from the DUCT by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Return Address:** In the 24-bit or 31-bit addressing mode, bit positions 1-31 of word 9 contain bits 33-63 of the updated instruction address, bits 97-127 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. Bits 1-31 of word 9 of the DUCT are restored to bit positions 97-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state. In the 64-bit addressing mode, words 8 and 9 contain the updated instruction address saved by BRANCH AND SET AUTHORITY executed in the base-author-
ity state. The contents of words 8 and 9 are restored to bit positions 64-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

In the 24-bit or 31-bit addressing mode, all zeros are stored in word 8 when saving occurs in the base-authority state. In any addressing mode, all zeros are stored in bit positions 16-23, 29, and 30 of word 5 when saving occurs in the base-authority state.

All other fields in words 5, 8, and 9 remain unchanged when bit 28 of word 5 is set to zero in the reduced-authority state.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

Base-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the base-authority state, as indicated by the reduced-authority bit (RA) in the DUCT being zero, R₂ must be nonzero; otherwise, a special-operation exception is recognized. R₁ may be zero or nonzero.

The contents of bit positions 32-63 of general register R₁ and of general register R₂ when the execution of the instruction begins in the base-authority state are as follows:

<table>
<thead>
<tr>
<th>R₁</th>
<th>Key Mask</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>48</td>
<td>56</td>
</tr>
</tbody>
</table>

In the 24-Bit or 31-Bit Addressing Mode

<table>
<thead>
<tr>
<th>R₂</th>
<th>Ignored</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>31</td>
</tr>
</tbody>
</table>

In the 64-Bit Addressing Mode

<table>
<thead>
<tr>
<th>R₂</th>
<th>Bits 33-63 of Branch Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>32</td>
</tr>
<tr>
<td>30</td>
<td>63</td>
</tr>
</tbody>
</table>

The problem-state bit in the PSW is set to one.

In the 24-bit or 31-bit addressing mode, bit 32 of general register R₂ is placed in bit position 32 of the PSW as the new basic-addressing-mode bit. A branch address is generated from bits 33-63 of general register R₂ under the control of the new basic addressing mode, and the result is placed in bit positions 64-127 of the PSW as the new instruction address.

In the 64-bit addressing mode, a branch address is generated from bits 0-63 of general register R₂ and is placed in bit positions 64-127 of the PSW as the new instruction address. Bit 32 of the PSW remains unchanged.

Bits 48-55 and 60-63 of general register R₁ may be used for future extensions and should be zeros; otherwise, the program may not operate compatibly in the future.

Reduced-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the reduced-authority state, as indicated by the reduced-authority (RA) bit in the DUCT being one, R₂ must be zero; otherwise, a special-operation exception is recognized. R₁ may be zero or nonzero. The

or 31-bit addressing mode, the contents of bit positions 0-31 of general register R₂ are ignored.

In the 24-bit or 31-bit addressing mode, PSW bits 32 and 97-127 are saved in word 9 of the DUCT, and zeros are stored in word 8. In the 64-bit addressing mode, PSW bits 64-127 are saved in words 8 and 9 of the DUCT. In any addressing mode, the PKM, the PSW key, and the problem-state bit are saved in word 5 of the DUCT, the RA bit in word 5 is set to one, and bits 16-23, 29, and 30 of word 5 are set to zeros.

Bits 56-59 of general register R₁ are placed in bit positions 8-11 of the PSW as the new PSW key. In the problem state, the new PSW key must be authorized by the PKM; otherwise, if the new PSW key is not authorized, a privileged-operation exception is recognized.

After the new PSW key has been placed in the PSW, bits 32-47 of general register R₁ are ANDed with the PKM in control register 3, and the result replaces the PKM in control register 3.

Bits 48-55 and 60-63 of general register R₁ may be used for future extensions and should be zeros; otherwise, the program may not operate compatibly in the future.
initial contents of general registers R₁ and R₂ are ignored.

If R₁ is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register R₁, and bits 0-31 of the register remain unchanged. If R₁ is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW are placed in bit positions 0-63 of general register R₁. If R₁ is zero, general register 0 remains unchanged.

In the 24-bit or 31-bit addressing mode, bit 0 of word 9 of the DUCT is placed in PSW bit position 32, and bits 1-31 of word 9, with 33 leftmost zeros appended, are placed in PSW bit positions 64-127.

In the 64-bit addressing mode, the contents of words 8 and 9 of the DUCT are placed in PSW bit positions 64-127, and bit 32 of the PSW remains unchanged.

In any addressing mode, the PKM, the PSW key, and the problem-state bit are restored from the DUCT, and the RA bit is set to zero, as previously described. There is no test for whether the restored PSW key is authorized by the restored PKM.

Special Conditions

R₂ must be nonzero in the base-authority state and zero in the reduced-authority state. If either of these rules is violated, a special-operation exception is recognized, and the operation is suppressed.

In the problem state, the execution of the instruction in the base-authority state is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

In the 24-bit or 31-bit addressing mode, the contents of word 9 of the DUCT are not checked for validity before they are loaded into the PSW. If the newly-loaded PSW contains a zero in bit position 32 and the contents of bit positions 97-103 are not zeros, then (a) the instruction is completed, (b) the resulting instruction-length code is 0, (c) a specification-exception is recognized, and (d) a program interruption occurs. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (dispatchable-unit control table)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state, base-authority operation only)
- Protection (low-address; dispatchable-unit control table)
- Special operation
- Specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-2 on page 10-9.

| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case. |
| 8.A | Trace exceptions. |
| 8.B | Protection exception (low-address protection) for access to dispatchable-unit control table. |
| 8.C.1 | Addressing exception for access to dispatchable-unit control table. |
| 8.C.2 | Special-operation exception due to R₂ being zero in the base-authority state or R₂ being nonzero in the reduced-authority state. |
| 8.C.3 | Privileged-operation exception due to selected PSW-key-mask bit being zero (base-authority operation only). |

Figure 10-2. Priority of Execution: BRANCH AND SET AUTHORITY (Part 1 of 2)
Programming Notes:

1. BRANCH AND SET AUTHORITY can improve performance by replacing to-current-primary forms of PROGRAM TRANSFER (PT-cp) and basic (nonstacking) PROGRAM CALL (PC-cp) instructions. PT-cp and PC-cp are often used (within a single address space) to reduce the authority of the PSW-key mask (PKM) or change from supervisor state to problem state during a calling linkage made by PT-cp and then to restore the PKM authority or supervisor state during a return linkage made by PC-cp. Also, the PSW-key-setting operations of BRANCH AND SET AUTHORITY can be substituted for SET PSW KEY FROM ADDRESS instructions, and, since BRANCH AND SET AUTHORITY combines branching with PSW-key setting, it can be used to change the PSW key when branching from or to a fetch-protected program.

2. Only one base-authority state and one reduced-authority state are available to a dispatchable unit. Nested use of BRANCH AND SET AUTHORITY, that is, use within different subroutine levels, is not possible. The requirement that R2 must be nonzero in the base-authority state and zero in the reduced-authority state provides detection of an attempt to use BRANCH AND SET AUTHORITY in the base-authority state when the dispatchable unit is already in the reduced-authority state because of a previous use of the instruction in the base-authority state.

3. BRANCH AND SET AUTHORITY in the base authority-state does not save an indication in the DUCT of whether the current addressing mode is the extended (64-bit) addressing mode or a basic (24-bit or 31-bit) addressing mode. The instruction, in either the base-authority state or the reduced-authority state, does not cause a switch between the extended addressing mode and a basic addressing mode. In the reduced-authority state, the contents of words 8 and 9 of the DUCT are interpreted based only on the current addressing mode. If saving occurs in the 31-bit addressing mode and then restoring occurs in the 64-bit addressing mode, bit 0 of word 9 of the DUCT will be used as an address bit instead of as the basic-addressing-mode bit. If saving occurs in the 64-bit addressing mode and then restoring occurs in the 24-bit addressing mode, an early specification exception may be recognized, after the instruction execution is completed, because bits 97-103 of the PSW may be nonzero when bit 32 is zero.

4. The instruction may be referred to as BSA-ba or BSA-ra depending on whether it is executed in the base-authority state or the reduced-authority state, respectively.

BRANCH AND STACK

<table>
<thead>
<tr>
<th>BAKR</th>
<th>R1,R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;B240&quot;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A linkage-stack branch state entry is formed, and the current PSW, except with an unpredictable PER mask and with the addressing-mode bits and instruction address replaced from the first operand, is placed in the state entry. Subsequently, the updated instruction address in the current PSW is replaced from the second operand. Indications of the current addressing-mode bits and the new instruction address are placed in the state entry, and the PSW-key mask, PASN, SASN, EAX, and contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. When the ASN-and-LX-reuse facility is installed and the ASN-and-LX-reuse control in control register 0 is one, the PASTEIN and SASTEIN also are placed in the state entry. The action associated with an operand is not performed if the R field designating the operand is zero.

When the R1 field is nonzero, the contents of general register R1 specify an address referred to as the return address.

When R1 is nonzero and bit 63 of general register R1 is zero, the return address is generated from the contents of the register under the control of the basic addressing mode specified by bit 32 of the register: 24-bit mode if bit 32 is zero, or 31-bit mode if bit 32 is one. Bit 32 of the register and the return address are substituted for the basic-addressing-mode bit, bit 32, and the updated instruction address, respectively, in the current PSW when the contents of that PSW are placed in the state entry. The extended-addressing-
mode bit, bit 31, is set to zero in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When R1 is nonzero and bit 63 of general register R1 is one, the return address is generated from the contents of the register under the control of the 64-bit addressing mode. Bits 0-62 of the return address, with a zero appended on the right, are substituted for the updated instruction address in the current PSW when the contents of that PSW are placed in the state entry. Bits 31 and 32 are set to one in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When the R1 field is zero, the current PSW is placed in the state entry without any change except for an unpredictable PER mask.

Subsequently, when the R2 field is nonzero, the instruction address in the current PSW is replaced by the branch address. The branch address is generated from the contents of general register R2 under the control of the current addressing mode. When the R2 field is zero, the operation is performed without branching.

The branch state entry is formed and information is placed in it as described in “Stacking Process” on page 5-85.

In the 24-bit or 31-bit addressing mode, bits 33-63 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 33-63 of bytes 144-151 in the state entry, bit 32 of the current PSW is placed in bit position 32 of those bytes, and zeros are placed in bit positions 0-31 of the bytes.

In the 64-bit addressing mode, bits 0-62 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 0-62 of bytes 144-151 in the state entry, and a one is placed in bit position 63 of those bytes.

The entry-type code in the state entry is 00011000 binary.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

**Special Conditions**

The CPU must be in the primary-space mode or access-register mode; otherwise, a special-operation exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Stack full
- Stack specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-3 on page 10-11.

| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case. |
| 7.B | Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode. |
| 8.A | Trace exceptions (only if R2 is nonzero). |
| 8.B.1 | Access exceptions (fetch) for entry descriptor of the current linkage-stack entry. |

**Note:** Exceptions 8.B.2-8.B.7 can occur only if there is not enough remaining free space in the current linkage-stack section.

| 8.B.2 | Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8. |

**Figure 10-3. Priority of Execution: BRANCH AND STACK**

*(Part 1 of 2)*
8.B.3 Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined.

8.B.4 Stack-full exception due to forward-section validity bit in the trailer entry being zero.

8.B.5 Access exceptions (fetch) for entry descriptor of the header entry of the next section. This entry is presumed to be a header entry; its entry-type field is not examined.

8.B.6 Stack-specification exception due to not enough remaining free space in the next section.

8.B.7 Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.

8.B.8 Access exceptions (store) for entry descriptor of the current entry and for the new state entry.

Figure 10-3. Priority of Execution: BRANCH AND STACK

Programming Notes:

1. Examples of the use of the BRANCH AND STACK instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. In no case does BRANCH AND STACK change the current addressing mode.

3. The effect when the \( R_1 \) field is zero is that the return address, which would otherwise be specified by the \( R_1 \) general register, is the address of the next sequential instruction. In this case, BRANCH AND STACK provides a program-linkage function that is comparable to the function of BRANCH AND SAVE.

4. BRANCH AND STACK with a nonzero \( R_1 \) field is intended for use at or near the entry point of a called program. The program may be called by means of BRANCH AND LINK (BALR) or BRANCH AND SAVE (BAS or BASR) from a program being executed in the 24-bit or 31-bit addressing mode, by means of BRANCH AND SAVE AND SET MODE from a program being executed in any addressing mode, or by means of a BRANCH AND SET MODE instruction located in a “glue module” and being executed in any addressing mode. In all of these cases when the nonzero \( R_1 \) field of the calling instruction is the same as the \( R_1 \) field of BRANCH AND STACK, and even when the addressing mode was changed during the calling linkage, BRANCH AND STACK correctly saves the addressing mode and return address of the calling program so that the subsequent execution of PROGRAM RETURN will return correctly to the calling program.

Provided that the current primary address space is in the subspace group, if any, associated with the current dispatchable unit, the access-list-entry token (ALET) in access register \( R_2 \) is translated by means of a special form of access-register translation (ART) to locate a destination ASN-second-table entry (DASTE). If the DASTE specifies the base space of the subspace group, the primary ASCE (PASCE) in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace of the group, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE. In either case, the following actions also occur.

In the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in bit positions 32 and 33-63, respectively, of general register \( R_1 \), and bits 0-31 of the register remain unchanged. Subsequently, the basic-addressing-mode bit and bits 33-63 of the instruction address in the current PSW are replaced from bit positions 32-63 of general register \( R_2 \), and bits 0-31 of the register are ignored.

In the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are saved in bit positions 0-63 of general register \( R_1 \). Subsequently, the instruction address in the current PSW is replaced from bit positions 0-63 of general register \( R_2 \). Bit 32 of the PSW remains unchanged.

In any addressing mode, general register 0 remains unchanged if the \( R_1 \) field is zero.
The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. Also, the secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4.

The current primary address space is in the subspace group for the dispatchable unit if the current primary-ASTE origin (PASTEO), bits 33-57 of control register 5, designates the ASTE for the base space of the group. The PASTEO designates the base-space ASTE if the PASTEO is equal to the base-ASTE origin (BASTEO), bits 1-25 of word 0 of the dispatchable-unit control table (DUCT). For determining whether the PASTEO equals the BASTEO, either the PASTEO may be compared to the BASTEO or the entire contents of bit positions 32-63 of control register 5 may be compared to the entire contents of word 0 of the DUCT.

Ordinary ART is described in “Access-Register-Translation Process” on page 5-60. The special ART performed by this instruction is contrasted to ordinary ART as follows:

1. The special ART is performed regardless of whether the CPU is in the access-register mode.
2. If the ALET being translated is 00000000 hex, called ALET 0, the DASTE is the ASTE for the base space. Bit 0 of the DASTE is ignored.
3. If the ALET is 00000001 hex, called ALET 1, the DASTE is the ASTE for the last subspace entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP. That ASTE is designated by the subspace-ASTE origin (SSASTEO), bits 1-25 of word 0 of the dispatchable-unit control table (DUCT). A special-operation exception is recognized if a subspace has not previously been entered, as indicated by an SSASTEO of all zeros. An ASTE-validity exception is recognized if bit 0 of the DASTE is one. An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the ASTESN in word 3 of the DUCT.

The DASTE located due to an ALET other than ALET 0 and ALET 1 may be the ASTE for the base space of the subspace group associated with the dispatchable unit. The DASTE is the base-space ASTE if the DASTE origin (DASTEO) obtained from an ALE by ART equals the BASTEO in the DUCT. For determining whether the DASTEO equals the BASTEO, either the DASTEO may be compared to the BASTEO, or the DASTEO with one leftmost and six rightmost zeros appended may be compared to the entire contents of word 0 of the DUCT. If the DASTE is not the base-space ASTE, the DASTE is treated as the ASTE for a subspace of the dispatchable unit's subspace group provided that (1) the subspace-group bit, bit 54, in the ASCE in the DASTE is one, and (2) the DASTE does not specify the base space of another subspace group. The DASTE specifies the base space of another subspace group if the base-space bit, bit 31 of word 0 of the DASTE, is one.

4. If the ALET is other than ALET 0 and ALET 1, an ASTE is located by obtaining its origin from an access-list entry (ALE) in a way similar to ordinary ART, and the DASTE is that located ASTE. In this case, as in ordinary ART:
   - An ALET-specification exception is recognized if bits 0-6 of the ALET are not zeros.
   - An ALEN-translation exception is recognized if the ALE is outside the effective access list or bit 0 of the ALE is one.
   - An ASTE-validity exception is recognized if bit 0 of the DASTE is one.
   - An ASTE-sequence exception is recognized if the ALE sequence number (ASTESN) in the DASTE does not equal the ASTESN in the ALE.

The operation differs from ordinary ART in that the ALE sequence number (ALESN) in the ALE is not compared to the ALESN in the ALET, and the private bit in the ALE is treated as zero. Thus, ALE-sequence and extended-authority exceptions cannot occur.

The fetch-only bit in the ALE is ignored.

When the ALET is other than ALET 0 and ALET 1, the special ART may be performed by using the ART-lookaside buffer (ALB).
special-operation exception is recognized if either of those two provisions is not met.

If the DASTE specifies the base space of the subspace group, the PASCE in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE, and bits 56 and 57 of the PASCE, the storage-alteration-event bit and space-switch-event-control bit, remain unchanged.

If R1 is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register R1, and bits 0-31 of the register remain unchanged. If R1 is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are placed in bit positions 0-63 of general register R1. If R1 is zero, general register 0 remains unchanged.

Whether R2 is nonzero or zero, in the 24-bit or 31-bit addressing mode, bits 32-63 of general register R2 specify the new basic addressing mode and designate the branch address. Bit 32 of the register specifies the new basic addressing mode and replaces bit 32 of the current PSW, and the branch address is generated from the contents of bits positions 33-63 of the register under the control of the new basic addressing mode.

When R2 is nonzero or zero in the 64-bit addressing mode, the contents of general register R2 designate the branch address. The branch address is generated from the contents of the register under the control of the 64-bit addressing mode. Bit 32 of the PSW remains unchanged.

Regardless of the addressing mode, the new value for the PSW is computed before general register R1 is changed.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. The secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4.

If the DASTE specifies the base space, the subspace-active bit, bit 0 of word 1 of the DUCT, is set to zero, and bits 1-31 of word 1 remain unchanged. If the DASTE specifies a subspace by means of ALET 1, then (1) the subspace-active bit is set to one, (2) the SSASTEO in bit positions 1-25 of word 1 remains unchanged, and (3) bits 26-31 of word 1 either are set to zeros or remain unchanged. If the DASTE specifies a subspace by means of an ALET other than ALET 1, then (1) the subspace-active bit is set to one, (2) the DASTEO is stored in bit positions 1-25 of word 1 as the SSASTEO, (3) zeros are stored in bit positions 26-31 of word 1, and (4) the ASTESN in the DASTE is stored in word 3 of the DUCT as the SSASTESN.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

The operation, since it changes a translation parameter in control register 1, causes all copies of prefetched instructions to be discarded, except when in the home-space mode.

**Special Conditions**

DAT must be on; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the current primary address space is not in a subspace group associated with the current dispatchable unit, if the ALET in access register R2 is ALET 1 but a subspace has not previously been entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP, or if the ALET used is other than ALET 0 and ALET 1 and the destination ASTE does not specify the base space or a subspace of the subspace group.

The primary space-switch-event-control bit, bit 57 of control register 1 either before or after the operation, does not cause a space-switch-event program interruption to occur.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

The operation is suppressed on all addressing and protection exceptions.
**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Addressing (dispatchable-unit control table, effective access-list designation, access-list entry, destination ASN-second-table entry)
- ALET specification
- ALEN translation
- ASTE sequence
- ASTE validity
- Protection (low-address; dispatchable-unit control table)
- Special operation
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in the Figure 10-4.

</tr>
</tbody>
</table>

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP (Part 1 of 2)
Programming Notes:

1. See the discussion of BRANCH IN SUBSPACE GROUP in "Subroutine Linkage without the Linkage Stack" on page 5-14. It is intended that there be a separate ASN-second-table entry (ASTE) for each of the base space and each subspace of a subspace group. The ASTEs for the subspaces can be "pseudo" ASTEs as described in the programming note in "Address-Space Number" on page 3-21. A subspace can contain a subset of the storage in the base space by having the DAT tables for the subspace designate a subset of the pages that are designated by the DAT tables for the base space. A dispatchable unit has access to a subspace if an access-list entry designating the ASTE for the subspace is in the primary-space or dispatchable-unit access list of the dispatchable unit.

2. BRANCH IN SUBSPACE GROUP can be used to give control from the base space to a subspace, from a subspace to another subspace, and from a subspace to the base space. The instruction can also be used to give control from the base space to the base space or from a subspace to the same subspace.

3. Since BRANCH IN SUBSPACE GROUP sets the secondary address-space-control element (ASCE) in control register 7 equal to the new primary ASCE in control register 1 (along with setting the secondary ASN in control register 3 equal to the primary ASN in control register 4), the program in an address space given control by BRANCH IN SUBSPACE GROUP does not have access to the calling program's address space by means of that address space being the secondary address space.

4. When a dispatchable unit has used BRANCH IN SUBSPACE GROUP to enter a subspace and has not subsequently used BRANCH IN SUBSPACE GROUP to return to the base space, the dispatchable unit is said to be "subspace active." When LOAD ADDRESS SPACE PARAMETERS, PROGRAM CALL, PROGRAM RETURN, PROGRAM TRANSFER, PROGRAM TRANSFER WITH INSTANCE, SET SECONDARY ASN, or SET SECONDARY ASN WITH INSTANCE places an ASCE in control register 1 as the primary ASCE or in control register 7 as the secondary ASCE, and if (1) the ASCE has the subspace-group bit on in it, (2) the dispatchable unit is subspace active, and (3) the ASCE was obtained from the ASN-second-table entry (ASTE) for the base space of the current dispatchable unit, then the instruction (any of the seven named instructions) replaces bits 0-55 and 58-63 of the ASCE in the control register with the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details about the effects of the subspace-group facility on the seven named instructions are given in "Subspace-Replace-Operation" on page 5-71 and in the definitions of the instructions.

5. The use of BRANCH IN SUBSPACE GROUP (BSG) along with PROGRAM CALL (PC) and either PROGRAM TRANSFER (PT) (or PROGRAM TRANSFER WITH INSTANCE) or PROGRAM RETURN (PR) can produce results that may be unexpected. Consider the following sequence of operations:
   a. Start in the base space
   b. BSG to a subspace
   c. PC (the first PC) to an address space that is not in the subspace group.
   d. PC (the second PC) to the base space. Since the dispatchable unit is subspace active, control is given to the subspace.
   e. BSG back to the base space.
   f. PT or PR (paired with the second PC) back to the address space that is not in the subspace group.
   g. PT or PR (paired with the first PC) back to the subspace group. Since the dispatchable unit is no longer subspace active, control is given to the base space even though the first PC was issued in the subspace.

6. BRANCH IN SUBSPACE GROUP does not perform the serialization or checkpoint-synchronization functions, but it does cause all copies of prefetched instructions to be discarded except when in the home-space mode.

7. Unlike the RR-format branch instructions, a value of zero in the R2 field for BRANCH IN SUBSPACE GROUP designates general register 0, and branching occurs.

8. When the R2 field designates access register 0, the access register is treated as containing ALET.
The first operand is called the compare value and is contained in bit positions 0-63 of general register \( R_1 \). Bit positions 0-63 of general register \( R_1 + 1 \) are called the replacement value.

The second operand is a doubleword in storage designated by general registers \( R_2 \) and \( R_2 + 1 \). Bits 59-61 of general register \( R_2 \) are the designated-table type (DTT), specifying the bits in general register \( R_2 \) that form the origin of a table in storage; the DTT also specifies the bits in general register \( R_2 + 1 \) that are used as the effective index into the table to locate the second operand, as follows:

<table>
<thead>
<tr>
<th>DTT (bits 59-61 of Reg. ( R_2 ))</th>
<th>Table Type</th>
<th>Table Origin Bits in Reg. ( R_2 )</th>
<th>Effective Index Bits in Reg. ( R_2 + 1 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Page</td>
<td>0-52</td>
<td>44-51</td>
</tr>
<tr>
<td>001-011</td>
<td>—</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>100</td>
<td>Segment</td>
<td>0-51</td>
<td>33-43</td>
</tr>
<tr>
<td>101</td>
<td>Region third</td>
<td>0-51</td>
<td>22-32</td>
</tr>
<tr>
<td>110</td>
<td>Region second</td>
<td>0-51</td>
<td>11-21</td>
</tr>
<tr>
<td>111</td>
<td>Region first</td>
<td>0-51</td>
<td>0-10</td>
</tr>
</tbody>
</table>

When the DTT is 000 binary, the contents of bit positions 0-52 of general register \( R_2 \), with eleven zeros appended on the right, form the table origin, and bits 53-58, 62, and 63 of the register are ignored. When the DTT is 100-111 binary, the contents of bit positions 0-51 of general register \( R_2 \), with twelve zeros appended on the right, form the table origin, and bits 52-58, 62, and 63 of the register are ignored. DTT values of 001, 010, and 011 binary are invalid; a specification exception is recognized if the DTT is invalid.

Bits 0-51 of general register \( R_2 + 1 \) have the format of the region index, segment index, and page index of a virtual address. The part of bits 0-51 normally used by DAT to select an entry in the type of table designated by the DTT is called the effective index. The part of bits 0-51 of general register \( R_2 + 1 \) to the right of the effective index is ignored. Bit positions 52-63 of general register \( R_2 + 1 \) are reserved and must contain zeros; otherwise, a specification exception is recognized.

If \( R_3 \) is nonzero, the contents of general register \( R_3 \) have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared.

The first and second operands are compared. If they are equal, the contents of general register \( R_1 + 1 \) are stored at the second-operand location, and the specified CPU or CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the replaced entry in storage, and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

If the first and second operands are unequal, the second operand is loaded at the first-operand location. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs. The result of the comparison is indicated by the condition code.

The \( R_1 \) and \( R_2 \) fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.
Bits 52-59, 62, and 63 of general register $R_3$ are ignored. If $R_3$ is zero, the entire contents of general register 0 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-15 on page 10-33.

Figure 10-5. Register Contents for COMPARE AND REPLACE DAT TABLE ENTRY

The $M_4$ field has the following format:

```
/ / / L
0 1 2 3
```

The bits of the $M_4$ field are defined as follows:

- **Reserved:** Bits 0-2 are reserved. Reserved bit positions of the $M_4$ field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- **Local-Clearing Control (LC):** The LC bit, bit 3 of the $M_4$ field controls whether only the TLB in the local CPU is cleared, or whether the TLBs in all CPUs of the configuration are cleared.

When the first and second operands are equal, the contents of general register $R_1 + 1$ are stored at the second-operand location, and the translation-lookaside buffers (TLBs) in the specified CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the original contents of the second operand in storage (that is, the contents of the second operand before it is replaced with the replacement value), and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

Depending on the table type, the table origin in general register $R_2$ and effective index in general register $R_2 + 1$ designate a table entry in accordance with the rules in “Lookup in a Table Designated by an Address-Space-Control Element” on page 3-53, or “Page-Table Lookup” on page 3-57, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The contents of the table entry are not examined for validity, and no exception conditions are recognized due to the contents of the table entry.

The fetch and store of the table entry are performed as a block-concurrent interlocked update. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations,
this serialization applies only to this CPU; other CPUs are not necessarily serialized.

When the first and second operands are equal, this CPU clears selected entries from its TLB. In addition to the clearing of the local CPU, if the LC bit in the $M_4$ field is zero, all other CPUs in the configuration are signalled to clear selected entries from their TLBs. Each TLB is cleared of at least those entries for which all of the following conditions are met:

- The effective index in general register $R_2 + 1$ matches the corresponding index in the TLB table entry of type designated by the DTT field in bits 59-61 of general register $R_2$. If the model implements a composite TLB entry that includes the index designated by the DTT field, bits to the left of the effective index in general register $R_2 + 1$ also match any corresponding bits provided in the designated TLB table entry.

- Either the $R_3$ field is zero, or the table-origin and designation-type fields in general register $R_3$ match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.

  If the $R_3$ field is zero, then the condition described in this step does not apply.

- If EDAT-1 applies and the entry replaced in storage is a segment-table entry, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry, the format control in the replaced entry matches that of the TLB entry.

- If the replaced entry in storage designates a lower-level translation table, the lower-level table origin in the entry matches the table-origin field in the TLB table entry.

- If EDAT-1 applies and the entry replaced in storage is a segment-table entry, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry in which the format control is one, the segment-frame absolute address or region-frame absolute address, respectively, in the replaced entry matches that of the TLB entry.

Each affected TLB is also cleared of at least any lower-level TLB table entries for which all of the following conditions are met:

- The lower-level TLB table entry was formed through use of the replaced entry in storage or through use of a higher-level TLB table entry formed through use of either the replaced entry in storage or a TLB entry cleared in this process.

- Either the $R_3$ field is zero or the table-origin and designation-type fields in general register $R_3$ match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the lower-level TLB table entry. This ASCE may be one that attached a translation path containing a higher-level table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed, or it may be one that made usable a higher-level TLB table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed. See “Formation of TLB Entries” on page 3-59 for the meaning of the terminology used here.

  If the $R_3$ field is zero, then the condition described in this step does not apply.

Special Conditions
A specification exception is recognized, and the operation is suppressed if any of the following is true:

- Either the R₁ or R₂ field is odd.
- The DTT field, bit positions 59-61 of general register R₂, contain 001, 010, or 011 binary.
- Bit positions 52-63 of general register R₂ + 1 contain nonzero values.

The operation is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:**

0  First and second operands equal, second operand replaced by contents of general register R₁ + 1
1  First and second operands unequal, first operand replaced by second operand
2  --
3  --

**Program Exceptions:**

- Addressing
- Operation (if the enhanced-DAT facility 2 is not installed)
- Privileged operation
- Protection (fetch and store, region-, segment-, or page-table entry, key-controlled protection and low-address protection)
- Specification
- Transaction constraint

**Programming Notes:**

1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required.

2. When clearing TLB entries associated with common segments, note that these entries may have been formed through use of address-space-control elements containing many different table origins.

3. The M₄ field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M₄ field is not specified, the assembler places zeros in that field of the instruction.

4. The local-clearing control should be specified as one only when either of the following are true; otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

   - The program is running in a uniprocessor configuration.
   - The program is assigned to run on a single CPU and the affinity between the program and that CPU is maintained.

On some models, use of COMPARE AND REPLACE DAT TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

### COMPARE AND SWAP AND PURGE

**CSP**  
\[
\text{R₁, R₂} \quad [\text{RRE}]
\]

\[
\text{01} \quad \text{24} \quad \text{16} \quad \text{0} \quad \text{B250}
\]

\[
\text{01} \quad \text{24} \quad \text{16} \quad \text{0} \quad \text{B98A}
\]

The first and second operands are compared. If they are equal, contents of general register R₁ + 1 are stored at the second-operand location, and a purging operation is performed. If they are unequal, the second operand is loaded at the first-operand location. The result of the comparison is indicated in the condition code.

The R₁ field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For COMPARE AND SWAP AND PURGE (CSP), the first operand is the contents of bit positions 32-63 of general register R₁. The second operand is a word in storage.

For COMPARE AND SWAP AND PURGE (CSPG), the first operand is the contents of bit positions 0-63...
of general register \( R_1 \). The second operand is a doubleword in storage.

For both CSP and CSPG, the location of the leftmost byte of the second operand is designated by contents of general register \( R_2 \).

The purging operation applies to ART-lookaside buffers (ALBs) and translation-lookaside buffers (TLBs) in all CPUs in the configuration. Either ALBs or TLBs, or both ALBs and TLBs, may be selected for purging. All entries are cleared from the selected buffers.

The purging operation is specified by means of bits 62 and 63 of general register \( R_2 \). When bit 62 is one, entries are cleared from ALBs. When bit 63 is one, entries are cleared from TLBs. When bits 62 and 63 both are ones, entries are cleared from ALBs and TLBs. When bits 62 and 63 both are zeros, no entries are cleared.

The handling of the address in general register \( R_2 \) is dependent on the addressing mode. For CSP in the 24-bit addressing mode, the contents of bit positions 40-61 of general register \( R_2 \), with two zeros appended on the right, constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-39 and 61 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-61 are ignored.

The contents of the registers just described are shown in Figure 10-6 on page 10-21 and Figure 10-7 on page 10-22. When an equal comparison occurs, the contents of bit positions 32-63 of general register \( R_1 +1 \) for CSP, or of bit positions 0-63 for CSPG, are stored at the second-operand location. The fetch of the second operand for purposes of comparison and the store into the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs.

When the result of the comparison is unequal, the second-operand is loaded at the first-operand location, bits 0-31 of general register \( R_1 \) remain unchanged for CSP only, and the second-operand location remains unchanged. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-
concurrent interlocked-update reference as observed by other CPUs.

A serialization function is performed before the operand is fetched and again after the operation is completed.

When an equal comparison occurs, this CPU clears entries from its ALB and TLB, as specified by bits 62 and 63 of general register R₂, and signals all CPUs in the configuration to clear the same specified entries from their ALBs and TLBs. The ALB entries that are cleared are all ALB access-list designations, access-list entries, ASN-second-table entries, and authority-table entries. The TLB entries that are cleared are all region-first-table entries, region-second-table entries, region-third-table entries, segment-table entries, page-table entries, and real-space entries.

Before the TLB purging operation, when bits 62 or 63 of general register R₂ are one, any active transactions on other CPUs in the configuration are aborted with abort code 255, condition code 2.

The execution of COMPARE AND SWAP AND PURGE is not completed on the CPU which executes it until (1) all specified entries have been cleared from the ALB and TLB of this CPU and (2) all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using the specified ALB and TLB entries.

**Special Conditions**

The R₁ field must designate an even register; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  First and second operands equal, second operand replaced by contents of general register R₁ + 1
1  First and second operands unequal, first operand replaced by second operand
2  --
3  --

**Program Exceptions:**

- Access (fetch and store, operand 2)
- Operation (if DAT-enhancement facility is not installed, CSPG only)
- Privileged operation
- Specification
- Transaction constraint

**Programming Note:** COMPARE AND SWAP AND PURGE provides a broadcast form of the PURGE ALB and PURGE TLB instructions, thus making it possible to avoid uses of SIGNAL PROCESSOR.

**DIAGNOSE**

The CPU performs built-in diagnostic functions, or other model-dependent functions. The purpose of
the diagnostic functions is to verify proper functioning of equipment and to locate faulty components. Other model-dependent functions may include disabling of failing buffers, reconfiguration of CPUs, storage, and channel paths, and modification of control storage.

Bits 8-31 may be used as in the SI or RS formats, or in some other way, to specify the particular diagnostic function. The use depends on the model.

The execution of the instruction may affect the state of the CPU and the contents of a register or storage location, as well as the progress of an I/O operation. Some diagnostic functions may cause the test indicator to be turned on.

Resulting Condition Code: The code is unpredictable.

Program Exceptions:

- Privileged operation
- Transaction constraint

Depending on the model, other exceptions may be recognized.

Programming Notes:

1. Since the instruction is not intended for problem-state-program or control-program use, DIAGNOSE has no mnemonic.

2. DIAGNOSE, unlike other instructions, does not follow the rule that programming errors are distinguished from equipment errors. Improper use of DIAGNOSE may result in false machine-check indications or may cause actual machine malfunctions to be ignored. It may also alter other aspects of system operation, including instruction execution and channel-program operation, to an extent that the operation does not comply with that specified in this publication. As a result of the improper use of DIAGNOSE, the system may be left in such a condition that the power-on reset or initial-microprogram-loading (IML) function must be performed. Since the function performed by DIAGNOSE may differ from model to model and between versions of a model, the program should avoid issuing DIAGNOSE unless the program recognizes the model number stored by STORE CPU ID.

EXTRACT AND SET EXTENDED AUTHORITY

The 16-bit PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register R₁. Bits 32-47 of the general register are set to zeros.

In the EXTRACT PRIMARY ASN AND INSTANCE operation, the PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of general register R₁. In the EXTRACT PRIMARY ASN operation, bits 0-31 of general register R₁ remain unchanged.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.
In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Operation (if the ASN-and-LX-reuse facility is not installed, EPAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-8.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.B.1 Operation exception if the ASN-and-LX-reuse facility is not installed (EPAIR only).

7.B.2 Special-operation exception due to DAT being off.

8. Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

**EXTRACT SECONDARY ASN AND INSTANCE**

</tbody>
</table>

The 16-bit SASN, bits 48-63 of control register 3, is placed in bit positions 48-63 of general register R₁. Bits 32-47 of the general register are set to zeros.

In the EXTRACT SECONDARY ASN AND INSTANCE operation, the SASTEIN, bits 0-31 of control register 3, is placed in bit positions 0-31 of general register R₁. In the EXTRACT SECONDARY ASN operation, bits 0-31 of general register R₁ remain unchanged.

**Special Conditions**

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Operation (if the ASN-and-LX-reuse facility is not installed, ESAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-9.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

10-24 IBM z/Architecture Principles of Operation
EXTRACT STACKED REGISTERS

For EXTRACT STACKED REGISTERS (EREG), the contents of bit positions 32-63 of the general registers are restored, and the contents of bit positions 0-31 of the registers remain unchanged. For EXTRACT STACKED REGISTERS (EREGG), the contents of bit positions 0-63 of the general registers are restored. In either case, the contents of bit positions 0-31 of the access registers are restored.

For each of the general registers and the access registers, the registers are loaded in ascending order of their register numbers, starting with register R₁ and continuing up to and including register R₂, with register 0 following register 15. The bit positions of each register are loaded from the position in the state entry where the contents of the bit positions were saved when the state entry was created. The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-87. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to references to the linkage stack.

**Special Conditions**

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-10.

Figure 10-10. Priority of Execution: EXTRACT STACKED REGISTERS (Part 1 of 2)
Sixty-four or 128 bits of status information in the last state entry in the linkage stack are placed in the pair of general registers designated by the R1 field. The condition code is set to indicate whether the state entry is a branch state entry or a program-call state entry.

The R1 field designates the even-numbered register of an even-odd pair of general registers.

Bits 56-63 of general register R2 are an unsigned binary integer that is used as a code to select the state-entry byte positions, or byte and bit positions, from which information is to be extracted, as shown in Figure 10-11.

<table>
<thead>
<tr>
<th>Code (Bits 56-63 of GR R2)</th>
<th>State-Entry Content</th>
<th>State-Entry Byte, or Byte and Bit Positions, Selected</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PKM, SASN, EAX, and PASN</td>
<td>128-135</td>
</tr>
<tr>
<td>1</td>
<td>PSW bits 0-32 and 97-127</td>
<td>136-139, 140.0, and 168-175.33-63 (see text)</td>
</tr>
<tr>
<td>2</td>
<td>Branch address or called space and PC number</td>

</tr>
<tr>
<td>4</td>
<td>PSW bits 0-127</td>
<td>136-143 and 168-175</td>
</tr>
<tr>
<td>5</td>
<td>Secondary and primary ASTEIN</td>
<td>176-183</td>
</tr>
</tbody>
</table>

For a code of 0, 2, or 3 in bit positions 56-63 of general register R2, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 32-63 of general register R1, and the contents of the rightmost four bytes of the status information are placed in bit positions 32-63 of general register R1 + 1. The contents of bit positions 0-31 of general registers R1 and R1 + 1 remain unchanged.

For a code of 1 in bit positions 56-63 of general register R2, the contents of bytes 136-139 of the state entry, which are bits 0-31 of the PSW in the state entry, are placed in bit positions 32-63 of general register R1; the contents of bit position 0 of byte 140 of the entry, which is bit 32 of that PSW, are placed in bit position 32 of general register R1 + 1; and the contents of bit positions 33-63 of bytes 168-175 of the entry, which are bits 97-127 of the PSW, are placed in bit positions 33-63 of general register R1 + 1. However, bit 44 of general register R1, which corresponds to bit 12 of the PSW in the state entry, is set to one, indicating the ESA/390 mode. Also, if bits 0-32 of bytes 168-175 of the state entry are not all zeros, bit 63 of general register R1 + 1 is set to one; otherwise, bit 63 remains with the value loaded from bit position 63 of bytes 168-175 of the state entry. The contents of bit positions 0-31 of general registers R1 and R1 + 1 remain unchanged.

For a code of 4 in bit positions 56-63 of general register R2, the contents of bytes 136-143 of the state entry, which are bits 0-63 of the PSW in the state entry, are placed in bit positions 0-63 of general reg-
ister R₁, and the contents of bytes 168-175 of the state entry, which are bits 64-127 of that PSW, are placed in bit positions 0-63 of general register R₁ + 1.

Code 5 in bit positions 56-63 of general register R₂ is valid only if the ASN-and-LX-reuse facility is installed. For code 5, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 0-31 of general register R₁, and the contents of the rightmost four bytes of the status information are placed in bit positions 0-31 of general register R₁ + 1. The contents of bit positions 32-63 of general registers R₁ and R₁ + 1 remain unchanged.

The format of byte positions 128-183 of the state entry is as follows:

<table>
<thead>
<tr>
<th>PKM</th>
<th>SASN</th>
<th>EAX</th>
<th>PASN</th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
<td>130</td>
<td>132</td>

<table>
<thead>
<tr>
<th>Secondary ASTEIN</th>
<th>Primary ASTEIN</th>
</tr>
</thead>
<tbody>
<tr>
<td>176</td>
<td>180</td>
</tr>
</tbody>
</table>

The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-87. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

When the entry-type code in the entry descriptor of the state entry is 0001100 binary, indicating a branch state entry, the condition code is set to 0. When the entry-type code is 0001101 binary, indicating a program-call state entry, the condition code is set to 1.

Key-controlled protection does not apply to references to the linkage stack.

Bits 0-55 of general register R₂ are ignored.

Special Conditions

A specification exception is recognized when R₁ is odd or the code in bit positions 56-63 of general register R₂ is greater than 4 when the ASN-and-LX-reuse facility is not installed or is greater than 5 when the facility is installed.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Branch state entry
1 Program-call state entry
2 --
3 --
Program Exceptions:

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Specification
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-12.

1.6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.B Special-operation exception due to DAT being off or the CPU being in secondary-space mode.

8.A Specification exception due to \( R_1 \) being odd or bits 56-63 of general register \( R_2 \) having a value greater than 4 when the ASN-and-LX-reuse facility is not installed or greater than 5 when the facility is installed.

8.B.1 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.

8.B.2 Stack-type exception due to current entry not being a state entry or header entry.

Note: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.

8.B.3 Access exceptions (fetch) for second word of the header entry.

8.B.4 Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.

8.B.5 Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.

8.B.6 Stack-specification exception due to preceding entry being a header entry.

8.B.7 Stack-type exception due to preceding entry not being a state entry.

The address-space-control bits, bits 16 and 17 of the current PSW, are placed in reversed order in bit positions 54 and 55 of general register \( R_1 \); that is, bit 16 is placed in bit position 55, and bit 17 is placed in bit position 54. Bits 48-53 of the register are set to zeros, and bits 0-47 and 56-63 of the register remain unchanged. The address-space-control bits are also used to set the condition code.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Resulting Condition Code:

0 PSW bits 16 and 17 zeros (indicating primary-space mode)
1 PSW bit 16 one and bit 17 zero (indicating secondary-space mode)
2 PSW bit 16 zero and bit 17 one (indicating access-register mode)
3 PSW bits 16 and 17 ones (indicating home-space mode)
**Program Exceptions:**

- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-13.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.B Special-operation exception due to DAT being off.
8. Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

**Special Conditions**

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Privileged operation (extraction-authority control is zero in the problem state)
- Transaction constraint

**INSERT STORAGE KEY EXTENDED**

The storage key for the block that is addressed by the contents of general register \( R_2 \) is inserted in general register \( R_1 \).

In the 24-bit addressing mode, bits 40-51 of general register \( R_2 \) designate a 4K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register \( R_2 \) designate a 4K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register \( R_2 \) designate a 4K-byte block in real storage, and bits 52-63 of the register are ignored.

The address designating the storage block, being a real address, is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The seven-bit storage key is inserted in bit positions 56-62 of general register \( R_1 \), and bit 63 is set to zero. The contents of bit positions 0-55 of the register remain unchanged.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
• Addressing (address specified by general register $R_2$
• Privileged operation
• Transaction constraint

**INSERT VIRTUAL STORAGE KEY**

The following diagram shows the storage key and the register positions just described.

The storage key for the location designated by the virtual address in general register $R_2$ is inserted in general register $R_1$.

Selected bits of general register $R_2$ are used as a virtual address. In the 24-bit addressing mode, the address is specified by bits 40-63 of the register, and bits 0-39 are ignored. In the 31-bit addressing mode, the address is specified by bits 33-63, and bits 0-32 is ignored. In the 64-bit addressing mode, the address is specified by bits 0-63 of the register.

The address is a virtual address and is subject to the address-space-control bits, bits 16 and 17 of the current PSW. The address is treated as a primary virtual address in the primary-space mode, as a secondary virtual address in the secondary-space mode, as an AR-specified virtual address in the access-register mode, or as a home virtual address in the home-space mode. The reference to the storage key is not subject to a protection exception.

Bits 0-4 of the storage key, which are the access-control bits and the fetch-protection bit, are placed in bit positions 56-60 of general register $R_1$, with bits 61-63 set to zeros. The contents of bit positions 0-55 of the register remain unchanged. The change and reference bits in the storage key are not inspected. The change bit is not affected by the operation. The reference bit, depending on the model, may or may not be set to one as a result of the operation.

**Special Conditions**

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (except for protection, address specified by general register $R_2$)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-14.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.B Special-operation exception due to DAT being off.

*Figure 10-14. Priority of Execution: INSERT VIRTUAL STORAGE KEY (Part 1 of 2)*
8. Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero.

9. Access exceptions (except for protection) for address specified by general register R2.

Figure 10-14. Priority of Execution: INSERT VIRTUAL STORAGE KEY (Part 2 of 2)

Programming Notes:

1. Since all bytes in a 4K-byte block are associated with the same page and the same storage key, bits 52-63 of general register R2 essentially are ignored. Similarly, since all bytes in a 1 M-byte block are associated with the same segment, bits 44-63 of general register R2 may be ignored when EDAT-1 applies and the STE-format and ACCF-validity controls are both one. Since all bytes in a 2 G-byte block are associated with the same region, bits 33-63 of general register R2 may be ignored when EDAT-2 applies and the RTTE-format and ACCF-validity controls are both one.

2. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

INVALIDATE DAT TABLE ENTRY

<table>
<thead>
<tr>
<th>IDTE</th>

<tbody>
<tr>
<td>'B98E'</td>
<td>R3</td>
<td>M4</td>
</tr>
</tbody>
</table>

0 16 20 24 28 31

Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-TLB-clearing facility is not installed, or when the facility is installed and the local-clearing-control (LC) bit in the M4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.

- When the local-TLB-clearing facility is installed and the LC bit in the M4 field is one, the term “specified CPU or CPUs” means only the CPU executing the IDTE instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

When the clearing-by-ASCE-option bit, bit 52 of general register R2, is zero, an operation called the invalidation-and-clearing operation is performed, as follows. The designated region-table entry or segment-table entry in storage, or a range of entries beginning with the designated entry, is invalidated, and the translation-lookaside buffers (TLBs) in the specified CPU or CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the invalidated entry or entries in storage, and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

When the clearing-by-ASCE-option bit is one, an operation called the clearing-by-ASCE operation is performed, as follows. The operation does not perform any invalidation of DAT-table entries in storage, but it does clear, from the TLBs in all CPUs in the configuration, all region-first-table entries, region-second-table entries, region-third-table entries, segment-table entries and page-table entries formed to translate addresses in a specified address space.

The two operations are described separately below, before the section “Common Operation.”

The M4 field has the following format:

The bits of the M4 field are defined as follows:

- **Reserved:** Bits 0-1 of the M4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- **Format-Control Summary (FS):** When EDAT-2 applies, bit 2 of the M4 field is the format-control summary (FS) for the invalidation-and-clearing operation. Bit 2 of the M4 field is ignored for the clearing-by-ASCE operation and when EDAT-2 does not apply.

The format-control summary applies when the designation type (DT), bits 60-61 of the general register R1, is 00 or 01 binary; when the DT in general register R1 is 10 or 11 binary, the format-
control summary is ignored. The meaning of the FS bit is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The format control is not known to be one in all of the table entries designated by the effective invalidation index and additional-entry count.</td>
</tr>
<tr>
<td>1</td>
<td>The format control is one in all of the table entries designated by the effective invalidation index and additional-entry count.</td>
</tr>
</tbody>
</table>

• **Local-Clearing Control (LC):** When the local-TLB-clearing facility is installed, the LC bit, bit 3 of the M₄ field, controls whether only the TLB in the local CPU is cleared or whether the TLBs in all CPUs of the configuration are cleared. When the local-TLB-clearing facility is not installed, bit 3 of the M₄ field is ignored.

### Invalidation-and-Clearing Operation

When bit 52 of general register R₂, the clearing-by-ASCE-option bit, is zero, the invalidation-and-clearing operation is specified.

The contents of general register R₁ have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. The table origin designates the DAT table in which one or more entries are to be invalidated, and DT specifies the type of that table.

Bits 52-59, 62, and 63 of general register R₁ are ignored.

Bits 0-43 of general register R₂ have the format of the region index and segment index of a virtual address. The part of bits 0-43 normally used by DAT to select an entry in the type of table designated by general register R₁ is called the effective invalidation index.

Bits 60 and 61 of general register R₁ specify a table type and an effective invalidation index as follows:

<table>
<thead>
<tr>
<th>Bits 60 and 61 of Reg. R₁</th>
<th>Table Type</th>
<th>Effective Invalidation Index in Reg. R₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Region first table</td>
<td>Region first index (bits 0-10)</td>
</tr>
<tr>
<td>10</td>
<td>Region second table</td>
<td>Region second index (bits 11-21)</td>
</tr>
<tr>
<td>01</td>
<td>Region third table</td>
<td>Region third index (bits 22-32)</td>
</tr>
<tr>
<td>00</td>
<td>Segment table</td>
<td>Segment index (bits 33-43)</td>
</tr>
</tbody>
</table>

The part of bits 0-43 of general register R₂ to the right of the effective invalidation index is ignored.

The table origin in general register R₁ and the effective invalidation index designate a DAT-table entry to be invalidated. Bits 53-63 of general register R₂ are an unsigned binary integer specifying the number of additional table entries to be invalidated. Therefore, the number of entries to be invalidated is 1-2,048, corresponding to a value of bits 53-63.

Bits 44-51 of general register R₂ must be zeros; otherwise, a specification exception is recognized.

If R₃ is nonzero, the contents of general register R₃ have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R₃ are ignored. If R₃ is zero, the entire contents of general register 0 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-15 on page 10-33.

The table origin in general register R₁ and effective invalidation index in general register R₂ designate a table entry in accordance with the rules in “Lookup in a Table Designated by an Address-Space-Control Element” on page 3-53, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current
INVALIDATE DAT TABLE ENTRY

addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The invalid bit, bit 58, of this region-table or segment-table entry is set to one. During this procedure, the entry is not checked for a format error or for whether the origin, in the entry, of the next-lower-level table would cause an addressing exception. The table-type field in the entry is ignored. If the entry is a segment-table entry, the common-segment bit in the entry is ignored. If EDAT-2 applies and the entry is a region-third-table entry, the common-region bit in the entry is ignored.

The entire table entry is fetched concurrently from storage. Subsequently, the byte containing the invalid bit is stored. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

If bits 53-63 of general register R2 are not all zeros, the setting of the invalid bit to one in a region-table or segment-table entry is repeated by adding one to the previously used value of the effective invalidation index, and this is done as many times as are specified by bits 53-63. A carry out of the leftmost bit position of the index is ignored, and wraparound in the table occurs in this case. The contents of general register R2 remain unchanged.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

After it has set an invalid bit to one, this CPU clears selected entries from its TLB. Then if the local-TLB-clearing facility is not installed, or if the facility is installed and LC bit in the M4 field is zero, this CPU signals all other CPUs in the configuration to clear selected entries from their TLBs. Each affected TLB is cleared of at least those entries for which all of the following conditions are met:

- The effective invalidation index in general register R3 matches the corresponding index in the TLB table entry of type designated by the DT field in bits 60-61 of general register R1. If the model implements a composite TLB entry that includes the index designated by the DT field, bits to the left of the effective index in general register R2 also match any corresponding bits provided in the designated TLB table entry. Note that when multiple table entries are invalidated due to bits 53-63 of general register R2, then the effective invalidation index is incremented, a carry out of the leftmost bit position of the index is lost, and TLB region- or segment-table entries are cleared for each value of the index so obtained.

- Either the R3 field is zero, or the table-origin and designation-type fields in general register R3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.

If the R3 field is zero, then the condition described in this step does not apply.

- If the entry invalidated in storage designates a lower-level translation table, the lower-level table origin in the invalidated entry matches the table-origin field in the TLB table entry.

Each affected TLB is also cleared of at least any lower-level TLB table entries for which all of the following conditions are met:
• The lower-level TLB table entry was formed through use of an entry invalidated in storage or through use of a higher-level TLB table entry formed through use of either an entry invalidated in storage or a TLB entry cleared in this process.

• Either the R₃ field is zero or the table-origin and designation-type fields in general register R₃ match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the lower-level TLB table entry. This ASCE may be one that attached a translation path containing a higher-level table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed, or it may be one that made usable a higher-level TLB table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed. See “Formation of TLB Entries” on page 3-59 for the meaning of the terminology used here.

If the R₃ field is zero, then the condition described in this step does not apply.

• If the entry invalidated in storage designates a lower-level translation table, the lower-level table origin in the invalidated entry matches the table-origin field in the TLB table entry.

Programming Notes:

1. Setting the format-control summary to one may provide improved performance on certain models.

2. When the designation type (DT), bits 60-61 of general register R₁, is 00 binary, the format-control summary applies to the segment-table entries being invalidated. When the DT in general register R₁ is 01 binary, the format-control summary applies to the region-third-table entries being invalidated.

3. The program should only set the format-control summary to one if it can ensure that format control (bit 53 of the table entry) is one in all of the table entries being invalidated. If the format-control summary is set to one, but the format control is not one in all of the table entries being invalidated, incomplete purging of the TLB may occur, resulting in unpredictable results from DAT.

4. The M₄ field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M₄ field is not specified, the assembler places zeros in that field of the instruction.

Storing in the region- or segment-table entry and the clearing of TLB entries may or may not occur if the invalid bit is already one in the region- or segment-table entry.

When multiple entries are invalidated, clearing of TLB entries may be delayed until all entries have been invalidated.

Clearing-by-ASCE Operation

When bit 52 of general register R₂, the clearing-by-ASCE-option bit, is one, the clearing-by-ASCE operation is specified.

The contents of general register R₃ have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R₃ are ignored. R₃ may be zero or nonzero, that is, any general register, including register 0, may be designated.

Bits 44-51 of general register R₃ must be zeros; otherwise, a specification exception is recognized.

The contents of general register R₁ and of bit positions 0-43 and 53-63 of general register R₂ are ignored.

The contents of the general registers just described are shown in Figure 10-16 on page 10-35.

The TLBs of the specified CPU or CPUs in the configuration are cleared at all levels of at least those entries for which the table-origin and designation-type fields in general register R₃ match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the entry. This ASCE is the one used in the translation during which the entry was formed. See “Formation of TLB Entries” on page 3-59 for the meaning of the terminology used here.

When the clearing-by-ASCE-option bit (bit 52 of general register R₂ is one), the M₄ field is ignored.
The execution of INVALIDATE DAT TABLE ENTRY is not completed on the CPU which executes it until the following occur:

1. All entries meeting the criteria specified above have been cleared from the TLB of this CPU. When the local-TLB-clearing facility is installed and the LC bit in the M₄ field is one, execution of INVALIDATE DAT TABLE ENTRY is complete at this point and the following step is not performed.

2. When the local-TLB-clearing facility is not installed, or when the facility is installed and the LC bit in the M₄ field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

Before the TLB purging operation, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which TLB entries are being cleared. It is unpredictable whether some or all other CPUs are affected as well.

The operations do not necessarily have any effect on TLB real-space entries.

### Special Conditions

Bits 44-51 of general register R₂ must be zeros; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions (invalidation-and-clearing operation only).

### Resulting Condition Code:
The code is unpredictable.

### Program Exceptions:

- Addressing (invalidated region- or segment-table entry, invalidation-and-clearing operation only).
- Operation (if the DAT-enhancement facility is not installed)
- Privileged operation
- Protection (fetch and store, region- or segment-table entry, key-controlled protection and low-address protection; invalidation-and-clearing operation only).
- Specification
- Transaction constraint

### Programming Notes:

1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. When the invalidation-and-clearing operation is performed, some models may clear all TLB entries when the effective invalidation index is not a segment index or may clear an entry regardless of the page-table origin in the entry. When that operation or the clearing-by-ASCE operation is performed, some models may clear a TLB entry regardless of the designation-type field in general register R₃. When either operation is performed, other models may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. When using the clearing-by-ASCE operation to clear TLB entries associated with common segments, note that these entries may have been
formed through use of address-space-control elements containing many different table origins.

The following notes apply when the invalidation-and-clearing operation is specified.

3. The clearing of TLB entries may make use of the page-table origin in a segment-table entry. Therefore, if the segment-table entry, when in the attached state, ever contained a page-table origin that is different from the current value, copies of entries containing the previous values may remain in the TLB.

4. INVALIDATE DAT TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.

5. The address of the DAT-table entry for INVALIDATE DAT TABLE ENTRY is a 64-bit address, and the address arithmetic is performed by following the normal rules for 64-bit address arithmetic, with wraparound at \(2^{64} - 1\). Also, offset and length fields are not used. Contrast this with implicit translation and the translations for LOAD REAL ADDRESS and STORE REAL ADDRESS, all of which may result either in wraparound or in an addressing exception when a carry occurs out of bit position 0 and which indicate an exception condition when the designated entry does not lie within its table. Accordingly, the DAT tables should not be specified to wrap from maximum storage locations to location 0, and the first designated entry and all additional entries specified by bits 53-63 of general register \(R_2\) should lie within the designated table.

6. When the local-TLB-clearing facility is installed, the local-clearing control should be specified as one when the ASCE used to form the TLB entries being cleared has been attached only to the CPU on which the IDTE instruction is executed (for example, if the program is running on a uniprocessor). Otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

On some models, use of INVALIDATE DAT TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

7. The \(M_4\) field of the instruction is considered to be optional, as indicated by the field being contained within brackets \([\ ]\) in the assembler syntax. When the \(M_4\) field is not specified, the assembler places zeros in that field of the instruction.

### INVALIDATE PAGE TABLE ENTRY

**IPTE** \[R_1,R_2[,R_3[,M_4]]\] \[RRF-a\]

**Note:** The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-TLB-clearing facility is not installed, or when the facility is installed and the local-clearing-control (LC) bit in the \(M_4\) field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.

- When the local-TLB-clearing facility is installed and the LC bit in the \(M_4\) field is one, the term “specified CPU or CPUs” means only the CPU executing the IPTE instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

The designated page-table entries are invalidated, and the translation-lookaside buffers (TLBs) in the specified CPU or CPUs in the configuration are cleared of the associated entries.

The contents of general register \(R_1\) have the format of a segment-table entry, with only the page-table origin used. The contents of general register \(R_2\) have the format of a virtual address, with only the page index used. The contents of fields that are not part of the page-table origin or page index are ignored.

When the IPTE-range facility is not installed, or when the \(R_3\) field is zero, the single page-table entry designated by the first and second operands is invalidated.

When the IPTE-range facility is installed and the \(R_3\) field is nonzero, bits 56-63 of general register \(R_3\) contain an unsigned binary integer specifying the count of additional page-table entries to be invalidated. Therefore, the number of page-table entries to be invalidated is \(1-256\), corresponding to a value of \(0-255\) in bits 56-63 of the register.
The contents of the general registers just described are shown in Figure 10-17 on page 10-37.

**Figure 10-17. Register Contents for INVALIDATE PAGE TABLE ENTRY**

When the IPTE-range facility is not installed, the R3 field is ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

The M4 field has the following format:

```
/ / / C
```

The bits of the M4 field are defined as follows:

- **Reserved**: Bits 0-2 are reserved. Reserved bit positions of the M4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- **Local-Clearing Control (LC)**: When the local-TLB-clearing facility is installed, the LC bit, bit 3 of the M4 field, controls whether only the TLB in the local CPU is cleared or whether the TLBs in all CPUs of the configuration are cleared. When the local-TLB-clearing facility is not installed, bit 3 of the M4 field is reserved.

The page-table origin and the page index designate a page-table entry, following the dynamic-address-translation rules for page-table lookup. The page-table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode, which is specified by bits 31 and 32 of the current PSW. A carry out of bit position 0 as a result of the addition of the page index and page-table origin cannot occur. The address formed from these two components is a real or absolute address. The page-invalid bit of this page-table entry is set to one. During this procedure, the page-table entry is not inspected for whether the page-invalid bit is already one or for format errors. Additionally, the page-frame real address contained in the entry is not checked for an addressing exception.

When the IPTE-range facility is installed and the R3 field is nonzero, the instruction is interruptible, and processing is as follows:

1. The invalidation process described above is repeated for each subsequent entry in the page table until either the number of additional entries specified in bits 56-63 of general register R3 have been invalidated or an interruption occurs.

2. The page-index in bits 44-51 of general register R2 is incremented by the number of page-table entries that were invalidated; a carry out of bit position 44 of general register R2 is ignored.

3. The additional-entry count in bits 56-63 of general register R3 is decremented by the number of page-table entries that were invalidated.

Therefore, when the IPTE-range facility is installed, the R3 field is nonzero, and an interruption occurs (other than one that causes termination), general registers R2 and R3 have been updated, so that the instruction, when reexecuted, resumes at the point of interruption.

When the IPTE-range facility is not installed, or when the R3 field is zero, the contents of registers R2, and R3 remain unchanged.

For each page-table entry that is invalidated, the entire page-table entry appears to be fetched concurrently from storage as observed by other CPUs. Subsequently, the byte containing the page-invalid bit is stored. The fetch access to each page-table entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.
A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

If no exceptions are recognized, this CPU clears selected entries from its TLB. Then if the local-TLB-clearing facility is not installed, or if the facility is installed and LC bit in the M₄ field is zero, this CPU signals all CPUs in the configuration to clear selected entries from their TLBs. For each page-table entry invalidated, each affected TLB is cleared of at least those entries that have been formed using all of the following:

- The page-table origin specified by general register R₁
- The page index specified by general register R₂
- The page-frame real address contained in the designated page-table entry

The execution of INVALIDATE PAGE TABLE ENTRY is not completed on the CPU which executes it until the following occur:

1. All page-table entries corresponding to the specified parameters have been invalidated.
2. All entries corresponding to the specified parameters have been cleared from the TLB of this CPU. When the local-TLB-clearing facility is installed and the LC bit in the M₄ field is one, the execution of INVALIDATE PAGE TABLE entry is complete at this point and the following step is not performed.
3. When the local-TLB-clearing facility is not installed, or when the facility is installed and LC bit in the M₄ field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

Before the TLB purging operation, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which TLB entries are being cleared. It is unpredictable whether some or all other CPUs are affected as well.

**Special Conditions**

When the IPTE-range facility is installed, the R₃ field is nonzero, and the page index in general register R₂ plus the additional-entry count in general register R₃ is greater than 255, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Addressing (page-table entry)
- Privileged operation
- Protection (fetch and store, page-table entry, key-controlled protection, and low-address protection)
- Specification
- Transaction constraint

**Programming Notes:**

1. The selective clearing of entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. Some models may clear all entries which contain the page-frame real addresses obtained from the page-table entries in storage. Others may clear all entries which contain the designated page index (or indices), and some implementations may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. The clearing of TLB entries may make use of the page-frame real addresses in the page-table entries. Therefore, if the page-table entries, when in the attached state, ever contained page-frame real addresses that are different from the current values, copies of entries containing the previous values may remain in the TLB.

3. INVALIDATE PAGE TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.
4. When the IPTE-range facility is installed and the R<sub>3</sub> field is nonzero, the following applies:

   a. All of the page-table entries to be invalidated must reside in the same page table. A specification exception is recognized if the page index in general register R<sub>1</sub> plus the additional-entry count in general register R<sub>3</sub> is greater than the maximum page index of 255.

   b. The number of page-table entries that are invalidated by INVALIDATE PAGE TABLE ENTRY may vary from one execution to another.

   c. The instruction cannot be used for situations where the program must rely on uninterrupted execution of the instruction. Similarly, the program should normally not use INVALIDATE PAGE TABLE ENTRY to invalidate a page-table entry, the page-frame-real address of which designates the 4K-byte block containing the instruction or of an execute-type instruction that executes the IPTE.

   d. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

5. When the local-TLB-clearing facility is installed, the local-clearing control should be specified as one when the ASCE used to form the TLB entries being cleared has been attached only to the CPU on which the IPTE instruction is executed (for example, if the program is running on a uniprocessor). Otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

   On some models, use of INVALIDATE PAGE TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

6. The R<sub>3</sub> and M<sub>4</sub> fields of the instruction are considered to be optional, as indicated by the fields being contained within brackets [ ] in the assembler syntax. When either field is not specified, the assembler places zeros in the corresponding field of the instruction. When the M<sub>4</sub> field is coded but the R<sub>3</sub> field is not required, a zero should be coded to designate the place of the third operand.

---

LOAD ADDRESS SPACE PARAMETERS

<table>
<thead>
<tr>
<th>LASP</th>
<th>D&lt;sub&gt;1&lt;/sub&gt;(B&lt;sub&gt;1&lt;/sub&gt;)</th>
<th>D&lt;sub&gt;2&lt;/sub&gt;(B&lt;sub&gt;2&lt;/sub&gt;)</th>
<th>[SSE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘E500’</td>
<td>B&lt;sub&gt;1&lt;/sub&gt;</td>
<td>D&lt;sub&gt;1&lt;/sub&gt;</td>
<td>D&lt;sub&gt;2&lt;/sub&gt;</td>
</tr>
</tbody>
</table>

The first operand contains values to be loaded into control registers 3 and 4, including a secondary ASN (SASN) and a primary ASN (PASN), and, possibly, a secondary ASTE instance number (SASTEIN) and a primary ASTE instance number (PASTEIN). Execution of the instruction consists in performing four major steps: PASN translation, SASN translation, SASN authorization, and control-register loading. Each of these steps may or may not be performed, depending on the outcome of certain tests and on the setting of bits 61-63 of the second-operand address. The first three of these steps, when performed and successful, obtain additional values, that are loaded into control registers 1, 5, and 7. When the first three steps are not successful when performed, no control registers are changed, and the reason is indicated in the condition code.

When the ASN-and-LX-reuse facility is not installed, or is installed but is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the first operand is a doubleword containing a PSW-key mask (PKM), a SASN, an authorization index (AX), and a PASN. When the ASN-and-LX-reuse facility is installed and enabled, the first operand is two consecutive doublewords containing those four values and also a SASTEIN and a PASTEIN.

The primary ASN may be translated by means of the ASN-translation tables to obtain a primary-ASTE (PASTE) origin (PASTEO) and, from the PASTE, a primary ASCE (PASCE). The secondary ASN may be translated by means of the ASN-translation tables to obtain a secondary ASCE (SASCE). If the first operand is two doublewords and PASN or SASN translation occurs, the ASTEIN in the located ASTE is checked for being equal to the PASTEIN or SASTEIN, respectively, in the first operand. An authority check for ensuring that the new AX is authorized to establish the new SASN can be prevented when SASN translation occurs, or it can be required and cause SASN translation even when SASN translation would not otherwise occur. The new AX, which is placed in a control register and is used in SASN authorization if that occurs, is the old AX if PASN...
translation has not occurred or is the AX in the located PASTE otherwise. However, in either of these cases, the new AX may be the AX specified in the first operand.

A doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Not Enabled

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function Specified in Second-Operand Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>61</td>
<td>ASN translation performed only when new ASN and old ASN are different.</td>
</tr>
<tr>
<td>62</td>
<td>AX associated with new PASN used.</td>
</tr>
<tr>
<td>63</td>
<td>SASN authorization performed.*</td>
</tr>
</tbody>
</table>

Explanation:

* SASN translation and SASN authorization are performed only when SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, the SASCE is set equal to the PASCE, the SASTEIN is set equal to the PASTEIN (if ASN-and-LX reuse is enabled), and no authorization is performed.

A two-doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Enabled

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function Specified in Second-Operand Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>61</td>
<td>ASN translation performed only when new ASN and old ASN are different.</td>
</tr>
<tr>
<td>62</td>
<td>AX associated with new PASN used.</td>
</tr>
<tr>
<td>63</td>
<td>SASN authorization performed.*</td>
</tr>
</tbody>
</table>

The “d” stands for designated value and is used to distinguish these fields from other fields with similar names which are referred to in the definition. The current contents of the corresponding fields in the control registers are referred to as SASTEIN-old, PKM-old, SASN-old, etc. The updated contents of the control registers are referred to as SASTEIN-new, PKM-new, SASN-new, etc.

The second-operand address is not used to address data; instead, the rightmost three bits are used to control portions of the operation. The remainder of the second-operand address is ignored. Bits 61-63 of the second-operand address are used as follows:

The operation of LOAD ADDRESS SPACE PARAMETERS is depicted in Figure 10-21 on page 10-48.

Note: In the following sections, the actions involving the PASTEIN and SASTEIN occur only if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0.

PASN Translation and Related Processing

In the PASN-translation process, the PASN-d is translated by means of the ASN first table and the ASN second table. The PASTEO resulting from PASN translation replaces the PASTEO in control register 5. The ASCE in the located ASTE replaces the PASCE in control register 1. When bit 62 of the second-operand address is zero, the AX in the ASTE replaces the AX in control register 4. When bit 62 is one, AX-d replaces the AX in the control register. When ASN-and-LX reuse is enabled, PASTEIN-d is compared to the ASTEIN in the ASTE, and, when equal, replaces the PASTEIN in control register 4.

When bit 61 of the second-operand address is one, PASN translation is always performed. When bit 61 is zero, PASN translation is performed only if PASN-d is not equal to PASN-old. When bit 61 is zero and PASN-d is equal to PASN-old, the PASCE-old, PASTE-old, and PASTEIN-old are left unchanged in the control registers and become the PASCE-new, PAS-
TEO-new, and PASTEIN-new, respectively. In this case, if bit 62 is zero, then the AX-old is left unchanged in the control register and becomes the AX-new, or, if bit 62 is one, AX-new is set equal to AX-d.

The PASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 1 is set. Condition code 1 is also set if PASN translation occurs, the ASN-and-LX-reuse facility is enabled, and PASTEIN-d is not equal to the ASTEIN in the ASTE. When a reason for setting condition code 1 does not exist and either the current primary space-switch-event-control bit in control register 1 is one or the space-switch-event-control bit in the ASTE is one, a space-switch event does not occur; instead, condition code 3 is set. When condition code 1 or 3 is set, the control registers remain unchanged.

The contents of the AX, ASCE, and ASTEIN fields in the ASTE which is accessed as a result of the PASN translation are referred to as AX-p, ASCE-p, and ASTEIN-p, respectively. The origin of the ASTE is referred to as PASTEO-p.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-p has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-p, is one, (2) the dispatchable unit is subspace active, and (3) PASTEO-p designates the ASTE for the base space of the dispatchable unit, then a copy of ASCE-p, called ASCE-rp, is made, and bits 0-55 and 58-63 of ASCE-rp are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 1 is set, and the control registers remain unchanged.

**SASN Translation and Related Processing**

In the SASN-translation process, the SASN-d is translated by means of the ASN first table and the ASN second table. The ASCE field obtained from the ASTE subsequently replaces the secondary ASCE (SASCE) in control register 7. When ASN-and-LX reuse is enabled, SASTEIN-d is compared to the ASTEIN in the ASTE, and, when equal, replaces the SASTEIN in control register 3.

SASN translation is performed only when, but not necessarily when, SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, SASCE-new and SASTEIN-new are set equal to SASCE-new and SASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to PASTEIN-d; SASTEIN-d is ignored. When SASN-d is not equal to PASN-d and is equal to SASN-old, bit 61 (force ASN translation) is zero, and bit 63 (skip SASN authorization) is one, SASN translation is not performed, and SASCE-old and SASTEIN-old become SASCE-new and SASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to SASTEIN-old; SASTEIN-d is ignored.

SASN translation is performed in each of the following cases:

- SASN-d is not equal to PASN-d or SASN-old.
- SASN-d is not equal to PASN-d but is equal to SASN-old, and either bit 61 (force ASN translation) of the second-operand address is one or bit 63 (skip secondary authority test) of that address is zero. (The translation must be performed when bit 63 is zero in order to obtain the ATO and ATL from the SASTE.)

The SASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 2 is set. Condition code 2 is also set if SASN translation occurs, the ASN-and-LX-reuse facility is enabled, and SASTEIN-d is not equal to the ASTEIN in the ASTE. When condition code 2 is set, the control registers remain unchanged.

The contents of the ASCE, ATO, ATL and ASTEIN fields in the ASTE which is accessed as a result of the SASN translation are referred to as ASCE-s, ATO-s, ATL-s, and ASTEIN-s, respectively. The origin of the ASTE is referred to as SASTEO-s.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-s has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-s, is one, (2) the dispatchable unit is subspace active, and (3) SASTEO-s designates the ASTE for the base space of the dispatchable unit,
then a copy of ASCE-s, called ASCE-rs, is made, and bits 0-55 and 58-63 of ASCE-rs are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTEEN) in the subspace ASTE does not equal the subspace ASTEEN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 2 is set, and the control registers remain unchanged.

SASN Authorization

SASN authorization is performed when bit 63 of the second-operand address is zero and SASN-d is not equal to PASN-d; it is performed in this case regardless of whether SASN-d is equal to SASN-old. When SASN-d is equal to PASN-d or when bit 63 of the second-operand address is one, SASN authorization is not performed.

SASN authorization is performed by using ATO-s, ATL-s, and the intended value for AX-new. When bit 62 of the second-operand address is zero and PASN translation was performed, the intended value for AX-new is AX-p. When bit 62 of that address is zero and PASN translation was not performed, the AX is not changed, and AX-new is the same as AX-old. When bit 62 of that address is one, the intended value for AX-new is AX-d. SASN authorization follows the rules for secondary authorization as described in “ASN-Authorization Process” on page 3-33. If the SASN is not authorized (that is, the authority-table length is exceeded, or the selected bit is zero), condition code 2 is set, and none of the control registers is updated.

Control-Register Loading

When the PASN-translation and SASN-translation functions and related functions, and the SASN-authorization functions and subspace-replacement operations, if called for in the instruction execution, are performed without encountering any exceptions or exception conditions, the execution is completed by replacing the contents of control registers 1, 3, 4, 5, and 7 with the new values, and condition code 0 is set. The control registers are loaded as follows.

The PSW-key-mask, bits 32-47, and SASN, bits 48-63, in control register 3 are replaced by the contents of the PKM-d and SASN-d fields of the first operand.

If ASN-and-LX reuse is enabled, the SASTEIN, bits 0-31, in control register 3 is replaced as follows:

- When SASN translation is performed, by SASTEIN-d.
- When SASN translation is not performed because SASN-d is equal to PASN-d, by PASTEIN-new.
- When SASN translation is not performed because (1) SASN-d is not equal to PASN-d but is equal to SASN-old, (2) bit 61 (force ASN translation) of the second-operand address is zero, and (3) bit 63 (skip secondary authority test) of the second-operand address is one, the SASTEIN remains unchanged.

When ASN-and-LX reuse is not enabled, bits 0-31 of control register 3 always remain unchanged.

The PASN, bits 48-63 of control register 4, is replaced by the PASN-d of the first operand. If ASN-and-LX reuse is enabled, the PASTEIN, bits 0-31 of control register 4, is replaced by the PASTEIN-d of the first operand; otherwise, bits 0-31 of the register remain unchanged.

The authorization index, bits 32-47 of control register 4, is replaced as follows:

- When bit 62 of the second-operand address is one, by AX-d.
- When bit 62 of the second-operand address is zero and PASN translation is performed, by AX-p.
- When bit 62 of the second-operand address is zero and PASN translation is not performed, the authorization index remains unchanged.

The primary address-space-control element (PASCE) in control register 1 and the primary-ASN-second-table-entry origin (PASTEIO) in control register 5 are replaced as follows:

- When PASN translation is performed, the PASCE in control register 1 is replaced by the ASCE-p obtained as a result of PASN translation, except that it is replaced by ASCE-rp if a subspace-replacement operation was performed on ASCE-p. Also, the PASTEIO in control register 5 is replaced by PASTEIO-p.
The PASTEO-p is placed in bit positions 33-57 of control register 5, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.

- When PASN translation is not performed, the contents of control registers 1 and 5 remain unchanged.

The secondary address-space-control element (SASCE) in control register 7 is replaced as follows:

- When SASN-d equals PASN-d, by the new contents of control register 1, the PASCE. The new contents may be PASCE-old, ASCE-p, or ASCE-rp.

- When SASN translation is performed, by ASCE-s, or by ASCE-rs if a subspace-replacement operation was performed on ASCE-s.

When SASN-d does not equal PASN-d and SASN translation is not performed, the SASCE remains unchanged.

**Other Condition-Code Settings**

When PASN translation is called for and cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and PASTEIN-d does not equal the ASTEIN in the ASTE or (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-p, condition code 1 is set, and the control registers are not changed.

When PASN translation is called for and completed and any required PASTEIN-d comparison and subspace-replacement operations on the ASCE-p are also completed, and then either (1) the current primary space-switch-event-control bit, bit 57 of control register 1, is one or (2) the space-switch-event-control bit in the ASTE designated by PASTEO-p is one, condition code 3 is set, and the control registers are not changed.

When SASN translation is called for and the translation cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and SASTEIN-d does not equal the ASTEIN in the ASTE, (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-s, or (3) SASN authorization is called for and the SASN is not authorized, or condition code 2 is set, and the control registers are not changed.

**Special Conditions**

The instruction can be executed only when the ASN-translation control, bit 44 of control register 14, is one. If the ASN-translation-control bit is zero, a special-operation exception is recognized.

The first operand must be designated on a double-word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Figure 10-20 on page 10-47 and Figure 10-18 on page 10-44 summarize the functions of the instruction.

**Resulting Condition Code:**

0  Translation and authorization complete; parameters loaded
1  Primary ASN or subspace not available; parameters not loaded
2  Secondary ASN not available or not authorized, or secondary subspace not available; parameters not loaded
3  Space-switch event specified; parameters not loaded

**Program Exceptions:**

- Access (fetch, operand 1)
- Addressing (ASN-first-table entry, ASN-second-table entry, authority-table entry, dispatchable-unit control table)
- Privileged operation
- Special operation
- Specification
- Transaction constraint
The priority of recognition of program exceptions for the instruction is shown in Figure 10-18.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Access exceptions for second and third instruction halfwords.

7.B.1 Privileged-operation exception.

7.B.2 Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero.

8. Specification exception.

10. PASN translation and related processing (when performed).

10.1 Addressing exception for access to ASN-first-table entry.

10.2 Condition code 1 due to I bit (bit 0) in ASN-first-table entry being one.

10.3 Addressing exception for access to ASN-second-table entry.

10.4 Condition code 1 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and primary ASTE instance number (PASTEIN) in first operand not being equal to ASTEIN in ASTE.

10.5 Addressing exception for access to dispatchable-unit control table.

10.6 Addressing exception for access to subspace ASN-second-table entry.

10.7 Condition code 1 due to I bit (bit 0) in subspace ASN-second-table entry being one.

10.8 Condition code 1 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.

10.9 Condition code 3 due to either the old or new space-switch-event-control bit being one.

11. SASN translation and related processing (when performed).

11.1 Addressing exception for access to ASN-first-table entry.

11.2 Condition code 2 due to I bit (bit 0) in ASN-first-table entry being one.

11.3 Addressing exception for access to ASN-second-table entry.

11.4 Condition code 2 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and secondary ASTE instance number (SASTEIN) in first operand not being equal to ASTEIN in ASTE.

12.A Execution of secondary authorization (when performed).

12.A.1 Condition code 2 due to authority-table entry being outside table.

12.A.2 Addressing exception for access to authority-table entry.

12.A.3 Condition code 2 due to S bit in authority-table entry being zero.

12.B.1 Addressing exception for access to dispatchable-unit control table.

12.B.2 Addressing exception for access to subspace ASN-second-table entry.

12.B.3 Condition code 2 due to I bit (bit 0) in subspace ASN-second-table entry being one.

12.B.4 Condition code 2 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.

Programming Notes:

1. Bits 61 and 63 in the second-operand address are intended primarily to provide improved performance for those cases where the associated action is unnecessary.

   When bit 61 is set to zero, the action of the instruction is based on the assumption that the current values for PASCE-old, PASTEO-old, and AX-old are consistent with PASN-old and that SASCE-old is consistent with SASN-old. When this is not the case, bit 61 should be set to one.

   Bit 63, when one, eliminates the SASN-authorization test. The program may be able to determine in certain cases that the SASN is
authorized, either because of prior use or because the AX being loaded is authorized to access all address spaces.

2. The SASN-translation and SASN-authorization steps are not performed when SASN-d is equal to PASN-d. This is consistent with the action in SET SECONDARY ASN to current primary (SSAR-cp), which does not perform the translation or ASN authorization.

3. The storage-operand references for LOAD ADDRESS SPACE PARAMETERS may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

4. See Figure 10-19 on page 10-46 for a listing of abbreviations used in this instruction description.

### Explanation:

1. Action in this case is the same regardless of the outcome of this comparison or of the setting of this bit.
2. Second-operand-address bits:
   - 61: Force ASN translation.
   - 62: Use AX from first operand.
   - 63: Skip secondary authority test.
3. PASN-new is ASCE-rp (a copy of ASCE-p except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.
4. SASCE-new is ASCE-rs (a copy of ASCE-s except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

### Explanation:

2. PASN-new is ASCE-rp (a copy of ASCE-p except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.
Figure 10-21. Execution of LOAD ADDRESS SPACE PARAMETERS

Explanation:
* PASCE-tmp is ASCE-rp if subspace replacement occurred.
** SASCE-tmp is ASCE-rs if subspace replacement occurred.
Note: Actions involving PASTEIN and SASTEIN occur only if ASN-and-LX reuse is enabled.
LOAD CONTROL

**LCTL**  \( R_1, R_2, D_2(B_2) \) \([RS-a]\)

<table>
<thead>
<tr>
<th>'B7'</th>
<th>R_1</th>
<th>R_3</th>
<th>B_2</th>
<th>D_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>

**LCTLG**  \( R_1, R_2, D_2(B_2) \) \([RSY-a]\)

<table>
<thead>
<tr>
<th>'EB'</th>
<th>R_1</th>
<th>R_3</th>
<th>B_2</th>
<th>DL_2</th>
<th>DH_2</th>
<th>'2F'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>40</td>
</tr>
</tbody>
</table>

Bit positions of the set of control registers starting with control register \( R_1 \) and ending with control register \( R_3 \) are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD CONTROL (LCTL), bit positions 32-63 of the control registers are loaded from successive words beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD CONTROL (LCTLG), bit positions 0-63 of the control registers are loaded from successive double-words beginning at the second-operand address. The control registers are loaded in ascending order of their register numbers, starting with control register \( R_1 \) and continuing up to and including control register \( R_3 \), with control register 0 following control register 15.

The information loaded into the control registers becomes active when instruction execution has ended.

The displacement for LCTL is treated as a 12-bit unsigned binary integer. The displacement for LCTLG is treated as a 20-bit signed binary integer.

**Special Conditions**

The second operand must be designated on a word boundary for LCTL or on a doubleword boundary for LCTLG; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

---

LOAD PAGE TABLE ENTRY ADDRESS

**LPTEA**  \( R_1, R_2, R_3, M_4 \) \([RRF-b]\)

<table>
<thead>
<tr>
<th>'B9AA'</th>
<th>R_3</th>
<th>M_4</th>
<th>R_1</th>
<th>R_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
<td>28</td>
<td>31</td>
</tr>
</tbody>
</table>

General register \( R_2 \) contains a virtual address that is processed by means of dynamic address translation to locate a page-table entry, the 64-bit real or absolute address of which is returned in general register \( R_1 \). The \( M_4 \) field contains a value designating the effective address-space-control element (ASCE) that is used by DAT, as shown in the following table:

<table>
<thead>
<tr>
<th>( M_4 ) Field (binary)</th>
<th>Effective Address-Space-Control Element Used by DAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Contents of control register 1</td>
</tr>
<tr>
<td>0001</td>
<td>The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the ( R_2 ) field.</td>
</tr>
<tr>
<td>0010</td>
<td>Contents of control register 7</td>
</tr>
<tr>
<td>0011</td>
<td>Contents of control register 13</td>
</tr>
<tr>
<td>0100</td>
<td>The address-space-control element corresponding to the current address-space-control bits, bits 16 and 17 of the PSW.</td>
</tr>
</tbody>
</table>
When the M4 field contains 0001 binary, or when the M4 field contains 0100 binary and bits 16-17 of the PSW contain 01 binary, then access-register translation precedes, as is normal, the dynamic address translation.

The R3 field is ignored but should be zero to permit possible future extensions.

The virtual address specified by the R2 field is translated by means of dynamic-address translation, regardless of whether DAT is on or off. ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively. The DAT process completes upon locating the page-table entry. The contents of the page-table entry are not examined for format errors, the I bit is not examined to determine whether the page is invalid, and the page-frame real address is not fetched.

Virtual address computation is performed according to the addressing mode specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses, regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

If the DAT process successfully locates the page-table entry, the 64-bit real or absolute address of the entry is placed in general register R1, and the condition code is set as follows:

- When EDAT-1 does not apply, the condition code is set based on the DAT-protection bit (P) of the segment-table entry used in the translation. Condition code 0 is set when the P bit is zero; condition code 1 is set when the P bit is one.
- When EDAT-1 applies, the condition code is set based on all of the DAT-protection bits encountered in the translation. If the DAT-protection bit is zero in the segment-table entry and the DAT-protection bits are zero in any and all region-table entries used in the translation, condition code 0 is set. If the DAT-protection bit is one in any region- or segment-table entry used in the translation, condition code 1 is set.

When EDAT-1 applies and the DAT process successfully locates a valid segment-table entry in which the STE-format control is one, bits 0-60 of the segment-table entry address are placed in bit positions 0-60 of general register R1, bit 61 of the register is set to the logical OR of the DAT-protection bit in the segment-table entry and any region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When EDAT-2 applies and the DAT process successfully locates a valid region-third-table entry in which the RTTE-format control is one, bits 0-60 of the region-third-table entry address are placed in bit positions 0-60 of general register R1, bit 61 of the register is set to the logical OR of the DAT-protection bit in the region-third-table entry and any higher-level region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When a condition exists that would normally cause one of the exceptions shown in Figure 10-22, processing is as follows:

1. General register R1 is updated as follows:
   a. Bits 0-60 of the table-entry address are placed in bit positions 0-60 of the register.
   b. When EDAT-1 does not apply, bit 61 of the register is set to zero. When enhanced DAT applies, bit 61 is set to the logical OR of the DAT-protection bits in all valid region-table entries used in the translation; if the DAT process does not require region-table entries, or if no valid region-table entries are encountered, bit 61 is set to zero.
   c. The expected table-type bits are placed in bit positions 62-63 of the register. When the region table or segment table containing the invalid entry is directly designated by the address-space-control element, then the expected table-type bits are those contained in the designation-type control (DT) in the ASCE. Otherwise, the expected table-type bits are one less than the value of those bits in the next-higher-level table.
2. The instruction is completed by setting condition code 2.

Figure 10-22. LPTEA Exception Conditions Causing CC2

When a condition exists that would normally cause one of the exceptions shown in Figure 10-23, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R1, and bits 0-47 of the register are set to zeros; and (2) the instruction is completed by setting condition code 3.

Figure 10-23. LPTEA Exception Conditions Causing CC3 (Part 1 of 2)

Special Conditions

If the M4 field contains any value other than 0000-0100 binary, a specification exception is recognized.

The address-space-control element used in the translation must not be a real-space designation; otherwise, a special-operation exception is recognized. The exception due to the address-space-control element has priority 9 in Figure 6-6 on page 6-49.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation, the access-list entry, the address-space-second-table entry, or the authority-table entry designates a location which is not available in the configuration. An addressing exception is also recognized when the address used by DAT to fetch a region-table entry or the segment-table entry designates a location which is not available in the configuration.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.
A translation-specification exception is recognized if an accessed region-table entry or the segment-table entry has a zero I bit and a format error.

The operation is suppressed on all addressing exceptions.

**Resulting Condition Code:**

0  PTE address returned; P bit is 0 in all DAT-table entries examined
1  PTE address returned; P bit is 1 in any DAT-table entry examined
2  Invalid bit is one in the region- or segment-table entry; EDAT-1 applies, a valid STE was located, and STE FC is 1; or EDAT-2 applies, a valid RTTE was located, and RTTE FC is 1
3  Exception condition exists

**Program Exceptions:**

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, or segment-table entry)
- Operation (DAT-enhancement facility 2 not installed)
- Privileged operation
- Special operation
- Specification
- Transaction constraint
- Translation specification

**Programming Notes:**

1. An addressing exception is not recognized if the page-table-entry address returned in general register R1 is not available in the configuration.

2. When EDAT-1 applies, the STE-format control is one, and no other exception conditions apply, the address of the segment-table entry is placed in general register R1, and condition code 2 is set. This effectively performs a load-segment-table-entry-address function, although no such instruction is defined.

   However, because condition code 2 is also used to indicate an invalid region-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid STE:

   a. Bit positions 62-63 of general register R1 (the expected table-type) must contain 00 binary.

2. Bit position 58 of the table entry designated by general register R1 must contain zero (indicating a valid table entry).

3. When EDAT-2 applies, the RTTE-format control is one, and no other exception conditions apply, the address of the region-third-table entry is placed in general register R1, and condition code 2 is set. This effectively performs a load-region-third-table-entry-address function, although no such instruction is defined.

   However, because condition code 2 is also used to indicate an invalid region-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid RTTE:

   a. Bit positions 62-63 of general register R1 (the expected table-type) must contain 01 binary.

   b. Bit position 58 of the table entry designated by general register R1 must contain 00 binary (indicating a valid table entry).

   c. The table-type field in bit positions 60-61 of the table entry designated by general register R1 must contain 00 binary (designating a segment-table entry).

The following program fragment illustrates this determination when only EDAT-1 applies. If no branch is taken, then the address in general register 1 is that of a segment-table entry in which the STE-format control is one:

```
LPTEA 1,0,2,4
BRC 8,PTE_WITH_NEITHER_STE_NOR_RTE_PROT
BRC 4,PTE_WITH_PROTECTED_STE_OR_RTE
BRC 1,EXCEPTION_EXISTS
TMLL 1,X'0003'
JNZ EXCEPTION_EXISTS
NILL 1,X'FFF8'
LURAG 10,1
TMLL 10,X'0020'
JO EXCEPTION_EXISTS
```
that of a region-third-table entry in which the RTTE-format control is one:

```
* Further check for EDAT-2
TMLL 10,X'000C
JZ VALID_F1_STE
* Must be valid F1 RTTE
```

4. When condition code 2 is set as a result of locating a valid segment-table entry in which the STE-format control is one, bit 61 of general register R1 indicates whether DAT protection applies to the segment. Similarly, when condition code 2 is set as a result of locating a valid region-third-table entry in which the RTTE-format control is one, bit 61 of general register R1 indicates whether DAT protection applies to the region.

5. When EDAT-1 does not apply, only the STE is examined in determining whether condition code 0 or 1 is set. When EDAT applies, all DAT-table entries used in the translation may be examined in determining whether condition code 0 or 1 is to be set.

**LOAD PSW**

LPSW  \[ D_3(B_2) \]  [S]

The current PSW is replaced by a 16-byte PSW formed from the contents of the doubleword at the location designated by the second-operand address.

Bit 12 of the doubleword must be one; otherwise, a specification exception may be recognized, depending on the model.

Bits 0-32 of the doubleword, except with bit 12 inverted, are placed in bit positions 0-32 of the current PSW. Bits 33-63 of the doubleword are placed in bit positions 97-127 of the current PSW. Bits 33-96 of the current PSW are set to zeros.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

**Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized. A specification exception may be recognized if bit 12 of the operand is zero, depending on the model.

The PSW fields which are to be loaded by the instruction are not checked for validity before they are loaded, except for the optional checking of bit 12. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of bits 0, 2-4, 12, or 25-30 is a one.
- Bit 24 is one (recognition of this condition is optional)
- Bits 31 and 32 are both zero, and bits 97-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.

In these cases, the operation is completed, and the resulting instruction-length code is 0.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:** The code is set as specified in the new PSW loaded.

**Program Exceptions:**

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

**Programming Note:** The second operand should have the format of an ESA/390 PSW. A specification exception will be recognized during or after the execution of LOAD PSW if bit 12 of the operand is zero.

**LOAD PSW EXTENDED**

LPSWE \[ D_3(B_2) \]  [S]

The operand must be designated on a doubleword boundary; otherwise, a specification exception is rec-
The current PSW is replaced by the contents of the 16-byte second operand.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

**Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The value which is to be loaded by the instruction is not checked for validity before it is loaded. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of the unassigned bits (0, 2-4, 25-30, or 33-63) is a one.
- Bit 12 is a one.
- Bit 24 is one (recognition of this condition is optional)
- Bits 31 and 32 are both zero, and bits 64-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.

In these cases, the operation is completed, and the resulting instruction-length code is zero.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:** The code is set as specified in the new PSW loaded.

**Program Exceptions:**

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

</tbody>
</table>

For LOAD REAL ADDRESS (LRA, LRAY) in the 24-bit or 31-bit addressing mode, if bits 0-32 of the 64-bit real or absolute address corresponding to the second-operand virtual address are all zeros, bits 32-63 of the real or absolute address are placed in bit positions 32-63 of general register \( R_1 \), and bits 0-31 of the register remain unchanged. If bits 0-32 of the real address or absolute are not all zeros, a special-operation exception is recognized.

For LRA or LRAY in the 64-bit addressing mode, and for LOAD REAL ADDRESS (LRAG) in any addressing mode, the 64-bit real or absolute address corresponding to the second-operand virtual address is placed in general register \( R_1 \).

When EDAT-1 does not apply, or when EDAT-1 applies but the second operand is translated by means of a segment-table entry in which the STE-format control is zero, the address placed in general register \( R_1 \) is real. When EDAT-1 applies and the second operand is translated by means of a segment-table entry in which the STE-format control is one, or when EDAT-2 applies and the second operand is translated by means of a region-third-table entry in which the RTTE-format control is one, the address placed in general register \( R_1 \) is absolute.

The virtual address specified by the \( X_2 \), \( B_2 \), and \( D_2 \) fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

The displacement for LRA is treated as a 12-bit unsigned binary integer. The displacement for LRAY and LRAG is treated as a 20-bit signed binary integer.
DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in Figure 10-24.

<table>
<thead>
<tr>
<th>PSW Bits 16 and 17</th>

</tr>
<tr>
<td>11</td>
<td>Contents of control register 13</td>
</tr>
</tbody>
</table>

Figure 10-24. Address-Space Control used by LOAD REAL ADDRESS

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The virtual-address computation is performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry, if used, are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

Condition code 0 is set when both ART, if applicable, and DAT can be completed and a special-operation exception is not recognized, that is, when an address-space-control element can be obtained, the entry in each DAT table lies within the table and has a zero I bit, and, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resulting real or absolute address are zeros. The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

When PSW bits 16 and 17 are 01 binary and an address-space-control element cannot be obtained because of a condition that would normally cause one of the exceptions shown in Figure 10-25, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R1, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

When ART is completed normally, the operation is continued through the performance of DAT.

When the segment-table entry is outside the table and bits 0-32 of the real or absolute address of the entry are all zeros, bits 32-63 of the entry address are placed in bit positions 32-63 of general register R1, bits 0-31 of the register remain unchanged, and the instruction completes by setting condition code 3. If bits 0-32 of the address are not all zeros, the result is as described in the section “DAT-Related Exceptions for LOAD REAL ADDRESS” on page 10-56.

When the I bit in the segment-table entry is one, the following applies:

- For LRA or LRAY in the 64-bit addressing mode or for LRAG in any addressing mode, the 64-bit real or absolute address of the segment-table entry is placed in general register R1, and the instruction is completed by setting condition code 1.
- For LRA or LRAY in the 24-bit or 31-bit addressing mode, the following applies:
  - If bits 0-32 of the address of the segment-table entry are all zeros, bits 32-63 of the real or absolute address of the segment-table entry are placed in bits 32-63 of general register R1, bits 0-31 of the register remain unchanged, and the instruction is completed by setting condition code 1.

Figure 10-25. Handling of ART-Related Exceptions for LOAD REAL ADDRESS
When the I bit in the page-table entry is one, the following applies:

- For LRA or LRAY in the 64-bit addressing mode or for LRAG in any addressing mode, the 64-bit real or absolute address of the page-table entry is placed in general register R1, and the instruction is completed by setting condition code 2.

- For LRA or LRAY in the 24-bit or 31-bit addressing mode, the following applies:
  - If bits 0-32 of the address of the page-table entry are all zeros, bits 32-63 of the real or absolute address of the page-table entry are placed in bits 32-63 of general register R1, bits 0-31 of the register remain unchanged, and the instruction is completed by setting condition code 2.
  - If bits 0-32 of the address of the page-table entry are not all zeros, the result is as described in the section “DAT-Related Exceptions for LOAD REAL ADDRESS”, below.

A segment-table-entry or page-table-entry address placed in general register R1 is real or absolute in accordance with the type of address that was used during the attempted translation.

### DAT-Related Exceptions for LOAD REAL ADDRESS

If a condition exists that would normally cause one of the exceptions shown in the Figure 10-26, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R1, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

<td>0011</td>
</tr>
</tbody>
</table>

Figure 10-26. Handling of DAT-Related Exceptions for LOAD REAL ADDRESS

### Special Conditions

A special-operation exception is recognized when, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resultant 64-bit real address are not all zeros.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table...
entry designates a location which is not available in the configuration or when the address used to fetch the region-table entry or entries, if any, segment-table entry, or page-table entry designates a location which is not available in the configuration.

A translation-specification exception is recognized when an accessed region-table entry or the segment-table entry or page-table entry has a zero I bit and a format error, that is, when any of the reasons listed in “Translation-Specification Exception” on page 6-44 applies.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

The operation is suppressed on all addressing exceptions.

**Resulting Condition Code:**

0  Translation available
1  Segment-table entry invalid (I bit one)
2  Page-table entry invalid (I bit one)
3  Address-space-control element not available, region-table entry outside table or invalid (I bit one), segment-table entry outside table, or, for LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros, segment-table entry or page-table entry invalid (I bit one)

**Program Exceptions:**

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, or page-table entry)
- Operation (LRAY, if the long-displacement facility is not installed)
- Privileged operation
- Special operation (LRA, LRAY only)
- Transaction constraint
- Translation specification

**Programming Notes:**

1. Caution must be exercised in the use of LOAD REAL ADDRESS in a multiprocessing configuration. Since INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY may set I bits in storage to one before causing the corresponding entries in TLBs of other CPUs to be cleared, the simultaneous execution of LOAD REAL ADDRESS on this CPU and either INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on another CPU may produce inconsistent results. Because LOAD REAL ADDRESS may access the tables in storage, the region-table entries, segment-table entry or page-table entry may appear to be invalid (condition codes 3, 1, or 2, respectively) even though the corresponding TLB entry has not yet been cleared, and the TLB entry may remain in the TLB until the completion of INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on the other CPU. There is no guaranteed limit to the number of instructions which may be executed between the completion of LOAD REAL ADDRESS and the TLB being cleared of the entry.

The above cautions for using LOAD REAL ADDRESS also apply when COMPARE AND SWAP AND PURGE or COMPARE AND REPLACE DAT TABLE ENTRY is used to explicitly set the invalid bit in a DAT-table entry.

2. Figure 10-27 on page 10-57 summarizes the resulting contents of general register R1, and the condition code.

- RA3: Bits 33-47 of the resultant real address.
- RA4: Bits 48-63 of the resultant real address.
- U: Unchanged.

*Figure 10-27. Summary of Results: LOAD REAL ADDRESS*
64-bit addressing mode, the leftmost 32 bits of the register must be set to zeros.

**LOAD USING REAL ADDRESS**

<table>
<thead>
<tr>
<th>LURA</th>
<th>R&lt;sub&gt;1&lt;/sub&gt;,R&lt;sub&gt;2&lt;/sub&gt;</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B24B'</td>
<td>0 16 24 28 31</td>
<td>R&lt;sub&gt;1&lt;/sub&gt;</td>
</tr>
</tbody>
</table>

For LOAD USING REAL ADDRESS (LURA), the word at the real-storage location addressed by the contents of general register R<sub>2</sub> is placed in bit positions 32-63 of general register R<sub>1</sub>, and the contents of bit positions 0-31 remain unchanged. For LOAD USING REAL ADDRESS (LURAG), the doubleword at that real-storage location is placed in bit positions 0-63 of general register R<sub>1</sub>.

In the 24-bit addressing mode, bits 40-63 of general register R<sub>2</sub> designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R<sub>2</sub> designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R<sub>2</sub> designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

**Special Conditions**

The contents of general register R<sub>2</sub> must designate a location on a word boundary for LURA or on a doubleword boundary for LURAG; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Addressing (address specified by general register R<sub>2</sub>)
- Privileged operation

**MODIFY STACKED STATE**

</tbody>
</table>

The contents of bit positions 32-63 of the pair of general registers designated by the R<sub>1</sub> field are placed in the modifiable area, byte positions 152-159, of the last state entry in the linkage stack.

The R<sub>1</sub> field designates the even-numbered register of an even-odd pair of general registers.

The last state entry is located as described in “Unstacking Process” on page 5-87. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to the references to the linkage stack, but low-address and DAT protection do apply.

**Special Conditions**

A specification exception is recognized when R<sub>1</sub> is odd.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-28 on page 10-60.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
• Access (fetch and store, except for key-controlled protection, linkage-stack entry)
• Special operation
• Specification
• Stack empty
• Stack specification
• Stack type
• Transaction constraint

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.B Special-operation exception due to DAT being off or the CPU being in secondary-space mode.

8.A Specification exception due to R_1 being odd.

8.B.1 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.

8.B.2 Stack-type exception due to current entry not being a state entry or header entry.

Note: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.

8.B.3 Access exceptions (fetch) for second word of the header entry.

8.B.4 Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.

8.B.5 Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.

8.B.6 Stack-specification exception due to preceding entry being a header entry.

8.B.7 Stack-type exception due to preceding entry not being a state entry.

8.B.8 Access exceptions (store) for the modifiable area of the state entry.

Figure 10-28. Priority of Execution: MODIFY STACKED STATE

Programming Note: The modifiable area can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE.

The first operand is replaced by the second operand. The first and second operands both are 4K bytes on 4K-byte boundaries. The results are indicated in the condition code. The accesses to the first-operand location or the second-operand location, but not to both locations, may be performed by using the key specified in general register 0; otherwise, the accesses to an operand location are performed by using the PSW key.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

Bits 56-59 of general register 0 are used as the specified access key. Bit 52 of general register 0, when one, specifies that the specified access key is to be used for accessing the first operand, and bit 53 specifies the same for the second operand. A specification exception is recognized if bits 52 and 53 are both ones. Bit 54 of general register 0 is a destination-reference-intention bit, and bit 55 is a condition-code-option bit. Bits 48-51 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-47 and 60-63 of general register 0 are ignored.

The contents of the registers just described are shown in Figure 10-29 on page 10-61.

When bit 52 of general register 0 is one, the fetch accesses to the second-operand location are performed by using the PSW key, and the store

MOVE PAGE

\[
\text{MVPG } R_1, R_2 \quad \text{[RRE]}
\]

The first operand is replaced by the second operand.

The first and second operands both are 4K bytes on 4K-byte boundaries. The results are indicated in the condition code. The accesses to the first-operand location or the second-operand location, but not to both locations, may be performed by using the key specified in general register 0; otherwise, the accesses to an operand location are performed by using the PSW key.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

Bits 56-59 of general register 0 are used as the specified access key. Bit 52 of general register 0, when one, specifies that the specified access key is to be used for accessing the first operand, and bit 53 specifies the same for the second operand. A specification exception is recognized if bits 52 and 53 are both ones. Bit 54 of general register 0 is a destination-reference-intention bit, and bit 55 is a condition-code-option bit. Bits 48-51 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-47 and 60-63 of general register 0 are ignored.

The contents of the registers just described are shown in Figure 10-29 on page 10-61.

When bit 52 of general register 0 is one, the fetch accesses to the second-operand location are performed by using the PSW key, and the store
accesses to the first-operand location are performed by using the key specified in general register 0. When bit 53 of general register 0 is one, the fetch accesses to the second-operand location are performed by using the key specified in general register 0, and the store accesses to the first-operand location are performed by using the PSW key. When bits 52 and 53 are both zeros, the PSW key is used for accessing both operands.

When 4K bytes have been moved, condition code 0 is set.

When a page-translation-exception condition exists, the exception is not recognized if the condition-code-option bit, bit 55 in general register 0, is one; instead, condition code 1 or 2 is set. Condition code 1 is set if a page-translation-exception condition exists for the first operand and not for the second operand. Condition code 2 is set if a page-translation-exception condition exists for the second operand, regardless of whether the condition exists for the first operand.

When an access exception can be recognized for both operands, it is unpredictable for which operand an exception is recognized. If one of the exceptions is a page-translation exception that would cause condition code 1 or 2 to be set, it is unpredictable whether the access exception for the other operand is recognized or condition code 1 or 2 is set.

When the instruction completes by setting condition codes 1 or 2, and a PER zero-address-detection condition also exists for either the first or second operand, it is unpredictable whether the zero-address-detection condition is recognized.

**Explanation:**

CCO  Condition-code-option bit.
DRI  Destination-reference-intention bit.
F When one, specified access key applies to first operand. A specification exception is recognized if F and S both are one.
Key  Specified access key.
S When one, specified access key applies to second operand. A specification exception is recognized if F and S both are one.

*Figure 10-29. Register Contents for MOVE PAGE*
The references to main storage are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

Special Conditions

In the problem state, when either bit 52 or bit 53 in general register 0 is one, the operation is performed only if the access key specified in general register 0 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid. When bits 52 and 53 are both zeros, the access key in general register 0 is not tested for validity.

In the problem state, when bits 52 and 53 in general register 0 are both ones and the access key in general register 0 is not permitted by the PSW-key mask, it is unpredictable whether a specification exception or a privileged-operation exception is recognized.

Resulting Condition Code:

0 Data moved
1 Condition-code-option bit one, page-table entry for first operand invalid, and page-table entry for second operand valid
2 Condition-code-option bit one and page-table entry for second operand invalid
3 --

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (access key specified, and selected PSW-key-mask bit is zero in the problem state)
- Specification
- Transaction constraint

Programming Notes:

1. MOVE PAGE, or a loop of MOVE PAGE instructions that moves multiple pages, may provide, on most models, better performance than a MOVE LONG instruction or a loop of MOVE (MVC) instructions that performs the same function. Whether MOVE PAGE provides better performance depends on control-program specifications and the method by which the control program handles page-translation exceptions.

2. The destination-reference-intention bit should be set to one when there is an intention to reference the first operand by means of an instruction other than MOVE PAGE. The bit may allow the control program to process a page-translation exception more efficiently.

3. The condition-code-option bit provides compatibility with the MOVE PAGE instruction of the ESA/390 move-page facility 1. The bit is for use by the MVS/ESA HSPSERV macro expansion.

4. The condition code set by the instruction normally need not be examined if the condition-code-option bit is zero or if DAT is off.

5. See the definitions of real locations 162 and 168-175 under “Assigned Storage Locations” in Chapter 3, “Storage” for a description of information stored during a program interruption due to a DAT-related translation exception recognized by MOVE PAGE.

MOVE TO PRIMARY

<table>
<thead>
<tr>
<th>MVCP</th>

<th>[SS-d]</th>
</tr>
</thead>
<tbody>
<tr>
<td>(DA')</td>
<td>(R_i)</td>
<td>(R_3)</td>
</tr>
</tbody>
</table>

MOVE TO SECONDARY

<table>
<thead>
<tr>
<th>MVCS</th>
<th>(D_i(R_i,B_i),D_2(B_2),R_3)</th>
<th>[SS-d]</th>
</tr>
</thead>
<tbody>
<tr>
<td>(DB')</td>
<td>(R_i)</td>
<td>(R_3)</td>
</tr>
</tbody>
</table>

The first operand is replaced by the second operand. One operand is in the primary address space, and the other is in the secondary address space. The accesses to the operand in the primary space are performed by using the PSW key; the accesses to the operand in the secondary space are performed by using the key specified by the third operand.

The addresses of the first and second operands are virtual, one operand address being translated by means of the primary address-space-control element and the other by means of the secondary address-space-control element. Operand-address translation is performed in the same way when the address-space-control bits in the current PSW specify either the primary-space mode or the secondary-space mode.
For MOVE TO PRIMARY, movement is to the primary space from the secondary space. The first-operand address is translated by using the primary address-space-control element, and the second-operand address is translated by using the secondary address-space-control element.

For MOVE TO SECONDARY, movement is to the secondary space from the primary space. The first-operand address is translated by using the secondary address-space-control element, and the second-operand address is translated by using the primary address-space-control element.

Bit positions 56-59 of general register R₃ are used as the secondary-space access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R₁ contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-30 on page 10-63.

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right. The storage-operand-consistency rules are the same as for MOVE (MVC), except that when the operands overlap in real storage, the use of the common real-storage locations is not necessarily recognized.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

For both MOVE TO PRIMARY and MOVE TO SECONDARY, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

**Special Conditions**

Since the secondary space is accessed, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recognized. A special-operation exception is also recognized when the address-space-control bits in the current PSW specify the access-register or home-space mode.

In the problem state, the operation is performed only if the secondary-space access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the secondary-space access key is valid.
**Resulting Condition Code:**

0  True length less than or equal to 256  
1  --  
2  --  
3  True length greater than 256

**Program Exceptions:**

- Access (fetch, primary virtual address, operand 2, MVCS; fetch, secondary virtual address, operand 2, MVCP; store, secondary virtual address, operand 1, MVCS; store, primary virtual address, operand 1, MVCP)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-31.

1. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
2. Access exceptions for second and third instruction halfwords.
3. Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero, to DAT being off, or to the CPU being in the access-register or home-space mode.
4. Transaction constraint.
5. Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
6. Completion due to length zero.

**Programming Notes:**

1. MOVE TO PRIMARY and MOVE TO SECONDARY can be used in a loop to move a variable number of bytes of any length. See the programming note under MOVE WITH KEY.

2. MOVE TO PRIMARY and MOVE TO SECONDARY should be used only when movement is between different address spaces. The performance of these instructions on most models may be significantly slower than that of MOVE WITH KEY, MOVE (MVC), or MOVE LONG. In addition, the definition of overlapping operands for MOVE TO PRIMARY and MOVE TO SECONDARY is not compatible with the more precise definitions for MOVE (MVC), MOVE WITH KEY, and MOVE LONG.

**MOVE WITH DESTINATION KEY**

\[ \text{MVC} \quad D_1(B_1), D_2(B_2) \quad \text{[SSE]} \]

The first operand is replaced by the second operand. The accesses to the destination-operand location are performed by using the key specified in general register 1, and the accesses to the source-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-32.

**Figure 10-31. Priority of Execution: MOVE TO PRIMARY and MOVE TO SECONDARY**

1. L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

**Figure 10-32. Register Contents of MOVE WITH DESTINATION KEY**
The fetch accesses to the second-operand location are performed by using the PSW key, and the store accesses to the first-operand location are performed by using the key specified in general register 1.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

**Special Conditions**

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

**Programming Note:** See the programming notes for the MOVE WITH SOURCE KEY instruction.

**MOVE WITH KEY**

```
MVCK D1(R1,B1),D2(B2),R3 [SS-d]
```

The first operand is replaced by the second operand. The fetch accesses to the second-operand location are performed by using the key specified in the third operand, and the store accesses to the first-operand location are performed by using the PSW key.

Bit positions 56-59 of general register R3 are used as the source access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R1 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-33.

```
<table>
<thead>
<tr>
<th>0 8 12 16 20 32 36 47</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘D9’ R1 R3 B1 D1 B2 D2</td>
</tr>
</tbody>
</table>
```

The first and second operands are of the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Figure 10-33. Register Contents of MOVE WITH KEY

Each storage operand is processed left to right. When the storage operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte was fetched. The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.
As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

Special Conditions

In the problem state, the operation is performed only if the source access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the source access key is valid.

Resulting Condition Code:

<p>| | | | | | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
</table>
| 0 | True length less than or equal to 256
| 1 | --
| 2 | --
| 3 | True length greater than 256

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-34.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A Access exceptions for second and third instruction halfwords.
8. Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9. Completion due to length zero.
10. Access exceptions for operands.

Figure 10-34. Priority of Execution: MOVE WITH KEY

Programming Notes:

1. MOVE WITH KEY can be used in a loop to move a variable number of bytes of any length, as follows:

   LOOP   MVCK   D1(R1,B1),D2(B2),R3
   BC     8,END
   AHI   B1,256
   AHI   B2,256
   AHI   R1,-256
   B   LOOP
   END   [Any instruction]

   The above program is for execution in the 24-bit or 31-bit addressing mode. In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

   2. The performance of MOVE WITH KEY on most models may be significantly slower than that of the MOVE (MVC) and MOVE LONG instructions. Therefore, MOVE WITH KEY should not be used if the keys of the source and the target are the same.

MOVE WITH OPTIONAL SPECIFICATIONS

<table>
<thead>
<tr>
<th>MVCOS</th>
<th>D1(B1),D2(B2),R3</th>
</tr>
</thead>
<tbody>
<tr>

</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>36</td>
</tr>
</tbody>
</table>

The first operand is replaced by the second operand. Bits in general register 0 determine the address-space-control modes and protection keys that are used to access the first and second operands.

The addresses of the first and second operands are virtual.

Bits 32-47 of general register 0 contain the operand-access control for the first operand (OAC1), and bits 48-63 of general register 0 contain the operand-access control for the second operand (OAC2). The operand-access control has the following format.

<table>
<thead>
<tr>
<th>Key</th>
<th>/</th>
<th>/</th>
<th>/</th>
<th>AS</th>
<th>/</th>
<th>/</th>
<th>/</th>
<th>KA</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>8</td>
<td>10</td>
<td>14</td>
<td>15</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Specified-Access Key (Key): Bits positions 0-3 contain the specified-access key that is used to
access the operand if the specified-access-key validity bit (K) is one; otherwise, the specified-access key is ignored.

**Specified-Address-Space Control (AS):** Bit positions 8-9 contain the address-space control that is used to access the operand when the specified-address-space-control validity bit (A) is one; otherwise, the specified-address-space control is ignored. The meaning of bits 8-9 is identical to that of the address-space control in bits 16-17 of the PSW.

**Specified-Access-Key Validity Bit (K):** Bit 14 controls whether the PSW key or the specified-access key is used to access the operand. When the K bit is zero, the PSW key is used. When the K bit is one, the specified-access key is used.

**Specified-Address-Space-Control Validity Bit (A):** Bit 15 controls whether the address-space control in the current PSW or the address-space control in the specified-ASC is used to access the operand. When the A bit is zero, the address-space control in the current PSW is used. When the A bit is one, the specified-address-space control is used.

Bits 0-31 of general register 0 are ignored. Bits 4-7 and 10-14 of both operand-access controls (that is, bits 36-39, 42-45, 52-55, and 58-61 of general register 0) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register R₃ contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-35.

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 4,096, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 4,096 or less, including zero, then the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 4,096, then the effective length is 4,096, and condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand real location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.
In the 24-bit addressing mode, wraparound is from location $2^{24} - 1$ to location 0; in the 31-bit addressing mode, wraparound is from location $2^{31} - 1$ to location 0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

**Special Conditions**

A special-operation exception is recognized for any of the following conditions:

- DAT is off.
- The address-space control in OAC1 designates the home-space mode, the address-space-control validity bit in OAC1 is one, and the current PSW is in the problem state (that is, bits 40-41 of general register 0 are 11 binary, bit 47 of the register is one, and bit 15 of the current PSW is one).
- The secondary-space control, bit 37 of control register 0, is zero, and either of the following is true:
  - The A bit of the OAC for either operand is zero, and bits 16-17 of the current PSW are 10 binary.
  - The A bit of the OAC for either operand is one, and the AS bits in the same OAC are 10 binary.

The secondary-space control is not examined for an operand that is accessed in the secondary-space mode as a result of access-register translation (that is, DAT is on, bits 16-17 of the current PSW are 01 binary, and the access register corresponding to the operand’s base register contains an ALET of 00000001 hex).

When MOVE WITH OPTIONAL SPECIFICATIONS is executed in the problem state, and either the first or second operand’s specified-access key (from GR0) or the implied-access key (from the PSW) is invalid, a privileged-operation exception is recognized. The validity of an access key is determined as follows:

- The specified-access key in OAC1 is invalid if the specified-access-key control, bit 46 of general register 0, is one; and the specified-access key, bits 32-35 of the register, designates a PSW-key-mask (PKM) bit position that contains zero.
- The implied-access key is invalid if both of the following conditions are true:
  - Either or both bits 46 and 62 of general register 0 are zero.
  - The PSW key, bits 8-11 of the PSW, designates a PKM bit position that contains zero.

In the supervisor state, any value for the implied- or specified-access key is valid.

**Resulting Condition Code:**

| 0 | True length less than or equal to 4,096 |
| 1 | -- |
| 2 | -- |
| 3 | True length greater than 4,096 |

**Program Exceptions:**

- Access (fetch, second operand; store first operand)
- Operation (MVCOS not installed)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-36.
Programming Notes:

1. MOVE WITH OPTIONAL SPECIFICATIONS can be used in a loop to move a variable number of bytes of any length.

2. An example of moving 16 K-bytes to the home address space from the secondary address space is shown below. The first operand is accessed using the PSW key, and the second operand is accessed using key 5.

   In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

3. The performance of MOVE WITH OPTIONAL SPECIFICATIONS may be significantly slower than that of individual MOVE (MVC) instructions.

4. When bits 46-47 and 62-63 of general register 0 are all zero, MOVE WITH OPTIONAL SPECIFICATIONS uses the key and address-space control in the current PSW to access both the first and second operands.

5. In the MVCDK, MVCK, MVCP, MVCS, and MVCSK instructions, one operand is accessed using an implied key from the PSW, and the other operand is accessed using a specified key in a register. In the problem state, only the specified key is checked for validity in the PSW-key mask (PKM).

   When MVCOS is executed in the problem state, the access keys for the first and second operands are both checked for validity in the PKM, regardless of whether the keys are implied or specified.

### MOVE WITH SOURCE KEY

\[
\text{MVCSK } D_1(B_1), D_2(B_2) \quad [\text{SSE}]
\]

The first operand is replaced by the second operand. The accesses to the source-operand location are performed by using the key specified in general register 1, and the accesses to the destination-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-37.

![Figure 10-37. Register Contents of MOVE WITH SOURCE KEY](image-url)

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the key specified in general register 1, and the store accesses to the first-operand location are performed by using the PSW key.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

### Special Conditions
In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

**Programming Notes:**
1. When data is to be moved alternately in both directions between two storage areas that are fetch protected by means of different keys, then MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY can be used while leaving the PSW key unchanged; and this may be, on most models, significantly faster than using MOVE WITH KEY along with SET PSW KEY FROM ADDRESS to change the PSW key.
2. MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY should be used only when movement is between storage areas having different keys. The performance of these instructions on most models may be significantly slower than that of the MOVE (MVC) instruction.
3. MOVE WITH SOURCE KEY or MOVE WITH DESTINATION KEY can be used in a loop to move a variable number of bytes as shown in the following example. In the example, the specified access key, the first-operand address, the second-operand address, and the length of each operand are assumed to be in general registers 1-4, respectively, at the beginning of the example. The length of each operand is treated as a 32-bit signed value, and a negative value is treated as zero.

```

AH 4,-256
BC 12.LAST
LA 0,255

LOOP MVCSK 0(2),0(3)
LA 2,256(2)
LA 3,256(3)
AH 4,-256
BC 2.Loop

LAST LA 0,255(4)
MVCSK 0(2),0(3)
END [Any instruction]
```

A page-in operation is performed which transfers a 4K-byte block to the real-storage location designated by general register $R_1$ from the expanded-storage block designated by general register $R_2$.

Bits 32-63 of general register $R_2$ are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4K-byte block of expanded storage which is to be transferred. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register $R_1$ are a real address which designates a 4K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 are ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE IN is not subject to key-controlled storage protection, but low-address protection does apply. PAGE IN is not subject to program-event recording for storage alteration.
A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

If the page-in operation is completed with no errors, condition code 0 is set.

If the page-in operation encounters an expanded-storage data error, condition code 1 is set. For an expanded-storage data-error condition, the contents of the entire 4K-byte block in real storage is unpredictable, but this condition does not result in the generation of invalid checking-block codes in real storage.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

Operation of PAGE IN in a Multiple-CPU Configuration

The accesses to main storage and to expanded storage by PAGE IN are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

See also the description under PAGE OUT.

Resulting Condition Code:

0 Page-in operation completed
1 Expanded-storage data error
2 --
3 Expanded-storage block not available

Program Exceptions:

- Addressing (block designated by general register \( R_i \))
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Protection (block designated by general register \( R_i \); low-address protection)
- Transaction constraint

PAGE OUT

\[
\text{PGOUT} \quad R_1, R_2 \quad [\text{RRE}]
\]

A page-out operation is performed which transfers a 4K-byte block from the real-storage location designated by general register \( R_1 \) to the expanded-storage block designated by general register \( R_2 \).

Bits 32-63 of general register \( R_2 \) are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4K-byte block of expanded storage which is to be replaced. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register \( R_1 \) are a real address which designates a 4K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 is ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE OUT is not subject to key-controlled protection.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

Depending on the model, after the data has been written to the expanded-storage block, a read-back-check operation may be performed to determine whether the data was written correctly. If the read-back-check operation determines that the data has been written correctly, condition code 0 is set. If the read-back-check operation encounters an expanded-storage data error, condition code 1 is set.

Most models do not perform the read-back-check operation, and, after the page-out operation is completed, condition code 0 is set.

Regardless of whether condition code 0 or condition code 1 is set, the entire 4K-byte block is written. Errors, if any, in the block after the block is written are
preserved. Thus, if a subsequent execution of PAGE IN addresses the same expanded-storage block, the expanded-storage data error will be detected and condition code 1 will be indicated.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

**Operation of PAGE OUT in a Multiple-CPU Configuration**

The accesses to main storage and to expanded storage by PAGE OUT are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

If two or more CPUs issue PAGE IN or PAGE OUT instructions at approximately the same instant in time, depending on the model, the operations may be performed one at a time, or the operations may be performed concurrently. Concurrent operation may occur even if the instructions address the same expanded-storage block.

When two or more PAGE OUT instructions addressing the same expanded-storage block are executed concurrently, the resulting values in the expanded-storage block for each group of bytes transferred may be from any of the instructions being executed simultaneously. The number of bytes transferred as a group depends on the model.

Similarly, for concurrent execution of a PAGE IN and a PAGE OUT instruction for the same expanded-storage block, the resulting values for each group of bytes transferred as a result of the execution of the PAGE IN instruction may be either the old or new values from the expanded-storage block.

Concurrent operation of paging instructions does not result in expanded-storage data errors.

**Resulting Condition Code:**

**Program Exceptions:**

- Addressing (block designated by general register R)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Transaction constraint

### PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION

**PCKMO [RRE]**

A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-38 on page 10-73 shows the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.
The function codes for PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION are as follows.

Explanation:

— Not applicable

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions.

Figure 10-39 on page 10-73 shows the contents of general registers 0 and 1.

In the access-register mode, access register 1 specifies the address space containing the parameter block.

As observed by other CPUs and channel programs, reference to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

PCKMO-Query (Function Code 0)
The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-73.

The parameter block used for the function has the following format:

![Figure 10-40. Parameter Block for PCKMO-Query](image-url)
A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PCKMO instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

**PCKMO-Encrypt-DEA-Key (Function Code 1)**

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-73.

The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>Cryptographic Key (K)</td>
</tr>
<tr>
<td>8-15</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>

<tr>
<td>16-23</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
<tr>
<td>24-31</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
</tbody>
</table>
```

*Figure 10-41. Parameter Block for PCKMO-Encrypt-DEA-Key*

The 8-byte cryptographic key, K, in byte offsets 0-7 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-374 for the encryption algorithm.) The result is placed back in byte offsets 0-7 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 8-31 of the parameter block.

**PCKMO-Encrypt-TDEA-128-Key (Function Code 2)**

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-73.

The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-15</td>
<td>Cryptographic Key (K)</td>
</tr>
<tr>
<td>16-31</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
<tr>
<td>32-47</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
</tbody>
</table>
```

*Figure 10-42. Parameter Block for PCKMO-Encrypt-TDEA-128-Key*

The 16-byte cryptographic key, K, in byte offsets 0-15 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-374 for the encryption algorithm.) The result is placed back in byte offsets 0-15 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 16-31 of the parameter block.

**PCKMO-Encrypt-TDEA-192-Key (Function Code 3)**

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-73.

The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-23</td>
<td>Cryptographic Key (K)</td>
</tr>
<tr>

<tr>
<td>48-63</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
</tbody>
</table>
```

*Figure 10-43. Parameter Block for PCKMO-Encrypt-TDEA-192-Key*

The 24-byte cryptographic key, K, in byte offsets 0-23 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-374 for the encryption algorithm.) The result is placed back in byte offsets 0-23 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 24-47 of the parameter block.

**PCKMO-Encrypt-AES-128-Key (Function Code 18)**

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-73.

The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-15</td>
<td>Cryptographic Key (K)</td>
</tr>
<tr>
<td>16-31</td>
<td>DEA Wrapping-Key Verification Pattern (WKdVP)</td>
</tr>
</tbody>
</table>
```

*Figure 10-44. Parameter Block for PCKMO-Encrypt-AES-128-Key*
The parameter block used for the function has the following format:

<table>

<td>AES Wrapping-Key Verification Pattern (WK_aVP)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Figure 10-46. Parameter Block for PCKMO-Encrypt-AES-256-Key

The 32-byte cryptographic key, K, in byte offsets 0-31 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-374 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

**Special Conditions**

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, parameter block; store, parameter block)
- Operation (if the message-security-assist-extension-3 facility is not installed)
- Privileged operation
- Specification
- Transaction constraint
**Programming Note:** Each set of PCKMO-Encrypt-DEA-Key functions and PCKMO-Encrypt-AES-Key functions can be independently disabled by an external means. When a set is disabled, functions in the set appear as if they were not installed.

**PERFORM FRAME MANAGEMENT FUNCTION**

```
PFMF R1,R2 [RRE]
```

Subject to the controls in the first-operand register, a frame-management function is performed for the storage frame designated by the second-operand address.

The contents of general register R1 are as follows:

**Frame-management function indications:** Bit positions 44-47 of general register R1 contain the frame-management function indications (FMFI), as follows:

- **Reserved:** Bits 44 and 45 are reserved and must contain zeros; otherwise, a specification exception is recognized.
- **Set-Key Control (SK):** Bit 46 controls whether the storage key for each 4K-byte block in the frame is set from bits 56-62 of general register R1. When the SK control is zero, the keys are not set; when the SK control is one, the keys are set.
- **Clear-Frame Control (CF):** Bit 47 controls whether the frame is set to zeros. When the CF control is zero, no clearing operation is performed. When the CF control is one, the frame is cleared to zeros.
- **Usage Indication (UI):** Bit position 48 of general register R1 contains the usage indication (UI). When bit 48 is zero, it indicates that the program does not anticipate immediate usage of the frame. When bit 48 is one, it indicates that program anticipates usage of the frame in the near future.

**Frame-Size Code (FSC):** Bits 49-51 of general register R1 contain the frame-size code (FSC), as follows:

<table>
<thead>
<tr>
<th>FSC</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4K-byte frame</td>
</tr>
<tr>
<td>1</td>
<td>1M-byte frame</td>
</tr>
<tr>
<td>2</td>
<td>2 G-byte frame</td>
</tr>
<tr>
<td>3-7</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Reference-Bit Update Mask (MR):** When the set-key control, bit 46 of general register R1, is one, bit 53 of general register R1 controls whether updates to the reference bit in the storage key may be bypassed, as described below. When the set-key control is zero, bit 53 of general register R1 is ignored.

**Change-Bit Update Mask (MC):** When the set-key control, bit 46 of general register R1, is one, bit 54 of general register R1 controls whether updates to the change bit in the storage key may be bypassed. When the set-key control is zero, bit 54 of general register R1 is ignored.

The handling of the MR and MC bits is identical to the handling of the corresponding bits of the M3 field of the SET STORAGE KEY EXTENDED instruction (described on page 10-126), except that general register R1 is not updated with the contents of the previous key, and the condition code is not changed.

**Key:** When the set-key control, bit 46 of general register R1, is one, bits 56-62 of the register contain the storage key to be set for each 4K-byte block in the frame, with the access-protection bits, fetch-protection bit, reference bit, and change bit in bit positions 56-59, 60, 61, and 62, respectively. When the set-key control is zero, bits 56-62 of general register R1 are ignored.

Bit positions 32-45, 55, and 63 of general register R1 are reserved and must contain zeros. When the nonquiescing key-setting facility is not installed, bit position 52 of general register R1 is also reserved and must contain zeros. If any reserved bit position in general register R1 does not contain zeros, a specification exception is recognized. When the nonquiescing key-setting facility is installed, bit position 52 of general register R1 is ignored.

General register R2 contains the real or absolute address of the storage frame upon which the frame-
management function is to be performed. When the frame-size code designates a 4K-byte block, the second-operand address is real; when the frame-size code designates a 1M-byte or 2 G-byte block the second-operand address is absolute. The handling of the address in general register $R_2$ depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of the register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

The contents of the registers just described are shown in Figure 10-47.

![Figure 10-47. Register Contents for PERFORM FRAME-MANAGEMENT FUNCTION](image)

Explanation:

- **ACC**: Access-protection bits of the storage key
- **C**: Change bit of the storage key
- **CF**: Clear-frame control
- **F**: Fetch-protection bit of the storage key
- **FMFI**: Frame-management function indication
- **FSC**: Frame-size code
- **MC**: Change-bit-update mask
- **MR**: Reference-bit-update mask
- **R**: Reference bit of the storage key
- **SK**: Set-key control
- **UI**: Usage indication

When the frame-size code is 0, the specified frame-management functions are performed for the 4K-byte frame specified by the second operand. General register $R_2$ is unmodified in this case.

When the frame-size code is 1, the specified frame-management functions are performed for one or more 4 K-byte blocks within the 1M-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1M-byte boundary.

When the enhanced-DAT facility 2 is installed and the frame-size code is 2, the specified frame-management functions are performed for one or more 4 K-byte blocks within the 2 G-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 2 G-byte boundary. When the enhanced-DAT facility 2 is not installed, a frame-size code of 2 is reserved.

PERFORM FRAME MANAGEMENT FUNCTION is interruptible. When the frame-size code is 1 or 2, an
PERFORM FRAME MANAGEMENT FUNCTION

When the clear-frame and set-key controls are one, an interruption may also occur between the clearing and key-setting operations for an individual 4 K-byte block.

When the frame-size code is 1 or 2, processing is as follows:

- When both the clear-frame and set-key functions are specified, both functions are completed for a 4 K-byte block before proceeding to the next block.
- When an interruption occurs (other than one that follows termination), the second-operand address in general register R₃ is updated by the number of 4K-byte blocks completely processed, so the instruction, when reexecuted, resumes at the point of interruption.
- When the instruction completes without interruption, the second-operand address in general register R₂ is updated to the next 1M-byte boundary (FSC=1) or 2 G-byte boundary (FSC=2).

When the CPU is in the 24-bit addressing mode and the frame-size code is 1, bits positions 32-39 of general register R₁ are set to zeros and bits 0-31 of the register are unchanged. When the CPU is in the 24-bit addressing mode and the frame-size code is 2, a specification exception is recognized.

When the CPU is in the 31-bit addressing mode, and the frame-size code is either 1 or 2, bit position 32 of general register R₂ is set to zero and bits 0-31 of general register R₂ are unchanged.

When the clear-frame control is one, references to main storage within the second operand may be multiple-access references and are not necessarily performed in a left-to-right direction as observed by other CPUs and by channel programs. The clear operation is not subject to key-controlled protection; however, low-address protection applies regardless of whether the frame-size code designates a 4 K-byte, 1 M-byte, or 2 G-byte frame (that is, regardless of whether the second-operand address is real or absolute, respectively).

When the set-key control is one, the operation for each 4K-byte block is similar to that described in “SET STORAGE KEY EXTENDED” on page 10-126, except that when the keys for multiple blocks are set, the condition code and the contents of general register R₁ are unchanged.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the seven bits of all storage keys to be set are the same as bits 56-62 of general register R₁, or when the MR and MC bits allow all the storage keys to remain unchanged, it is unpredictable whether the serialization and checkpoint-synchronization functions are performed after the operation completes. See “SET STORAGE KEY EXTENDED” on page 10-126 for details on the cases where setting of the key may be bypassed.

When the set-key control is one, and the nonquiescing key-setting facility is not installed, a quiescing operation is performed. When the set-key control is one, and the nonquiescing key-setting facility is installed, a quiescing operation is not necessarily performed. See “Storage-Key Accesses” on page 5-118 for a discussion of the effects of quiescing on key-setting instructions, and see “Quiescing” on page 5-131 for details on the quiescing operation.

Provided that there is no other access to the storage by other CPUs or the channel subsystem, the final results of the instruction reflect the specified key value, including the specified R and C values when MR and MC are zero, respectively. Subject to this constraint, it is unpredictable whether the clear-frame or the set-key operation is performed first when both of the respective controls are one. When both the clear-frame and set-key controls are one, and either the MR or MC bit is also one, and the clear operation is performed first, the storage key that is compared with bits 56-62 of general register R₁ in the set-key operation is the key following the clear operation (that is, both the R and C bits will have been set to one by the clear operation).

Before a quiescing key-setting operation is performed, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which storage keys are being set. It is unpredictable whether some or all other CPUs are affected as well.

Special Conditions
A specification exception is recognized and the operation is suppressed for any of the following conditions:

- Bits 32-45, 55, or 63 of general register R1 are not zero.
- When the nonquiescing key-setting facility is not installed, bit 52 of general register R1 is not zero.
- The frame-size code specifies a reserved value.
- The CPU is in the 24-bit addressing mode and the frame-size code is 2.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, low-address-protection only, operand 2, when the clear-frame control is one)
- Addressing (operand 2)
- Operation (enhanced-DAT facility not installed)
- Privileged operation
- Specification
- Transaction constraint

**Programming Notes:**

1. When PFMF is issued with the set-key control set to one, the program must ensure that no other CPU or channel subsystem is simultaneously accessing the storage designated by general register R2. Otherwise, unpredictable results may be observed by the other CPUs and channel subsystem, including the alteration of the block designated by general register R2.

2. Access exceptions may be recognized for the second operand, even when the clear-frame and set-key controls and the usage indication are all zero.

3. See the programming note on page 5-120 for restrictions on the use of the PFMF set-key operation.

---

**PERFORM TIMING FACILITY FUNCTION**

<table>
<thead>
<tr>
<th>PTFF</th>
<th>[E]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0104</td>
<td></td>
</tr>
</tbody>
</table>

A timing facility function specified by the function code in general register 0 is performed. The condition code is set to indicate the outcome of the function. General register 1 contains the address of a parameter block in storage. PTFF query functions place information in the parameter block; PTFF control functions use information obtained from the parameter block.

As observed by other CPUs and channel programs, references to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-49 on page 10-80 shows the assigned function codes. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.
Figure 10-48 on page 10-80 shows the contents of the general registers just described.

</tbody>
</table>
```

Explanation:

- P: Privileged: Available only in the supervisor state.
- U: Unprivileged: Available in both the problem state and the supervisor state.

Function codes for PERFORM TIMING FACILITY FUNCTION are as follows.

- All other function codes are unassigned.
- The PTFF-QAF (Query Available Functions) function provides the means of indicating the availability of the other functions.

### Function 0: PTFF-QAF (Query Available Functions)

The parameter block used for the function has the following format:

```
<table>
<thead>
<tr>
<th>Hex</th>
<th>Dec</th>
<th>Status Bits 0-31</th>
<th>Status Bits 32-63</th>
<th>Status Bits 64-95</th>
<th>Status Bits 95-127</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>pb.w1</td>
<td>pb.w2</td>
<td>pb.w3</td>
<td>pb.w4</td>
</tr>
</tbody>
</table>
```

A 128-bit field is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PTFF instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed. The availability of an installed function is indicated by the condition code returned by the attempted execution of the function.
Function 1: PTFF-QTO (Query TOD Offset)
The parameter block used for the function has the following format:

<table>
<thead>
<tr>
<th>Hex</th>
<th>Dec</th>
<th>Description</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>Physical Clock (0:31)</td>
<td>pb.Tu</td>
</tr>
<tr>
<td>04</td>
<td>4</td>
<td>Physical Clock (32:63)</td>
<td></td>
</tr>
<tr>
<td>08</td>
<td>8</td>
<td>TOD Offset (0:31)</td>
<td>pb.d</td>
</tr>
<tr>
<td>OC</td>
<td>12</td>
<td>TOD Offset (32:63)</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>16</td>
<td>Logical TOD Offset (0:31)</td>
<td>pb.dl</td>
</tr>
<tr>
<td>14</td>
<td>20</td>
<td>Logical TOD Offset (32:63)</td>
<td></td>
</tr>
<tr>
<td>18</td>
<td>24</td>
<td>TOD Epoch Difference (0:31)</td>
<td>pb.ed</td>
</tr>
<tr>
<td>1C</td>
<td>28</td>
<td>TOD Epoch Difference (32:63)</td>
<td></td>
</tr>
</tbody>
</table>

When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. When the STP-hardware-based-TOD-clock-steering facility is installed, the 64-bit physical-clock value returned is the current physical clock.

The TOD offset returned is a 64-bit signed binary integer (pb.d) that indicates the value of the TOD-offset (d). This value indicates the amount of steering that has been applied (actually in the case of offset-based TOD-clock steering, or conceptually in the case of hardware-based TOD-clock steering) to the physical clock to form the system TOD clock. The TOD epoch difference is not included in this value.

The 64-bit logical-TOD-offset value returned (pb.dl) indicates the current value of the difference between the TOD clock and the physical clock. This value includes the TOD epoch difference. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be set to zero by the machine.

The 64-bit TOD epoch difference value returned (pb.ed) is the TOD epoch difference (includes both the user-specified epoch difference and the sync-check offset). Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be set to zero by the machine.

Function 2: PTFF-QSI (Query Steering Information)
The parameter block used for the function has the following format:

<table>
<thead>
<tr>
<th>Hex</th>
<th>Dec</th>
<th>Description</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>Physical Clock (0:31)</td>
<td>pb.Tu</td>
</tr>
<tr>
<td>04</td>
<td>4</td>
<td>Physical Clock (32:63)</td>
<td></td>
</tr>
<tr>
<td>08</td>
<td>8</td>
<td>Old Episode Start Time (0:31)</td>
<td>pb.old.s</td>
</tr>
<tr>
<td>OC</td>
<td>12</td>
<td>Old Episode Start Time (32:63)</td>
<td>pb.old.g</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
<td>Old Episode Base Offset (0:31)</td>
<td>pb.old.b</td>
</tr>
<tr>
<td>14</td>
<td>20</td>
<td>Old Episode Base Offset (32:63)</td>
<td></td>
</tr>
<tr>
<td>18</td>
<td>24</td>
<td>Old Episode Fine-Steering Rate</td>
<td>pb.old.f</td>
</tr>
<tr>
<td>1C</td>
<td>28</td>
<td>Old Episode Gross-Steering Rate</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>32</td>
<td>New Episode Start Time (0:31)</td>
<td>pb.new.s</td>
</tr>
<tr>
<td>24</td>
<td>36</td>
<td>New Episode Start Time (32:63)</td>
<td></td>
</tr>
<tr>
<td>28</td>
<td>40</td>
<td>New Episode Base Offset (0:31)</td>
<td>pb.new.b</td>
</tr>
<tr>
<td>2C</td>
<td>44</td>
<td>New Episode Base Offset (32:63)</td>
<td></td>
</tr>
<tr>
<td>30</td>
<td>48</td>
<td>New Episode Fine-Steering Rate</td>
<td>pb.new.f</td>
</tr>
<tr>
<td>34</td>
<td>52</td>
<td>New Episode Gross-Steering Rate</td>
<td></td>
</tr>
</tbody>
</table>

When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. When the STP-hardware-based-TOD-clock-steering facility is installed, the 64-bit physical-clock value returned is the current physical clock.

The remaining fields are the values of the old-episode and new-episode registers.

Function 3: PTFF-QPT (Query Physical Clock)
The parameter block used for the function has the following format:

<table>
<thead>
<tr>
<th>Hex</th>
<th>Dec</th>
<th>Description</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>Physical Clock (0:31)</td>
<td>pb.Tr</td>
</tr>
<tr>
<td>04</td>
<td>4</td>
<td>Physical Clock (32:63)</td>
<td></td>
</tr>
</tbody>
</table>

The 64-bit physical-clock value returned (pb.Tr) is the current value of the physical clock. Zeros are stored for the rightmost bit positions that are not provided by the physical clock. When the clock is running, two
executions of PTFF-QPT, either on the same or different CPUs, do not necessarily return different values of the clock.

Function 4: PTFF-SUI (Query UTC Information)
The parameter block used for the function has the following format:

```
Hex Dec
00 0 UTC Information Block (UIB)
```

The UIB is described in “UTC Information Block (UIB)” on page 4-51.

Function 5: PTFF-QTOU (Query TOD Offset User)
The parameter block used for the function has the following format:

```
Hex Dec
00 0 Physical Clock (0:31) pb.Tu
04 4 Physical Clock (32:63)
08 8 TOD Offset (0:31) pb.d
0C 12 TOD Offset (32:63)
10 16 Logical TOD Offset (0:31) pb.dl
14 20 Logical TOD Offset (32:63)
18 24 TOD Epoch Difference (0:31) pb.ed
1C 28 TOD Epoch Difference (32:63)
20 32 TOD User Specified Epoch Difference (0:31) pb.edu
24 36 TOD User Specified Epoch Difference (32:63)
```

The 64-bit TOD user specified epoch difference value returned is the user-specified portion of the guest epoch difference for the current level of CPU execution. It does not include the sync-check offset portion of the guest epoch difference. When executed at the basic-machine or LPAR hypervisor level, this value is zero. When executed at the guest 1 level, this value is the guest epoch difference excluding the guest 1 sync-check offset portion of the guest 1 epoch difference. When executed at the guest 2 level, this value is the guest epoch difference excluding the guest 2 sync-check offset portion of the guest 2 epoch difference.

Function 65: PTFF-STO (Set TOD Offset)
The parameter block used for the function has the following format:

```
Hex Dec
00 0 New TOD Epoch Difference (0:31) pb.d
04 4 New TOD Epoch Difference (32:63)
```

The function specifies a value that is to replace the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. The function operates only on the TOD epoch difference (D); no new episode is scheduled, and the change takes place immediately. The function operates on the combined TOD-epoch difference (D = SCO + Du) and does not modify the sync-check offset. If the sync-check offset is nonzero, a subsequent sync-check-offset correction will modify the TOD epoch difference to reflect the amount of the correction. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be ignored by the machine and treated as if they were zeros.

Function 69: PTFF-STOU (Set TOD Offset User)
The parameter block used for the function has the following format:

```
Hex Dec
00 0 New TOD User Specified Epoch Difference (0:31) pb.du
04 4 New TOD User Specified Epoch Difference (32:63)
```

The function specifies a value that is to replace the user-specified portion of the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be
ignored by the machine and treated as if they were zeros.

**Special Conditions**

A privileged operation exception is recognized if a PTFF control function is issued in the problem state.

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

**Resulting Condition Code:**

0 Requested function performed
1 --
2 --
3 Requested function not available

**Program Exceptions:**

- Access (fetch, parameter block for control functions; store, parameter block for query functions)
- Operation (if the PERFORM TIMING FACILITY FUNCTION instruction is not installed)
- Privileged operation (attempt to execute a PTFF control function in the problem state)
- Specification
- Transaction constraint

The priority of execution for the PTFF instruction is shown in Figure 10-58.

1. Access exceptions for an access to the parameter block.
2. Condition code 0 indicating successful completion.

**Programming Notes:**

1. When the STP-hardware-based-TOD-clock-steering facility is not installed, the physical time (pb.Tu) returned in the parameter block for PTFF-QTO, PTFF-QTOU, and PTFF-QSI is the current value of the physical clock, but with zeros in positions to the right of the bit position incremented concurrently with each TOD-offset-update event. This value is not necessarily unique. The same value may be returned if the PTFF instruction is issued multiple times on the same CPU or issued at approximately the same time on different CPUs.

2. When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit value of the physical clock at the most recent TOD-offset-update event (pb.Tu) returned by PTFF-QTO, PTFF-QTOU, and PTFF-QSI may be used by the program to ensure that all events during a short routine occurred with no intervening TOD-offset-update events. This can be accomplished by issuing one of these queries at the beginning of the routine and the other at the end and reiterating if the value of pb.Tu before and the value of pb.Tu after are different.

3. When the STP-hardware-based-TOD-clock-steering facility is installed, there are no TOD-offset-update events, and pb.Tu reports the current value of the physical clock. Steering episode changes are reflected in the old and new episode start times.

4. For Query Steering Information, pb.Tu can be used to determine whether the machine is operating in the old or new episode. When pb.new.s ≤ pb.Tu, the machine is operating in the new episode, and none of the information returned by the query has changed since the most recent TOD-offset-update event. When pb.new.s > Pb.Tr, the machine is operating in the old episode, a new episode has been scheduled and has not yet taken effect. The program should avoid any dependency on the new episode val-
ues returned in this case, as it is possible the values may change again before the new episode takes effect.

5. Two or more executions of PTFF-QPT within a short period of time, either on the same or different CPUs, do not appear to step backwards, but are not necessarily unique. Thus, it is not always possible to use the values to determine the sequence of execution.

6. The Network Time Protocol (NTP) is used extensively in the Internet. A description of NTP may be found in Request for Comments (RFC) 1305. Figure 10-60 on page 10-85 shows the value of the TOD clock and NTP timestamp for 00:00:00 (0 am), UTC time, for several dates: January 1, 1900, January 1, 1972, and for that instant in time just after each of the 26 leap seconds that will have occurred through July, 2015. Each of these leap seconds is inserted in the UTC time scale beginning at 23:59:60 UTC of the day previous to the one listed and ending at 00:00:00 UTC of the day listed. Also included are values for the beginning of each year since the most recent leap second. Figure 10-59 on page 10-84 shows the values of the TOD clock and NTP timestamp for those instants just after the leftmost bit of one or the other has changed. For instants in the future, the number of leap seconds must be applied and this value is not yet known.

<table>
<thead>
<tr>
<th>YYYY MM DD hh mm ss</th>
<th>TOD Clock (Hex)</th>

</tr>
</tbody>
</table>

Explanation:
* Value is not exact.
+ Leap seconds must be added to this value.
– Leap seconds must be subtracted from this value.

Figure 10-59. TOD Clock and NTP Timestamps When a Leftmost Bit Changes
PERFORM TOPOLOGY FUNCTION

The contents of general register R₁ specify a function code in bit positions 56-63, as illustrated in Figure 10-61.
The defined function codes are as follows:

<table>
<thead>
<tr>
<th>FC</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request horizontal polarization.</td>
</tr>
<tr>
<td>1</td>
<td>Request vertical polarization.</td>
</tr>
<tr>
<td>2</td>
<td>Check topology-change status.</td>
</tr>
</tbody>
</table>

Undefined function codes in the range 0-255 are reserved for future extensions.

Upon completion, if condition code 2 is set, a reason code is stored in bit positions 48-55 of general register R1.

Bits 16-23 and 28-31 of the instruction are ignored.

**Operation of Function Codes 0 and 1**

When no exceptional conditions are detected, a process is initiated to place all CPUs in the configuration into the polarization specified by the function code, and condition code 0 is set. Completion of the process is asynchronous with respect to execution of the instruction and may or may not be completed when execution of the instruction completes.

Execution completes with condition code 2, and the reason code is set, for any of the following reasons:

<table>
<thead>
<tr>
<th>RC</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No reason specified.</td>
</tr>
<tr>
<td>1</td>
<td>The configuration is already polarized as specified by the function code.</td>
</tr>
<tr>
<td>2</td>
<td>A topology change is already in process</td>
</tr>
</tbody>
</table>

**Operation of Function Code 2:**

The topology-change-report-pending condition is checked. When a topology-change-report is not pending, condition code 0 is set. When a topology-change report is pending, condition code 1 is set.

A topology change is any alteration such that the contents of a SYSIB 15.1.2 would be different from the contents of the SYSIB 15.1.2 prior to the topology change.

A topology-change-report-pending condition is created when a topology-change process completes. A topology-change-report-pending condition is cleared for the configuration when any of the following is performed:

- Execution of PERFORM TOPOLOGY FUNCTION specifies function-code 2 that completes with condition code 1.
- Subsystem reset is performed.

**Special Conditions**

A specification exception is recognized for either of the following conditions:

- Bit positions 0-55 of general register R1 are not zeros.
- An undefined function code is specified.

**Resulting Condition Code:** When the function code is 0 or 1, the condition code is set as follows:

| 0  | Topology-change initiated |
| 1  | --                        |
| 2  | Request rejected          |
| 3  | --                        |

When the function code is 2, the condition code is set as follows:

| 0  | Topology-change-report not pending |
| 1  | Topology-change report pending    |
| 2  | --                                |
| 3  | --                                |

**Program Exceptions:**

- Operation (configuration-topology facility is not installed)
- Privileged operation
- Specification
- Transaction constraint

**Programming Note:** Further information on configuration topology may be found in “SYSIB 15.1.2 - 15.1.6 (Configuration Topology)” on page 10-150.

**PROGRAM CALL**

<table>
<thead>
<tr>
<th>PC</th>
<th>D&lt;sub&gt;2&lt;/sub&gt;</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;B218&quot;</td>
<td>0 16 20 31</td>
<td>B&lt;sub&gt;2&lt;/sub&gt; D&lt;sub&gt;2&lt;/sub&gt;</td>
</tr>
</tbody>
</table>

A program-call number specified by the second-operation address is used in a two-level or three-level lookup to locate an entry-table entry (ETE). The pro-
gram is authorized to use the ETE when the AND of the PSW-key mask in control register 3 and the authorization key mask in the ETE is nonzero or when the CPU is in the supervisor state.

When the PC-type bit, bit 128 of the ETE, is zero, an operation called basic PROGRAM CALL is performed. When the PC-type bit is one, an operation called stacking PROGRAM CALL is performed.

Basic PROGRAM CALL, in the 24-bit or 31-bit addressing mode, loads the basic-addressing-mode bit, bits 33-62 of the updated instruction address, and the problem-state bit from the PSW into bit positions 32-63 of general register 14, and it leaves bits 0-31 of this register unchanged. In the 64-bit addressing mode, bits 0-62 of the updated instruction address and the problem-state bit are placed in bit positions 0-63 of general register 14. In any addressing mode, the PSW-key mask and PASN are placed in bit positions 32-63 of general register 3, and bits 0-31 of this register remain unchanged.

Stacking PROGRAM CALL places the entire PSW contents, except with an unpredictable PER mask, and also the PSW-key mask, PASN, SASN, and EAX in a linkage-stack program-call state entry that it forms. A called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, the numeric part of the program-call number, and the contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. If the ASN-and-LX-reuse facility is installed and enabled, the PASTEIN and SASTEIN also are placed in the state entry.

For basic PROGRAM CALL, the extended-addressing-mode bit, bit 31 of the PSW, must have the same value as the entry-extended-addressing-mode bit, bit 129 of the ETE; otherwise, a special-operation exception is recognized. Basic PROGRAM CALL does not change bit 31 of the PSW and, therefore, does not switch between a basic addressing mode (the 24-bit or 31-bit mode) and the extended addressing mode (the 64-bit mode). In the 24-bit or 31-bit addressing mode, basic PROGRAM CALL sets the basic-addressing-mode bit, bit 32 of the PSW, with the value of the entry-basic-addressing-mode bit, bit 32 of the ETE, and, thus, it may switch between the 24-bit and 31-bit addressing modes. In the 64-bit addressing mode, bit 32 of the PSW remains unchanged.

Stacking PROGRAM CALL, when bit 129 of the ETE is zero, sets bit 31 of the PSW to zero and sets bit 32 of the PSW with the value of bit 32 of the ETE. When bit 129 of the ETE is one, stacking PROGRAM CALL sets bits 31 and 32 of the PSW to one. Thus, stacking PROGRAM CALL can set the 24-bit, 31-bit, or 64-bit addressing mode.

When the resulting addressing mode is the 24-bit or 31-bit mode, both basic and stacking PROGRAM CALL place bits 33-62 of the entry instruction address in the ETE, which are bits 33-62 of the ETE, with 33 leftmost and one rightmost zeros appended, in bit positions 64-127 of the PSW as the new instruction address, and they place the entry-problem-state bit, bit 63 of the ETE, in bit position 15 of the PSW as the new problem-state bit. Bits 32-63 of the entry parameter in the ETE are placed in bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged.

When the resulting addressing mode is the 64-bit mode, both basic and stacking PROGRAM CALL place bits 0-62 of the entry instruction address, bits 0-62 of the ETE, with one rightmost zero appended, in bit positions 64-127 of the PSW, and they place bit 63 of the ETE in bit position 15 of the PSW. Bits 0-63 of the entry parameter in the ETE are placed in general register 4.

Basic PROGRAM CALL ORs the entry key mask from the ETE into the PSW-key mask in control register 3. Stacking PROGRAM CALL does the same, or it replaces the PSW-key mask with the entry key mask, as determined by the PSW-key-mask control in the ETE.

Stacking PROGRAM CALL optionally replaces the PSW key in the PSW and the EAX in control register 8 from the ETE, and it sets the address-space-control bits in the PSW, as determined by control bits in the ETE.

The ETE causes a space-switching operation to occur if it contains a nonzero ASN. When the ETE contains a zero ASN, the operation is called PROGRAM CALL to current primary (PC-cp); when the ETE contains a nonzero ASN, the operation is called PROGRAM CALL with space switching (PC-ss). When space switching is specified, the new PASN is loaded into control register 4 from the ETE, and a new primary-ASTE origin (PASTE) is loaded into control register 5, also from the ETE. From the PASTE, a new primary ASCE (PASCE) and AX are
loaded into control registers 1 and 4, respectively. If ASN-and-LX reuse is enabled, a new primary ASTE instance number (PASTEIN) is loaded into control register 4, also from the PASTE.

In both PC-cp and PC-ss, the SASN and secondary ASCE (SASCE) are set equal to the original PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the secondary ASTE instance number (SASTEIN) in control register 3 is set equal to the original PASTEIN. However, the space-switching stacking PROGRAM CALL operation may instead set the SASN and SASCE equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, set the SASTEIN equal to the new PASTEIN, as determined by a control bit in the ETE.

In a PC-ss to the base space of the dispatchable unit when the dispatchable unit is subspace active, bits 0-55 and 58-63 of the new PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This occurs before the possible setting of the SASCE equal to the PASCE.

PROGRAM CALL PC-Number Translation

The second-operand address is not used to address data; instead, the rightmost 20 or 32 bits of the address are used as a PC number divided into two fields: a linkage index (LX) and an entry index (EX). The entry index is always the rightmost eight bits of the PC number. When the ASN-and-LX-reuse is not installed or is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the PC number is 20 bits, and the leftmost 12 bits of the number are the linkage index. In this case, the second-operand address has the following format:

Second-Operand Address when ASN-and-LX Reuse Is Not Enabled

```
  0  31
  LX EX
```

Bit 44 of the effective address has no special meaning and may be zero or one.

When the ASN-and-LX-reuse facility is installed and enabled, referred to simply by saying that ASN-and-LX reuse is enabled, the linkage index is further divided into a linkage first index (LFX) and a linkage second index (LSX). The linkage second index is always the five bits immediately on the left of the entry index. The size and format of the linkage first index depend on whether the PC number is 20 bits or 32 bits, which in turn depends on whether bit 44 of the second-operand address is zero or one, respectively. In these cases, the second-operand address has the following formats:

Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is Zero

```
  0  31
  LX
```

```
  0  32  44  45  51  56  63
  LFX2 LSX EX
```

Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is One

```
  0  31
  LX
```

```
  0  32  44  45  51  56  63
  LFX1 LFX2 LSX EX
```

When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, the PC number is 20 bits, and the linkage first index is bits 44-50, or bits 45-50 (LFX2) with a zero appended on the left. Thus, the linkage first index is seven bits of which the leftmost bit is always zero. When bit 44 is one, the PC number is 32 bits, and the linkage first index is bits 45-50 (LFX2) with bits 32-43 (LFX1) appended on the left, or 18 bits, and bit 44 is not a numeric part of the PC number. However, a linkage first table can contain at most 16,384 entries, and, therefore, the leftmost four bits of the linkage first index, bits 32-35 of the second-operand address, must always be zeros; otherwise, an LFX-translation exception is recognized.

**Linkage Index (LX):** When ASN-and-LX reuse is not enabled, bits 44-55 of the second-operand address are the linkage index and are used to select an entry from the linkage table designated by the linkage-table designation in the primary ASTE.
**Linkage First Index (LFX):** When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, bits 44-50 of the second-operand address are the linkage first index. When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is one, bits 45-50 with bits 32-43 appended on the left are the linkage first index. In either case, the linkage first index is used to select an entry from the linkage first table designated by the linkage-first-table designation in the primary ASTE.

**Linkage Second Index (LSX):** When ASN-and-LX reuse is enabled, bits 51-55 of the second-operand address are the linkage second index and are used to select an entry from the linkage second table designated by the linkage-second-table entry.

**Entry Index (EX):** Bits 56-63 of the second-operand address are the entry index and are used to select an entry from the entry table designated by the linkage-table entry or the linkage-second-table entry.

When the PC number is 20 bits, bits 32-43 of the second-operand address are ignored. Bits 0-31 of the second-operand address are always ignored.

When ASN-and-LX reuse is enabled, the second word of the linkage-second-table entry used contains a linkage-second-table-entry sequence number (LSTESN). When this LSTESN is nonzero, it must be equal to an LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized. When ASN-and-LX reuse is not enabled (including when it is not installed) or the LSTESN in the linkage-second-table entry is zero, bits 0-31 of general register 15 are ignored.

The 32-byte entry-table entry (ETE) has the following format:

For basic PROGRAM CALL in the 24-bit or 31-bit addressing mode when bit 32 of the ETE (A) is zero (specifying the 24-bit mode), and for stacking PROGRAM CALL when bits 32 (A) and 129 (G) are zeros (specifying the 24-bit mode), bits 33-39 must be zeros; otherwise, a PC-translation-specification exception is recognized.

After the ETE has been fetched, if the current PSW specifies the problem state, the current PSW-key mask in control register 3 is tested against the AKM field in the ETE to determine whether the program is authorized to access this entry. The AKM and PSW-key mask are ANDed, and, if the result is zero, a privileged-operation exception is recognized. The PSW-key mask in control register 3 remains unchanged.

If the result of the AND of the AKM and the PSW-key mask is not zero, or if the CPU is in the supervisor state, the execution of the instruction continues.

If bit 128 of the ETE (T) is zero, the basic PROGRAM CALL operation is specified. If bit 128 of the ETE is one, the stacking PROGRAM CALL operation is specified.

**Basic PROGRAM CALL**

The following operations are performed when basic PROGRAM CALL is specified.

Bit 31 of the current PSW (the extended-addressing-mode bit) must equal bit 129 (G) of the ETE; otherwise, a special-operation exception is recognized.
PROGRAM CALL

In the 24-bit or 31-bit addressing mode, bits 97-126 of the PSW (bits 33-62 of the updated instruction address) are placed in bit positions 33-62 of general register 14, bit 32 of the PSW (the basic-addressing-mode bit) is placed in bit position 32 of the register, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register. Bits 0-31 of the register remain unchanged.

In the 64-bit addressing mode, bits 64-126 of the PSW (bits 0-62 of the updated instruction address) are placed in bit positions 0-62 of general register 14, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register.

In the 24-bit or 31-bit addressing mode, bits 32 and 33-62 of the ETE (A and the EIA), with a zero appended on the right of bits 33-62, are placed in PSW bit positions 32 and 97-127, respectively (the basic-addressing-mode bit and bits 33-63 of the instruction address). In the 64-bit addressing mode, bits 0-62 of the ETE, with a zero appended on the right, are placed in PSW bit positions 64-127 (the instruction address), and PSW bit 32 remains unchanged. In any addressing mode, bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

The PSW-key mask, bits 32-47 of control register 3, is placed in bit positions 32-47 of general register 3, and the current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register 3. Bits 0-31 of general register 3 remain unchanged.

Bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3.

In the 24-bit or 31-bit addressing mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Stacking PROGRAM CALL

The following operations are performed when stacking PROGRAM CALL is specified.

The stacking process is performed to form a linkage-stack program-call state entry and place the following information in the state entry: current PSW (with an unpredictable PER mask), PSW-key mask, PASN, SASN, EAX, called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, numeric part of the program-call number, contents of general registers 0-15, and contents of access registers 0-15, and, if ASN-and-LX reuse is enabled, PASTEIN and SASTEIN. This is described in “Stacking Process” on page 5-85. The entry-type code in the state entry is 0001101 binary.

When bit 129 of the ETE (G) is zero, bit 31 of the PSW (the extended-addressing-mode bit) is set to zero, and bit 32 of the ETE (A) is placed in bit position 32 of the PSW (the basic-addressing-mode bit). (The addressing mode is set to the 24-bit mode if bit 32 is zero or to the 31-bit mode if bit 32 is one.) When bit 129 of the ETE is one, bits 31 and 32 of the PSW are set to one. (The 64-bit addressing mode is set.)

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 32-62 of the ETE (the EIA), with 33 leftmost and one rightmost zeros appended, are placed in PSW bit positions 64-127 (the instruction address). When the resulting addressing mode is the 64-bit mode, bits 0-62 of the ETE (the EIA), with one rightmost zero appended, are placed in PSW bit positions 64-127.

Bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

When bit 131 of the ETE (K) is zero, bits 8-11 of the PSW (the PSW key) remain unchanged. When bit 131 of the ETE is one, bits 136-139 of the ETE (the EK) replace the PSW key in the PSW.

When bit 132 of the ETE (M) is zero, bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3.

When bit 132 of the ETE is one, bits 96-111 of the ETE replace the PSW-key mask in control register 3.

When bit 133 of the ETE (E) is zero, the EAX, bits 32-47 of control register 8, remains unchanged. When bit 133 of the ETE is one, bits 144-159 of the ETE (the EEAX) replace the EAX in control register 8.
When bit 134 of the ETE (C) is zero, bits 16 and 17 of the PSW (the address-space-control bits) are set to 00 binary (primary-space mode). When bit 134 of the ETE is one, the address-space-control bits in the PSW are set to 01 binary (access-register mode).

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged. When the resulting addressing mode is the 64-bit mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Key-controlled protection does not apply to references to the linkage stack, but low-address and DAT protection do apply.

**PROGRAM CALL to Current Primary (PC-cp)**

If bits 80-95 of the ETE (the ASN), are zeros, PROGRAM CALL to current primary (PC-cp) is specified, and the execution of the instruction is completed after the operations described in “PROGRAM CALL PC-Number Translation” and either “Basic PROGRAM CALL” or “Stacking PROGRAM CALL” have been performed and the following operations have been performed.

Bits 80-95 of the ETE (the ASN) are placed in bit positions 48-63 of control register 4 as the new PASN.

Bits 161-185 of the ETE, with six zeros appended on the right, are used as the real address of the ASTE designated by the new PASN. An ASX-translation exception is recognized if bit 0 of the ASTE is one.

Bits 64-127 of the ASTE (the ASCE) are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE (the AX) are placed in bit positions 32-47 of control register 4 as the new authorization index.

If ASN-and-LX reuse is enabled, bits 352-383 of the ASTE (the ASTEIN) are placed in bit positions 0-31 of control register 4 as the new PASTEIN.

In basic PROGRAM CALL, or in stacking PROGRAM CALL when bit 135 of the ETE (S) is zero, the PASN existing before the PASN is replaced from the ETE is placed in bit positions 48-63 of control register 3 to become the current SASN, and the PASCE existing before the PASCE is replaced from the ASTE is placed in control register 7 to become the current SASCE. If ASN-and-LX reuse is enabled, the PASTEIN existing before the PASTEIN is replaced from the ASTE is placed in bit positions 0-31 of control register 3 to become the current SASTEIN. (The SASN and SASCE are set equal to the old PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the SASTEIN is set equal to the old PASTEIN.)

In stacking PROGRAM CALL when bit 135 of the ETE (S) is one, the SASN is replaced by the PASN after the PASN is replaced from the ETE, and the SASCE is replaced by the PASCE after the PASCE is replaced from the ASTE. If ASN-and-LX reuse is enabled, the SASTEIN is replaced by the PASTEIN after the PASTEIN is replaced from the ASTE. (The SASN and SASCE are set equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse
is enabled, the SASTEIN is set equal to the new PASTEIN.)

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in “Subspace-Replacement Operations” on page 5-71.

The PC-ss operation is depicted in parts 1 and 4-6 of Figure 10-63 on page 10-95.

PROGRAM CALL Serialization

For both the PC-cp and PC-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The basic PROGRAM CALL operation can be performed successfully only when (1) the CPU is in the primary-space mode at the beginning of the operation, (2) the subsystem-linkage control, bit 0 of the linkage-table designation or linkage-first-table designation in the current primary ASN-second-table entry, is one, and (3) the extended-addressing-mode bit, bit 31 of the current PSW, equals the entry-extended-addressing-mode bit, bit 129 of the entry-table entry. Stacking PROGRAM CALL can be performed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation and the subsystem-linkage control is one. In addition, PC-ss can be performed successfully only when the ASN-translation control, bit 44 of control register 14, is one. If any of these rules is violated, a special-operation exception is recognized.

When ASN-and-LX reuse is enabled and the LSTESN in the linkage-second-table entry is non-zero, that LSTESN must be equal to the LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

When, for PC-ss, the primary space-switch-event-control bit, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PC-ss operation if a PER event is reported.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; linkage-table entry; linkage-first-table entry; linkage-second-table entry, entry-table entry; ASN-second-table entry, PC-ss only)
- ASX translation (PC-ss only)
- EX translation
- LFX translation
- LSTE sequence
- LSX translation
- LX translation
- PC-translation specification
- Privileged operation (AND of AKM and PSW-key mask is zero in the problem state)
- Space-switch event (PC-ss only)
- Special operation
- Stack full (stacking PC only)
- Stack specification (stacking PC only)
- Subspace replacement (PC-ss only)
- Trace
- Transaction constraint
The priority of recognition of program exceptions for the instruction is shown in Figure 10-62.

Figure 10-63. Execution of PROGRAM CALL (Part 4 of 5).
The PSW, except for the PER-mask bit, saved in the last linkage-stack state entry is restored as the current PSW. The PER mask in the current PSW remains unchanged. The contents of general registers 2-14 and access registers 2-14 also are restored from the state entry. When the entry-type code in the entry descriptor of the state entry is 0001101 binary, indicating a program-call state entry, (1) the primary ASN (PASN), secondary ASN (SASN), PSW-key mask (PKM), and extended authorization index (EAX) in the control registers also are restored from the state entry and (2) if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the primary ASTE instance number (PASTEIN) and secondary ASTE instance number (SASTEIN) in the control registers also are restored from the state entry. When the entry-type code is 0001100 binary, indicating a branch state entry, the current PASN, SASN, PKM, EAX, PASTEIN, and SASTEIN remain unchanged.

The last state entry is located, and information in it is restored, as described in "Unstacking Process" on page 5-87. The state entry is logically deleted from
the linkage stack, and the linkage-stack-entry address in control register 15 is replaced by the address of the next preceding state or header entry. This also is described in “Unstacking Process”.

When the state entry is a program-call state entry, it causes a space-switching operation to occur if it contains a PASN that is not equal to the current PASN. When the state entry contains a PASN that is equal to the current PASN, the operation is called PROGRAM RETURN to current primary (PR-cp); when the state entry contains a PASN that is not equal to the current PASN, the operation is called PROGRAM RETURN with space switching (PR-ss). PASN translation occurs in PR-ss. SASN translation and authorization may occur in either PR-cp or PR-ss. The terms PR-cp and PR-ss do not apply when the state entry is a branch state entry.

When the ASN-and-LX-reuse facility is installed and enabled and PASN or SASN translation occurs, the PASTEIN or SASTEIN, respectively, saved in the state entry is compared to the ASTEIN in the located ASTE.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

The sections “PASN Translation,” “SASN Translation,” “SASN Authorization,” and “PROGRAM RETURN Serialization” apply only when the unstacked state entry is a program-call state entry. The functions described in those sections are not performed when the state entry is a branch state entry.

The actions involving the PASTEIN and SASTEIN occur only when ASN-and-LX reuse is enabled by the ASN-and-LX reuse control in control register 0.

PASN Translation

If the new PASN is equal to the old PASN in bit positions 48-63 of control register 4, PASN translation is not performed, the PASTEIN in control register 4 remain as restored from the state entry, and the PASCE in control register 1 and primary-ASTE origin (PASTE) in control register 5 are not changed. In this case, there is not a test of whether the new PASTEIN is equal to the old PASTEIN.

If the new PASN is not equal to the old PASN, the new PASN replaces the PASN in bit positions 48-63 of control register 4 and is translated to locate a 64-byte ASTE. The ASN table-lookup process is described in “ASN Translation” on page 3-27. The exceptions associated with ASN translation are collectively called ASN-translation exceptions. These exceptions and their priority are described in Chapter 6, “Interruptions.”

If ASN-and-LX reuse is enabled, the PASTEIN saved in bytes 180-183 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE are placed in bit positions 32-47 of control register 4 as the new AX. The PASN and PASTEIN in control register 4 remain as restored from the state entry.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged.

The description in this paragraph applies to use of the subspace-group facility when PASN translation has occurred. If (1) the subspace-group-control bit, bit 54, in the new PASCE is one, (2) the dispatchable unit is subspace active, and (3) the new primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the new PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs, in the case when the new SASN is equal to the new PASN, before the SASCE is set equal to the PASCE. Further details are in “Subspace-Replacement Operations” on page 5-71.

SASN Translation

If the new SASN is equal to the new PASN, the SASCE in control register 7 is set equal to the new PASCE in control register 1. The SASTEIN, PKM, and SASN in control register 3 remain as restored from the state entry. In this case, there is not a test of whether the new SASTEIN is equal to the new PASTEIN.

If the new SASN is not equal to the new PASN, the new SASN is translated to locate a 64-byte ASTE.
If ASN-and-LX reuse is enabled, the SASTEIN saved in bytes 176-179 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 7 as the new SASCE.

Control register 3 remains as restored from the state entry.

SASN Authorization

If the new SASN is not equal to the new PASN, the authority-table origin (ATO) from the ASTE for the new SASN is used as the base for a third table lookup. The new authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in “ASN Authorization” on page 3-32.

The description in this paragraph applies to use of the subspace-group facility when SASN translation and authorization have occurred. If (1) the subspace-group-control bit, bit 54, in the new SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE origin obtained by SASN translation designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 are replaced by the same bits of the ASCE of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71.

PROGRAM RETURN Serialization

When the unstacked state entry is a program-call state entry, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The instruction can be executed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation. In addition, if ASN-translation is required for either the PASN or the SASN, it can only be performed when the ASN-translation control, bit 44 of control register 14, is one. If either of these rules is violated, a special-operation exception is recognized.

A stack-empty, stack-operation, stack-specification, or stack-type exception may be recognized during the unstacking process.

If ASN-and-LX reuse is enabled, the restored PAS-TEIN must equal the ASTEIN in the located ASTE if PASN translation is performed, and the restored SASTEIN must equal the ASTEIN in the located ASTE if SASN translation is performed; otherwise, an ASTE-instance exception is recognized.

When, for PR-ss, the primary space-switch-event control, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PR-ss operation if a PER event is reported.

The PSW which is to be loaded by the instruction is not checked for validity before it is loaded. However, after loading, a specification exception is recognized, and a program interruption occurs, if any of bits 0, 2-4, 12, 24-30, and 33-63 of the PSW is a one, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are one and zero, respectively. In these cases, the operation is completed, and the resulting instruction-length code is 0. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-9.

If a space-switch event is indicated and the PSW that was loaded by the instruction is invalid because of a reason described in the preceding paragraph, it is unpredictable whether the resulting instruction-length code is 0 or 1, or 0 or 2 if EXECUTE was used, or 0 or 3 if EXECUTE RELATIVE LONG was used.

The operation is suppressed on all addressing and protection exceptions.
**Resulting Condition Code:** The code is set as specified in the new PSW loaded.

**Program Exceptions:**

- Access (fetch and store, except key-controlled protection, linkage-stack entry)
- Addressing (authority-table entry, if SASN translation occurs)
- ASN translation (if PASN or SASN translation occurs)
- ASTE instance (if ASN-and-LX reuse is enabled and PASN or SASN translation occurs)
- Secondary authority (if SASN translation occurs)
- Space-switch event
- Special operation
- Specification
- Stack empty
- Stack operation
- Stack specification
- Stack type
- Subspace replacement (if PASN or SASN translation occurs)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-64.

**Figure 10-64. Priority of Execution: PROGRAM RETURN (Part 1 of 3)**
Programming Note: Because PROGRAM CALL cannot be executed successfully in the secondary-space or home-space mode, PROGRAM RETURN is not intended to load a PSW specifying one of these translation modes. PROGRAM RETURN, unlike SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST, does not recognize a space-switch event because of loading a PSW that specifies the home-space mode.

PROGRAM TRANSFER

PT \( R_1, R_2 \) [RRE]

Note: In this instruction definition, the name “PROGRAM TRANSFER (WITH INSTANCE)” refers to the PROGRAM TRANSFER instruction and the PROGRAM TRANSFER WITH INSTANCE instruction.

Bits 32-63 of general register \( R_1 \) are used as the new values for the PSW-key mask, the PASN, and the SASN. Bits 32-63 or 0-63 of general register \( R_2 \), depending on the current addressing mode, are used as the new values for the problem-state bit, basic-addressing-mode bit, and instruction address in the current PSW. In the PROGRAM TRANSFER WITH INSTANCE operation, bits 0-31 of general register \( R_1 \) are an ASTEIN and are compared against the new value of the PASTEIN if the PASN is changed. In the PROGRAM TRANSFER operation, bits 0-31 of general register \( R_1 \) are ignored.

The format of general registers \( R_1 \) and \( R_2 \) are shown in Figure 10-65.

For PROGRAM TRANSFER

\[ \begin{array}{c|c|c}
0 & 16 & 24 \hline
32 & 48 & 63 \\
\hline
PSW-Key Mask & ASN \\
\end{array} \]

For PROGRAM TRANSFER WITH INSTANCE

\[ \begin{array}{c|c|c}
0 & 32 & 48 \hline
32 & 48 & 63 \\
\hline
ASTEIN & PSW-Key Mask & ASN \\
\end{array} \]

In 24-Bit or 31-Bit Addressing Mode

\[ \begin{array}{c|c|c}
0 & 32 & 33 \hline
32 & 33 & 63 \\
\hline
Instruction Address & P \\
\end{array} \]

In 64-Bit Addressing Mode

\[ \begin{array}{c|c|c}
0 & 63 \\
\hline
Instruction Address & P \\
\end{array} \]

When the contents of bit positions 48-63 of general register \( R_1 \) are equal to the current PASN, the operation is called PROGRAM TRANSFER (WITH INSTANCE) to current primary (PT-cp or PTI-cp); when the fields are not equal, the operation is called PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss).

The contents of general register \( R_2 \) are used to update the problem-state bit and the instruction address in the current PSW and, in the 24-bit or 64-bit addressing mode.
In the 24-bit or 31-bit addressing mode, bit 32 of general register \( R_2 \) replaces the basic-addressing-mode bit, bit 32 of the current PSW, and bits 33-62 of the register, with one rightmost zero appended, replace bits 33-63 of the instruction address in the PSW, bits 97-127 of the PSW. In the 64-bit addressing mode, bits 0-62 of general register \( R_2 \), with one rightmost zero appended, replace the instruction address, and the basic-addressing-mode bit remains unchanged.

Bits 32-47 of general register \( R_1 \) are ANDed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask. Bits 0-31 of general register \( R_1 \) are ignored.

In any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, the ASN specified by bits 48-63 of general register \( R_1 \) replaces the SASN in control register 3, and the SASCE in control register 7 is replaced by the final contents of control register 1.

In the PROGRAM TRANSFER operation, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in control register 3 is replaced by the final value of the PASTEIN in control register 4. This replacement occurs in the PROGRAM TRANSFER WITH INSTANCE operation regardless of the value of the ASN-and-LX-reuse control.

PROGRAM TRANSFER (WITH INSTANCE) to Current Primary (PT-cp or PTI-cp)

The PT-cp operation is depicted in part 1 of Figure 10-67 on page 10-108. The PTI-cp operation is depicted in part 1 of Figure 10-68 on page 10-110. The PT-cp or PTI-cp operation is completed when the common portion of the PROGRAM TRANSFER (WITH INSTANCE) operation, described above, is completed. The PASTEIN, authorization index, ASN, primary ASCE, and contents of control register 5 (primary-ASN-second-table-entry origin) are not changed by PT-cp or PTI-cp. In this case in the PTI-cp operation, there is not a test of whether the current PASTEIN equals the ASTEIN specified in bit positions 0-31 of general register \( R_1 \); the ASTEIN is ignored.

PROGRAM TRANSFER (WITH INSTANCE) with Space Switching (PT-ss or PTI-ss)

If the ASN in bit positions 48-63 of general register \( R_1 \) is not equal to the current PASN, a PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss) operation is specified, and the ASN is translated by means of a two-level table lookup.

The PT-ss operation is depicted in parts 1 and 2 of Figure 10-67 on page 10-108. The PTI-ss operation is depicted in parts 1 and 2 of Figure 10-68 on page 10-110. The PT-ss or PTI-ss operation is completed as follows.

In PT-ss or PTI-ss, the contents of bit positions 48-63 of general register \( R_1 \) are used as an ASN, which is translated by means of a two-level table lookup.

Bits 48-57 of general register \( R_1 \) are a 10-bit AFX that is used to select an entry from the ASN first table. Bits 58-63 are a six-bit ASX that is used to select an entry from the ASN second table. The ASN table-lookup process is described in “ASN Translation” on page 3-27. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In PT-ss if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register \( R_1 \) must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The authority-table origin from the ASN-second-table entry (ASTE) is used as the base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to
locate the entry in the authority table. The authority-
table lookup is described in “ASN Authorization” on
page 3-32.

The PT-ss or PTI-ss operation is completed by plac-
ing bits 64-127 of the ASTE in control register 1 as
the new PASCE and in control register 7 as the new
SASCE. The contents of bit positions 32-47 of the
ASTE replace the authorization index in bit positions
32-47 of control register 4. Bits 33-57 of the ASTE
address are placed in bit positions 33-57 of control
register 5 as the new primary-ASTE origin, and zeros
are placed in bit positions 32 and 58-63. Bits 0-31 of
this register remain unchanged. The ASN, bits 48-63
of general register R1, replaces the SASN and PASN
in bit positions 48-63 of control registers 3 and 4. In
PT-ss if ASN-and-LX reuse is enabled, and in PTI-ss
regardless of that enablement, the ASTEIN in the
ASTE replaces the SASTEIN and PASTEIN in bit
positions 0-31 of control registers 3 and 4.

The description in this paragraph applies to use of
the subspace-group facility. After the new PASCE
has been placed in control register 1 and the new pri-
mary-ASTE origin has been placed in control register
5, if (1) the subspace-group-control bit, bit 54, in the
PASCE is one, (2) the dispatchable unit is subspace
active, and (3) the primary-ASTE origin designates
the ASTE for the base space of the dispatchable unit,
then bits 0-55 and 58-63 of the PASCE in control reg-
ister 1 are replaced by the same bits of the ASCE in
the ASTE for the subspace in which the dispatchable
unit last had control. This replacement occurs before
a replacement of the SASCE in control register 7 by
the PASCE. Further details are in “Subspace-
Replacement Operations” on page 5-71.

**PROGRAM TRANSFER (WITH INSTANCE) Serial-
ization**

For any of the PT-cp, PTI-cp, PT-ss, and PTI-ss op-
erations, a serialization and checkpoint-synchronization
function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store
into a trace-table entry from which a subsequent
instruction is fetched will be observed by the CPU
that performed the store.

**Special Conditions**

The instruction can be executed only when the CPU
is in the primary-space mode and the subsystem-
linkage control, bit 0 of the linkage-table designation,
or linkage-first-table designation in the current pri-
mary ASN-second-table entry, is one. If the CPU is in
the real mode, secondary-space mode, access-reg-
ister mode, or home-space mode, or if the subsys-
tem-linkage control is zero, a special-operation
exception is recognized.

In PT-ss when ASN-and-LX reuse is enabled, the
reusable-ASN bit in the ASN-second-table entry
(ASTE) must be zero; otherwise, a special-operation
exception is recognized. In PTI-ss, regardless of the
ASN-and-LX-reuse control, a special-operation
exception is recognized if the controlled-ASN bit in
the ASTE is one and the CPU is in the problem state
at the beginning of the operation, and an ASTE-
instance exception is recognized if the ASTEIN in
general register R1 is not equal to the ASTEIN in the
ASTE.

Bit 63 of general register R3 is placed in the problem-
state bit position, PSW bit position 15, unless the
operation would cause PSW bit 15 to change from
one to zero (problem state to supervisor state). If
such a change would occur, a privileged-operation
exception is recognized.

In the 24-bit or 31-bit addressing mode, the instruc-
tion is completed only if bits 32-39 of general register
R2 specify a valid combination of PSW bits 32 and
97-103. If bit 32 of general register R2 is zero and bits
33-39 are not all zeros, a specification exception is
recognized.

In addition to the above requirements, when a PT-ss
or PTI-ss instruction is specified, the ASN-translation
control, bit 44 of control register 14, must be one;
otherwise, a special-operation exception is recog-
nized.

When, for PT-ss or PTI-ss, the primary space-switch-
event-control bit, bit 57 of register 1, is one either
before or after the execution of the instruction, a
space-switch-event program interruption occurs after
the operation is completed. A space-switch-event
program interruption also occurs after the completion
of a PT-ss or PTI-ss operation if a PER event is
reported.

The operation is suppressed on all addressing
exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
The priority of recognition of program exceptions for the instruction is shown in Figure 10-66.

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

**Programming Notes:**

1. The operation of PROGRAM TRANSFER (PT) is such that it may be used to restore the CPU to the state saved by a previous basic PROGRAM CALL operation. This restoration is accomplished by issuing PT 3,14. Though general registers 3 and 14 are not restored to their original values, the PASN, PSW-key mask, problem-state bit, and instruction address are restored, and the authorization index, PASCE, and primary-ASN-second-table-entry origin are made consistent with the restored PASN. In the 24-bit or 31-bit addressing mode, the basic-addressing-mode bit also is restored. If ASN-and-LX reuse is enabled, the PASTEIN also is made consistent with the restored PASN. Note that the SASN is not saved by PROGRAM CALL or restored by PROGRAM TRANSFER; PROGRAM TRANSFER sets the
SASN equal to the restored PASN. PROGRAM TRANSFER WITH INSTANCE is the same as PROGRAM TRANSFER except that the PAS-TEIN is made consistent regardless of ASN-and-LX-reuse enablement.

2. With proper authority, and while being executed in a common area, PROGRAM TRANSFER (WITH INSTANCE) may be used to change the primary address space to any desired space. The secondary address space is also changed to be the same as the new primary address space.

3. Unlike the RR-format branch instructions, a value of zero in the R₂ field for PROGRAM TRANSFER (WITH INSTANCE) designates general register 0, and branching occurs.

4. A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.

*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.
**: Bits 0-55 and 58-63 of PASCE and SASCE may be replaced from a subspace ASCE
**PURGE ALB**

The ART-lookaside buffer (ALB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The ALB appears cleared of its original contents beginning with the execution of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Privileged operation
- Transaction constraint

**PURGE TLB**

The translation-lookaside buffer (TLB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The TLB appears cleared of its original contents beginning with the fetching of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Privileged operation
- Transaction constraint

**RESET REFERENCE BIT EXTENDED**

The reference bit in the storage key for the 4K-byte block that is addressed by the contents of general register R₂ is set to zero. The contents of general register R₁ are ignored.

In the 24-bit addressing mode, bits 40-51 of general register R₂ designate a 4K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R₂ designate a 4K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R₂ designate a 4K-byte block in real storage, and bits 52-63 of the register are ignored.

Because it is a real address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The remaining bits of the storage key, including the change bit, are not affected.

The condition code is set to reflect the state of the reference and change bits before the reference bit is set to zero.

**Resulting Condition Code:**

0 Reference bit zero; change bit zero
1 Reference bit zero; change bit one
2 Reference bit one; change bit zero
3 Reference bit one; change bit one

**Program Exceptions:**
- Addressing (address specified by general register R₂)
- Privileged operation
- Transaction constraint
Beginning with the block designated by the address in general register \( R_2 \), the reference bits in the storage keys of the 64 consecutive 4 K-byte blocks are inspected and reset. For each of the 64 blocks, the reference bit is placed in an ascending bit position of general register \( R_1 \), beginning with bit position 0 of the register. Subsequent to the inspection of each reference bit, the reference bit in the storage key is reset to zero.

General register \( R_2 \) designates the first of 64 blocks in absolute storage on a 64-block (256 K-byte) boundary. In the 24-bit addressing mode, bits 40-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-39 and 46-63 of the register are ignored. In the 31-bit addressing mode, bits 33-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-32 and 46-63 of the register are ignored. In the 64-bit addressing mode, bits 0-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 46-63 of the register are ignored.

Because it is an absolute address, the address designating the first storage block is not subject to dynamic address translation. The references to the storage keys are not subject to protection exceptions.

The remaining bits of the storage keys are not affected.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Addressing (address specified by general register \( R_2 \))
- Operation (reset-reference-bits-multiple facility not installed)
- Privileged operation
- Transaction constraint

Certain contents of the current PSW and of access register and general register \( B_2 \) are replaced from three or four corresponding fields in the second operand. The size of the PSW field in the second operand, the size or number of general-register fields in the second operand, and the offsets of the fields in the second operand are specified in a parameter list that immediately follows the instruction in the instruction address space.

The instruction address space is the address space from which instructions are fetched. It is composed of real addresses if DAT is off.

The first 64 bits of the parameter list have the following format:

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 P R D Offset of PSW Field
0 1 3 5 1 6 3 1 Offset of AR Field Offset of GR Field 1
32 48 63 Offset of GR Field 2
64 79
```

When bits 14 (R) and 15 (D) of the parameter list are both one, the list is an additional 16 bits in length, as follows:

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 P R D Offset of PSW Field
0 1 3 5 1 6 3 1 Offset of AR Field Offset of GR Field 1
32 48 63 Offset of GR Field 2
64 79
```

Bit 13 of the parameter list (P) specifies the size of the PSW field in the second operand. The field is eight bytes if bit 13 is zero or 16 bytes if bit 13 is one.

Bits 14 and 15 of the parameter list (R and D) provide specifications about one or two general-register fields in the second operand, as follows:

- When bit 14 is zero, then bit 15 is ignored, the general-register field 1 in the second operand is four bytes, from which bits 32-63 of general register \( B_2 \) will be replaced, there is not a general-register field 2 in the second operand, and bits 0-31 of general register \( B_2 \) will remain unchanged.
RESUME PROGRAM

- When bit 14 is one and bit 15 is zero, then the general-register field 1 is eight bytes, from which bits 0-63 of general register $B_2$ will be replaced, and there is not a general-register field 2.

- When bits 14 and 15 are both one, then the general-register fields 1 and 2 are both four bytes, bits 32-63 of general register $B_2$ will be replaced from field 1, and bits 0-31 of the register will be replaced from field 2. (The letter “D” stands for disjoint.)

Bits 16-31 of the parameter list are an unsigned binary integer that is the offset in bytes from the beginning of the second operand to a field that has the format of an eight-byte or 16-byte PSW, depending on bit 13, and from which fields in the current PSW will be replaced. Bits 32-47 similarly are an offset to a four-byte field from which the contents of access register $B_2$ will be replaced. Bits 48-63 similarly are an offset to a four-byte or eight-byte field, depending on bits 14 and 15, from which bits 32-63 or 0-63, respectively, of general register $B_2$ will be replaced. If bits 64-79 of the parameter list exist, they similarly are an offset to a four-byte field from which bits 0-31 of general register $B_2$ will be replaced.

Bits 0-12 of the parameter list must be zeros; otherwise, a specification exception is recognized.

An eight-byte second-operand PSW field has the ESA/390 PSW format, as follows:

<table>
<thead>
<tr>
<th>16 and 17</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>18 and 19</td>
<td>Address-space control (AS)</td>
</tr>
<tr>
<td>20-23</td>
<td>Condition code (CC)</td>
</tr>
<tr>
<td>31</td>
<td>Program mask</td>
</tr>
<tr>
<td>32</td>
<td>Extended addressing mode (EA)</td>
</tr>
<tr>
<td>64-127</td>
<td>Basic addressing mode (BA)</td>
</tr>
<tr>
<td></td>
<td>Instruction address</td>
</tr>
</tbody>
</table>

The remaining fields in the PSW field in the second operand are ignored. Specifically, there is no test for whether bit 12 is one in an eight-byte PSW or zero in a 16-byte PSW. There is also no test for whether bit 31 is zero in an eight-byte PSW.

Unassigned fields in the PSW may be assigned in the future and may then be among those restored by RESUME PROGRAM. Therefore, these fields in the PSW field in the second operand should contain zeros; otherwise, the program may not operate compatibly in the future.

When PSW bits 64-127 are replaced from an eight-byte PSW field in the second operand, they are replaced with bits 33-63 of the field, with 33 zeros appended on the left.

The fields in the second operand are fetched before the contents of access register $B_2$ and general register $B_2$ are changed.

When RESUME PROGRAM is the target of an execute-type instruction, the parameter list immediately follows the RESUME PROGRAM instruction, not the execute-type instruction.

The references to the parameter list are storage-operand fetches, not instruction fetches.

**Special Conditions**

The instruction is completed only if the bits 31, 32, and 64-127 that are to be placed in the current PSW are valid for placement in the PSW. If bits 31 and 32 are both zero and bits 64-103 are not all zeros, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are one and zero, respectively, or if bit 127 is one, a specification exception is recognized. A specification exception
may or may not result when bit 24 in the second operand is one.

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized. When DAT is off, the values of bits 16 and 17 of the PSW field in the second operand are not tested.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

The operation is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:** The code is set as specified by the new condition code loaded.

**Program Exceptions:**

- Access (fetch, parameter list and operand 2)
- Privileged operation (attempt to set the home-space mode when in the problem state)
- Space-switch event
- Specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-69.

| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case. |
| 8.A | Trace exceptions. |
| 8.B.1 | Access exceptions for bits 0-63 of parameter list. |

**Programming Notes:**

1. As described in “Instruction Fetching” on page 5-116, the bytes of an instruction may be fetched piecemeal, and the instruction may be fetched multiple times for a single execution. Therefore, the results are unpredictable when instructions are fetched for execution from storage that is being changed by another CPU or a channel program. This warning is particularly applicable when RESUME PROGRAM is the target of an execute-type instruction since the execute-type instruction may be refetched in order to generate, from its second operand, the address of the parameter list used by RESUME PROGRAM. If the execute-type instruction is refetched, there is not necessarily a test for whether storage still contains either the execute-type instruction or the RESUME PROGRAM instruction.

2. The storage-operand references for RESUME PROGRAM may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

**Figure 10-69. Priority of Execution: RESUME PROGRAM (Part 1 of 2)**

<table>

</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>

Bits 52-55 of the second-operand address are used as a code to set the address-space-control bits in the PSW. The second-operand address is not used to address data; instead, bits 52-55 form the code. Bits 0-51 and 56-63 of the second-operand address are ignored. Bits 52 and 53 of the second-operand address must be zeros; otherwise, a specification exception is recognized.

The following figure summarizes the operation of SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST:

Second-Operand Address

<table>
<thead>
<tr>

<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>32 52 56 63</td>
<td></td>
</tr>
</tbody>
</table>

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation (attempt to set the home-space mode in the problem state)
- Space-switch event
- Special operation
- Specification
- Transaction constraint

The priority of recognition of program exceptions for the instructions is shown in Figure 10-70.

Special Conditions

For SET ADDRESS SPACE CONTROL, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recognized. The same rules apply also to SET ADDRESS SPACE CONTROL FAST, except that whether the secondary-space control is tested is unpredictable.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.B Special-operation exception due to DAT being off.

7.C Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero. May be omitted for SET ADDRESS SPACE CONTROL FAST.

8. Privileged-operation exception due to attempt to set home-space mode when in problem state.

9. Specification exception due to nonzero value in bit positions 52 and 53 of second-operand address.

10. Space-switch event.

Figure 10-70. Priority of Execution: SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST
Programming Notes:

1. SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST are defined in such a way that the mode to be set can be placed directly in the displacement field of the instruction or can be specified from the same bit positions of a general register as those in which the mode is saved by INSERT ADDRESS SPACE CONTROL.

2. SET ADDRESS SPACE CONTROL FAST may provide better performance than SET ADDRESS SPACE CONTROL, depending on the model.

3. Because SET ADDRESS SPACE CONTROL FAST does not perform the serialization function, it does not cause copies of prefetched instructions to be discarded. To ensure predictable results after SET ADDRESS SPACE CONTROL FAST is used to switch to or from the home-space mode, the program must cause prefetched instructions to be discarded before an instruction is executed in a location that does not contain the same instruction in both the primary and home address spaces. The operations that cause prefetched instructions to be discarded are described in "Instruction Fetching" on page 5-116.

4. If a program stores into the instruction stream at a location following a subsequent SET ADDRESS SPACE CONTROL FAST instruction, and the SET ADDRESS SPACE CONTROL FAST instruction changes the translation mode either from or to the home-space mode, a copy of a prefetched instruction may be executed instead of the value that was stored. To avoid this situation, either SET ADDRESS SPACE CONTROL must be used instead of SET ADDRESS SPACE CONTROL FAST or some other means must be used to cause prefetched instructions to be discarded after the conceptual store occurs.

SET CLOCK

The current value of the TOD clock is replaced by the contents of the doubleword designated by the second-operand address, and the clock enters the stopped state.

The doubleword operand replaces the contents of the clock, as determined by the resolution of the clock. Only those bits of the operand are set in the clock that correspond to the bit positions which are updated by the clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock. In some models, starting at or to the right of bit position 52, the rightmost bits of the second operand are ignored, and the corresponding positions of the clock which are implemented are set to zeros. Zeros are also placed in positions to the right of bit position 63 of the clock.

After the clock value is set, the clock enters the stopped state. The clock leaves the stopped state to enter the set state and resume incrementing under control of the TOD-clock-sync control, bit 34 of control register 0, of the CPU which most recently caused the clock to enter the stopped state. When the bit is zero, the clock enters the set state at the completion of the instruction. When the bit is one, the clock remains in the stopped state until the bit is set to zero or until another CPU executes a SET CLOCK instruction affecting the clock. If an external time reference (ETR) is installed, a signal from the ETR may be used to set the set state from the stopped state. When the system is not in the interpretive-execution mode, and an external time reference (ETR) is not attached to the configuration, the TOD-clock-sync control is treated as being zero, regardless of its actual value; in this case, the clock enters the set state and resumes incrementing upon completion of the instruction.

The value of the clock is changed and the clock is placed in the stopped state only if the manual TOD-clock control of any CPU in the configuration is set to the enable-set position or the TOD-clock-control-override control, bit 42 of control register 14, is one. If the TOD-clock control of all CPUs is set to the secure position and the TOD-clock-control-override control is zero, the value and state of the clock are not changed. Whether the clock is set or remains unchanged is distinguished by condition codes 0 and 1, respectively.

When the clock is not operational, the value and state of the clock are not changed, regardless of the settings of the TOD-clock control and the TOD-clock-control-override control, and condition code 3 is set.
SET CLOCK COMPARATOR

SCKC \( D_j(B_j) \) [S]

<table>
<thead>
<tr>
<th>0</th>
<th>16</th>
<th>20</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B206'</td>
<td>( B_2 )</td>
<td>( D_2 )</td>
<td></td>
</tr>
</tbody>
</table>

The current value of the clock comparator is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the clock comparator that correspond to the bit positions to be compared with the TOD clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock comparator.

### Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

### Programming Notes:

1. SET CLOCK should be issued only while all other activity on all CPUs in the configuration has been suspended. This activity should not be resumed until after the TOD clock has entered the set state.

2. To ensure predictable operation of the CPU timer after the TOD clock enters the set state, SET CPU TIMER should be issued on all CPUs in the configuration.

3. To ensure predictable operation of clock-comparator interruptions after the TOD clock enters the set state, one of the following instructions should be issued on each CPU in the configuration: SET CLOCK COMPARATOR (SCKC), STORE CLOCK (STCK), or STORE CLOCK EXTENDED (STCKE). (Execution of STCKF does not necessarily include the interlocks required for this special situation.)

4. SET CLOCK is provided for compatibility purposes. It is recommended that, where possible, the program use the PTFF control function PTFF-STO (Set TOD Offset), rather than SET CLOCK.

---

SET CLOCK PROGRAMMABLE FIELD

SCKPF [E]

![Table with values '0107']

Bits 48-63 of general register 0 are placed in bit positions 16-31 of the TOD programmable register. Zeros are placed in bit positions 0-15 of the TOD programmable register.

### Special Conditions
Bits 32-47 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-31 of general register 0 are ignored.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Privileged operation
- Specification
- Transaction constraint

**Programming Note:** The values in the TOD programmable registers of a configuration should be the same and should be unique within a multiple-configuration system.

## SET CPU TIMER

```plaintext
SPX  D(B)
  \[B208\] B2 D2 [S]
```

The current value of the CPU timer is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the CPU timer that correspond to the bit positions to be updated; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the CPU timer.

**Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

## SET PREFIX

```plaintext
SPX  D(B)
  \[B210\] B2 D2 [S]
```

The contents of bit positions 33-50 of the prefix register are replaced by the contents of bit positions 1-18 of the word at the location designated by the second-operand address. The ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) of this CPU are cleared of entries.

After the second operand is fetched, the value is tested for validity before it is used to replace the contents of the prefix register. Bits 1-18 of the operand with 13 zeros appended on the right and 33 zeros appended on the left are used as an absolute address of the 8K-byte new prefix area in storage. This address is treated as a 64-bit address regardless of the addressing mode specified by the current PSW. The two 4K-byte blocks within the new prefix area are accessed; if either is not available in the configuration, an addressing exception is recognized, and the operation is suppressed. The accesses to the blocks are not subject to protection; however, the accesses may cause the reference bits for the blocks to be set to ones.

If the operation is completed, the new prefix is used for any interruptions following the execution of the instruction and for the execution of subsequent instructions. The contents of bit positions 0 and 19-31 of the second operand are ignored.

The ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) are cleared of entries. The ALB and TLB appear cleared of their original contents, beginning with the fetching of the next sequential instruction.

A serialization function is performed before or after the second operand is fetched and again after the operation is completed.

**Special Conditions**

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.
**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Addressing (new prefix area)
- Privileged operation
- Specification
- Transaction constraint

### SET PSW KEY FROM ADDRESS

```
SPKA      D2(B2)  [S]
'B20A'    B2     D2
```

The four-bit PSW key, bits 8-11 of the current PSW, is replaced by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the new PSW key. Bits 0-55 and 60-63 of the second-operand address are ignored.

**Special Conditions**

In the problem state, the execution of the instruction is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

**Programming Notes:**
1. The format of SET PSW KEY FROM ADDRESS permits the program to set the PSW key either from the general register designated by the B2 field or from the D2 field in the instruction itself.

2. When one program requests another program to access a location designated by the requesting program, SET PSW KEY FROM ADDRESS can be used by the called program to verify that the requesting program is authorized to make this access, provided the storage location of the called program is not protected against fetching. The called program can perform the verification by replacing the PSW key with the requesting-program PSW key before making the access and subsequently restoring the called-program PSW key to its original value. Caution must be exercised, however, in handling any resulting protection exceptions since such exceptions may cause the operation to be terminated. See TEST PROTECTION and the associated programming notes for an alternative approach to the testing of addresses passed by a calling program.

### SET SECONDARY ASN

```
SSAR      R1      [RRE]
'B225'    R1      [RRE]
```

**Note:** In this instruction definition, the name “SET SECONDARY ASN (WITH INSTANCE)” refers to the SET SECONDARY ASN instruction and the SET SECONDARY ASN WITH INSTANCE instruction.

The ASN specified in bit positions 48-63 of general register R1 replaces the secondary ASN in control register 3, and the address-space-control element corresponding to that ASN replaces the SASCE in control register 7.

The contents of bit positions 48-63 of general register R1 are called the new ASN. For SET SECONDARY ASN WITH INSTANCE, bits 0-31 of the register are an STEIN and are compared against the new SASTEIN if the SASTEIN is not set equal to the PASTEIN, and bits 32-47 of the register are ignored. For
SET SECONDARY ASN, bits 0-47 of the register are ignored.

When the new ASN is equal to the current PASN, the operation is called SET SECONDARY ASN (WITH INSTANCE) to current primary (SSAR-cp or SSAIR-cp); when the fields are not equal, the operation is called SET SECONDARY ASN (WITH INSTANCE) with space switching (SSAR-ss or SSAIR-ss). The SSAR-cp and SSAR-ss operations are depicted in Figure 10-72 on page 10-124. The SSAIR-cp and SSAIR-ss operations are depicted in Figure 10-73 on page 10-125.

SET SECONDARY ASN (WITH INSTANCE) to Current Primary (SSAR-cp or SSAIR-cp)

In the SSAR-cp or SSAIR-cp operation, the new ASN is equal to the PASN. The new ASN replaces the SASN, bits 48-63 of control register 3; the PASCE in control register 1 replaces the SASCE in control register 7.

In SSAR-cp, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in bit positions 0-31 of control register 3 is replaced by the PASTEIN in bit positions 0-31 of control register 4. This replacement occurs in SSAIR-cp regardless of the value of the ASN-and-LX-reuse control. In SSAR-cp, there is not a test of whether the current PASTEIN equals the ASTEIN in bit positions 0-31 of general register R1; the ASTEIN is ignored. The operation is completed.

SET SECONDARY ASN (WITH INSTANCE) with Space Switching (SSAR-ss or SSAIR-ss)

In the SSAR-ss or SSAIR-ss operation, the new ASN is not equal to the PASN, and the new ASN is translated by means of a two-level table lookup. Bits 0-9 of the new ASN (bits 48-57 of the register) are a 10-bit AFX which is used to select an entry from the ASN first table. Bits 10-15 of the new ASN (bits 58-63 of the register) are a six-bit ASX which is used to select an entry from the ASN second table. The two-level lookup is described in “ASN Translation” on page 3-27. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In SSAR-ss, if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero in the problem state; otherwise, a special-operation exception is recognized. Also in SSAIR-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register R1 must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The ASN-second-table entry (ASTE) obtained as a result of the second lookup contains the address-space-control element and the authority-table origin and length associated with the ASN.

The authority-table origin from the ASTE is used as a base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in “ASN Authorization” on page 3-32.

The new ASN, bits 48-63 of general register R1, replaces the SASN, bits 48-63 of control register 3. The address-space-control element in the ASTE replaces the SASCE in control register 7. In SSAR-ss if ASN-and-LX reuse is enabled, and in SSAIR-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN in bit positions 0-31 of control register 3.

The description in this paragraph applies to use of the subspace-group facility. After the new SASCE has been placed in control register 7, if (1) the subspace-group-control bit, bit 54, in the SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE obtained by ASN translation is the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the SASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71.

SET SECONDARY ASN (WITH INSTANCE) Serialization

For any of the SSAR-cp, SSAIR-cp, SSAR-ss, and SSAIR-ss operations, a serialization and checkpoint-
synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

**Special Conditions**

The operation is performed only when the ASN-translation control, bit 44 of control register 14, is one and DAT is on. When either the ASN-translation-control bit is zero or DAT is off, a special-operation exception is recognized.

In SSAR-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state, and an ASTE-instance exception is recognized if the ASTEIN in general register R₁ is not equal to the ASTEIN in the ASTE.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Addressing (authority-table entry, SSAR-ss and SSAIR-ss only)
- ASN translation (SSAR-ss and SSAIR-ss only)
- ASTE instance (SSAR-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, SSAIR-ss only)
- Secondary authority (SSAR-ss and SSAIR-ss only)
- Special operation
- Subspace replacement (SSAR-ss and SSAIR-ss only)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-71 on page 10-122.

<table>

</tbody>
</table>

**Programming Note:** A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may
return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.
Figure 10-72. Execution of SET SECONDARY ASN

R: Address is real
*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.
**: For SSAR-ss only, bits 0-55 and 58-63 of SASCE may be replaced from a subspace ASCE
Figure 10-73. Execution of SET SECONDARY ASN WITH INSTANCE Instruction
SET STORAGE KEY EXTENDED

SSKE R1,R2[M3] [RFF-c]

The storage key for one or more 4K-byte blocks is replaced by the value in the first-operand register. When the conditional-SSKE facility is installed, certain functions of the key-setting operation may be bypassed.

When the conditional-SSKE facility is not installed, or when the conditional-SSKE facility is installed and both the MR and MC bits of the M3 field are zero, the storage key for the 4K-byte block that is addressed by the contents of general register R2 is replaced by bits from general register R1. The instruction completes without changing the condition code.

When the conditional-SSKE facility is installed and either or both of the MR and MC bits are one, the access-control bits, fetch-protection bit, and, optionally, the reference bit and change bit of the storage key that is addressed by the contents of general register R2 are compared with corresponding bits in general register R1. If the compared bits are equal, then no change is made to the key; otherwise, selected bits of the key are replaced by the corresponding bits in general register R1. The storage key prior to any modification is inserted in general register R1, and the result is indicated by the condition code.

When the enhanced-DAT facility is installed, the above operations may be repeated for the storage keys of multiple 4K-byte blocks within the same 1MB block, subject to the control of the multiple-block control, described below.

The M3 field has the following format:

<table>
<thead>
<tr>
<th>MMMM</th>
<th>O</th>
<th>R</th>
<th>C</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

The bits of the M3 field are defined as follows:

- **Nonquiescing Control (NQ):** The NQ bit, bit 0 of the M3 field, controls whether a quiescing operation is performed, as described below.

- **Reference-Bit-Update Mask (MR):** The MR bit, bit 1 of the M3 field, controls whether updates to the reference bit in the storage key may be bypassed, as described below.

- **Change-Bit-Update Mask (MC):** The MC bit, bit 2 of the M3 field, controls whether updates to the change bit in the storage key may be bypassed, as described below.

- **Multiple-Block Control (MB):** The MB bit, bit 3 of the M3 field, controls whether the storage keys for multiple 4K-byte blocks of storage may be set, as described in “Setting Storage Keys in Multiple 4K-Byte Blocks” on page 10-128.

When the nonquiescing key-setting facility is not installed, bit 0 of the M3 field is ignored. When the conditional-SSKE facility is not installed, bit positions 1 and 2 of the M3 field are ignored. When the enhanced-DAT facility is not installed, bit position 3 of the M3 field is ignored.

When the conditional-SSKE facility is installed, processing is as follows:

1. When both the MR and MC bits, bits 1 and 2 of the M3 field, are zero, the instruction completes as though the conditional-SSKE facility was not installed. The storage key for the 4K-byte block that is addressed by the contents of general register R2 is replaced by bits from general register R1, and the instruction completes without changing the condition code.

2. When either or both the MR and MC bits are one, processing is as follows:

   a. Prior to any modification, the contents of the storage key for the 4K-byte block that is addressed by general register R2 are placed in bit positions 48-54 of general register R1, and bit 55 of general register R1 is set to zero. Bits 0-47 and 56-63 of the register remain unchanged.

   If an invalid checking-block code (CBC) is detected when fetching the storage key, then (a) the entire storage key for the 4K-byte block is replaced by bits 56-62 of general register R1, (b) the contents of bit positions 48-55 of general register R1 are unpredictable, and (c) the instruction completes by setting condition code 3.
b. The access-control bits and fetch-protection bit of the storage key for the designated 4K-byte block are compared with the corresponding fields in bits 56-60 of general register R1. If the respective fields are not equal, the entire storage key for the 4K-byte block is replaced by bits from general register R1, and the instruction completes by setting condition code 1.

When the access-control and fetch-protection bits in the storage key are equal to the respective bits in general register R1, processing continues as described below.

c. When both the MR and MC bits are one, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

d. When the MR bit is zero and the MC bit is one, then the reference bit of the storage key for the designated 4K-byte block is compared with bit 61 of general register R1. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

If the bits are not equal, then either (a) the entire storage key for the designated 4K-byte block is replaced by the bits in general register R1, and the instruction completes by setting condition code 1; or (b) the reference bit for the storage key is replaced by bit 62 of general register R1, the reference bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

When the enhanced-DAT facility 1 is not installed, or when the facility is installed but the multiple-block control is zero, general register R2 contains a real address. When the enhanced-DAT facility 1 is installed and the multiple-block control is one, general register R2 contains an absolute address.

In the 24-bit addressing mode, bits 40-51 of general register R2 designate a 4K-byte block in real or absolute storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R2 designate a 4K-byte block in real or absolute storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R2 designate a 4K-byte block in real or absolute storage, and bits 52-63 of the register are ignored.

Because it is a real or absolute address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The new seven-bit storage-key value, or selected bits thereof, is obtained from bit positions 56-62 of general register R1. The contents of bit positions 0-55 and 63 of the register are ignored. When the conditional-SSKE facility is installed, and either or both the MR and MC bits are one, bit position 63 should contain a zero; otherwise, the program may not operate compatibly in the future.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the conditional-SSKE facility is installed and the resulting condition code is 0, it is unpredictable whether a serialization and checkpoint-synchronization function is performed after the operation completes.

When the nonquiescing key-setting facility is not installed, or when the facility is installed and the nonquiescing control (NQ) is zero, the following applies:

- A quiescing operation is performed.
For any store access, by any CPU or channel program, completed to the designated 4K-byte block either before or after the setting of the key by this instruction, the associated setting of the reference and change bits to one in the storage key for the block also is completed before or after, respectively, the execution of this instruction.

When the nonquiescing key-setting facility is installed and the NQ control is one, a quiescing operation is not necessarily performed. See “Storage-Key Accesses” on page 5-118 for a discussion the effects of quiescing on key-setting instructions, and see “Quiescing” on page 5-131 for details on the quiescing operation.

Setting Storage Keys in Multiple 4K-Byte Blocks
When the enhanced-DAT facility 1 is not installed, or when the facility is installed, but the multiple-block control is zero, the storage key for a single 4K-byte block is set, as described above.

When the enhanced-DAT facility 1 is installed, and the multiple-block control is one, the storage keys for multiple 4K-byte blocks within a 1M-byte block may be set, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1M-byte boundary. In this case, SET STORAGE KEY EXTENDED is interruptible, and processing is as follows:

- When an interruption occurs (other than one that follows termination), the leftmost bits of general register \( R_2 \) comprising the 4K-byte block address have been updated so the instruction, when reexecuted, resumes at the point of interruption. If either or both the MR or MC bits are one, the condition code is unpredictable; otherwise, the condition code is unchanged.

- When the instruction completes without interruption, the leftmost bits of general register \( R_2 \) comprising the 4K-byte block address have been updated to the next 1M-byte boundary. If either or both the MR or MC bits are one, condition code 3 is set; otherwise, the condition code is unchanged.

In either of the above two cases, the following applies:

- Bits 52-63 of general register \( R_2 \) remain unchanged.

Bits 48-55 of general register \( R_1 \) are unpredictable.

When multiple-block processing occurs and the \( R_1 \) and \( R_2 \) fields designate the same register, the second-operand address is placed in the register. When multiple-block processing occurs in the 24-bit or 31-bit addressing modes, the leftmost bits which are not part of the address in bit positions 32-63 of general register \( R_2 \) are set to zeros; bits 0-31 of the register are unchanged.

Before a quiescing key-setting operation is performed, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which storage keys are being set. It is unpredictable whether some or all other CPUs are affected as well.

Resulting Condition Code:
When the conditional-SSKE facility is not installed, or when both the MR and MC bits of the \( M_3 \) field are zero, the condition code remains unchanged.

When the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one, the condition code is set as follows:

0 Storage key not set
1 Entire storage key set
2 Partial storage key set
3 Entire storage key set; bits 48-55 of general register \( R_1 \) are unpredictable.

Program Exceptions:
- Addressing (address specified by general register \( R_2 \))
- Privileged operation
- Transaction constraint

Programming Notes:
1. The \( M_3 \) field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax.
When the M₃ field is not specified, the assembler places zeros in that field of the instruction.

2. When setting multiple storage keys within the same 1M-byte block to the same value, use of the multiple-block control (MB, bit 3 of the M₃ field) may yield better performance than executing separate SSKE instructions for each 4K-byte block in the megabyte.

3. If the program does not rely on the setting of the reference bit, it may set the MR bit of the M₃ field to one, regardless of whether or not the conditional-SSKE facility is installed. Similarly, if the program does not rely on the setting of the change bit, it may set the MC bit of the M₃ field to one, regardless of whether or not the conditional-SSKE facility is installed. In these cases, the program cannot rely on the condition code or the key value returned in general register R₃. Conversely, if the program depends on accurate setting of the reference or change bit, then the MR and MC bits should be set to zero, such that reference and change bit recording are properly maintained when the conditional-SSKE facility is installed.

4. When SSKE is issued, the program must ensure that no channel subsystem is simultaneously altering the storage designated by general register R₂. The program also must ensure that no other CPU or channel subsystem is accessing the storage designated by general register R₂ when the nonquiescing (NQ) control is one. Otherwise, unpredictable results may be observed by the other CPUs and channel subsystem, including the alteration of the block designated by general register R₂.

5. Even when the enhanced-DAT facility 2 is installed, the multiple-block control is limited to setting keys in a 1 M-byte block; no provision is made for setting keys in a 2 G-byte block with SSKE. PERFORM FRAME MANAGEMENT FUNCTION with a set-key control of 1 and frame-size code of 2 may be used to set the keys of a 2 G-byte block. See “PERFORM FRAME MANAGEMENT FUNCTION” on page 10-76 for additional details.

6. See the programming note on page 5-120 for restrictions on the use of the nonquiescing control.

### SET SYSTEM MASK

<table>
<thead>
<tr>
<th>SSM</th>
<th>D₃(B₂)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>16</td>
</tr>
</tbody>
</table>

Bits 0-7 of the current PSW are replaced by the byte at the location designated by the second-operand address.

**Special Conditions**

When the SSM-suppression-control bit, bit 33 of control register 0, is one and the CPU is in the supervisor state, a special-operation exception is recognized.

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if the contents of bit positions 0 and 2-4 of the PSW are not all zeros. In this case, the instruction is completed, and the instruction-length code is set to 2 or 3. The specification exception, which is listed as a program exception for this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

### SIGNAL PROCESSOR

An eight-bit order code and, if called for, a 64-bit parameter are transmitted to the CPU designated by the CPU address contained in the third operand. The result is indicated by the condition code and may be
detailed by status assembled in bit positions 32-63 of the first-operand location.

The second-operand address is not used to address data; instead, bits 56-63 of the address contain the eight-bit order code. Bits 0-55 of the second-operand address are ignored. The order code specifies the function to be performed by the addressed CPU. The assignment and definition of order codes appear in “CPU Signaling and Response” on page 4-64.

The 16-bit binary number contained in bit positions 48-63 of general register R₃ forms the CPU address. Bits 0-47 of the register are ignored. When the specified order is the set-architecture or set multithreading order, the CPU address is ignored; all CPUs in the configuration are considered to be addressed. See “CPU-Address Identification” on page 4-63 for details on the CPU address.

The general register containing the 64-bit parameter in bit positions 0-63 is R₁ or R₁+1, whichever is the odd-numbered register. It depends on the order code whether a parameter is provided and for what purpose it is used.

The operands just described have the following formats:

General register designated by R₁:

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

Status

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

General register designated by R₁ or R₁+1, whichever is the odd-numbered register:

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

Parameter

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

Parameter (continued)

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

General register designated by R₃:

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

CPU Address

```
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
```

A serialization function is performed before the operation begins and again after the operation is completed.

When the order code is accepted and no nonzero status is returned, condition code 0 is set. When status information is generated by this CPU or returned by the addressed CPU, the status is placed in bit positions 32-63 of general register R₁, bits 0-31 of the register remain unchanged, and condition code 1 is set.

When the access path to the addressed CPU is busy, or the addressed CPU is operational but in a state where it cannot respond to the order code, condition code 2 is set.

When the addressed CPU is not operational (that is, it is not provided in the installation, it is not in the configuration, it is in any of certain customer-engineer test modes, or its power is off), condition code 3 is set.

**Resulting Condition Code:**

0 Order code accepted
1 Status stored
2 Busy
3 Not operational

**Program Exceptions:**

- Privileged operation
- Transaction constraint

**Programming Notes:**

1. A more detailed discussion of the condition-code settings for SIGNAL PROCESSOR is contained in “CPU Signaling and Response” on page 4-64.
2. To ensure that presently written programs will be executed properly when new facilities using additional bits are installed, only zeros should appear in the unused bit positions of the second-oper-
and address and in bit positions 32-47 of general register R3.

3. Certain SIGNAL PROCESSOR orders are provided with the expectation that they will be used primarily in special circumstances. Such orders may be implemented with the aid of an auxiliary maintenance or service processor, and, thus, the execution time may take several seconds. Unless all of the functions provided by the order are required, combinations of other orders, in conjunction with appropriate programming support, can be expected to provide a specific function more rapidly. The following orders are the only orders which are intended for frequent use:

- Conditional emergency signal
- Emergency-signal
- External-call
- Sense
- Sense-running-status

The following orders are intended for infrequent use, and performance therefore may be much slower than for frequently used orders:

- CPU reset
- Initial CPU reset
- Restart
- Set architecture
- Set multithreading
- Set prefix
- Store additional status at address
- Store status at address
- Start
- Stop
- Stop and store status

An alternative to the set-prefix order, for faster performance when the receiving CPU is not already stopped, is the use of the emergency-signal or external-call order, followed by the execution of a SET PREFIX instruction on the addressed CPU. Clearing the TLB of entries is ordinarily accomplished more rapidly through the use of the emergency-signal or external-call order, followed by execution of the PURGE TLB instruction on the addressed CPU, than by use of the set-prefix order.

---

### STORE CLOCK COMPARATOR

<table>
<thead>
<tr>
<th>STCKC</th>
<th>D2(B2)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>B207</td>
<td>B2</td>
<td>D2</td>
</tr>
</tbody>
</table>

The current value of the clock comparator is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions of the clock comparator that are not compared with the TOD clock.

**Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

---

### STORE CONTROL

<table>
<thead>
<tr>
<th>STCTL</th>
<th>R1,R3,D2(B2)</th>
<th>[RS-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>B6</td>
<td>R1 R3 B2 D2</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>STCTG</th>
<th>R1,R3,D2(B2)</th>
<th>[RSY-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>EB</td>
<td>R1 R3 B2 DL2 DH2</td>
<td>'25'</td>
</tr>
</tbody>
</table>

Bits of the set of control registers starting with control register R1 and ending with control register R3 are stored at the locations designated by the second-operand address.

For STORE CONTROL (STCTL), bits 32-63 of the control registers are stored in successive words beginning at the second-operand address, and bits 0-31 of the registers are ignored. For STORE CONTROL (STCTG), bits 0-63 of the control registers are...
stored in successive doublewords beginning at the second-operand address.

The storage area where the contents of the control registers are placed starts at the location designated by the second-operand address and continues through as many storage words, for STCTL, or doublewords, for STCTG, as the number of control registers specified. The contents of the control registers are stored in ascending order of their register numbers, starting with control register R1 and continuing up to and including control register R3, with control register 0 following control register 15. The contents of the control registers remain unchanged.

The displacement for STCTL is treated as a 12-bit unsigned binary integer. The displacement for STCTG is treated as a 20-bit signed binary integer.

Special Conditions

The second operand must be designated on a word boundary for STCTL or on a doubleword boundary for STCTG; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE CPU ADDRESS

STAP D j (B j) [S]

The CPU address by which this CPU is identified in a multiprocessing configuration is stored at the halfword location designated by the second-operand address.

Special Conditions

The operand must be designated on a halfword boundary; otherwise, a specification exception is recognized.

STORE CPU ID

STIDP D j (B j) [S]

Information identifying either (1) the CPU or (2) the configuration and the logical partition in which the program is being executed is stored at the doubleword location designated by the second-operand address.

The information stored has the following format:

<table>
<thead>
<tr>
<th>Bit positions 0-7</th>
<th>8-31</th>
<th>32-47</th>
<th>48-63</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU Identification Number</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Machine-Type Number</td>
<td>F</td>
<td>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
<td></td>
</tr>
</tbody>
</table>

Bit positions 8-31 contain the CPU identification number, consisting of six four-bit digits. Some or all of these digits are selected from the physical serial number stamped on the CPU.

The format bit (F) in bit position 48 specifies the format of the first two digits of the CPU identification number.

When the format bit is zero, the contents of the CPU-identification-number field identifies the CPU. When the format bit is one, the CPU-identification number identifies the system configuration as opposed to an individual CPU within the configuration, and it identifies the logical partition in which the program is being executed.

Bit positions 32-47 contain the machine-type number of the CPU. Bit positions 0-7 and 49-63 contain zeros.

Special Conditions
The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

**Programming Notes:**

1. The program should allow for the possibility that the CPU identification number may contain the hexadecimal digits A-F as well as the digits 0-9.

2. When the format bit in bit position 48 of the second operand is one, the CPU-identification number identifies the system configuration as opposed to an individual CPU within the configuration, and it identifies the requesting logical partition. The CPU identity can be obtained using the STORE CPU ADDRESS or the STORE SYSTEM INFORMATION instruction.

3. In versions of *Enterprise Systems Architecture/390 Principles of Operation* prior to SA22-7201-03, the machine-type-number field was called the model-number field.

4. In ESA/390, bit positions 0-7 of the information stored contain a version code. When the version code is nonzero, it is usually indicative of the model number of the model and the number of CPUs contained in the model. In both ESA/390 and z/Architecture, the STORE SYSTEM INFORMATION instruction can be used to determine the model number and the number of CPUs in the model.

5. The CPU identification number has the hex format:
   - “Annnnn” in the basic mode, or
   - LPnnnn” in the LPAR (logically-partitioned) mode, when the format bit is zero, or
   - PPnnnn” in the LPAR mode, when the format bit is one.

   Where:
   - A is the CPU address of the CPU.
   - L is a logical CPU address.
   - P is a logical-partition identifier.
   - PP is the user partition identifier (UPID). The UPID is an eight-bit unsigned binary integer bound to a logical partition.
   - n is a digit derived from the serial number of the CPU.

The terminology above that is not defined in this publication is defined in the appropriate System Library publications for the model.

6. The format bit is always stored as a zero in the basic mode.

7. IBM eServer zSeries 800 and 900 machines always store the format bit as a zero.

8. When STORE CPU ID is executed in a virtual machine, the VM operating system replaces bits 0-7 of the information stored with FF hex. See *z/VM CP Programming Services* (SC24-6179) for additional details.

9. In order to ensure world-wide unique identification of the configuration of the issuing CPU, the STORE SYSTEM INFORMATION instruction specifying SYSIB 1.1.1, 1.2.1, or 2.2.1 should be used.

**STORE CPU TIMER**

STPT D 2(B2) [S]

The current value of the CPU timer is stored at the doubleword location designated by the second operand address.

Zeros are provided for the rightmost bit positions that are not updated by the CPU timer.

**Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Privileged operation

10-133
STORE FACILITY LIST

STFL D2(B2) [S]

A list of bits providing information about facilities is stored in the word at real address 200. The meanings of the bits are identical to the first 32 bits stored by STORE FACILITY LIST EXTENDED. Figure 4-24, “Assigned Facility Bits” on page 4-76 shows the meanings of the assigned facility bits.

The second-operand address is ignored but should be zero to permit possible future extensions.

Key-controlled and low-address protection do not apply.

Condition Code:  The code remains unchanged.

Program Exceptions:
- Privileged operation
- Specification
- Transaction constraint

Programming Note:  STORE FACILITY LIST stores only a 32-bit indication of facilities. STORE FACILITY LIST EXTENDED may be used to store the entire list of installed facilities.

STORE PREFIX

STPX D2(B2) [S]

The contents of bit positions 33-50 of the prefix register are stored in bit positions 1-18 of the word location designated by the second-operand address, and zeros are stored in bit positions 0 and 19-31 of the word.

Special Conditions

The operand must be designated on a word boundary; otherwise, a specification exception is recognized.

Condition Code:  The code remains unchanged.

Program Exceptions:
- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE REAL ADDRESS

STRAG D4(B4),D2(B2) [SSE]

The 64-bit real address corresponding to the second-operand virtual address is stored in the doubleword at the location designated by the first-operand address.

The virtual address specified by the B2 and D2 fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in the following table:

<table>
<thead>
<tr>
<th>PSW Bits 16 and 17</th>
<th>Address-Space-Control Element Used by DAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Contents of control register 1</td>
</tr>
<tr>
<td>10</td>
<td>Contents of control register 7</td>
</tr>
<tr>
<td>01</td>
<td>The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the B2 field</td>
</tr>
<tr>
<td>11</td>
<td>Contents of control register 13</td>
</tr>
</tbody>
</table>

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The resultant 64-bit real address is stored at the first-operand location.

The translated address is not inspected for boundary alignment or for addressing or protection exceptions.
The address computations for the operands are performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

**Special Conditions**

The first operand must be designated on a double-word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2, except for an addressing or protection exception for the designated location; store, operand 1)
- Privileged operation
- Specification
- Transaction constraint

**Programming Note:** STORE REAL ADDRESS is contrasted to LOAD REAL ADDRESS as follows:

- In the 24-bit or 31-bit addressing mode, LOAD REAL ADDRESS (LRA) loads bits 33-63 of the real address if bits 0-32 of the address are all zeros or recognizes a special-operation exception if bits 0-32 are not all zeros. LRA in the 64-bit addressing mode, and LOAD REAL ADDRESS (LRAG) in any addressing mode, loads bits 0-63 of the real address. STORE REAL ADDRESS stores bits 0-63 of the real address in any addressing mode.

- LOAD REAL ADDRESS, for most access-exception conditions, does not recognize the conditions as exceptions but instead sets the condition code to indicate the occurrence of the conditions. STORE REAL ADDRESS recognizes all access-exception conditions as exceptions, resulting in a program interruption.

**STORE SYSTEM INFORMATION**

<table>
<thead>
<tr>
<th>STSI</th>
<th>D₂(B₂)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>'B27D'</td>
<td></td>
</tr>
</tbody>
</table>

Depending on a function code in general register 0, either an identification of the level of the configuration executing the program is placed in general register 0 or information about a component or components of a configuration is stored in a system-information block (SYSIB). When information about a component or components is requested, the information is specified by further contents of general register 0 and by contents of general register 1. The SYSIB, if any, is designated by the second-operand address.

The machine is considered to provide one, two, or three levels of configuration. The levels are:

1. The basic machine, which is the machine as if it were operating in the basic mode.
2. A logical partition, which is provided if the machine is operating in the LPAR, or logically-partitioned, mode. A logical partition is provided by the LPAR hypervisor, which is a part of the machine. A basic machine exists even when the machine is operating in the LPAR mode.
3. A virtual machine, which is provided by a virtual-machine (VM) control program that is executed either by the basic machine or in a logical partition. A virtual machine may itself execute a VM control program that provides a higher-level (more removed from the basic machine) virtual machine, which also is considered a level-3 configuration.

The terms basic mode, LPAR mode, logical partition, hypervisor, and virtual machine, and any other terms related specifically to those terms, are not defined in this publication; they are defined in the machine manuals.

A program being executed by a level-1 configuration (the basic machine) can request information about that configuration. A program being executed by a level-2 configuration (in a logical partition) can request information about the logical partition and about the underlying basic machine. A program being executed by a level-3 configuration (a virtual machine) can request information about the virtual...
machine and about the one or two underlying levels; a basic machine is always underlying, and a logical partition may or may not be between the basic machine and the virtual machine. When information about a virtual machine is requested, information is provided about the configuration executing the program and about any underlying level or levels of virtual machine.

The function code determining the operation is an unsigned binary integer in bit positions 32-35 of general register 0 and is as follows:

<table>
<thead>
<tr>
<th>Function Code</th>
<th>Information Requested</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Current-configuration-level number</td>
</tr>
<tr>
<td>1</td>
<td>Information about level 1 (the basic machine)</td>
</tr>
<tr>
<td>2</td>
<td>Information about level 2 (a logical partition)</td>
</tr>
<tr>
<td>3</td>
<td>Information about level 3 (a virtual machine)</td>
</tr>
<tr>
<td>4-14</td>
<td>None; codes are reserved</td>
</tr>
<tr>
<td>15</td>
<td>Current-configuration-level information</td>
</tr>
</tbody>
</table>

Invalid Function Code

The level of the configuration executing the program is called the current level. The configuration level specified by a nonzero function code (other than 15) is called the specified level. When the specified level is numbered higher than the current level, then the function code is called invalid, the condition code is set to 3, and no other action (including checking) is performed. Function code 15 is invalid when the configuration-topology facility is not installed.

Valid Function Code

When the function code is equal to or less than the number of the current level, or 15, it is called valid. In this case, bits 36-55 of general register 0 and bits 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized. Bits 0-31 of general registers 0 and 1 always are ignored.

When the function code is 0, an unsigned binary integer identifying the current configuration level (1 for basic machine, 2 for logical partition, or 3 for virtual machine) is placed in bit positions 32-35 of general register 0, the condition code is set to 0, and no further action is performed.

When the function code is valid and nonzero, general registers 0 and 1 contain additional specifications about the information requested, as follows:

- Bit positions 56-63 of general register 0 contain an unsigned binary integer, called selector 1, that specifies a component or components of the specified configuration.
- Bit positions 48-63 of general register 1 contain an unsigned binary integer, called selector 2, that specifies the type of information requested.

The contents of general registers 0 and 1 are as follows:

**General Register 0**

<table>
<thead>
<tr>
<th>Selector 1</th>
<th>0000000000000000000000000000000000000000000000000000000000000000</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0000000000000000000000000000000000000000000000000000000000000000</td>
</tr>
</tbody>
</table>

**General Register 1**

<table>
<thead>
<tr>
<th>Selector 2</th>
<th>0000000000000000000000000000000000000000000000000000000000000000</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0000000000000000000000000000000000000000000000000000000000000000</td>
</tr>
</tbody>
</table>

When the function code is valid and nonzero, information may be stored in a system-information block (SYSIB) beginning at the second-operand location. The SYSIB is 4K bytes and must begin at a 4K-byte boundary; otherwise, a specification exception may be recognized, depending on selector 1 and selector 2 and on whether access exceptions are recognized due to references to the SYSIB (see “Special Conditions”).

Selector 1 can have values as follows:

<table>
<thead>
<tr>
<th>Selector 1</th>
<th>Information Requested</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>None; selector is reserved</td>
</tr>
<tr>
<td>1</td>
<td>Information about the configuration level specified by the function code.</td>
</tr>
<tr>
<td>2</td>
<td>Information about one or more CPUs in the specified configuration level</td>
</tr>
<tr>
<td>3-255</td>
<td>None; selectors are reserved</td>
</tr>
</tbody>
</table>

When selector 1 is 1, selector 2 can have values as follows:

**Selector 2**

<table>
<thead>
<tr>
<th>When Selector 1 Is 1</th>
<th>Information Requested</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>None; selector is reserved</td>
</tr>
<tr>
<td>1</td>
<td>Information about the specified configuration level</td>
</tr>
</tbody>
</table>
When selector 1 is 2, selector 2 can have values as follows:

<table>
<thead>
<tr>
<th>Selector 2 when Selector 1 Is 2</th>
<th>Information Requested</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>None; selector is reserved</td>
</tr>
<tr>
<td>1</td>
<td>Information about the CPU executing the program in the specified configuration level</td>
</tr>
<tr>
<td>2</td>
<td>Information about all CPUs in the specified configuration level</td>
</tr>
<tr>
<td>3-65,535</td>
<td>None; selectors are reserved</td>
</tr>
</tbody>
</table>

Only certain combinations of the function code, selector 1, and selector 2 are valid, as shown in Figure 10-74.

**SYSIB 1.1.1 (Basic-Machine Configuration)**

SYSIB 1.1.1 is illustrated in Figure 10-75:

```
0 1 1 Basic-machine configuration
1 1 2 Basic-machine CPU
1 2 2 Basic-machine CPUs
2 2 1 Logical-partition CPU
2 2 2 Logical-partition CPUs
3 2 2 Virtual-machine CPUs
15 1 2-6 Topology information of current configuration
```

**Explanation:**

- Ignored.

Figure 10-74. Valid Function-Code, Selector-1, and Selector-2 Combinations for STORE SYSTEM INFORMATION

When the specified function-code, selector-1, and selector-2 combination is invalid (is other than as shown in Figure 10-74), or if it is valid but the requested information is not available because the specified level does not implement or does not fully implement the instruction or because a necessary part of the level is uninstalled or not initialized, and provided that an exception is not recognized (see “Special Conditions”), the condition code is set to 3. When the function code is nonzero, the combination is valid, the requested information is available, and there is no exception, the requested information is stored in a system-information block (SYSIB) at the second-operand address.

Some or all of the SYSIB may be fetched before it is stored.

A SYSIB may be identified in references by means of “SYSIB fc.s1.s2,” where “fc,” “s1,” and “s2” are the values of a function code, selector 1, and selector 2, respectively.

Following sections describe the defined SYSIBs by means of figures and related text. In the figures, the offsets shown on the left are word values. “The configuration” refers to the configuration level specified by the function code (the configuration level about which information is requested).

**Note:** In the descriptions of the system-information block (SYSIB) stored by STSI, the term “CPU or core” (or briefly, “CPU/core”) indicates the applicability of the text. When the multithreading facility is not installed at the selected configuration level, certain STSI functions store information relevant to logical or physical CPU attributes. When the multithreading facility is installed at the selected configuration level, these STSI functions store information relevant to logical or physical core attributes.
STORE SYSTEM INFORMATION

<table>
<thead>
<tr>
<th>Word 0</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bit Meaning**

0  When bit 0 of byte 0 (P) is one, the type-percentage bytes, located in words 40-41, are valid. When P is zero, the bytes are stored as zeros, but have no meaning.

1-5 Bits 1-5 of byte 0 are reserved and stored as zeros.

6  When bit 6 of byte 0 (M) is zero, the multithreading facility is not installed in the basic machine configuration. When M is one, the multithreading facility is installed in the basic machine configuration.

7  Bit 7 of byte 0 (T), when one, indicates that the condition represented by the CCR and CAI fields is relatively transient.

**Reserved:** The contents of bits 1-5 of word 0, words 1-7, 13-15, and 45-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**IBM:** Byte 1 of word 0 is assigned to IBM internal use.

**Capacity-Change Reason (CCR):** When the CAI byte is nonzero, the content of byte 2 of word 0 is an 8-bit unsigned integer whose value indicates one of the following reasons which is associated with the present values contained in SYSIB 1.1.1.

**CCR Capacity-Change Reason**

0  Machine is running at nominal capacity.

1  The capacity change is due solely to the setting of a manual control, such as intentional power-save.

2  The capacity change is due to a machine-exception condition, such as detection of overheating.

3  The capacity change is due to a non-exception machine condition, such as concurrent service.

4  The capacity change is due to an exception condition external to the machine, such as detection of supplied power or cooling falling outside required tolerances.

5-255  Reserved.

When the CAI byte is zero, the CCR field is undefined, and stored as zero.

When multiple capacity-change reasons exist, CCR is set according to the following priority:

1b. External-exception condition, CCR=4.

2. Non-exception machine condition, CCR=3.

**Capacity-Adjustment Indication (CAI):** Byte 3 of word 0, when nonzero, is an 8-bit unsigned integer whose value is in the range 1-100 and represents the aggregate position of model-dependent controls. Temporary capacity changes that affect machine performance are not included; such changes include those caused by capacity-backup (CBU), on/off-capacity-on-demand (OOCoD), and capacity-planned-event (CPE) features. When zero, the indication is not reported. When in the range 1-99, some amount of reduction is indicated. When 100, the machine is operating at its normal capacity.

Primary CPUs and all secondary-type CPUs are similarly affected.

The model-capacity rating is not affected. A change in the CAI may also reflect a change in CPU-capability fields of SYSIB 1.2.2.

**Manufacturer:** Words 8-11 contain the 16-character (0-9 or uppercase A-Z) EBCDIC name of the manufacturer of the configuration. The name is left justified with trailing blanks if necessary.

**Type:** Word 12 contains the four-character (0-9) EBCDIC type number of the configuration. (This is called the machine-type number in the definition of STORE CPU ID.)

**Model-Capacity Identifier (C):** Words 16-19 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-capacity identifier of the configuration. The model-capacity identifier is left justified with trailing blanks if necessary.

**Sequence Code:** Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The sequence code is right justified with leading EBCDIC zeros if necessary.

**Plant of Manufacture:** Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

**Model:** When word 25 is not binary zeros, words 25-28 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model identification of the configuration. The model identification is left justified with trailing blanks if necessary. (This is called the model number in programming note 4 on page 10-133 of STORE CPU ID.) When word 25 is binary zeros, the contents of words 16-19 represent both the model-capacity identifier and the model.

**Model-Permanent-Capacity Identifier (P):** When nonzero, words 29-32 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-permanent-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

**Model-Temporary-Capacity Identifier (T):** When nonzero, words 33-36 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-temporary-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

**Model-Capacity Rating (CR):** When nonzero, word 37 contains a 32-bit unsigned integer whose value is associated with the model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used to generate this integer.

**Model-Permanent-Capacity Rating (PR):** When nonzero, word 38 contains a 32-bit unsigned integer whose value is associated with the model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer.

**Model-Temporary-Capacity Rating (TR):** When nonzero, word 39 contains a 32-bit unsigned integer whose value is associated with the model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer.

**Type N Pctg.** Each of the byte fields in words 40-41 that is designated as a type-N percentage contains an 8-bit unsigned binary integer whose value is in the range 0-100 and represents a percentage. When nonzero, the percentage may be used to affect the use and allowed utilization of the secondary-CPU whose CPU type corresponds to the particular byte. When a byte in this range contains a value of zero, use rules of the corresponding secondary-CPU type are not overridden. The reserved bytes in word 41
are reserved for the potential addition of new second-
ary CPU types.

Nominal Model-Capacity Rating (NCR): When nonzero, word 42 contains a 32-bit unsigned integer whose value is associated with the nominal model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NCR value equals the CR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the CR value is less than the NCR value.

Nominal Model-Permanent-Capacity Rating (NPR): When nonzero, word 43 contains a 32-bit unsigned integer whose value is associated with the nominal model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NPR value equals the PR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the PR value is less than the NPR value.

Nominal Model-Temporary-Capacity Rating (NTR): When nonzero, word 44 contains a 32-bit unsigned integer whose value is associated with the nominal model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NTR value equals the TR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the TR value is less than the NTR value.

Worldwide Unique Identification: Taken together, the machine type, manufacturer, plant of manufacture, and sequence code allow for worldwide unique identification of the system.

Programming Notes:

1. The fields of the SYSIB 1.1.1 are similar to those of the node descriptor described in the publication Common I/O-Device Commands and Self Description, SA22-7204. However, the contents of the SYSIB fields may not be identical to the contents of the corresponding node-descriptor fields because the SYSIB fields:
   - Allow more characters.
   - Are more flexible regarding the type of characters allowed.
   • Provide information that is justified differently within the field.
   • May not use the same method to determine the contents of fields such as the sequence-code field.

2. The model field in a node descriptor corresponds to the content of the STSI model field and not the STSI model-capacity-identifier field.

3. The model field specifies the model of the machine (i.e., the physical model); the model-capacity identifier field specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.

4. Each of the three model-capacity-identifier fields specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.

5. Each of the three model-capacity-rating fields, corresponding one-to-one with the three model-capacity-identifier fields, specifies a numeric value that may or may not represent the actual capacity of the machine.

6. The term capacity backup (CBU) represents a methodology by which spare capacity in a CPC can be used to replace capacity from another CPC within an enterprise, normally for a relatively limited period of time. Typically CBU is used when another CPC of the enterprise has failed, and the CPC operating under CBU rules is making up for the missing CPC’s capacity. However, CBU can also indicate a capacity that reflects a net reduction such that the current capacity would be less than the permanent capacity.

7. The term On/Off Capacity on Demand (On/Off CoD) represents a methodology by which spare capacity in a CPC can be made available to increase the total capacity within an enterprise, normally for a limited period of time. For example, On/Off CoD may be used to acquire additional capacity in order to handle a workload peak.

8. The content of the model-capacity identifier (C) field corresponds to the current capacity at which the central-processing complex (CPC) is operating.
9. The content of the model-permanent-capacity identifier (P) corresponds to the capacity of the CPC exclusive of temporarily-available increased capacity and temporarily-available replacement capacity.

10. The content of the model-temporary-capacity identifier (T) corresponds to the total of permanent capacity and temporarily-available increased capacity but exclusive of any temporarily-available replacement capacity.

11. When the T bit in byte 0 is one, the current capacity values and indicators are in a relatively-short period of transition and should be permitted to stabilize, that is, a result where T is zero, before any resultant action proceeds.

SYSIB 1.2.1 (Basic-Machine CPU/Core)

**Figure 10-76. Format of the SYSIB 1.2.1**

**Reserved:** The contents of words 0-19, bytes 0 and 1 of word 25, and words 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**Sequence Code:** Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

**Plant of Manufacture:** Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

**CPU Address:** When the multithreading facility is not installed in the machine, bytes 2 and 3 of word 25 contain the CPU address by which this CPU is identified in a multiprocessor configuration. The CPU address is a 16-bit unsigned binary integer. The CPU address is the same as is stored by STORE CPU ADDRESS when the program is executed by a machine operating in the basic mode.

**Core Identification:** When multithreading is installed in the machine, bytes 2 and 3 of word 25 contain a 16-bit unsigned core identification, right justified in the field. The core ID field contains the core-ID portion of the value that would be stored by STORE CPU ADDRESS when executed by a machine operating in the basic mode; no thread ID is included.

**Worldwide Unique Identification:** Taken together, the machine type and manufacturer (from SYSIB 1.1.1) with the plant of manufacture and sequence code allow for worldwide unique identification of the system.

**Programming Note:** Multiple CPUs in the same configuration have the same sequence code, and it is necessary to use other information, such as the CPU address, to establish a unique CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

SYSIB 1.2.2 (Basic-Machine CPUs)
The general format of the SYSIB 1.2.2 is illustrated in Figure 10-77. Some fields may or may not be valid, as indicated by the contents of the format field in byte 0 of word zero.

When the multithreading facility is not installed (as indicated by bit 0 of word 1), fields labelled “CPU/Core” apply to a CPU. When the multithreading
When 64 or more words are needed to contain the information for all the CPUs, the portion of the SYSIB following the adjustment-factor list in a format-0 SYSIB or the alternate-adjustment-factor list in a format-1 SYSIB, up to and including word 1023 are reserved and may be stored as zeros or may remain unchanged.

**Format:** Byte 0 of word 0 contains an 8-bit unsigned binary integer that specifies the format of SYSIB 1.2.2.

**Alternate-CPU/Core-Capability Offset:** When the format field has a value of one, bytes 2-3 of word 0 contain a 16-bit unsigned binary integer that specifies the offset in bytes of the alternate-CPU-capability field in the SYSIB. Zeros are stored in the rightmost two bits of the ACC offset field, thus the ACC offset is a multiple of four and designates word N in Figure 10-77.

**MT Installed:** When bit 0 of the MT-installed field (byte 0 of word 1) is zero, the remainder of the field and the MT-general field are not meaningful and stored as zeros. When bit 0 of the MT-installed field is one, the remainder of the field and the MT-general field are meaningful, as described below.

**Bits** | **Meaning**
---|---
0 | When zero, the multithreading facility is not installed in the machine. When one, the multithreading facility is installed in the machine.
1-2 | Reserved (stored as zeros).
3-7 | A 5-bit unsigned integer whose value is the highest supported thread identification (TID) for a core in the machine. The value is in the range 1-31, indicating a minimum of two and a maximum of 32 CPUs per core. A specialty core may operate with this thread count.

**MT General:** The contents of byte 1 of word 1 are meaningful only when bit 0 of word 1 is one.

**Bits** | **Meaning**
---|---
0-2 | Reserved.
3-7 | A 5-bit unsigned integer whose value is the highest supported thread identification for a core comprising general CPUs. The value is in the range 0-31, indicating a minimum of one and a maximum of 32 CPUs per core.
The value is less than or equal to the value in bits 3-7 of the MT-installed field. A value of zero indicates that multithreading is not available for a general core. For a sub-capacity model, bits 3-7 of the MT-general field contain zeros.

**Primary CPU/Core Speed:** When not zero, word 4 contains a 32-bit unsigned binary integer whose value represents the dynamic speed of a primary CPU, encoded as the approximate number of CPU cycles per microsecond.

**Secondary CPU/Core Speed:** When not zero, word 5 contains a 32-bit unsigned binary integer whose value represents the dynamic speed of a secondary CPU, encoded as the approximate number of CPU cycles per microsecond.

**Nominal CPU/Core Capability:** Word 6, when not zero, is formatted and encoded the same as word 8, CPU capability, including that a lower value indicates a proportionally higher CPU capability.

When the CAI byte of SYSIB 1.1.1 is zero, the nominal CPU capability (word 6) is stored as zero. The nonzero value equals the word-8 value when the CAI byte of SYSIB 1.1.1 contains a value of 100. When the CAI byte of SYSIB 1.1.1 is nonzero and less than 100, the word-6 value indicates a CPU speed greater than the CPU speed indicated by the word-8 value.

**Secondary CPU/Core Capability:** Word 7, when not zero, is formatted and encoded the same as word 8, CPU capability, including that a lower value indicates a proportionally higher CPU capability, and specifies a secondary capability that may be applied to certain types of CPUs in the configuration.

There is no formal description of the algorithm used to generate this value, except that it is the same as the algorithm used to generate the primary CPU capability. The value is used as an indication of the capability of a CPU relative to the capability of other CPU models, and also relative to the capability of other CPU types within a model.

The capability value applies to each of the specialty CPUs/cores of one or more applicable CPU/core types in the configuration. That is, all CPUs in the configuration of an applicable type or types have the same capability. When the value is zero, all CPUs of any CPU type in the configuration have the same capability, as specified by the CPU capability.

The secondary CPU capability may or may not be the same value as the CPU-capability value.

The multiprocessing-CPU-capability-adjustment factors are also applicable to CPUs whose capability is specified by the secondary CPU capability.

**CPU/Core Capability:** Word 8 specifies the capability of one of the CPUs in the configuration.

If bits 0-8 of word 8 are zero, the word contains a 32-bit unsigned binary integer (I) in the range $1 \leq I < 2^{23}$. If bits 0-8 of word 8 are nonzero, the word contains a 32-bit binary floating point short-format number instead of an unsigned binary integer.

Regardless of encoding, the value represents the capability of one of the CPUs in the configuration, and a lower value indicates a proportionally higher CPU capability. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the capability of the CPU relative to the capability of other CPU models.

The capability value applies to each of the general CPUs in the configuration. That is, all non-secondary CPUs in the configuration have the same capability.

**Total CPU/Core Count:** Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of general CPUs or cores comprising general CPUs in the configuration. This number includes all general CPUs/cores in the configured state, the standby state, or the reserved state.

**Configured CPU/Core Count:** Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the configured state. A CPU/core is in the configured state when it is in the configuration and available to be used to execute programs.

**Standby CPU/Core Count:** Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the standby state. A CPU/core is in the standby state when it is in the configuration, is not available to be used to execute pro-
Reserved CPU/Core Count: Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the reserved state. A CPU/core is in the reserved state when it is in the configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place a reserved CPU in the standby or configured state by means of manual actions.)

Multiprocessing CPU/Core-Capability Adjustment Factors: Beginning with bytes 0 and 1 of word 11, the SYSIB contains a series of contiguous two-byte fields, each containing a 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If \( 0 < V \leq 100 \), a denominator of 100 is indicated which produces a fraction of \( V/100 \).
- If \( 100 < V \leq 255 \), a denominator of 255 is indicated which produces a fraction of \( V/255 \).
- If \( 255 < V \leq 65,535 \), a denominator of 65,536 is indicated which produces a fraction of \( V/65,536 \).

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

Programming Note: The applicable MP adjustment factor is an approximation that is sensitive to the particular workload.

Alternate CPU/Core Capability: When the format field has a value of one, the location of word N is the sum of the address of the SYSIB plus the byte-offset value in the alternate-CPU-capability-offset field. If bits 0-8 of word N are zero, the word contains a 32-bit unsigned binary integer (I) in the range \( 0 \leq I < 2^{23} \) that specifies the announced capability of one of the CPUs in the configuration. If bits 0-8 of word N are nonzero, the word contains a 32-bit binary floating point short-format number instead of a 32-bit unsigned binary integer.

Regardless of encoding, a lower value indicates a proportionally higher CPU capacity. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the announced capability of the CPU relative to the announced capability of other CPU models.

The alternate-capability value applies to each of the general CPUs or cores comprising general CPUs in the configuration. That is, all general CPUs/cores in the configuration have the same alternate capability.

Alternate Multiprocessing CPU/Core-Capability Adjustment Factors: When the format field has a value of one, the location of word N + 1 is the sum of the address of the SYSIB plus the byte-offset value in the alternate-CPU-capability-offset field plus four. Beginning with bytes 0 and 1 of word N + 1, the SYSIB contains a series of contiguous two-byte fields, each containing a 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the alternate-CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If \( 0 < V \leq 100 \), a denominator of 100 is indicated which produces a fraction of \( V/100 \).
- If \( 100 < V \leq 255 \), a denominator of 255 is indicated which produces a fraction of \( V/255 \).
- If \( 255 < V \leq 65,535 \), a denominator of 65,536 is indicated which produces a fraction of \( V/65,536 \).

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.
The number of alternate-adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The alternate-adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first alternate-adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive alternate-adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

**SYSIB 2.2.1 (Logical-Partition CPU/Core)**

SYSIB 2.2.1 is illustrated in Figure 10-78.

<table>
<thead>
<tr>

</tbody>
</table>

Figure 10-78. Format of the SYSIB 2.2.1

**Reserved:** The contents of words 0-19 and 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**Sequence Code:** Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

**Plant of Manufacture:** Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

**Logical-CPU ID:** Bytes 0 and 1 of word 25 contain a 16-bit unsigned binary integer that can be used in conjunction with the logical-CPU address to distinguish the logical CPU from the other logical CPUs provided by the same LPAR hypervisor.

**Logical-CPU Address:** When the multithreading facility is not enabled in the level-2 configuration, bytes 2 and 3 of word 25 contain the logical-CPU address by which this logical CPU is identified within the level-2 configuration. The logical-CPU address is a 16-bit unsigned binary integer. The logical-CPU-address field contains the same information as is stored by STORE CPU ADDRESS when the machine is operating in the LPAR mode.

**Logical-Core Identification:** When the multithreading facility is enabled in the level-2 configuration, bytes 2 and 3 of word 25 contain a 16-bit unsigned core identification by which the core is identified within the configuration, right justified in the field.

**Worldwide Unique Identification:** Taken together, the machine type and manufacturer (from SYSIB 1.1.1) with the plant of manufacture and sequence code allow for worldwide unique identification of the system.

**Programming Note:** Multiple logical CPUs in the same level-2 configuration have the same logical-CPU sequence code, and it is necessary to use other information, such as the logical-CPU address, to establish a unique logical-CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

**SYSIB 2.2.2 (Logical-Partition CPUs / Cores)**

SYSIB 2.2.2 is illustrated in Figure 10-79.

When the multithreading facility is not enabled (as indicated by the PSMTID field), fields labelled with an asterisk (*) apply to a primary CPU. When the multithreading facility is enabled, fields labelled with an asterisk apply to a core comprising primary CPUs.
The number of logical CPUs/cores that are provided using dedicated level-1 CPUs/cores is specified by the dedicated-LCPU-count value in bytes 0 and 1 of word 18.

When zero, bit 0 indicates that none of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that are dedicated to this level-2 configuration.

1 Shared: When one, bit 1 indicates that one or more of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that can be used to provide logical CPUs/cores for other level-2 configurations. The number of logical CPUs/cores that are provided using shared level-1 CPUs/cores is specified by the shared-LCPU-count value in bytes 2 and 3 of word 18.

When zero, bit 1 indicates that none of the logical CPUs/cores for this level-2 configuration are provided using shared level-1 CPUs/cores.

2 Utilization Limit: When one, bit 2 indicates that the amount of use of the level-1 CPUs/cores that are used to provide the logical CPUs/cores for this level-2 configuration is limited.

When zero, bit 2 indicates that the amount of use of the level-1 CPUs/cores that are used to provide the logical CPUs/cores for this level-2 configuration is unlimited.

3-7 Reserved.

Total Logical-CPU/Core Count: Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of primary logical CPUs/cores that are provided for this level-2 configuration. This number includes all of the logical CPUs/cores that are in the configured state, the standby state, or the reserved state.

Configured Logical-CPU/Core Count: Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the configured state.

A logical CPU/core is in the configured state when it is in the level-2 configuration and is available to be used to execute programs.

Standby Logical-CPU/Core Count: Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores that are in the standby state for this level-2 configuration.
that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the standby state.

A logical CPU/core is in the standby state when it is in the level-2 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved Logical-CPU/Core Count: Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the reserved state.

A logical CPU/core is in the reserved state when it is in the level-2 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the reserved CPU/core in the standby or configured state through manual actions.)

Logical-Partition Name: Words 11-12 contain the 8-character EBCDIC name of this level-2 configuration. The name is left justified with trailing blanks if necessary.

Logical-Partition Capability Adjustment Factor (CAF): Word 13 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-configuration capability that is allowed to be used for this level-2 configuration by the LPAR hypervisor. The fraction of level-1-configuration capability is determined by dividing the CAF value by 1000.

MT Installed: When bit 0 of the MT-installed field (byte 0 of word 16) is zero, the remainder of the field and the MT-general and PSMTID fields are not meaningful and stored as zeros. When bit 0 of the MT-installed field is one, the remainder of the field and the MT-general and PSMTID fields are meaningful, as described below.

<table>
<thead>
<tr>
<th>Bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>When zero, the multithreading facility is not installed in the level-2 configuration. When one, the multithreading facility is installed in the level-2 configuration.</td>
</tr>
<tr>
<td>1-2</td>
<td>Reserved (stored as zeros).</td>
</tr>
</tbody>
</table>

3-7 A 5-bit unsigned integer whose value is the highest supported thread identification (TID) for a core of the level-2 configuration. The value is in the range 1-31, indicating a minimum of two and a maximum of 32 CPUs per core. A specialty core may operate with this thread count.

MT General: The contents of byte 1 of word 16 are meaningful only when bit 0 the MT-installed field is one.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-2</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

3-7 A 5-bit unsigned integer whose value is the highest supported thread identification for a core comprising general CPUs. The value is in the range 0-31, indicating a minimum of one and a maximum of 32 CPUs per core. The value is less than or equal to the value in bits 3-7 of the MT-installed field. A value of zero indicates that multithreading is not available for a general core. For a sub-capacity model, bits 3-7 of the MT-general field contain zeros.

Program-Specified Maximum TID (PSMTID): The contents of byte 2 of word 16 are meaningful only when bit 0 of word 16 is one.

<table>
<thead>
<tr>
<th>Bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-2</td>
<td>Reserved (stored as zeros).</td>
</tr>
</tbody>
</table>

3-7 When the multithreading facility is enabled in the level-2 configuration, bit positions 3-7 contain the program-specified maximum thread identification as set by the SIGNAL PROCESSOR set-multithreading order; the value is copied from bit positions 59-63 of the SIGP parameter register. When the multithreading facility is not enabled in the level-2 configuration, bit positions 3-7 contain zeros.

Dedicated Logical-CPU Count/Core: Bytes 0 and 1 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state primary logical CPUs/cores for this level-2 configuration that are provided using dedicated level-1 CPUs/cores. (See the description of bit 0 of the logical-CPU-characteristics field.)
**Shared Logical-CPU/Core Count:** Bytes 2 and 3 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state primary logical CPUs/cores for this level-2 configuration that are provided using shared level-1 CPUs/cores. (See the description of bit 1 of the logical-CPU-characteristics field.)

**SYSIB 3.2.2 (Virtual-Machine CPUs / Cores)**

SYSIB 3.2.2 is illustrated in Figure 10-80:

![Figure 10-80. Format of the SYSIB 3.2.2](image)

- **Reserved:** The contents of words 0-6, bits 0-27 of word 7, and words 136-1023 are reserved and are stored as zeros.

- **Description-Block Count (DBCT):** Bits 28-31 of word 7 contain a four-bit unsigned binary integer that specifies the number (up to eight) of virtual-machine description blocks that are stored in the SYSIB beginning at word 8.

- **Virtual-Machine Description Blocks:** Words 8-135 contain from one to eight 64-byte virtual-machine description blocks, depending on the number of nested level-3 configurations, if any, and their processing characteristics.

When a level-3 configuration is provided by a virtual-machine control program and the control program is being executed by a level-3 configuration provided by another virtual-machine control program, the level-3 configurations are said to be “nested.” Level-3 configurations can be nested in this way for several levels.

The collection of nested level-3 configurations that is in the path between a program being executed by a level-3 configuration and the basic machine is called a “level-3-configuration stack.” The level-3 configurations in a stack are consecutively numbered. The level-3 configuration provided by a virtual-machine control program being executed by either a level-2 configuration or a level-1 configuration is the lowest-numbered (0) level-3 configuration in the stack. The level-3 configuration that is executing the program containing this instruction is the highest numbered (N) level-3 configuration in the stack.

If more than one virtual-machine description block is stored in words 8-135 of the SYSIB, the blocks are stored according to the following rules:

- The collection of level-3 configurations described is a contiguous subset of the total collection of level-3 configurations in the level-3-configuration stack. The subset always includes the highest-numbered level-3 configuration in the stack. One or more level-3 configurations at the bottom of the stack may not be described because STORE SYSTEM INFORMATION is not implemented by the highest of those configurations or the limit of eight description blocks would be exceeded.

- The highest-numbered level-3 configuration in the level-3-configuration stack is always described by the first description block in the SYSIB. The lowest-numbered level-3 configuration in the stack, of those that are included in the subset that is described, is described by the last description block in the SYSIB.

The contents of the SYSIB subsequent to the virtual-machine description blocks and prior to word 136 are reserved and are stored as zeros.
The virtual-machine description block is illustrated in Figure 10-81.

Explanation:

* Field applies to a primary CPU or to a core comprising primary CPUs. The CPUs may either be primary or specialty CPUs.

**Total Logical-CPU/Core Count:** Bytes 0 and 1 of word 1 contain a 16-bit unsigned binary integer that specifies the total number of primary logical CPUs/cores that are provided for this level-3 configuration. This number includes all of the primary logical CPUs/cores that are in the configured state, the standby state, and the reserved state.

**Configured Logical-CPU/Core Count:** Bytes 2 and 3 of word 1 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the configured state.

A logical CPU/core is in the configured state when it is in the level-3 configuration and is available to be used to execute programs.

**Standby Logical-CPU/Core Count:** Bytes 0 and 1 of word 2 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the standby state.

A logical CPU/core is in the standby state when it is in the level-3 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

**Reserved Logical-CPU/Core Count:** Bytes 2 and 3 of word 2 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the reserved state.

A logical CPU/core is in the reserved state when it is in the level-3 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the logical CPU/core in the standby or configured state through manual actions.)

**Virtual-Machine Name:** Words 3-4 contain the eight-character EBCDIC name of this level-3 configuration. The name is left justified with trailing blanks if necessary.

**Virtual-Machine Capability Adjustment Factor (CAF):** Word 5 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-, level-2-, or level-3-configuration capability that is allowed to be used for this level-3 configuration by the virtual-machine control program. The fraction of the underlying capability is determined by dividing the CAF value by 1000.

**Control-Program Identifier:** Words 6-9 contain the 16-character EBCDIC identifier of the virtual-machine control program that provides this level-3 configuration. This identifier may include qualifiers such as version number and release level. The identifier is left justified with trailing blanks if necessary.
SYSIBs 15.1.2 through 15.1.6 are illustrated in each have the following format:

```
<table>
<thead>
<tr>
<th>Word</th>
<th>Reserved</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Mag6</td>
<td>Mag5</td>
</tr>
<tr>
<td>1</td>
<td>Mag4</td>
<td>Mag3</td>
</tr>
<tr>
<td>2</td>
<td>Mag2</td>
<td>Mag1</td>
</tr>
<tr>
<td>3</td>
<td>Reserved</td>
<td>MNest</td>
</tr>
<tr>
<td>4</td>
<td>Topology List</td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>N</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1023</td>
<td>Reserved</td>
<td></td>
</tr>
</tbody>
</table>
```

Selector 2 specifies the MNest value to which the response is limited. STSI completes with condition code 3 for the following cases:

1. If the maximum-MNest facility is installed and selector 2 exceeds the nonzero model-dependent maximum-selector-2 value.
2. If the maximum-MNest facility is not installed and selector 2 is not specified as two.

Reserved: The contents of bytes 0-1 of word 0, byte 2 of word 2, and word 3 are reserved and are stored as zeros. The contents of words N-1023 are reserved and may be stored as zeros or may remain unchanged.

Length: Bytes 2-3 of word 0 contain a 16-bit unsigned binary integer whose value is the count of bytes of the entire SYSIB 15.1.2. The length of just the topology list is determined by subtracting 16 from the length value in bytes 2-3 of word 0. N in Figure 10-83 is determined by evaluating the formula N=Length/4.

Mag1-6: Word 1 and bytes 0-1 of word 2 constitute six one-byte fields where the content of each byte indicates the maximum number of container-type topology-list entries (TLE) or CPU-type TLEs at the corresponding nesting level. CPU-type TLEs are always found only at the Mag1 level. Additionally, the Mag1 value also specifies the maximum number of CPUs that may be represented by a container-type TLE of the Mag2 level. When the value of the nesting level is greater than one, containing nesting levels above the Mag1 level are occupied only by container-type TLEs. A dynamic change to the topology may alter the number of TLEs and the number of CPUs at the Mag1 level, but the limits represented by the values of the Mag1-6 fields do not change within a model family of machines.

The topology is a structured list of entries where an entry defines one or more CPUs or else is involved with the nesting structure. The following illustrates the meaning of the magnitude fields:

- When all CPUs of the machine are peers and no containment organization exists, other than the entirety of the central-processing complex itself, the value of the nesting level is 1, Mag1 is the only nonzero magnitude field, and the number of CPU-type TLEs stored does not exceed the Mag1 value.
- When all CPUs of the machine are subdivided into peer groups such that one level of containment exists, the value of the nesting level is 2, Mag1 and Mag2 are the only nonzero magnitude fields, the number of container-type TLEs stored does not exceed the Mag2 value, and the number of CPU-type TLEs stored within each container does not exceed the Mag1 value.
- The Mag3-6 bytes similarly become used (proceeding in a right-to-left direction) when the value of the nesting level falls in the range 3-6.

M Nest: When the maximum-MNest facility is not installed, byte 3 of word 2 specifies the nesting level of the topology to which the configuration may be extended without requiring a re-IPL. The maximum MNest value is model dependent in the range 2-6; the minimum is one. If MNest is one, there is no actual TLE nesting structure, Mag1 is the only non-zero field in the Mag1-6 range, and only CPU-type TLEs are represented in the topology list. The MNest value indicates the number of nonzero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1), proceeding left when MNest is greater than one, and with the remaining magnitude fields stored as zeros.

The value of MNest is the maximum possible nesting. No dynamic configuration change exceeds this limit.
When the maximum-MNest facility is installed, the maximum possible nesting is indicated by other means and the MNest value in byte 3 of word 2 reflects both the requested selector-2 value and the number of nonzero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1).

**Topology List:** Words of Figure 10-83 in the range 4 through N-1 specify a list of one or more topology-list entries (TLE). Each TLE is an eight-byte or sixteen-byte field; thus N is an even number of words, and a corollary is that a TLE always starts on a doubleword boundary.

**Topology-List Entries:** The first TLE in the topology list begins at a nesting level equal to MNest-1. The entire topology list represents the configuration of the issuer of the STSI instruction specifying SYSIB 15.1.x; no outermost container TLE entry is used as it would be redundant with the entire list, and the entire configuration. Therefore, the highest nesting level may have more than a single peer container.

Figure 10-83 illustrates the container type of TLE, and Figure 10-84 illustrates the CPU type of TLE.

**Nesting Level (NL):** Byte 0 of word 0 specifies the TLE nesting level.

| NL Meaning | 00 | The TLE is a CPU-type TLE. |
| 01-05 | The TLE is a container-type TLE. The first container-type TLE stored in a topology list or a parent container has a container-ID in the range 1-255. If sibling containers exist within the same parent, they proceed in an ascending order of container IDs, that may or may not be consecutive, to a maximum value of 255. |
| 06-FF | Reserved |

Sibling TLEs have the same value of nesting level which is equivalent to either the value of the nesting level minus one of the immediate parent TLE, or the value of MNest minus one, because the immediate parent is the topology list rather than a TLE.

**Reserved, 0:** For a container-type TLE, bytes 1-3 of word 0 and bytes 0-2 of word 1 are reserved and stored as zeros. For a CPU-type TLE, bytes 1-3 of word 0 and bits 0-4 of word 1 are reserved and stored as zeros.

**Container ID:** Byte 3 of word 1 of a container-type TLE specifies an 8-bit unsigned nonzero binary integer whose value is the identifier of the container. The container ID for a TLE is unique within the same parent container.

**Fields Specific to a CPU-type TLE**

The remaining fields described below are specific to a CPU-type TLE. When the multithreading facility is not installed, or when it the facility is installed but not enabled, these fields describe one or more CPUs in the configuration having common topology attributes. When the multithreading facility is installed and enabled, these fields describe one or more cores in the configuration having common topology attributes; each core comprises a set of CPUs that have the same topology attributes.

**Dedicated (D):** Bit 5 of word 1 of a CPU-type TLE, when one, indicates that the one or more CPUs represented by the TLE are dedicated. When D is zero, the one or more CPUs of the TLE are not dedicated.

**Polarization (PP):** Bits 6-7 of word 1 of a CPU-type TLE specify the polarization value and, when polarization is vertical, the degree of vertical polarization.
also called entitlement (high, medium, low) of the corresponding CPU(s) represented by the TLE. The following values are used:

<table>
<thead>
<tr>
<th>PP</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The one or more CPUs represented by the TLE are horizontally polarized.</td>
</tr>
<tr>
<td>1</td>
<td>The one or more CPUs represented by the TLE are vertically polarized. Entitlement is low.</td>
</tr>
<tr>
<td>2</td>
<td>The one or more CPUs represented by the TLE are vertically polarized. Entitlement is medium.</td>
</tr>
<tr>
<td>3</td>
<td>The one or more CPUs represented by the TLE are vertically polarized. Entitlement is high.</td>
</tr>
</tbody>
</table>

Polarization is only significant in a logical and virtual multiprocessing configuration that uses shared host processors and addresses how the resource assigned to a configuration is applied across the CPUs of the configuration. When horizontal polarization is in effect, each CPU of a configuration is guaranteed approximately the same amount of resource. When vertical polarization is in effect, CPUs of a configuration are classified into three levels of resource entitlement: high, medium, and low.

Both subsystem reset and successful execution of the SIGP set-architecture order specifying ESA/390 mode place a configuration and all of its CPUs into horizontal polarization. The CPUs immediately affected are those that are in the configured state. When a CPU in the standby state is configured, it acquires the current polarization of the configuration and causes a topology change of that configuration to be recognized.

A dedicated CPU is either horizontally or vertically polarized. When a dedicated CPU is vertically polarized, entitlement is always high. Thus, when D is one, PP is either 00 binary or 11 binary.

**CPU Type:** Byte 1 of word 1 of a CPU-type TLE specifies an 8-bit unsigned binary integer whose value is the CPU type of the one or more CPUs represented by the TLE. The CPU-type value specifies either a primary-CPU type or any one of the possible secondary-CPU types.

**CPU-Address Origin:** When the multithreading facility is installed and enabled, the TLE represents one or more cores, each CPU of which has the same CPU type.

**CPU Mask:** Words 2-3 of a CPU-type TLE specify a 64-bit mask where each bit position represents a CPU or core. When the multithreading facility is installed and enabled, bytes 2-3 of word 1 specify a right-justified 16-bit unsigned binary integer whose value is the first core identification in the range of cores represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask.

When the multithreading facility is installed and enabled, bytes 2-3 of word 1 of a CPU-type TLE specify a 16-bit unsigned binary integer whose value is the CPU address of the first CPU in the range of CPUs represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask. The value of a CPU-address origin is the same as that stored by the STORE CPU ADDRESS (STAP) instruction when executed on the CPU represented by bit position 0 in the CPU mask.

When the multithreading facility is installed and enabled, bytes 2-3 of word 1 specify a right-justified 16-bit unsigned binary integer whose value is the first core identification in the range of cores represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask.

The CPU-address origin is evenly divisible by 64.

**CPU Mask:** Words 2-3 of a CPU-type TLE specify a 64-bit mask where each bit position represents a CPU or core. When the multithreading facility is installed and enabled, the following applies:

- The value of the CPU-address origin field plus a bit position in the CPU mask equals the CPU address for the corresponding CPU.
- When a CPU-mask bit is zero, the corresponding CPU is not represented by the TLE. Either the CPU is not in the configuration, or else it must be represented by another CPU-type TLE.
- When a CPU mask bit is one, the corresponding CPU has the modifier-attribute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

When the multithreading facility is installed and enabled, the following applies:

- The value of the CPU-address origin field plus a bit position in the CPU mask equals the core ID for the corresponding core.
- When a CPU-mask bit is zero, the corresponding core is not represented by the TLE. Either the core is not in the configuration or else must be represented by another CPU-type TLE.
- When a CPU-mask bit is one, the corresponding core and each of its CPUs has the modifier-attri-
bute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

Programming Notes:

1. The following example applies when the multithreading facility is not installed, or when the facility is installed but disabled: If the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, CPU 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.

2. The following examples apply when the multithreading facility is installed and enabled:

   A CPU-address-origin value of 0000 hex represents a set of core IDs in the range 0 to 63, 0040 hex represents a set of core IDs in the range 64 to 127, as so forth.

   If the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, core ID 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.

   In this example, if multithreading had been enabled with a program-specified maximum thread identification of three (that is, with four threads per core, thus a TID width of 2 bits), the CPU addresses of any CPU in the core can be determined by multiplying the core ID by four (that is, shifting it left TID-width bit positions), and adding the thread ID. Thus, the CPU addresses for core 79 are 316 - 319 (013C-013F hex).

TLE Ordering: The modifier attributes that apply to a CPU-type TLE are CPU type, polarization, entitlement, and dedication. Polarization and entitlement (for vertical polarization) are taken as a single attribute, albeit with four possible values (horizontal, vertical-high, vertical-medium, and vertical-low).

A single CPU TLE is sufficient to represent as many as 64 CPUs or cores that all have the same modifier-attribute values.

When more than 64 CPUs or cores exist, or the entire range of CPU addresses are not covered by a single CPU-address origin, and the modifier attributes are constant, a separate sibling CPU TLE is stored for each CPU-address origin, as necessary, in ascending order of CPU-address origin. Each such TLE stored has at least one CPU or core represented. The collection of one or more such CPU TLEs is called a CPU-TLE set.

When multiple CPU types exist, a separate CPU-TLE set is stored for each, in ascending order of CPU type.

When multiple polarization-and-entitlement values exist, a separate CPU-TLE set is stored for each, in descending order of polarization value and degree (vertical high, medium, low, then horizontal). When present, all polarization CPU-TLE sets of a given CPU type are stored before the first CPU-TLE set of the next CPU type.

When both dedicated and not-dedicated CPUs exist, a separate CPU-TLE set is stored for each, dedicated appearing before not-dedicated.

All TLEs are ordered assuming a depth-first traversal where the sort order from major to minor is as follows:

1. CPU type
   a. Lowest CPU-type value
   b. Highest CPU-type value

2. Polarization-Entitlement
   a. Vertical high
   b. Vertical medium
   c. Vertical low
   d. Horizontal

3. Dedication (when applicable)
   a. Dedicated
   b. Not dedicated

The ordering by CPU-address origin and modifier attributes of sibling CPU TLEs within a parent container is done according to the following list, which proceeds from highest to lowest.

1. CPU-TLE set of lowest CPU-type value, vertical high, dedicated

2. CPU-TLE set of lowest CPU-type value, vertical high, not-dedicated
3. CPU-TLE set of lowest CPU-type value, vertical medium, not-dedicated
4. CPU-TLE set of lowest CPU-type value, vertical low, not-dedicated
5. CPU-TLE set of lowest CPU-type value, horizontal, dedicated
6. CPU-TLE set of lowest CPU-type value, horizontal, not-dedicated
7. CPU-TLE set of highest CPU-type value, vertical high, dedicated
8. CPU-TLE set of highest CPU-type value, vertical high, not-dedicated
9. CPU-TLE set of highest CPU-type value, vertical medium, not-dedicated
10. CPU-TLE set of highest CPU-type value, vertical low, not-dedicated
11. CPU-TLE set of highest CPU-type value, horizontal, dedicated
12. CPU-TLE set of highest CPU-type value, horizontal, not-dedicated

**Other TLE Rules:**

1. A container-type TLE is located at nesting levels in the range 1-5.
2. A CPU-type TLE is located at nesting level 0.
3. The number of sibling container-type TLEs in a topology list or a given parent container does not exceed the value of the magnitude byte (Mag2-6) of the nesting level corresponding to the siblings.
4. The number of CPUs represented by the one or more CPU-type TLEs of the parent container does not exceed the value of the Mag1 magnitude byte.
5. The content of a TLE is defined as follows:
   - If a TLE is a container-type TLE, the content is a list that immediately follows the parent TLE, comprised of one or more child TLEs, and each child TLE has a nesting level of one less than the nesting level of the parent TLE or topology-list end.
   - If a TLE is a CPU-type TLE, the content is one or more CPUs, as identified by the other fields of a CPU TLE.
6. When the first TLE at a nesting level is a CPU entry, the maximum nesting level 0 has been reached.

**CPU Topology Overview**

With the advent of the IBM System z9 Enterprise Class and subsequent models, and even previously, machine organization into nodal structures has resulted in a non-uniform memory access (NUMA) behavior, sometimes also called “lumpiness”. The purpose of the SYSIB 15.1.2 and the PERFORM TOPOLOGY FUNCTION (PTF) instruction is to provide additional machine topology awareness to the program so that certain optimizations can be performed to improve cache-hit ratios and thereby improve overall performance.

The amount of host-CPU resource assigned to a multiprocessing (MP) guest configuration has generally been spread evenly across the number of configured guest CPUs. Such an even spread implies that no particular guest CPU or CPUs are entitled to any extra host-CPU provisioning than any other, arbitrarily-determined guest CPUs. This condition of the guest configuration, affecting all CPUs of the configuration, is called horizontal polarization.

Under horizontal polarization, assignment of a host CPU to a guest CPU is approximately the same amount of provisioning for each guest CPU. When the provisioning is not dedicated, the same host CPUs provisioning the guest CPUs also may be used to provision guest CPUs of another guest, or even other guest CPUs of the same guest configuration. When the other guest configuration is a different logical partition, a host CPU, when active in each partition, typically must access main storage more because the cache-hit ratio is reduced by having to share the caches across multiple relocation zones. If host-CPU provisioning can alter the balance such that some host CPUs are mostly, or even exclusively, assigned to a given guest configuration, and that becomes the normal behavior, then cache-hit ratios improve, as does performance. Such an uneven spread implies that one or more guest CPUs are entitled to extra host-CPU provisioning versus other, arbitrarily-determined guest CPUs that are entitled to less host-CPU provisioning. This condition of the guest configuration, affecting all CPUs of the configuration, is called vertical polarization.
The architecture categorizes vertical polarization into three levels of entitlement of provisioning, high, medium, and low:

- High entitlement guarantees approximately 100% of a host CPU being assigned to a logical/virtual CPU, and the affinity is maintained as a strong correspondence between the two. With respect to provisioning of a logical partition, when vertical polarization is in effect, the entitlement of a dedicated CPU is defined to be high.

- Medium entitlement guarantees an unspecified amount of host CPU resource (one or more host CPUs) being assigned to a logical/virtual CPU, and any remaining capacity of the host CPU is considered to be slack that may be assigned elsewhere. The best case for the available slack would be to assign it as local slack if that is possible. A less-beneficial result occurs if that available slack is assigned as remote slack. (See “CPU Slack” on page 10-155 for descriptions of the two slack terms.) It is also the case that the resource percentage assigned to a logical CPU of medium entitlement is a much softer approximation as compared to the 100% approximation of a high-entitlement setting.

- Low entitlement guarantees approximately 0% of a host CPU being assigned to a logical/virtual CPU. However, if slack is available, such a logical/virtual CPU may still receive some CPU resource.

A model of nested containers using polarization is intended to provide a level of intelligence about the machine's nodal structure as it applies to the requesting configuration, so that, generally, clusters of host CPUs can be assigned to clusters of guest CPUs, thereby improving as much as possible the sharing of storage and the minimizing of different configurations essentially colliding on the same host CPUs.

Polarization and entitlement indicate the relationship of physical CPUs to logical CPUs or logical CPUs to virtual CPUs in a guest configuration, and how the capacity assigned to the guest configuration is apportioned across the CPUs that comprise the configuration. Historically, a guest configuration has been horizontally polarized. For however many guest CPUs were defined to the configuration, the host-CPU resource assigned was spread evenly across all of the guest CPUs in an equitable, non-entitled manner. It can be said that the weight of a single logical CPU in a logical partition when horizontal polarization is in effect is approximately equal to the total configuration weight divided by the number of CPUs. However, with the introduction of the 2097 and family models, it becomes imperative to be able to spread the host-CPU resource in a different manner, which is called vertical polarization of a configuration, and then the degree of provisioning of guest CPUs with host CPUs being indicated as high, medium, or low entitlement. High entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is entirely backed by the same host CPU. Medium entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is partially backed by a host CPU. Low entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is not guaranteed any host-CPU resource, other than what might become available due to slack resource becoming available.

CPU Slack

Regarding slack CPU resource, there are two kinds:

- Local slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used within the configuration of that CPU. Local slack is preferred over remote slack as better hit ratios on caches are expected when the slack is used within the configuration.

- Remote slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used outside the configuration of that CPU. Remote slack is expected to exhibit lower hit ratios on caches, but it is still better than not running a logical/virtual CPU at all.

The goal is to maximize the CPU cache hit ratios.

For a logical partition, the amount of physical-CPU resource is determined by the overall system weightings that determine the CPU resource assigned to each logical partition. For example, in a logical 3-way MP that is assigned physical-CPU resource equivalent to a single CPU, and is horizontally polarized, each logical CPU would be dispatched independently and thus receive approximately 33% physical-CPU resource. If the same configuration were to be vertically polarized, only a single logical CPU would be run and would receive approximately 100% of the assigned physical-CPU resource (high entitlement).
while the remaining two logical CPUs would not normally be dispatched (low entitlement). Such resource assignment is normally an approximation. Even a low-entitlement CPU may receive some amount of resource if only to help ensure that a program does not get stuck on such a CPU.

By providing a means for a control program to indicate that it understands polarization, and to receive an indication for each CPU of its polarization and, if vertical polarization, the degree of entitlement, the control program can make more-intelligent use of data structures that are generally thought to be local to a CPU vs. available to all CPUs of a configuration. Also, such a control program can avoid dispatching work to any low-entitlement CPU.

The actual physical-CPU resource assigned might not constitute an integral number of CPUs, so there is also the possibility of one or more CPUs in an MP vertically-polarized configuration being entitled but not to a high degree, thereby resulting in such CPUs having either medium or low vertical entitlement.

It is possible for any remaining low-entitlement CPUs to receive some amount of host-CPU resource. For example, this may occur when such a CPU is targeted, such as via a SIGP order and slack host-CPU resource is available. Otherwise, such a logical/virtual CPU might remain in an undispatched state, even if it is otherwise capable of being dispatched.

A 2-bit polarization field is defined for the CPU-type topology-list entry (TLE) of the STORE SYSTEM INFORMATION (STSI) instruction. The degree of vertical-polarization entitlement for each CPU is indicated as high, medium, or low. The assignment is not a precise percentage but rather is somewhat fuzzy and heuristic.

In addition to vertical polarization as a means of reassigning weighting to guest CPUs, another concept exists, which is the creation and management of slack capacity (also called “white space”). Slack capacity is created under the following circumstances:

- A high-vertical CPU contributes to slack when its average utilization (AU) falls below 100 percent (100-AU).
- A medium-vertical CPU that has an assigned provisioning of M percent of a host CPU contributes to slack when its average utilization (AU) falls below M percent (M-AU > 0).
- A low-vertical CPU does not contribute to slack.
- A high-vertical CPU is not a consumer of slack.
- A medium-vertical CPU may or may not be a consumer of slack.
- A low-vertical CPU is only a consumer of slack.

Depending upon its utilization and pattern of being dispatched, a horizontally-polarized CPU can be either a contributor to slack or a consumer of it.

**Programming Note:** A possible examination process of a topology list is described. Before an examination of a topology list is begun, the current-TLE pointer is initialized to reference the first or top TLE in the topology list, the prior-TLE pointer is initialized to null, and then TLEs are examined in a top-to-bottom order.

As a topology-list examination proceeds, the current-TLE pointer is advanced by incrementing the current-TLE pointer by the size of the current TLE to which it points. A container-type TLE is advanced by adding eight to the current-TLE pointer. A CPU-type TLE is advanced by adding sixteen to the current-TLE pointer. The process of advancing the current-TLE pointer includes saving its value as the prior-TLE pointer just before it is incremented. TLE examination is not performed if the topology list has no TLEs.

The examination process is outlined in the following steps:

1. If the current-TLE nesting level is zero, and the prior-TLE nesting level is null or one, the current TLE represents the first CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when a new group of one or more CPUs is first observed. Go to step 5.

2. If the current-TLE nesting level is zero, and the prior-TLE nesting level is zero, the current TLE represents a subsequent CPU-type TLE of a group of CPU-type TLEs that represent siblings of the CPUs previously observed in steps 1 or 2. The program should perform whatever action is appropriate for when the size of an existing sibling group of one or more CPUs is increased. Go to step 5.
3. If the current-TLE nesting level is not zero, and the prior-TLE nesting level is zero, the prior TLE represents a last or only CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed. Go to step 5.

4. Go to step 5.

By elimination, this would be the case where the current-TLE nesting level is not zero, and the prior-TLE nesting level is not zero. If the current-TLE nesting level is less than the prior-TLE nesting level, the direction of topology-list traversal is toward a CPU-type TLE. If the current-TLE nesting level is greater than the prior-TLE nesting level, the direction of topology-list traversal is away from a CPU-type TLE. Container-type TLEs are being traversed leading to either (1) another group of CPU-type TLEs that are a separate group in the overall topology, or (2) the end of the topology list. In either case, no particular processing is required beyond advancing to the next TLE.

5. Advance to the next TLE position based upon the type of the current TLE. If the advanced current-TLE pointer is equivalent to the end of the topology list:
   a. No more TLEs of any type exist.
   b. If the prior-TLE nesting level is zero, the program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed.
   c. The examination is complete.

Otherwise go to step 1.

Special Conditions

The condition code is set to 3 if the function code in bit positions 32-35 of general register 0 is greater than the current-level number.

Bits 36-55 of general register 0 and 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized.

When the function code is valid and nonzero, the following special conditions apply in an unpredictable order:

- The second operand must be designated on a 4K-byte boundary; otherwise, a specification exception is recognized.
- If the function-code, selector-1, and selector-2 combination is invalid, or if it is valid but the requested information is not available, the condition code is set to 3.

Resulting Condition Code:

<table>
<thead>
<tr>
<th>0</th>
<th>Requested configuration-level number placed in general register 0 or requested SYSIB information stored</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>--</td>
</tr>
<tr>
<td>2</td>
<td>--</td>
</tr>
<tr>
<td>3</td>
<td>Requested SYSIB information not available</td>
</tr>
</tbody>
</table>

Program Exceptions:

- Access (store, operand 2, only if function code nonzero)
- Privileged operation
- Specification
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-85.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

8. Condition code 3 due to function code greater than current-level number.

9. Specification exception due to bits 36-55 of general register 0 or bits 32-47 of general register 1 not zero.

10. Condition code 0 due to function code 0.

11.A Specification exception due to second-operand address not designating a 4K-byte boundary.

Figure 10-85. Priority of Execution: STORE SYSTEM INFORMATION (Part 1 of 2)
11.B Condition code 3 due to invalid function-code, selector-1, and selector-2 combination or requested information not available.

12. Access exceptions (store) for system-information block.

13. Condition code 0 due to information stored in system-information block.

Figure 10-85. Priority of Execution: STORE SYSTEM INFORMATION (Part 2 of 2)

**Programming Note:** The storage-operand references for STORE SYSTEM INFORMATION may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

### STORE THEN AND SYSTEM MASK

<table>
<thead>
<tr>
<th>STNSM</th>
<th>D&lt;sub&gt;i&lt;/sub&gt;(B&lt;sub&gt;j&lt;/sub&gt;)&lt;sub&gt;_1&lt;/sub&gt;</th>
<th>[SI]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'AC'</td>
<td>I&lt;sub&gt;2&lt;/sub&gt; B&lt;sub&gt;1&lt;/sub&gt; D&lt;sub&gt;1&lt;/sub&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical AND of their original contents and the second operand.

**Special Conditions**

The operation is suppressed on addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 1)
- Privileged operation
- Transaction constraint

### STORE THEN OR SYSTEM MASK

<table>
<thead>
<tr>
<th>STOSM</th>
<th>D&lt;sub&gt;i&lt;/sub&gt;(B&lt;sub&gt;j&lt;/sub&gt;)&lt;sub&gt;_2&lt;/sub&gt;</th>
<th>[SI]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'AD'</td>
<td>I&lt;sub&gt;2&lt;/sub&gt; B&lt;sub&gt;1&lt;/sub&gt; D&lt;sub&gt;1&lt;/sub&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical OR of their original contents and the second operand.

**Special Conditions**

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if the contents of bit positions 0 and 2-4 of the PSW are not all zeros. In this case, the instruction is completed, and the instruction-length code is set to 2 or 3. The specification exception, which is listed as a program exception for this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 1)
- Privileged operation
- Specification
- Transaction constraint

**Programming Note:** STORE THEN OR SYSTEM MASK permits the program to set selected bits in the system mask to ones while retaining the original contents for later restoration. For example, it may be necessary that a program, which has no record of the present status, disable program-event recording for a few instructions.

---

11.B Condition code 3 due to invalid function-code, selector-1, and selector-2 combination or requested information not available.

12. Access exceptions (store) for system-information block.

13. Condition code 0 due to information stored in system-information block.

**Programming Note:** The storage-operand references for STORE SYSTEM INFORMATION may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

### STORE THEN AND SYSTEM MASK

<table>
<thead>
<tr>
<th>STNSM</th>
<th>D&lt;sub&gt;i&lt;/sub&gt;(B&lt;sub&gt;j&lt;/sub&gt;)&lt;sub&gt;_1&lt;/sub&gt;</th>
<th>[SI]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'AC'</td>
<td>I&lt;sub&gt;2&lt;/sub&gt; B&lt;sub&gt;1&lt;/sub&gt; D&lt;sub&gt;1&lt;/sub&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical AND of their original contents and the second operand.

**Special Conditions**

The operation is suppressed on addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 1)
- Privileged operation
- Transaction constraint

**Programming Note:** STORE THEN AND SYSTEM MASK permits the program to set selected bits in the system mask to zeros while retaining the original contents for later restoration. For example, it may be necessary that a program, which has no record of the present status, disable program-event recording for a few instructions.
STORE USING REAL ADDRESS

STURA \( R_1, R_2 \) [RRE]

\[ 'B246' \]

STURG \( R_1, R_2 \) [RRE]

\[ 'B925' \]

For STORE USING REAL ADDRESS (STURA), bits 32-63 of general register \( R_1 \) are stored in the word at the real-storage location addressed by the contents of general register \( R_2 \). For STORE USING REAL ADDRESS (STURG), bits 0-63 of general register \( R_1 \) are stored in the doubleword at that real-storage location.

In the 24-bit addressing mode, bits 40-63 of general register \( R_2 \) designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register \( R_2 \) designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register \( R_2 \) designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

Special Conditions

The contents of general register \( R_2 \) must designate a location on a word boundary for STURA or on a doubleword boundary for STURG; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register \( R_2 \))
- Privileged operation
- Protection (store, operand 2, key-controlled protection and low-address protection)
- Specification
- Transaction constraint

TEST ACCESS

TAR \( R_1, R_2 \) [RRE]

\[ 'B24C' \]

The access-list-entry token (ALET) in access register \( R_1 \) is tested for exceptions recognized during access-register translation (ART). The extended authorization index (EAX) used is bits 32-47 of general register \( R_2 \). The ALET is also tested for whether it designates the dispatchable-unit access list or the primary-space access list and for whether it is 00000000 or 00000001 hex.

When \( R_1 \) is 0, the actual contents of access register 0 are used in ART, instead of the 00000000 hex that is usually used.

Bits 0-31 and 48-63 of general register \( R_2 \) are ignored.

The operation does not depend on the translation mode — bits 5, 16, and 17 of the PSW are ignored.

When the ALET specified by means of the \( R_1 \) field is other than 00000000 or 00000001 hex, the ART process is applied to the ALET. The EAX specified by means of the \( R_2 \) field is called the effective EAX, and it is the EAX which is used by ART. When a condition exists that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

<table>
<thead>
<tr>
<th>Exception Name</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALET specification</td>
<td>ALET bits 0-6 not all zeros</td>
</tr>
<tr>
<td>ALEN translation</td>
<td>Access-list entry (ALE) outside list or invalid (bit 0 is one)</td>
</tr>
<tr>
<td>ALE sequence</td>
<td>ALE sequence number (ALESN) in ALET not equal to ALESN in ALE</td>
</tr>
<tr>
<td>ASTE validity</td>
<td>ASN-second-table entry (ASTE) invalid (bit 0 is one)</td>
</tr>
<tr>
<td>ASTE sequence</td>
<td>ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE</td>
</tr>
<tr>
<td>Extended authority</td>
<td>ALE private bit not zero, ALE authorization index (ALEAX) not equal to effective EAX, and secondary bit selected by effective EAX either outside authority table or zero</td>
</tr>
</tbody>
</table>
When ART is completed without one of the above conditions being present, the instruction is completed by setting condition code 1 or 2, depending on whether the effective access list is the dispatchable-unit access list or the primary-space access list, respectively. The effective access list is the dispatchable-unit access list if bit 7 of the ALET is zero, or it is the primary-space access list if bit 7 is one. ART, including the obtaining of the effective access-list designation, is described in “Access-Register-Translation Process” on page 5-60.

When the ALET is 00000000 hex, the instruction is completed by setting condition code 0. When the ALET is 00000001 hex, the instruction is completed by setting condition code 3.

Special Conditions

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

- 0  Access-list-entry token (ALET) is 00000000 hex
- 1  ALET designates the dispatchable-unit access list and does not cause exceptions in access-register translation (ART)
- 2  ALET designates the primary-space access list and does not cause exceptions in ART
- 3  ALET is 00000001 hex or causes exceptions in ART

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, or authority-table entry)
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-86.

<table>

</tr>
<tr>
<td>19.</td>
<td>Condition code 1 if ALET bit 7 is zero; otherwise, condition code 2.</td>
</tr>
</tbody>
</table>

Figure 10-86. Priority of Execution: TEST ACCESS

Programming Notes:

1. TEST ACCESS permits a called program to check whether an ALET passed from the calling program is authorized for use by means of the
calling program's EAX. The calling program's EAX can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE. The called program can thus avoid performing an operation for the calling program, through the use of the called program's EAX, which the calling program is not authorized to perform by means of its own EAX.

2. When an ALET equal to 00000000 hex is passed during a program linkage performed by PROGRAM CALL with space switching (PC-ss), and the ALET conceptually designates the calling program's primary address space and the called program's secondary address space, the ALET must be changed to 00000001 hex before it is used by the called program. Condition code 0 of TEST ACCESS indicates a 00000000 hex ALET so that the ALET can be changed to 00000001 hex by the called program.

3. PROGRAM CALL to current primary (PC-cp) sets the secondary address space equal to the primary address space. PC-ss sets the secondary address space equal to the calling program's primary address space, except that stacking PC-ss sets it equal to the called program's primary address space when the secondary-ASN control in the entry-table entry used is one. In all these cases, a passed 00000001 hex ALET that conceptually designates the calling program's secondary address space is not usable by the called program, even after any transformation (unless the operation was PC-cp and the calling program's PASN and SASN are equal). This is why TEST ACCESS sets condition code 3 when the tested ALET is 00000001 hex.

4. After a PC-ss, a passed ALET that conceptually designates an entry in the primary-space access list of the calling program is not usable by the called program. This is why TEST ACCESS sets condition code 2, instead of condition code 1, when the tested ALET designates the primary-space access list.

5. The control program may manage the ASN-secondary-table entry in a way that causes a correctable ASTE-validity or ASTE-sequence exception situation to exist; that is, a situation which, if it were to cause a program interruption during access-register translation, would be corrected by the control program so that access-register translation could be completed successfully. In this case, the program should not use TEST ACCESS directly but should instead use a control-program service that uses TEST ACCESS and that corrects the situation, if possible, when condition code 3 is set. MVS/ESA provides the TESTSTART macro instruction for use instead of the direct use of TEST ACCESS.

### TEST BLOCK

<table>
<thead>
<tr>
<th>TB</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B22C'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The storage locations and storage key of a 4K-byte block are tested for usability, and the result of the test is indicated in the condition code. The test for usability is based on the susceptibility of the block to the occurrence of invalid checking-block code.

The block tested is addressed by the contents of general register R2. The contents of general register R1 are ignored.

A complete testing operation is necessarily performed only when the initial contents of bit positions 32-63 of general register 0 are zero in the 24-bit or 31-bit addressing mode, or the initial contents of bit positions 0-63 of that register are zero in the 64-bit addressing mode. In the 24-bit or 31-bit addressing mode, the contents of bit positions 32-63 of general register 0 are set to zero at the completion of the operation, and bits 0-31 of the register always are ignored and remain unchanged. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register are set to zero at the completion of the operation.

If the block is found to be usable, the 4K bytes of the block are cleared to zeros, the contents of the storage key are unpredictable, and condition code 0 is set. If the block is found to be unusable, the data and the storage key are set, as far as is possible by the model, to a value such that subsequent fetches to the area do not cause a machine-check condition, and condition code 1 is set.

In the 24-bit addressing mode, bits 40-51 of general register R2 designate a 4K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of the register designate the block, and bits 0-32 and 52-63 are ignored. In the 64-bit addressing mode, bits 0-51 of
the register designate the block, and bits 52-63 are ignored.

The address of the block is a real address, and the accesses to the block designated by the second-operand address are not subject to key-controlled, access-list-controlled, or DAT protection. Low-address protection does apply. The operation is terminated on addressing and protection exceptions. If termination occurs, the condition code and the contents of bit positions 32-63 of general register 0 are unpredictable in the 24-bit or 31-bit addressing mode, or the condition code and bits 0-63 of the register are unpredictable in the 64-bit addressing mode. The contents of the storage block and its associated storage key are not changed when these exceptions occur.

Depending on the model, the test for usability may be performed (1) by alternately storing and reading out test patterns to the data and storage key in the block or (2) by reference to an internal record of the usability of the blocks which are available in the configuration, or (3) by using a combination of both mechanisms.

In models in which an internal record is used, the block is indicated as unusable if a solid failure has been previously detected, or if intermittent failures in the block have exceeded the threshold implemented by the model. In such models, depending on the criteria, attempts to store may or may not occur. Thus, if block 0 is not usable, and no store occurs, low-address protection may or may not be indicated.

In models in which test patterns are used, TEST BLOCK may be interruptible. When an interruption occurs after a unit of operation, other than the last one, the condition code is unpredictable, and the contents of bit positions 32-63 of general register 0 may contain a record of the state of intermediate steps in the 24-bit or 31-bit addressing mode, or the contents of bit positions 0-63 may contain that record in the 64-bit addressing mode. When execution is resumed after an interruption, the condition code is ignored, but the record in general register 0 may be used to determine the resumption point.

If (1) TEST BLOCK is executed with an initial value other than zero in bit positions 32-63 of general register 0 in the 24-bit or 31-bit addressing mode or bit positions 0-63 in the 64-bit addressing mode, or (2) the interrupted instruction is resumed after an interruption with a value in bit positions 32-63 or 0-63 (depending on the addressing mode) of general register 0 or a value in the storage block or its associated storage key other than the corresponding value which was present at the time of the interruption, or (3) the block or its associated storage key is accessed by another CPU or by the channel subsystem during the execution of the instruction, then the contents of the storage block, its associated storage key, and bit positions 32-63 or 0-63 of general register 0 are unpredictable, along with the resultant condition-code setting.

Invalid checking-block-code errors initially found in the block or encountered during the test do not normally result in machine-check conditions. The test-block function is implemented in such a way that the frequency of machine-check interruptions due to the instruction execution is not significant. However, if, during the execution of TEST BLOCK for an unusable block, that block is accessed by another CPU (or by the channel subsystem), error conditions may be reported both to this CPU and to the other CPU (or to the channel subsystem).

A serialization function is performed before the block is accessed and again after the operation is completed (or partially completed).

**Resulting Condition Code:**

0 Block usable
1 Block not usable
2 --
3 --

**Program Exceptions:**

- Addressing (fetch and store, operand 2)
- Privileged operation
- Protection (store, operand 2, low-address protection only)
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-87.

| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case. |

*Figure 10-87. Priority of Execution: TEST BLOCK (Part 1 of 2)*
Programming Notes:

1. The execution of TEST BLOCK on most models is significantly slower than that of the MOVE LONG instruction with padding; therefore, the instruction should not be used for the normal case of clearing storage.

2. The program should use TEST BLOCK at initial program loading and as part of the vary-storage-online procedure to determine if blocks of storage exist which should not be used.

3. The program should use TEST BLOCK when an uncorrected error is reported in either the data or storage key of a block. This is because in the execution of TEST BLOCK the attempt is made, as far as is possible on the model, to leave the contents of a block in a state such that subsequent prefetches or unintended references to the block do not cause machine-check conditions. The program may use the resulting condition code in this case to determine if the block can be reused. (The block could be indicated as usable if, for example, the error were an externally generated error or an indirect storage error.) This procedure should be followed regardless of whether the indirect-storage-error indication is reported.

4. The model may or may not be successful in removing the errors from a block when TEST BLOCK is executed. The program therefore should take every reasonable precaution to avoid referencing an unusable block. For example, the program should not place the page-frame real address of an unusable block in an attached and valid page-table entry.

5. On some models, machine checks may be reported for a block even though the block is not referenced by the program. When a machine check is reported for a storage-key error in a block which has been marked as unusable by the program, it is possible that SET STORAGE KEY EXTENDED may be more effective than TEST BLOCK in validating the storage key.

6. The storage-operand references for TEST BLOCK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

The location designated by the first-operand address is tested for protection exceptions by using the access key specified by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the access key to be used in testing. Bits 0-55 and 60-63 of the second-operand address are ignored.

The first-operand address is a logical address. When the CPU is in the access-register mode (when DAT is on and PSW bits 16 and 17 are 01 binary), the first-operand address is subject to translation by means of both the access-register-translation (ART) and the dynamic-address-translation (DAT) processes. ART applies to the access register designated by the B1 field, and it obtains the address-space-control element to be used by DAT. When DAT is on but the CPU is not in the access-register mode, the first-operand address is subject to translation by DAT. In this case, DAT uses the address-space-control element contained in control register 1, 7, or 13 when the CPU is in the primary-space, secondary-space, or home-space mode, respectively. When DAT is off, the first-operand address is a real address not subject to translation by either ART or DAT.

When the CPU is in the access-register mode and an address-space-control element cannot be obtained
by ART because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

<table>
<thead>
<tr>
<th>Exception Name</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALET specification</td>
<td>Access-list-entry-token (ALET) bits 0-6 not all zeros</td>
</tr>
<tr>
<td>ALEN translation</td>
<td>Access-list entry (ALE) outside list or invalid (bit 0 is one)</td>
</tr>
<tr>
<td>ALE sequence</td>
<td>ALE sequence number (ALESN) in ALET not equal to ALESN in ALE</td>
</tr>
<tr>
<td>ASTE validity</td>
<td>ASN-second-table entry (ASTE) invalid (bit 0 is one)</td>
</tr>
<tr>
<td>ASTE sequence</td>
<td>ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE</td>
</tr>
<tr>
<td>Extended authority</td>
<td>ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero</td>
</tr>
</tbody>
</table>

When the access register contains 00000000 hex or 00000001 hex, ART obtains the address-space-control element from control register 1 or 7, respectively, without accessing the access list. When the B_1 field designates access register 0, ART treats the access register as containing 00000000 hex and does not examine the actual contents of the access register.

When ART is completed successfully, the operation is continued through the performance of DAT.

When DAT is on and the first-operand address cannot be translated because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

<table>
<thead>
<tr>
<th>Exception Name</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCE type</td>
<td>Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of first-operand address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of first-operand address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of first-operand address not all zeros.</td>
</tr>
<tr>
<td>Region first translation</td>
<td>Region-first-table entry outside table or invalid.</td>
</tr>
<tr>
<td>Region second translation</td>
<td>Region-second-table entry outside table or invalid.</td>
</tr>
<tr>
<td>Region third translation</td>
<td>Region-third-table entry outside table or invalid.</td>
</tr>
<tr>
<td>Segment translation</td>
<td>Segment-table entry outside table or invalid</td>
</tr>
<tr>
<td>Page translation</td>
<td>Page-table entry invalid</td>
</tr>
</tbody>
</table>

When translation of the first-operand address can be completed, or when DAT is off, the storage key for the block designated by the first-operand address is tested against the access key specified in bit positions 56-59 of the second-operand address, and the condition code is set to indicate whether store and fetch accesses are permitted, taking into consideration all applicable protection mechanisms. Thus, for example, if low-address protection is active and the first-operand effective address is in the range 0-511 or 4096-4607, then a store access is not permitted. Access-list-controlled protection, DAT protection, storage-protection override, and fetch-protection override also are taken into account.

When EDAT-1 does not apply, when EDAT-1 applies but the STE-format control is zero, or when EDAT-2 applies but the RTTE-format control is zero, bits 0-4 of the storage key for the 4K-byte block corresponding to the virtual address in the first operand are examined to determine the condition code. When EDAT-1 applies and both the STE-format and AV controls in the STE are one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the segment-table entry used in the translation of the first operand are examined to determine the condition code. When EDAT-2 applies and both the RTTE-
format and AV controls in the RTTE are one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the region-third-table entry used in the translation of the first operand are examined to determine the condition code.

The contents of storage, including the change bit, are not affected. Depending on the model, the reference bit for the first-operand address may be set to one, even for the case in which the location is protected against fetching.

Special Conditions

When the CPU is in the access-register mode, an addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

When DAT is on, an addressing exception is recognized when the address of the region-table entry or entries, segment-table entry, or page-table entry or the operand real address after translation designates a location which is not available in the configuration. Also, a translation-specification exception is recognized when a region-table entry or the segment-table entry or page-table entry has a format error, that is, when any of the reasons listed in “Translation-Specification Exception” on page 6-44 applies. When DAT is off, only the addressing exception due to the operand real address applies.

For all of the above cases, the operation is suppressed.

Resulting Condition Code:

0  Fetching permitted; storing permitted
1  Fetching permitted; storing not permitted
2  Fetching not permitted; storing not permitted
3  Translation not available

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, page-table entry, or operand 1)
- Privileged operation
- Translation specification
- Transaction constraint

Programming Notes:

1. TEST PROTECTION permits a program to determine the protection attributes of an address passed from a calling program without incurring program exceptions. The instruction sets a condition code to indicate whether fetching or storing is permitted at the location designated by the first-operand address of the instruction. The instruction takes into consideration all of the protection mechanisms in the machine: access-list controlled, DAT, key-controlled, and low-address protection, storage-protection override, and fetch-protection override. Additionally, since ASCE-type, region-translation, segment-translation, and page-translation-exception conditions may be a program substitute for a protection violation, these conditions are used to set the condition code rather than cause a program exception.

When the CPU is in the access-register mode, TEST PROTECTION additionally permits the program to check the usability of an access-list-entry token (ALET) in an access register without incurring program exceptions. The ALET is checked for validity (absence of an ALET-specification, ALEN-translation, and ALE-sequence-exception condition) and for being authorized for use by the program (absence of an ASTE-validity, ASTE-sequence, and extended-authority-exception condition).

2. See the programming notes under SET PSW KEY FROM ADDRESS for more details and for an alternative approach to testing the key-controlled protection attributes of addresses passed by a calling program. The approach using TEST PROTECTION has the advantage of a test which does not result in interruptions; however, the test and use are separated in time and may not be accurate if the possibility exists that the storage key of the location in question can change between the time it is tested and the time it is used.

3. In the handling of dynamic address translation, TEST PROTECTION is similar to LOAD REAL ADDRESS in that the instructions do not cause ASCE-type, region-translation, segment-translation, and page-translation exceptions. Instead, these exception conditions are indicated by means of a condition-code setting. Similarly, access-register translation sets a condition code for certain exception conditions when performed during either of the two instructions. Conditions
which result in condition codes 1, 2, and 3 for LOAD REAL ADDRESS result in condition code 3 for TEST PROTECTION. The instructions also differ in several other respects. The first-operand address of TEST PROTECTION is a logical address and thus is not subject to dynamic address translation when DAT is off. The second-operand address of LOAD REAL ADDRESS is a virtual address which is always translated.

Access-register translation applies to TEST PROTECTION only when the CPU is in the access-register mode (DAT is on), whereas it applies to LOAD REAL ADDRESS when PSW bits 16 and 17 are 01 binary regardless of whether DAT is on or off. When condition code 3 is set because of an exception condition in access-register translation, LOAD REAL ADDRESS, but not TEST PROTECTION, returns in a general register the program-interruption code assigned to the exception.

4. Condition code 3 does not necessarily indicate that the first-operand location will always be inaccessible to the program; rather it merely indicates that the current conditions prevent the instruction from determining the protection attributes of the operand. For example, in a virtual storage environment, condition code 3 may be set if the storage location has been paged out by the operating system. If the program attempts to access the location, the operating system may resolve the page-translation exception and subsequently make the location accessible to the program.

Similarly, condition code 1 does not necessarily indicate that the address cannot ever be stored into. In an operating system that implements a Posix fork function, DAT protection is used to alert the operating system of a copy-on-write event (as described in Programming Note 1 on page 3-15). Following the operating-system resolution of the copy-on-write event, the program may be given store access to the location.

The displacement for TRACE is treated as a 12-bit unsigned binary integer. The displacement for TRACG is treated as a 20-bit signed binary integer.

The trace entry is composed of an entry-type identifier, a count of the number of general registers whose partial or entire contents are placed in the entry, a field whose contents indicate whether the entry was formed by TRACE (TRACE) or TRACE (TRACG), selected bits of the TOD clock, the second operand, and the partial or entire contents of a range of general registers. For TRACE (TRACE), bits 16-63 of the TOD clock and bits 32-63 of the general registers are placed in the trace entry. For TRACE (TRACG), bits 0-79 of the clock and bits 0-63 of the registers are placed in the entry.

The general registers are stored in ascending order of their register numbers, starting with general register R1 and continuing up to and including general register R3, with general register 0 following general register 15. The trace table and the trace-entry formats are described in “Tracing” on page 4-10.

When a trace entry is made, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store. Additionally, when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 12 is one, it is unpredictable whether explicit tracing causes serialization to be performed.

Special Conditions
A privileged-operation exception is recognized in the problem state, even when explicit tracing is off or bit 0 of the second operand is one.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized. It is unpredictable whether the specification exception is recognized when explicit tracing is off.

It is unpredictable whether access exceptions or PER zero-address-detection events are recognized for the second operand when explicit tracing is off.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Trace
- Transaction constraint

**Programming Notes:**

1. Bits 1-15 of the second operand are reserved for model-dependent functions and should therefore be set to zeros.

2. When the store-clock-fast facility is not installed, or when the TOD-clock-control in bit 32 of control register 0 is zero, the entire 32-bit TRACE operand is stored in bits 64-95 of the trace entry for TRACE (TRACE) and in bits 96-127 of the trace entry for TRACE (TRACG).

3. When the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, the following conditions apply:
   - Two executions of the instruction do not necessarily store different values in the TOD-clock bits of the trace entry.
   - The contents of bit positions 0-7 and 16-31 of the TRACE operand are stored in bits 64-71 and 80-95, respectively, of the trace entry for TRACE (TRACE) and in bits 96-103 and 112-127, respectively, of the trace entry for TRACE (TRACG).
   - Bits 72-79 of the trace entry for TRACE (TRACE) and bits 104-111 of the trace entry for TRACE (TRACG) are set to a model-dependent value.

**TRAP**

<table>
<thead>
<tr>
<th>TRAP2</th>
<th>[E]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'01FF'</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TRAP4</th>
<th>D2(B2)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B2FF'</td>
<td>B2</td>
<td>D2</td>
</tr>
</tbody>
</table>

A trap operation is performed if the CPU is in the primary-space or access-register mode and the TRAP-enabled bit in byte 47 of the dispatchable-unit control table (DUCT) is one. Otherwise, a special-operation exception is recognized.

The trap operation obtains a trap-control-block address from the DUCT and then a trap-save-area address and a trap-program address from the trap control block. State information is stored in the trap save area. Then the trap-control-block address is loaded into general register 15. Finally, the current PSW is updated by setting the basic-addressing-mode bit to one (which will leave the addressing mode as either the 31-bit mode or the 64-bit mode or will change the addressing mode from the 24-bit mode to the 31-bit mode) and the address-space-control bits to zeros (primary-space mode) and by replacing the instruction address with the trap-program address. Compatibility with the ESA/390 operation of TRAP optionally is provided.

For TRAP4, the second-operand address is not used to address data; instead, bits 33-63 of the address are stored in the trap save area.

**Dispatchable-Unit Control Table**

Bytes 44-47 (word 10) of the dispatchable-unit-control table (DUCT) are used by this instruction. The contents of those bytes are as follows:

<table>
<thead>
<tr>
<th>DUCT Bytes 44-47</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trap-Control-Block Address</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
The fields in bytes 44-47 of the DUCT are allocated as follows:

**Trap-Control-Block Address:** Bits 1-28, with three zeros appended on the right, form the 31-bit home virtual address of the trap control block. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. This address, with a zero appended on the left, is placed in bit positions 32-63 of general register 15 after the contents of that register have been saved in the trap save area. If the current addressing mode is the 64-bit mode, bits 0-31 of general register 15 are set to zeros.

**TRAP-Enabled Bit (E):** Bit 31 specifies, when one, that the trap operation is to be performed. TRAP recognizes a special-operation exception if bit 31 is zero.

Bits 0, 29, and 30 of bytes 44-47 are ignored, but they should be zeros to permit possible future extensions.

**Trap Control Block**

The trap control block is 64 bytes aligned on a doubleword boundary. The format of the trap control block is:

```
<table>
<thead>
<tr>
<th>Hex</th>
<th>Dec</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td></td>
</tr>
<tr>
<td>04</td>
<td>4</td>
</tr>
<tr>
<td>08</td>
<td>8</td>
</tr>
<tr>
<td>0C</td>
<td>12</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
</tr>
<tr>
<td>14</td>
<td>20</td>
</tr>
<tr>
<td>18</td>
<td>24</td>
</tr>
<tr>
<td>1C</td>
<td>28</td>
</tr>
<tr>
<td>20</td>
<td>32</td>
</tr>
<tr>
<td>3C</td>
<td>60</td>
</tr>
</tbody>
</table>
```

The fields in the trap control block are allocated as follows:

**PSW Control (P):** Bit 13 of bytes 0-3 controls the allowed value of bit 31 of the current PSW and how bits 12 and 33-127 of the current PSW are stored in the PSW-values field in the trap save area. When bit 13 is zero.

- Bit 31 of the current PSW, the extended-addressing-mode bit, must be zero; otherwise, a special-operation exception is recognized.
- A one is stored in bit position 12 of the PSW-values field even though bit 12 of the current PSW is zero.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of the PSW-values field, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of the PSW-values field.

When bit 13 is one:

- Bit 31 of the current PSW may be zero or one.
- Bit 12 of the current PSW is stored in bit position 12 of the PSW-values field.
- Bits 64-127 of the current PSW are stored in bit positions 64-127 of the PSW-values field.

**General-Registers Control (R):** Bit 14 of bytes 0-3 controls how the contents of the general registers are stored in the general-registers 0-15 field in the trap save area. When R is zero, bits 32-63 of the general registers are stored in consecutive four-byte locations beginning at the beginning of the general-registers 0-15 field, bits 0-31 of the registers are not stored, and the last 64 bytes of the general-registers 0-15 field remain unchanged. When R is one, bits 0-63 of the general registers are stored in consecutive eight-byte locations in the general-registers 0-15 field.

**Trap-Save-Area Address:** Bits 1-28 of bytes 12-15, with three zeros appended on the right, form the 31-bit home virtual address of the trap save area. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. Bits 0 and 29-31 of bytes 12-15 are ignored.

**Trap-Program Address:** Bits 1-31 of bytes 20-23 form the 31-bit primary virtual address of the trap program. This address is treated as a 31-bit primary virtual address regardless of the current addressing mode.

Bit positions 0-12 and 15-31 of bytes 0-3 and bytes 4-11, 16-19, and 32-63 of the trap control block are
reserved and should contain zeros. Bytes 24-31 are available for use by programming.

**Trap Save Area**

The trap save area is 256 bytes aligned on a double-word boundary.

The trap operation stores information into the trap save area as follows:

<table>
<thead>
<tr>
<th>Hex</th>
<th>Dec</th>
<th>Trap Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Reserved (Zeros Stored)</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>8</td>
<td>Bits 33-63 of Second-Op Address of TRAP4</td>
</tr>
<tr>
<td>C</td>
<td>12</td>
<td>Access Register 15</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>32</td>
<td>PSW Values</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>General Registers 0-15</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0 160</td>
</tr>
<tr>
<td>A4 164</td>
</tr>
<tr>
<td>A8 168</td>
</tr>
<tr>
<td>: : :</td>
</tr>
<tr>
<td>FC 252</td>
</tr>
</tbody>
</table>

The fields in the trap save area are allocated as follows:

**Trap Flags:** Information identifying the instruction(s) causing the trap operation is stored in byte positions 0-3. The detailed format of bytes 0-3 is as follows:

<table>
<thead>
<tr>
<th>Flag Bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>TRAP was target of an execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG)</td>
</tr>
<tr>
<td>1</td>
<td>TRAP is TRAP4 (not TRAP2)</td>
</tr>
<tr>
<td>2-12</td>
<td>Reserved, zeros stored</td>
</tr>
<tr>
<td>13-14</td>
<td>Instruction-length code (ILC)</td>
</tr>
<tr>
<td>15-31</td>
<td>Reserved, zeros stored</td>
</tr>
</tbody>
</table>

Bit 0 of bytes 0-3 is set to one if TRAP was the target of an execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG).

Bit 1 of bytes 0-3 is set to one if TRAP is TRAP4 (not TRAP2).

Bits 13 and 14 are the instruction-length code (ILC) that specifies the length of the TRAP instruction, or the length of the execute-type instruction if TRAP was the target of an execute-type instruction.

Bits 2-12 and 15-31 are reserved and are stored as zeros.

**Bits 33-63 of Second-Operand Address of TRAP4:** For TRAP4, bits 33-63 of the second-operand address, generated under the control of the current addressing mode and with a zero appended on the left, are stored in byte positions 8-11. Only bits 33-63 of the second-operand address are stored even when the current addressing mode is the 64-bit mode. For TRAP2, all zeros are stored in byte positions 8-11.

**Access Register 15:** The contents of access register 15 are stored in byte positions 12-15.

**PSW Values:** The following description applies when the PSW control, bit 13 of bytes 0-3 of the trap control block, is one.

Certain information from the current PSW is stored in byte positions 16-31. The PSW has the following format:

<table>
<thead>
<tr>
<th>Instruction Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Instruction Address (Continued)</th>
</tr>
</thead>
<tbody>
<tr>
<td>32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60 61 62 63</td>
</tr>
</tbody>
</table>

Bits 0-127 of bytes 16-31 correspond one-to-one with bits 0-127 of the PSW. For some bit positions of bytes 16-31, the corresponding PSW bits are stored. For the other bit positions of bytes 16-31, unpredictable.
able values are stored. Information is stored in bytes 16-31 as follows:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Zero</td>
</tr>
<tr>
<td>1</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>2-4</td>
<td>Zero</td>
</tr>
<tr>
<td>5-11</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>12</td>
<td>Zero</td>
</tr>
<tr>
<td>13</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>14</td>
<td>Wait state (W)</td>
</tr>
<tr>
<td>15</td>
<td>Problem state (P)</td>
</tr>
<tr>
<td>16-17</td>
<td>Address-space control (AS)</td>
</tr>
<tr>
<td>18-19</td>
<td>Condition code (CC)</td>
</tr>
<tr>
<td>20-23</td>
<td>Program mask</td>
</tr>
<tr>
<td>25-30</td>
<td>Zero</td>
</tr>
<tr>
<td>31</td>
<td>Extended addressing mode (EA)</td>
</tr>
<tr>
<td>32</td>
<td>Basic addressing mode (BA)</td>
</tr>
<tr>
<td>33-63</td>
<td>Zero</td>
</tr>
<tr>
<td>64-127</td>
<td>Instruction address</td>
</tr>
</tbody>
</table>

In summary, bits 0, 2-4, 12, 24-30, and 33-63 are zero, bits 1, 5-11, and 13 are unpredictable, and the other bits are set with variable information from the PSW.

The wait-state, problem-state, address-space-control, condition-code, program-mask, extended-addressing-mode, and basic-addressing-mode values specify the state of the CPU before the TRAP instruction was executed. The instruction-address value is the updated instruction address, which is the address of the instruction following TRAP, or the address of the instruction following the execute-type instruction if TRAP was the target of an execute-type instruction.

When the PSW control in the trap control block is zero, the operation is as described above except as follows:

- Bit 31 of the current PSW must be zero; otherwise, a special-operation exception is recognized.
- A one is stored in bit position 12 of bytes 16-31.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of bytes 16-31, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of bytes 16-31 (bytes 24-31).

In this case, bytes 16-23 have the format of an ESA/390 PSW, which is as follows:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Zero</td>
</tr>
<tr>
<td>1</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>2-4</td>
<td>Zero</td>
</tr>
<tr>
<td>5-11</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>12</td>
<td>Zero</td>
</tr>
<tr>
<td>13</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>14</td>
<td>Wait state (W)</td>
</tr>
<tr>
<td>15</td>
<td>Problem state (P)</td>
</tr>
<tr>
<td>16-17</td>
<td>Address-space control (AS)</td>
</tr>
<tr>
<td>18-19</td>
<td>Condition code (CC)</td>
</tr>
<tr>
<td>20-23</td>
<td>Program mask</td>
</tr>
<tr>
<td>25-30</td>
<td>Zero</td>
</tr>
<tr>
<td>31</td>
<td>Extended addressing mode (EA)</td>
</tr>
<tr>
<td>32</td>
<td>Basic addressing mode (BA)</td>
</tr>
<tr>
<td>33-63</td>
<td>Zero</td>
</tr>
<tr>
<td>64-127</td>
<td>Instruction address</td>
</tr>
</tbody>
</table>

General Registers 0-15: Contents of general registers 0-15 are stored in byte positions 32-159 as described in “General-Registers Control (R)” on page 10-168. When bits 32-63 or 0-63 of the general registers are stored, they are stored in ascending order of register numbers, starting with register 0 and continuing up to and including register 15.

Bytes 160-255 always remain unchanged. Bytes 168-255 are reserved. Bytes 160-167 are available for use by programming.

Special Conditions

The CPU must be in the primary-space mode or access-register mode, and bit 31 in bytes 44-47 of the dispatchable-unit control table must be one; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the PSW control, bit 13 of bytes 0-3 of the trap control block is zero and bit 31 of the current PSW, the extended-addressing-mode bit, is one.

All protection mechanisms apply in the usual way to the accesses to the trap control block and trap save area. Access exceptions may or may not be recognized for sections of the trap control block and trap save area that are not referenced by the TRAP instruction.

The trap-program address in the trap control block is not tested before it replaces the instruction address in the PSW. An odd address will cause a specification exception to be recognized as part of the execution of the next instruction.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:
The priority of recognition of program exceptions for the instruction is shown in Figure 10-88.

<table>
<thead>
<tr>
<th>1.-6.</th>
<th>Exceptions with the same priority as the priority of program-interruption conditions for the general case.</th>

</tr>
</tbody>
</table>

Figure 10-88. Priority of Execution: TRAP

**Programming Notes:**

1. It is intended that TRAP instructions will overlay instructions in an application program in order to give control to a trap program, which might be a program for performing fix-ups of data used by the application program, such as dates that may be a “Year-2000” problem. TRAP2 can overlay a two-byte instruction, and TRAP4 can overlay a four-byte instructions or the first four bytes of a six-byte instruction. The trap program is to simulate the overlaid instruction and perform fix-ups as appropriate, and it is then to return control to the application program.

2. The trap program can use the RESUME PROGRAM instruction to return control to the application program. For example, the trap program can restore the contents of all registers except access and general registers 15, and then, using those registers (or at least the general register) to address the trap save area, can restore the contents of those registers and also PSW fields from the trap save area. RESUME PROGRAM has control bits in its parameter list that allow it to restore PSW fields from a field having either the ESA/390 PSW format or the z/Architecture PSW format and to restore either bits 32-63 or 0-63 of a general register.

3. The trap control block and trap save area are in the home address space, and the trap program is in the primary address space. The trap-control-block address placed in general register 15 by TRAP can be useful to the trap program if (1) the primary address space and home address space are the same address space, (2) the trap control block and trap save area are at the same locations in the primary address space as in the home address space, or (3) the trap program can use access registers to access the home address space.

4. The storage-operand references for TRAP may be multiple-access references. (See “Storage-Operand Consistency” on page 5-123.)

to assist in program-damage assessment and recovery. The interruption supplies the program with information about the extent of the damage and the location and nature of the cause. Equipment malfunctions, errors, and other situations which can cause machine-check interruptions are referred to as machine checks.

Machine-Check Detection

Machine-check-detection mechanisms may take many forms, especially in control functions for arithmetic and logical processing, addressing, sequencing, and execution. For program-addressable information, detection is normally accomplished by encoding redundancy into the information in such a manner that most failures in the retention or transmission of the information result in an invalid code. The encoding normally takes the form of one or more redundant bits, called check bits, appended to a group of data bits. Such a group of data bits and the associated check bits are called a checking block. The size of the checking block depends on the model.

The inclusion of a single check bit in the checking block allows the detection of any single-bit failure within the checking block. In this arrangement, the check bit is sometimes referred to as a "parity bit." In other arrangements, a group of check bits is included to permit detection of multiple errors, to permit error correction, or both.

For checking purposes, the contents of the entire checking block, including the redundancy, are called the checking-block code (CBC). When a CBC completely meets the checking requirements (that is, no failure is detected), it is said to be valid. When both detection and correction are provided and a CBC is not valid but satisfies the checking requirements for correction (the failure is correctable), it is said to be near-valid. When a CBC does not satisfy the checking requirements (the failure is uncorrectable), it is said to be invalid.

Correction of Machine Malfunctions

Four mechanisms may be used to provide recovery from machine-detected malfunctions: error checking and correction, CPU retry, channel-subsystem recovery, and unit deletion.

Machine failures which are corrected successfully may or may not be reported as machine-check interruptions. If reported, they are system-recovery conditions, which permit the program to note the cause of CPU delay and to keep a log of such incidents.

Error Checking and Correction

When sufficient redundancy is included in circuitry or in a checking block, failures can be corrected. For example, circuitry can be triplicated, with a voting circuit to determine the correct value by selecting two matching results out of three, thus correcting a single failure. An arrangement for correction of failures of one order and for detection of failures of a higher order is called error checking and correction (ECC). Commonly, ECC allows correction of single-bit failures and detection of double-bit failures.

Depending on the model and the portion of the machine in which ECC is applied, correction may be reported as system recovery, or no report may be given.

Uncorrected errors in storage and in the storage key may be reported, along with a failing-storage address, to indicate where the error occurred. Depending on the situation, these errors may be reported along with system recovery or with the damage or backup condition resulting from the error.

CPU Retry

In some models, information about some portion of the state of the machine is saved periodically. The point in the processing at which this information is saved is called a checkpoint. The information saved is referred to as the checkpoint information. The action of saving the information is referred to as establishing a checkpoint. The action of discarding previously saved information is called invalidation of the checkpoint information. The length of the interval
between establishing checkpoints is model-dependent. Checkpoints may be established at the beginning of each instruction or several times within a single instruction, or checkpoints may be established less frequently.

Subsequently, this saved information may be used to restore the machine to the state that existed at the time when the checkpoint was established. After restoring the appropriate portion of the machine state, processing continues from the checkpoint. The process of restoring to a checkpoint and then continuing is called CPU retry.

CPU retry may be used for machine-check recovery, to effect nullification and suppression of instruction execution when certain program interruptions occur, and in other model-dependent situations.

**Effects of CPU Retry**

CPU retry is, in general, performed so that there is no effect on the program. However, change bits which have been changed from zeros to ones are not necessarily set back to zeros. As a result, change bits may appear to be set to ones for blocks which would have been accessed if restoring to the checkpoint had not occurred. If the path taken by the program is dependent on information that may be changed by another CPU or by a channel program or if an interruption occurs, then the final path taken by the program may be different from the earlier path; therefore, change bits may be ones because of stores along a path apparently never taken.

During the execution of the following instructions, CPU retry may result in condition code 3 being set with possibly incorrect data having been stored in the first operand location at or to the right of the location designated by the final address in general register R1:

- COMPRESSION CALL
- CONVERT UTF-16 TO UTF-32
- CONVERT UTF-16 TO UTF-8
- CONVERT UTF-32 TO UTF-16
- CONVERT UTF-32 TO UTF-8
- CONVERT UTF-8 TO UTF-16
- CONVERT UTF-8 TO UTF-32
- CIPHER MESSAGE
- CIPHER MESSAGE WITH CHAINING
- CIPHER MESSAGE WITH COUNTER
- CIPHER MESSAGE WITH CIPHER FEEDBACK
- CIPHER MESSAGE WITH OUTPUT FEEDBACK
- TRANSLATE ONE TO ONE
- TRANSLATE ONE TO TWO
- TRANSLATE TWO TO ONE
- TRANSLATE TWO TO TWO

During the execution of the PERFORM PSEUDO-RANDOM NUMBER OPERATION instruction’s generate operation, CPU retry may result in condition code 3 being set with possibly incorrect data having been stored in the first operand location at or to the left of the rightmost byte of the first operand (that is, to the left of the location designated by the combination of general registers R1 and R1 + 1).

The amount of data stored depends on the operation and the point in time at which CPU retry occurred. The amount of incorrect data stored will not exceed the minimum of (a) the length of the first operand, (b) the length of the second operand (for instructions having a second operand), and (c) the data processed in a single unit of operation of the instruction. In all cases, the storing will occur again, with correct data stored, if the instruction is executed again to continue processing the same operands.

**Checkpoint Synchronization**

Checkpoint synchronization consists in the following steps.

1. The CPU operation is delayed until all conceptually previous accesses by this CPU to storage have been completed, both for purposes of machine-check detection and as observed by other CPUs and by channel programs.
2. All previous checkpoints, if any, are invalidated.
3. Optionally, a new checkpoint is established.

The CPU operation is delayed until all of these actions appear to be completed, as observed by other CPUs and by channel programs.

**Handling of Machine Checks during Checkpoint Synchronization**

When, in the process of completing all previous stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully but can successfully restore the machine to a previous checkpoint, processing backup is reported.
When, in the process of completing all stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully and cannot successfully restore the machine to a previous checkpoint, the type of machine-check-interruption condition reported depends on the origin of the store. Failure to successfully complete stores associated with instruction execution may be reported as instruction-processing damage, or some less critical machine-check-interruption condition may be reported with the storage-logical-validity bit set to zero. A failure to successfully complete stores associated with the execution of an interruption, other than program or supervisor call, is reported as system damage.

When the machine check occurs as part of a checkpoint-synchronization action before the execution of an instruction, the execution of the instruction is nullified. When it occurs before the execution of an interruption, the interruption condition, if the interruption is external, I/O, or restart, is held pending. If the checkpoint-synchronization operation was a machine-check interruption, then along with the originating condition, either the storage-logical-validity bit is set to zero or instruction-processing damage is also reported. Program interruptions, if any, are lost.

Checkpoint-Synchronization Operations
All interruptions and the execution of certain instructions cause a checkpoint-synchronization action to be performed. The operations which cause a checkpoint-synchronization action are called checkpoint-synchronization operations and include:

- CPU reset
- All interruptions: external, I/O, machine check, program, restart, and supervisor call
- The BRANCH ON CONDITION (BCR) instruction with the M₁ and R₂ fields containing all ones and all zeros, respectively
- The instructions LOAD PSW, LOAD PSW EXTENDED, SET STORAGE KEY EXTENDED, and SUPERVISOR CALL
- All I/O instructions
- The instructions MOVE TO PRIMARY, MOVE TO SECONDARY, PROGRAM CALL, PROGRAM TRANSFER, SET ADDRESS SPACE CONTROL, and SET SECONDARY ASN, and PROGRAM RETURN when the state entry to be unstacked is a program-call state entry
- The four trace functions: branch tracing, ASN tracing, mode tracing, and explicit tracing, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether explicit tracing causes a checkpoint-synchronization action.

- PAGE IN and PAGE OUT

Programming Note: The instructions which are defined to cause the checkpoint-synchronization action invalidate checkpoint information but do not necessarily establish a new checkpoint. Additionally, the CPU may establish a checkpoint between any two instructions or units of operation, or within a single unit of operation. Thus, the point of interruption for the machine check is not necessarily at an instruction defined to cause a checkpoint-synchronization action.

Checkpoint-Synchronization Action
For all interruptions except I/O interruptions, a checkpoint-synchronization action is performed at the completion of the interruption. For I/O interruptions, a checkpoint-synchronization action may or may not be performed at the completion of the interruption. For all interruptions except program, supervisor-call, and exigent machine-check interruptions, a checkpoint-synchronization action is also performed before the interruption. The fetch access to the new PSW may be performed either before or after the first checkpoint-synchronization action. The store accesses and the changing of the current PSW associated with the interruption are performed after the first checkpoint-synchronization action and before the second.

For all checkpoint-synchronization instructions except BRANCH ON CONDITION (BCR), I/O instructions, and SUPERVISOR CALL, checkpoint-synchronization actions are performed before and after the execution of the instruction. For BCR, only one checkpoint-synchronization action is necessarily performed, and it may be performed either before or after the instruction address is updated. For SUPERVISOR CALL, a checkpoint-synchronization action is performed before the instruction is executed, including the updating of the instruction address in the PSW. The checkpoint-synchronization action taken after the supervisor-call interruption is considered to be part of the interruption action and not part of the instruction execution. For I/O instructions, a checkpoint-synchronization action is always performed.
before the instruction is executed and may or may not be performed after the instruction is executed.

The four trace functions — branch tracing, ASN tracing, mode tracing, and explicit tracing — cause checkpoint-synchronization actions to be performed before the trace action and after completion of the trace action, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether checkpoint-synchronization actions are performed for explicit tracing.

**Channel-Subsystem Recovery**

When errors are detected in the channel subsystem, the channel subsystem attempts to analyze and recover the internal state associated with the various channel-subsystem functions and the state of the channel subsystem and various subchannels. This process, which is called channel-subsystem recovery, may result in a complete recovery or may result in the termination of one or more I/O operations and the clearing of the affected subchannels. Special channel-report-pending machine-check-interruption conditions may be generated to indicate to the program the status of the channel-subsystem recovery.

Malfunctions associated with the I/O operations, depending on the severity of the malfunction, may be reported by means of the I/O-interruption mechanism or by means of the channel-report-pending and channel-subsystem-damage machine-check-interruption conditions.

**Unit Deletion**

In some models, malfunctions in certain units of the system can be circumvented by discontinuing the use of the unit. Examples of cases where unit deletion may occur include the disabling of all or a portion of a cache or of a translation-lookaside buffer (TLB). Unit deletion may be reported as a degradation machine-check-interruption condition.

**Handling of Machine Checks**

A machine check is caused by a machine malfunction and not by data or instructions. This is ensured during the power-on sequence by initializing the machine controls to a valid state and by placing valid CBC in the CPU registers, in the storage keys, and in main storage.

Designation of an unavailable component, such as a storage location, subchannel, or I/O device, does not cause a machine-check indication. Instead, such a condition is indicated by the appropriate program or I/O interruption or condition-code setting. In particular, an attempt to access a storage location which is not in the configuration, or which has power off at the storage unit, results in an accessing exception when detected by the CPU and does not generate a machine-check condition, even though the storage location or its associated storage key has invalid CBC. Similarly, if the channel subsystem attempts to access such a location, an I/O-interruption condition indicating program check is generated rather than a machine-check condition.

A machine check is indicated whenever the result of an operation could be affected by information with invalid CBC or when any other malfunction makes it impossible to establish reliably that an operation can be, or has been, performed correctly. When information with invalid CBC is fetched but not used, the condition may or may not be indicated, and the invalid CBC is preserved.

When a machine malfunction is detected, the action taken depends on the model, the nature of the malfunction, and the situation in which the malfunction occurs. Malfunctions affecting operator-facility actions may result in machine checks or may be indicated to the operator. Malfunctions affecting certain other operations such as SIGNAL PROCESSOR may be indicated by means of a condition code or may result in a machine-check-interruption condition.

A malfunction detected as part of an I/O operation may cause a machine-check-interruption condition, an I/O-error condition, or both. I/O-error conditions are indicated by an I/O interruption or by the appropriate condition-code setting during the execution of an I/O instruction. When the machine reports a failing-storage location detected during an I/O operation, both I/O-error and machine-check conditions may be indicated. The I/O-error condition is the primary indication to the program. The machine-check condition is a secondary indication, which is presented as system recovery together with a failing-storage address.
Certain malfunctions detected as part of I/O instructions and I/O operations are reported by means of special machine-check conditions called I/O machine-check conditions. Thus, malfunctions detected as part of an operation which is I/O related may be reported, depending on the error, in any of three ways: I/O-error condition, I/O machine-check condition, or non-I/O machine-check condition. In some cases, the definition requires the error to be reported by only one of these mechanisms; in other cases, any one, or in some cases, more than one, may be indicated.

**Programming Note:** Although the definition for machine-check conditions is that they are caused by machine malfunctions and not by data and instructions, there are certain unusual situations in which machine-check conditions are caused by events which are not machine malfunctions. Two examples follow:

1. In some cases, the channel-report-pending machine-check-interruption condition indicates a non-error situation. For example, this condition is generated at the completion of the function specified by RESET CHANNEL PATH.

2. Improper use of DIAGNOSE may result in machine-check conditions.

**Validation**

Machine errors can be generally classified as solid or intermittent, according to the persistence of the malfunction. A persistent machine error is said to be solid, and one that is not persistent is said to be intermittent. In the case of a register or storage location, a third type of error must be considered, called externally generated. An externally generated error is one where no failure exists in the register or storage location but invalid CBC has been introduced into the location by actions external to the location. For example, the value could be affected by a power transient, or an incorrect value may have been introduced when the information was placed at the location.

Invalid CBC is preserved as invalid when information with invalid CBC is fetched or when an attempt is made to update only a portion of the checking block. When an attempt is made to replace the contents of the entire checking block and the block contains invalid CBC, it depends on the operation and the model whether the block remains with invalid CBC or is replaced. An operation which replaces the contents of a checking block with valid CBC, while ignoring the current contents, is called a validation operation. Validation is used to place a valid CBC in a register or at a location which has an intermittent or externally generated error.

Validating a checking block does not ensure that a valid CBC will be observed the next time the checking block is accessed. If the failure is solid, validation is effective only if the information placed in the checking block is such that the failing bits are set to the value to which they fail. If an attempt is made to set the bits to the state opposite to that in which they fail, then the validation will not be effective. Thus, for a solid failure, validation is only useful to eliminate the error condition, even though the underlying failure remains, thereby reducing the exposure to additional reports. The locations, however, cannot be used, since invalid CBC will result from attempts to store other values at the location. For an intermittent failure, however, validation is useful to restore a valid CBC such that a subsequent partial store into the checking block will be permitted. (A partial store is a store into a checking block without replacing the entire checking block.)

When a checking block consists of multiple bytes in storage, or multiple bits in CPU registers, the invalid CBC can be made valid only when all of the bytes or bits are replaced simultaneously.

For each type of field in the system, certain instructions are defined to validate the field. Depending on the model, additional instructions may also perform validation; or, in some models, a register is automatically validated as part of the machine-check-interruption sequence after the original contents of the register are placed in the appropriate save area.

When an error occurs in a checking block, the original information contained in the checking block should be considered lost even after validation. Automatic register validation leaves the contents unpredictable. Programmed and manual validation of checking blocks causes the contents to be changed explicitly.

**Programming Note:** The machine-check-interruption handler must assume that the registers require validation. Thus, each register should be loaded, using an instruction defined to validate, before the register is used or stored.
Invalid CBC in Storage

The size of the checking block in storage depends on the model but is never more than 4K bytes.

When invalid CBC is detected in storage, a machine-check condition may occur; depending on the circumstances, the machine-check condition may be system damage, instruction-processing damage, or system recovery. If the invalid CBC is detected as part of the execution of a channel program, the error is reported as an I/O-error condition. When a CCW, indirect-data-address word, modified-indirect-data-address word, or data is prefetched from storage, is found to have invalid CBC, but is not used in the channel program, the condition is normally not reported as an I/O-error condition. The condition may or may not be reported as a machine-check-interruption condition. Invalid CBC detected during accesses to storage for other than CPU-related accesses may be reported as system recovery with storage error uncorrected indicated, since the primary error indication is reported by some other means.

When the storage checking block consists of multiple bytes and contains invalid CBC, special storage-validation procedures are generally necessary to restore or place new information in the checking block. Validation of storage is provided with the manual load-clear and system-reset-clear operations and is also provided as a program function. Programmed storage validation is done a block at a time, by executing the privileged instruction TEST BLOCK. Manual storage validation by clear reset validates all blocks which are available in the configuration.

A checking block with invalid CBC is never validated unless the entire contents of the checking block are replaced. An attempt to store into a checking block having invalid CBC, without replacing the entire checking block, leaves the data in the checking block (including the check bits) unchanged. Even when an instruction or a channel-program-input operation specifies that the entire contents of a checking block are to be replaced, validation may or may not occur, depending on the operation and the model.

Programming Note: Machine-check conditions may be reported for prefetched and unused data. Depending on the model, such situations may or may not be successfully retried. For example, a BRANCH AND LINK (BALR) instruction which specifies an R

Invalid CBC in Storage Keys

Provided that an invalid CBC does not exist in the storage key associated with a 4K-byte block, the instruction TEST BLOCK causes the entire 4K-byte block to be set to zeros with a valid CBC, regardless of the current contents of the storage. TEST BLOCK thus removes an invalid CBC from a location in storage which has an intermittent, or one-time, failure. However, if a permanent failure exists in a portion of the storage, a subsequent fetch may find an invalid CBC.

Programmed Validation of Storage

Depending on the model, each storage key may be contained in a single checking block, or the access-control and fetch-protection bits and the reference and change bits may be in separate checking blocks.

Figure 11-1 on page 11-8 describes the action taken when the storage key has invalid CBC. The figure indicates the action taken for the case when the access-control and fetch-protection bits are in one checking block and the reference and change bits are in a separate checking block. In machines where both fields are included in a single checking block, the action taken is the combination of the actions for each field in error, except that completion is permitted only if an error in all affected fields permits completion. References to main storage to which key-controlled protection does not apply are treated as if an access key of zero is used for the reference. This includes such references as channel-program references during initial program loading and implicit references, such as interruption action and DAT-table accesses.

### Explanation:

1. CPU virtual- and logical-address store accesses are subject to DAT protection. When the DAT-protection bit is one, the location will not be changed; however, the machine may indicate a machine-check condition if the storage key or the data itself has invalid CBC.
2. The contents of the main-storage location are not changed.
3. The contents of the reference and change bits are set to ones if the “complete” action is taken.
4. The action shown for an access key of zero is also applicable to references to which key-controlled protection does not apply.

**Complete**: The condition does not cause termination of the execution of the instruction, and, unless an unrelated condition prohibits it, the execution of the instruction is completed, ignoring the error condition. No machine-check-damage conditions are reported, but system recovery may be reported.

**Correct**: The reference and change bits are set to ones with valid CBC.

**Preserve**: The contents of the entire checking block having invalid CBC are left unchanged.

**Validate**: The entire key is set to the new value with valid CBC. When the conditional-SSKE facility is installed and either or both the MR and MC bits of the M3 field are one, condition code 3 is set when the instruction completes.

**CPF**
- Invalid CBC in the storage key for a CPU prefetch which is unused, or for instructions which do not examine the reference and change bits, may result in any of the following situations:
  - The operation is completed; no machine-check condition is reported.
  - The operation is completed; system recovery, with storage-key error uncorrected, is reported.
  - Instruction-processing damage, with or without backup and with storage-key error uncorrected, is reported.

**IPF**
- Invalid CBC in the storage key for a channel-program prefetch which is unused may result in any of the following:
  - The I/O operation is completed; no machine-check condition is reported.
  - The I/O operation is completed; system recovery, with storage-key error uncorrected, is reported.

**MC**
- Same as PD for CPU references, but a channel-subsystem reference may result in the following combinations of I/O-error conditions and machine-check conditions:
  - An I/O-error condition is reported; no machine-check condition is reported.
  - An I/O-error condition is reported; system recovery, with or without storage-key error uncorrected, is reported.

**PD**
- Instruction-processing damage, with or without backup and with or without storage-key error uncorrected, is reported.

**Note**: When storage-key error uncorrected is reported, a failing storage address may or may not also be reported.

---

*Figure 11-1. Invalid CBC in Storage Keys*
Invalid CBC in Registers

When invalid CBC is detected in a CPU register, a machine-check condition may be recognized. CPU registers include the general, floating-point, floating-point-control, access, control, vector, and TOD programmable registers, the current PSW, the prefix register, the TOD clock, the CPU timer, and the clock comparator.

When a machine-check interruption occurs, whether or not it is due to invalid CBC in a CPU register, the following actions affecting the CPU registers, other than the prefix register and the TOD clock, are taken as part of the interruption.

1. The contents of the registers are saved in assigned storage locations. Any register which is in error is identified by a corresponding validity bit of zero in the machine-check-interruption code. Malfunctions detected during register saving do not result in additional machine-check-interruption conditions; instead, the correctness of all the information stored is indicated by the appropriate setting of the validity bits.

2. On some models, registers with invalid CBC are then validated, their actual contents being unpredictable. On other models, programmed validation is required.

The prefix register and the TOD clock are not stored during a machine-check interruption, have no corresponding validity bit, and are not validated.

On those models in which registers are not automatically validated as part of the machine-check interruption, a register with invalid CBC will not cause a machine-check-interruption condition unless the contents of the register are actually used. In these models, each register may consist of one or more checking blocks, but multiple registers are not included in a single checking block. When only a portion of a register is accessed, invalid CBC in the unused portion of the same register may cause a machine-check-interruption condition. For example, invalid CBC in the right half of a floating-point register may cause a machine-check-interruption condition if a LOAD (LE) operation attempts to replace the left half, or short form, of the register.

Invalid CBC associated with the prefix register cannot safely be reported by the machine-check interruption, since the interruption itself requires that the prefix value be applied to convert real addresses to the corresponding absolute addresses. Invalid CBC in the prefix register causes the CPU to enter the check-stop state immediately.

On those models which do not validate registers during a machine-check interruption, the following instructions will cause validation of a register, provided the information in the register is not used before the register is validated. Other instructions, although they replace the entire contents of a register, do not necessarily cause validation.

General registers are validated by BRANCH AND SAVE and LOAD ADDRESS executed in the 64-bit addressing mode, by LOAD (LGR), and by LOAD (LG) and LOAD MULTIPLE (LMG) if the operand is on a doubleword boundary.

Floating-point registers are validated by LOAD (LDR) and, if the operand is on a doubleword boundary, by LOAD (LD).

The floating-point-control register is validated by LOAD FLOATING POINT CONTROL REGISTER.

Vector registers and corresponding floating-point registers are validated by VECTOR LOAD (VL) and VECTOR LOAD MULTIPLE (VLM).

Access registers are validated by LOAD ACCESS MULTIPLE. Only the even-odd access-register pairs that are included in the set of access registers specified for LOAD ACCESS MULTIPLE are validated. Thus, when a single access register is specified, or when a pair of access registers starting with an odd-numbered register is specified, no register is validated.

Control registers may be validated either singly or in groups by using the instruction LOAD CONTROL (LCTLG).

The TOD programmable register, CPU timer, clock comparator, and prefix register are validated by SET CLOCK PROGRAMMABLE REGISTER, SET CPU TIMER, SET CLOCK COMPARATOR, and SET PREFIX, respectively.

The TOD clock is validated by a SET CLOCK instruction that sets the clock.

Programming Note: Depending on the register and the model, the contents of a register may be vali-
dated by the machine-check interruption, or the model may require that a program execute a validating instruction after the machine-check interruption has occurred. In the case of the CPU timer, depending on the model, both the machine-check interruption and validating instructions may be required to restore the CPU timer to full working order.

Check-Stop State

In certain situations, it is impossible or undesirable to continue operation when a machine error occurs. In these cases, the CPU may enter the check-stop state, which is indicated by the check-stop indicator. In general, the CPU may enter the check-stop state whenever an uncorrectable error or other malfunction occurs and the machine is unable to recognize a specific machine-check-interruption condition.

The CPU always enters the check-stop state if any of the following conditions exists:

- PSW bit 13 is zero, and an exigent machine-check condition is generated.
- During the execution of an interruption due to one exigent machine-check condition, another exigent machine-check condition is detected.
- During a machine-check interruption, the machine-check-interruption code cannot be stored successfully, or the new PSW cannot be fetched successfully.
- Invalid CBC is detected in the prefix register.
- A malfunction in the receiving CPU, which is detected after accepting the order, prevents the successful completion of a SIGNAL PROCESSOR order and the order was a reset, or the receiving CPU cannot determine what the order was. The receiving CPU enters the check-stop state.

There may be many other conditions for particular models when an error may cause check stop.

When the CPU is in the check-stop state, instructions and interruptions are not executed. The TOD clock is normally not affected by the check-stop state. The CPU timer may or may not run in the check-stop state, depending on the error and the model. The start key and stop key are not effective in this state.

The CPU may be removed from the check-stop state by CPU reset.

In a multiprocessing configuration, a CPU entering the check-stop state generates a request for a malfunction-alert external interruption to all CPUs in the configuration. Except for the reception of a malfunction alert, other CPUs and the I/O system are normally unaffected by the check-stop state in a CPU. However, depending on the nature of the condition causing the check stop, other CPUs may also be delayed or stopped, and channel subsystem and I/O activity may be affected.

System Check Stop

In a multiprocessing configuration, some errors, malfunctions, and damage conditions are of such severity that the condition causes all CPUs in the configuration to enter the check-stop state. This condition is called a system check stop. The state of the channel subsystem and I/O activity is unpredictable.

Machine-Check Interruption

A request for a machine-check interruption, which is made pending as the result of a machine check, is called a machine-check-interruption condition. There are two types of machine-check-interruption conditions: exigent conditions and repressible conditions.

Exigent Conditions

Exigent machine-check-interruption conditions are those in which damage has or would have occurred such that execution of the current instruction or interruption sequence cannot safely continue. Exigent conditions include two subclasses: instruction-processing damage and system damage. In addition to indicating specific exigent conditions, system damage is used to report any malfunction or error which cannot be isolated to a less severe report.

Exigent conditions for instruction sequences can be either nullifying exigent conditions or terminating exigent conditions, according to whether the instructions affected are nullified or terminated. Exigent conditions for interruption sequences are terminating exi-
gent conditions. The terms “nullification” and “termination” have the same meanings as those used in Chapter 5, “Program Execution”, except that more than one instruction may be involved. Thus, a nullifying exigent condition indicates that the CPU has returned to the beginning of a unit of operation prior to the error. A terminating exigent condition means that the results of one or more instructions may have unpredictable values.

Repressible Conditions

Repressible machine-check-interruption conditions are those in which the results of the instruction-processing sequence have not been affected. Repressible conditions can be delayed, until the completion of the current instruction or even longer, without affecting the integrity of CPU operation. Repressible conditions are of three groups: recovery, alert, and repressible damage. Each group includes one or more subclasses.

A malfunction in the CPU, storage, or operator facilities which has been successfully corrected or circumvented internally without logical damage is called a recovery condition. Depending on the model and the type of malfunction, some or all recovery conditions may be discarded and not reported. Recovery conditions that are reported are grouped in one subclass, system recovery.

A machine-check-interruption condition not directly related to a machine malfunction is called an alert condition. The alert conditions are grouped in two subclasses: degradation and warning.

A malfunction resulting in an incorrect state of a portion of the system not directly affecting sequential CPU operation is called a repressible-damage condition. Repressible-damage conditions are grouped in five subclasses, according to the function affected: timing-facility damage, external damage, channel report pending, channel-subsystem damage, and service-processor damage.

Programming Notes:

1. Even though repressible conditions are usually reported only at normal points of interruption, they may also be reported with exigent machine-check conditions. Thus, if an exigent machine-check condition causes an instruction to be abnormally terminated and a machine-check interruption occurs to report the exigent condition, any pending repressible conditions may also be reported. The meaningfulness of the validity bits depends on what exigent condition is reported.

2. Classification of damage as either exigent or repressible does not imply the severity of the damage. The distinction is whether action must be taken as soon as the damage is detected (exigent) or whether the CPU can continue processing (repressible). For a repressible condition, the current instruction can be completed before taking the machine-check interruption if the CPU is enabled for machine checks; if the CPU is disabled for machine checks, the condition can safely be kept pending until the CPU is again enabled for machine checks.

For example, the CPU may be disabled for machine-check interruptions because it is handling an earlier instruction-processing-damage interruption. If, during that time, an I/O operation encounters a storage error, that condition can be kept pending because it is not expected to interfere with the current machine-check processing. If, however, the CPU also makes a reference to the area of storage containing the error before re-enabling machine-check interruptions, another instruction-processing-damage condition is created, which is treated as an exigent condition and causes the CPU to enter the check-stop state.

3. A repressible condition may be a floating condition. A floating repressible condition is eligible to cause an interruption on any CPU in the configuration. At the point when a CPU performs an interruption for a floating repressible condition, the condition is no longer eligible to cause an interruption on the remaining CPUs in the configuration.

Interruption Action

A machine-check interruption causes the following actions to be taken. An architectural-mode identification with the value 01 hex is stored at real location 163. The PSW reflecting the point of interruption is stored as the machine-check old PSW in the quadword at real location 352. The contents of other registers are stored in register-save areas at real locations 4608-4863, 4892-4895, 4900-4911, 4913-4919, 4928-5119, and in a machine-check extended
save area designated by the contents of real locations 4528-4535. After the contents of the registers are stored in register-save areas and extended save area, depending on the model, the registers may be validated with the contents being unpredictable. A machine-check-interruption code (MCIC) of eight bytes is stored at real locations 232-239. An external-damage code may be stored at real locations 244-247, and a failing-storage address may be stored at real locations 248-255. The new PSW is fetched from real locations 480-495. In addition, a machine-check logout may have occurred.

The machine-generated addresses used to access the old and new PSW, the MCIC, extended interruption information, and the fixed-logout area are all real addresses.

The fields in assigned storage locations that are accessed during the machine-check interruption are summarized in Figure 11-2.

**Explanation:**
* All locations are in real storage.

Figure 11-2. Machine-Check-Interruption Locations

When the vector facility for z/Architecture is installed, and bits 0-53 of real locations 4528-4535 are not all zeros, then other fields are stored in the machine-check extended save area. Figure 11-3 lists the fields that are stored, their offsets within the area, and their lengths. Bytes 512-1023 of the extended save area remain unchanged.

<table>

Figure 11-3. Machine-Check Extended Save Area Locations

If the machine-check-interruption code cannot be stored successfully or the new PSW cannot be fetched successfully, the CPU enters the check-stop state.

A repressible machine-check condition can initiate a machine-check interruption only if both PSW bit 13 is one and the associated subclass mask bit, if any, in control register 14 is also one. When it occurs, the interruption does not terminate the execution of the current instruction; the interruption is taken at a normal point of interruption, and no program or supervisor-call interruptions are eliminated. If the machine check occurs during the execution of a machine function, such as a CPU-timer update, the machine-check interruption takes place after the machine function has been completed.

When the CPU is disabled for a particular repressible machine-check condition, the condition remains pending. Depending on the model and the condition, multiple repressible conditions may be held pending for a particular subclass, or only one condition may be held pending for a particular subclass, regardless of the number of conditions that may have been detected for that subclass.

When a repressible machine-check interruption occurs because the interruption condition is in a subclass for which the CPU is enabled, pending conditions in other subclasses may also be indicated by the same interruption code, even though the CPU is disabled for those subclasses. All indicated conditions are then cleared.

If a machine check which is to be reported as a system-recovery condition is detected during the execution of the interruption procedure due to a previous machine-check condition, the system-recovery condition may be combined with the other conditions, discarded, or held pending.
An exigent machine-check condition can cause a machine-check interruption only when PSW bit 13 is one. When a nullifying exigent condition causes a machine-check interruption, the interruption is taken at a normal point of interruption. When a terminating exigent condition causes a machine-check interruption, the interruption terminates the execution of the current instruction and may eliminate the program and supervisor-call interruptions, if any, that would have occurred if execution had continued. Proper execution of the interruption sequence, including the storing of the old PSW and other information, depends on the nature of the malfunction. When an exigent machine-check condition occurs during the execution of a machine function, such as a CPU-timer update, the sequence is not necessarily completed.

If, during the execution of an interruption due to one exigent machine-check condition, another exigent machine check is detected, the CPU enters the check-stop state. If an exigent machine check is detected during an interruption due to a repressible machine-check condition, system damage is reported.

When PSW bit 13 is zero, an exigent machine-check condition causes the CPU to enter the check-stop state.

Machine-check-interruption conditions are handled in the same manner regardless of whether the wait-state bit in the PSW is one or zero: a machine-check condition causes an interruption if the CPU is enabled for that condition.

Machine checks which occur while the rate control is set to the instruction-step position are handled in the same manner as when the control is set to the process position; that is, recovery mechanisms are active, and machine-check interruptions occur when allowed. Machine checks occurring during a manual operation may be indicated to the operator, may generate a system-recovery condition, may result in system damage, or may cause a check stop, depending on the model.

Every reasonable attempt is made to limit the side effects of any machine check and the associated interruption. Normally, interruptions, as well as the progress of I/O operations, remain unaffected. The malfunction, however, may affect these activities, and, if the currently active PSW has bit 13 set to one, the machine-check interruption will indicate the total extent of the damage caused, and not just the damage which originated the condition.

**Point of Interruption**

The point in the processing which is indicated by the interruption and used as a reference point by the machine to determine and indicate the validity of the status stored is referred to as the point of interruption.

Because of the checkpoint capability in models with CPU retry, the interruption resulting from an exigent machine-check-interruption condition may indicate a point in the CPU processing sequence which is logically prior to the error. Additionally, the model may have some choice as to which point in the CPU processing sequence the interruption is indicated, and, in some cases, the status which can be indicated as valid depends on the point chosen.

Only certain points in the processing may be used as a point of interruption. For repressible machine-check interruptions, the point of interruption must be after one unit of operation is completed and any associated program or supervisor-call interruption is taken, and before the next unit of operation is begun.

Exigent machine-check conditions for instruction sequences are those in which damage has or would have occurred to the instruction stream. Thus, the damage can normally be associated with a point part way through an instruction, and this point is called the point of damage. In some cases, there may be one or more instructions separating the point of damage and the point of interruption, and the processing associated with one or more instructions may be damaged. When the point of interruption is a point prior to the point of damage due to a nullifiable exigent machine-check condition, the point of interruption can be only at the same points as for repressible machine-check conditions.

In addition to the point of interruption permitted for repressible machine-check conditions, the point of interruption for a terminating exigent machine-check condition may also be after the unit of operation is completed but before any associated program or supervisor-call interruption occurs. In this case, a valid PSW instruction address is defined as that which would have been stored in the old PSW for the program or supervisor-call interruption. Since the operation has been terminated, the values in the
result fields, other than the instruction address, are unpredictable. Thus, the validity bits associated with fields which are due to be changed by the instruction stream are meaningless when a terminating exigent machine-check condition is reported.

When the point of interruption and the point of damage due to an exigent machine-check condition are separated by a checkpoint-synchronization function, the damage has not been isolated to a particular program, and system damage is indicated.

When an exigent machine-check-interruption condition occurs, the point of interruption which is chosen affects the amount of damage which must be indicated. An attempt is made, when possible, to choose a point of interruption which permits the minimum indication of damage. In general, the preference is the interruption point immediately preceding the error.

When all the status information stored as a result of an exigent machine-check-interruption condition does not reflect the same point, an attempt is made, when possible, to choose the point of interruption so that the instruction address which is stored in the machine-check old PSW is valid.

**Machine-Check-Interruption Code**

On all machine-check interruptions, a machine-check-interruption code (MCIC) is stored in the doubleword starting at real location 232. The code has the format shown in Figure 11-4.

Bits in the MCIC which are not assigned or not implemented by a particular model are stored as zeros.

**Figure 11-4. Machine-Check Interruption-Code Format**

### Subclass

Bits 0-2 and 4-11 are the subclass bits which identify the type of machine-check condition causing the interruption. At least one of the subclass bits is stored as a one. When multiple errors have occurred, several subclass bits may be set to ones.
System Damage
Bit 0 (SD), when one, indicates that damage has occurred which cannot be isolated to one or more of the less severe machine-check subclasses. When system damage is indicated, the ancillary-report bit, bit 44, is meaningful, the remaining bits in the machine-check-interruption code are not meaningful, and information stored in the register-save areas and machine-check extended-interruption fields is not meaningful.

System damage is a terminating exigent condition and has no subclass-mask bit.

Instruction-Processing Damage
Bit 1 (PD), when one, indicates that damage has occurred to the instruction processing of the CPU.

The exact meaning of bit 1 depends on the setting of the backed-up bit, bit 14. When the backed-up bit is one, the condition is called processing backup. When the backed-up bit is zero, the condition is called processing damage. These two conditions are described in “Synchronous Machine-Check-Interruption Conditions” on page 11-17.

Instruction-processing damage can be a nullifying or a terminating exigent condition and has no subclass-mask bit.

System Recovery
Bit 2 (SR), when one, indicates that malfunctions were detected but did not result in damage or have been successfully corrected. Some malfunctions detected as part of an I/O operation may result in a system-recovery condition in addition to an I/O-error condition. The presence and extent of the system-recovery capability depend on the model.

System recovery is a repressible condition. It is masked by the recovery subclass-mask bit, which is in bit position 36 of control register 14.

Programming Notes:

1. System recovery may be used to report a failing-storage address detected by a CPU prefetch or by an I/O operation.

2. Unless the corresponding validity bits are ones, the indication of system recovery does not imply storage logical validity or that the fields stored as a result of the machine-check interruption are valid.

Timing-Facility Damage
Bit 4 (CD), when one, indicates that damage has occurred to the TOD clock, CPU timer, clock comparator, or TOD programmable register, or to the CPU-timer or clock-comparator external-interruption conditions. The timing-facility-damage machine-check condition is set whenever any of the following occurs:

1. The TOD clock enters the error or not-operational state.

2. The CPU timer is damaged, and the CPU is enabled for CPU-timer external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for CPU-timer interruptions. Depending on the model, the machine-check condition may be generated only as the CPU timer enters an error state. Or, the machine-check condition may be continuously generated whenever the CPU is enabled for CPU-timer interruptions, until the CPU timer is validated.

3. The clock comparator is damaged, and the CPU is enabled for clock-comparator external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for clock-comparator interruptions.

Timing-facility damage may also be set along with instruction-processing damage when an instruction which accesses the TOD clock, CPU timer, or clock comparator produces incorrect results. Depending on the model, the TOD programmable register, CPU timer, or clock comparator may be validated by the interruption which reports the TOD programmable register, CPU timer, or clock comparator as invalid.

Timing-facility damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

Timing-facility-damage conditions for the CPU timer and the clock comparator are not recognized on most models when these facilities are not in use. The facilities are considered not in use when the CPU is disabled for the corresponding external interruptions (PSW bit 7, or the subclass-mask bits, bits 52 and 53 of control register 0, are zeros), and when the corresponding set and store instructions are not executed. Timing-facility-damage conditions that are already...
pending remain pending, however, when the CPU is disabled for the corresponding external interruption.

Timing-facility-damage conditions due to damage to the TOD clock are always recognized.

With TOD-clock steering, damage to the TOD clock is considered to be of such severity that it is undesirable to continue operation. When the TOD-clock-steering facility is installed, and damage has occurred to the TOD-clock-steering registers or the TOD clock and the damage is limited to a single CPU, then that CPU enters the check-stop state. If the TOD clock is in the not-operational state or error state, or when damage has occurred to the TOD-clock-steering registers or the TOD clock, and the damage affects all CPUs, then a system check stop occurs.

**External Damage**

Bit 5 (ED), when one, indicates that damage has occurred during operations not directly associated with processing the current instruction.

When bit 5, external damage, is one and bit 26, external-damage-code validity, is also one, the external-damage code has been stored to indicate, in more detail, the cause of the external-damage machine-check interruption. When the external damage cannot be isolated to one or more of the conditions as defined in the external-damage code, or when the detailed indication for the condition is not implemented by the model, external damage is indicated with bit 26 set to zero. The presence and extent of reporting external damage depend on the model.

External damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

**Degradation**

Bit 7 (DG), when one, indicates that continuous degradation of system performance, more serious than that indicated by system recovery, has occurred. Degradation may be reported when system-recovery conditions exceed a machine-preestablished threshold or when unit deletion has occurred. The presence and extent of the degradation-report capability depend on the model.

Degradation is a repressible condition. It is masked by the degradation subclass-mask bit, which is in bit position 37 of control register 14.

**Warning**

Bit 8 (W), when one, indicates that damage is imminent in some part of the system (for example, that power is about to fail, or that a loss of cooling is occurring). Whether warning conditions are recognized depends on the model.

If the condition responsible for the imminent damage is removed before the interruption request is honored (for example, if power is restored), the request does not remain pending, and no interruption occurs. Conversely, the request is not cleared by the interruption, and, if the condition persists, more than one interruption may result from the same condition.

Warning is a repressible condition. It is masked by the warning subclass-mask bit, which is in bit position 39 of control register 14.

**Channel Report Pending**

Bit 9 (CP), when one, indicates that a channel report, consisting of one or more channel-report words, has been made pending, and the contents of the channel-report words describe, in further detail, the effect of the malfunction and the results of analysis or the action performed. A channel report becomes pending when one of the following conditions has occurred:

1. Channel-subsystem recovery has been completed. The channel-subsystem recovery may have been initiated with no prior notice to the program or may have been a result of a condition previously reported to the program.

2. The function specified by RESET CHANNEL PATH has been completed.

A channel report may also become pending under other conditions.

The channel-report words which make up the channel report may be cleared, one at a time, by execution of the instruction STORE CHANNEL REPORT WORD, which is described in “I/O Instructions” on page 14-1.

Bit 9 is meaningless when channel-subsystem damage is reported.
Channel report pending is a floating repressible condition. It is masked by the channel-report-pending subclass-mask bit, which is in bit position 35 of control register 14.

**Service-Processor Damage**

Bit 10 (SP), when one, indicates that damage has occurred to the service processor. Service-processor damage may be made pending at all CPUs in the configuration, or it may be detected independently by each CPU. The presence and extent of reporting service-processor damage depend on the model.

Service-processor damage is a repressible condition and has no subclass-mask bit.

**Channel-Subsystem Damage**

Bit 11 (CK), when one, indicates that an error or malfunction has occurred in the channel subsystem, or that the channel subsystem is in the check-stop state. The channel subsystem enters the check-stop state when a malfunction occurs which is so severe that the channel subsystem cannot continue, or if power is lost in the channel subsystem.

Channel-subsystem damage is a floating repressible condition and has no subclass-mask bit.

**Subclass Modifiers**

Bits 14 (B), 34 (DA), and 44 (AP) of the machine-check-interruption code act as modifiers to the subclass bits.

**Backed Up**

Bit 14 (B), when one, indicates that the point of interruption is at a checkpoint before the point of error. This bit is meaningful only when the instruction-processing-damage bit, bit 1, is also set to one. The presence and extent of the capability to indicate a backed-up condition depend on the model.

**Delayed Access Exception**

Bit 34 (DA), when one, indicates that an access exception was detected during a storage access using DAT when no such exception was detected by an earlier test for access exceptions.

Bit 34 is a modifier to instruction-processing damage (bit 1) and is meaningful only when bit 1 of the machine-check-interruption code is one. When bit 1 is zero, bit 34 has no meaning. The presence and extent of reporting delayed access exception depend on the model.

**Programming Note:** The occurrence of a delayed access exception normally indicates that the program is using an improper procedure to update the DAT tables.

**Ancillary Report**

Bit 44 (AP), when one, indicates that a malfunction of a system component has occurred which has been recognized previously or which has affected the activities of multiple system elements such as CPUs and subchannels. When the malfunction affects the activities of multiple elements, an ancillary-report condition is recognized for all of the affected elements except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful for all conditions indicated by either the machine-check-interruption code or the external-damage code.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions. When ancillary-report recognition is not provided, bit 44 is set to zero.

**Synchronous Machine-Check- Interruption Conditions**

The instruction-processing damage and backed-up bits, bits 1 and 14 of the machine-check-interruption code, identify, in combination, two conditions.

<table>
<thead>
<tr>
<th>Bit 1</th>
<th>Bit 14</th>
<th>Name of Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>Processing damage</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Processing backup</td>
</tr>
</tbody>
</table>

**Processing Backup**

The processing-backup condition indicates that the point of interruption is prior to the point, or points, of error. This is a nullifying exigent condition. When all of the other CPU-related-damage subclasses and modifiers of the machine-check-interruption code are zero, and certain validity bits associated with CPU status are indicated as valid, then the machine has successfully returned to a checkpoint prior to the malfunction, and no damage has yet occurred to the CPU.
The subclass bits which must be zero for no damage to have occurred are as follows:

**MCIC**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>System damage</td>
</tr>
<tr>
<td>4</td>
<td>Timing-facility damage</td>
</tr>
</tbody>
</table>

The delayed-access-exception subclass-modifier bit, MCIC bit 34, must be zero for no damage to have occurred.

The validity bits in the machine-check-interruption code which must be one for no damage to have occurred are as follows:

**MCIC**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

**Programming Note:** The processing-backup condition is reported rather than system recovery to indicate that a malfunction or failure stands in the way of continued operation of the CPU. The malfunction has not been circumvented, and damage would have occurred if instruction processing had continued.

**Processing Damage**

The processing-damage condition indicates that damage has occurred to the instruction processing of the CPU. The point of interruption is a point beyond some or all of the points of damage. Processing damage is a terminating exigent condition; therefore, the contents of result fields may be unpredictable and still indicated as valid.

Processing damage may include malfunctions in program-event recording, monitor call, tracing, access-register translation, and dynamic address translation. Processing damage causes any supervisor-call-interruption condition and program-interruption condition to be discarded. However, the contents of the old PSW and interruption-code locations for these interruptions may be set to unpredictable values.

**Storage Errors**

Bits 16-18 of the machine-check-interruption code are used to indicate an invalid CBC or a near-valid CBC detected in main storage or an invalid CBC in a storage key. Bit 19, storage degradation, may be indicated concurrently with bit 17. The failing-storage-address field, when indicated as valid, identifies a location within the storage checking block containing the error, or, for storage-key error uncorrected, within the block associated with the storage key. Bit 32, indirect storage error, may be set to one to indicate that the location designated by the failing-storage address is not the original source of the error.

The storage-error-uncorrected and storage-key-error-uncorrected bits do not in themselves indicate the occurrence of damage because the error detected may not have affected a result. The portion of the configuration affected by an invalid CBC is indicated in the subclass field of the machine-check-interruption code.

Storage errors detected for a channel program, when indicated as I/O-error conditions, may also be reported as system recovery. CBC errors that occur in storage or in the storage key and that are detected on prefetched or unused data for a CPU program may or may not be reported, depending on the model.

**Storage Error Uncorrected**

Bit 16 (SE), when one, indicates that a checking block in main storage contained invalid CBC and that the information could not be corrected. The contents of the checking block in main storage have not been changed. The location reported may have been accessed or prefetched for this CPU or another CPU or a channel program, or it may have been accessed as the result of a model-dependent storage access.
Storage Error Corrected
Bit 17 (SC), when one, indicates that a checking block in main storage contained near-valid CBC and that the information has been corrected before being used. Depending on the model, the contents of the checking block in main storage may or may not have been restored to valid CBC. The location reported may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access. The presence and extent of the storage-error-correction capability depend on the model. This indication may or may not be accompanied by an indication of storage degradation, bit 19 (DS).

Storage-Key Error Uncorrected
Bit 18 (KE), when one, indicates that a storage key contained invalid CBC and that the information could not be corrected. The contents of the checking block in the storage key have not been changed. The storage key may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access.

Storage Degradation
Bit 19 (DS), when one, indicates that degradation of the recovery characteristics has occurred for the 4K-byte block reported by the failing-storage address.

Storage degradation indicates that although the associated storage error has been corrected, there are solid failures associated with the storage block (or with its associated key) that cause the correction process to take a substantial amount of time, and that if an additional error occurs in the block, the error may not be correctable or may go undetected. Thus, this bit indicates that use of the indicated block of storage should be avoided, if possible.

The indication of storage degradation has meaning only when failing-storage-address validity, MCIC bit 24, is also one. The presence and extent of reporting storage degradation depend on the model.

Because storage degradation is normally reported with system recovery, the recovery subclass mask, bit 36 of control register 14, should be set to one in order for storage degradation to be indicated.

Indirect Storage Error
Bit 32 (IE), when one, indicates that the physical main-storage location identified by the failing-storage address is not the original source of the error. Instead, the error originated in another level of the storage hierarchy and has been propagated to the current physical-storage portion of the storage hierarchy. Bit 32 is meaningful only when bit 16 or 18 (storage error uncorrected or storage-key error uncorrected) of the machine-check-interruption code is one. When bits 16 and 18 are both zeros, bit 32 has no meaning.

For errors originating outside the storage hierarchy, the attempt to store is rejected, and the appropriate error indication is presented. When an error is detected during implicit movement of information inside the storage hierarchy, the action is not rejected and reported in this manner because the movement may be asynchronous and may be initiated as the result of an attempt to access completely unrelated information. Instead, errors in the contents of the source during implicit moving of information from one portion of the storage hierarchy to another may be preserved in the target area by placing a special invalid CBC in the checking block associated with the target location. These propagated errors, when detected later, are reported as indirect storage errors. The original source of such an error may have been in a cache associated with an I/O processor or a CPU, or the error may have been the result of a data-path failure in transmitting data from one portion of the storage hierarchy to another. Additionally, a propagated error may be generated during the movement of data from one physical portion of storage to another as the result of a storage-reconfiguration action.

The presence and extent of reporting indirect storage error depend on the model.

Programming Note: See the programming notes under TEST BLOCK in Chapter 10, “Control Instructions” for the action which should be taken after storage errors are reported.

Machine-Check Interruption-Code Validity Bits

Bits 20-29, 31 33, 42, 43, 46, and 47 of the machine-check-interruption code are validity bits. Each bit indicates the validity of a particular field in storage. With
the exception of the storage-logical-validity bit (bit 31), each bit is associated with a field stored during the machine-check interruption. When a validity bit is one, it indicates that the saved value placed in the corresponding storage field is valid with respect to the indicated point of interruption and that no error was detected when the data was stored.

When a validity bit is zero, one or more of the following conditions may have occurred: the original information was incorrect, the original information had invalid CBC, additional malfunctions were detected while storing the information, or none or only part of the information was stored. Even though the information is unpredictable, the machine attempts, when possible, to place valid CBC in the storage field and thus reduce the possibility of additional machine checks being caused.

The validity bits for the floating-point registers, general registers, control registers, access registers, vector registers, TOD programmable register, floating-point control register, CPU timer, and clock comparator indicate the validity of the saved value placed in the corresponding save area. The information in these registers after the machine-check interruption is not necessarily correct even when the correct value has been placed in the save area and the validity bit set to one. The use of the registers and the operation of the facility associated with the control registers, floating-point control register, TOD programmable register, CPU timer, and clock comparator are unpredictable until these registers are validated. (See “Invalid CBC in Registers” on page 9.)

**PSW-MWP Validity**
Bit 20 (WP), when one, indicates that bits 12-15 of the machine-check old PSW are correct.

**PSW Mask and Key Validity**
Bit 21 (MS), when one, indicates that the system mask, PSW key, and miscellaneous bits of the machine-check old PSW are correct. Specifically, this bit covers bits 0-11, 16, 17, 24-30, and 33-63 of the PSW.

**PSW Program-Mask and Condition-Code Validity**
Bit 22 (PM), when one, indicates that the program mask and condition code of the machine-check old PSW are correct.

**PSW-Instruction-Address Validity**
Bit 23 (IA), when one, indicates that the addressing-mode and instruction-address bits, bits 31, 32, and 64-127, of the machine-check old PSW are correct.

**Failing-Storage-Address Validity**
Bit 24 (FA), when one, indicates that a correct failing-storage address has been stored at real location 248-255 after a storage-error-uncorrected, storage-key-error-uncorrected, or storage-error-corrected condition has occurred. The presence and extent of the capability to identify the failing-storage location depend on the model. When no such errors are reported, that is, bits 16-18 of the machine-check-interruption code are zeros, the failing-storage address is meaningless, even though it may be indicated as valid.

**Vector Register Validity**
Bit 25 (VR), when one, indicates that the contents of locations 0-1023 of the machine-check extended save area reflect the correct state of the vector registers 0-31 at the point of the interruption.

Bit 25 is zero when the vector facility for z/Architecture is not installed or the machine-check extended save area address formed from the contents of real locations 4528-4535 is either invalid or all zeros.

**External-Damage-Code Validity**
Bit 26 (EC), when one, and provided that bit 5, external damage, is also one, indicates that a valid external-damage code has been stored in the word at real location 244. When bit 5 is zero, bit 26 has no meaning.

**Floating-Point-Register Validity**
Bit 27 (FP), when one, indicates that the contents of the floating-point-register save area at real locations 4608-4735 reflect the correct state of the floating-point registers at the point of interruption.

**General-Register Validity**
Bit 28 (GR), when one, indicates that the contents of the general-register save area at real locations 4736-4863 reflect the correct state of the general registers at the point of interruption.

**Control-Register Validity**
Bit 29 (CR), when one, indicates that the contents of the control-register save area at real locations 4992-
5119 reflect the correct state of the control registers at the point of interruption.

**Storage Logical Validity**
Bit 31 (ST), when one, indicates that the storage locations, the contents of which are modified by the instructions being executed, contain the correct information relative to the point of interruption. That is, all stores before the point of interruption are completed, and all stores, if any, after the point of interruption are suppressed. When a store before the point of interruption is suppressed because of an invalid CBC, the storage-logical-validity bit may be indicated as one, provided that the invalid CBC has been preserved as invalid.

When instruction-processing damage is indicated but processing backup is not indicated, the storage-logical-validity bit has no meaning.

Storage logical validity reflects only the instruction-processing activity and does not reflect errors in the state of storage as the result of either I/O operations or the storing of the old PSW and other interruption information.

**Access-Register Validity**
Bit 33 (AR), when one, indicates that the contents of the access-register save area at real locations 4928-4991 reflect the correct state of the access registers at the point of interruption.

**TOD-Programmable-Register Validity**
Bit 42 (PR), when one, indicates that the contents of the TOD-programmable-register save area at real locations 4900-4903 reflect the correct state of the TOD programmable register at the point of interruption.

**Floating-Point-Control-Register Validity**
Bit 43 (FC), when one, indicates that the contents of the floating-point-control-register save area at real locations 4892-4895 reflect the correct state of the floating-point-control register at the point of interruption.

**CPU-Timer Validity**
Bit 46 (CT), when one, indicates that the CPU timer is not in error and that the contents of the CPU-timer save area at real locations 4904-4911 reflect the correct state of the CPU timer at the time the interruption occurred.

**Clock-Comparator Validity**
Bit 47 (CC), when one, indicates that the clock comparator is not in error, that the contents of the clock-comparator save area at real locations 4913-4919 reflect the correct state of the clock comparator at the time the interruption occurred, and that zeros have been stored at real location 4912.

**Programming Note:** The validity bits must be used in conjunction with the subclass bits and the backed-up bit in order to determine the extent of the damage caused by a machine-check condition. No damage has occurred to the system when all of the following are true:

- The four PSW-validity bits, the seven register-validity bits, the two timing-facility-validity bits, and the storage-logical-validity bit are all ones.
- Subclass bits 0, 4, 5, 10, and 11 are zeros.
- The instruction-processing-damage bit is zero or, if one, the backed-up bit is also one.
- The delayed-access-exception bit is zero.

**Machine-Check Extended Interruption Information**
As part of the machine-check interruption, in some cases, extended interruption information is placed in fixed areas assigned in storage. The contents of registers associated with the CPU are placed in register-save areas. For external damage, additional information is provided for some models by storing an external-damage code. When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated, the failing-storage address is saved.

Each of these fields has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

**Register-Save Areas**
As part of the machine-check interruption, the current contents of the CPU registers, except for the prefix register and the TOD clock, are stored in eight regis-
ter-save areas assigned in storage. Each of these areas has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

The following are the eight sets of registers and the real locations in storage where their contents are saved during a machine-check interruption.

Locations | Registers
---|---
4608-4735 | Floating-point registers 0-15
4736-4863 | General registers 0-15
4892-4895 | Floating-point-control register
4900-4903 | TOD programmable register
4904-4911 | CPU timer
4913-4919 | Clock comparator
4928-5119 | Access registers 0-15
4992-5119 | Control registers 0-15

**External-Damage Code**

The word at real location 244 is the external-damage code. This field, when implemented and indicated as valid, describes the cause of external damage. The field is valid only when the external-damage bit and the external-damage-code-validity bit (bits 5 and 26 in the machine-check-interruption code) are both ones. The presence and extent of reporting an external-damage code depend on the model.

The external-damage code has the following format:

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
  0 19 24 28 31
```

**ETR Sync Check (SC):** Bit 19, when one, indicates that bits 32 through the rightmost incremented bit of a running clock are not in synchronism with the same bits of the ETR.

If the condition happens more than once before the interruption occurs, the condition is generated only once. The condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**STP Sync Check (SS):** Bit 24, when one, indicates that an STP-sync-check has occurred. The STP-sync-check condition is generated when the configuration is in the STP-timing mode and the timing state changes from the synchronized state to the unsynchronized or stopped state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**Island Condition (IC):** Bit 25, when one, indicates that an island condition has been detected. The island condition is generated when an attached server attempts to communicate over an STP link and both of the following conditions are detected:

- The servers have matching CTN IDs, and
- Both servers have valid stratum-1-configurations and the configurations do not match.

The island condition indicates that two separate CTNs may be operating with the same CTN ID.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**CTN Configuration Change (CC):** Bit 26, when one, indicates that a CTN-configuration-change has occurred in the CTN. The conditions that cause the CTN-configuration-change condition to be generated include the following:

- A new node with a matching CTN ID has attached to this node.
- An attached node that had a matching CTN ID is no longer attached to this node
- The CTN ID for this node has changed.
- The stratum level of this node has changed, or a change in the stratum-1 or alternate-stratum-1 for the network has changed.
- STP active or maximum version number has changed.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**STP Clock Source Error (CS):** Bit 27, when one, indicates that an STP-clock-source error has occurred. The STP-clock-source condition is generated when the configuration is in the STP-timing mode and the timing state changes from the synchronized state to the unsynchronized or stopped state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.
mode and the STP-clock-source state changes from the usable state to the not-usable state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

Reserved: Bits 0-7, 10-16, 21-23, and 28-31 are reserved for future expansion and are always set to zero.

Failing-Storage Address

When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated in the machine-check-interruption code, the associated address, called the failing-storage address, is stored at real locations 248-255. The field is valid only if the failing-storage-address validity bit, bit 24 of the machine-check-interruption code, is one.

In the case of storage errors, the failing-storage address may designate any byte within the checking block. For storage-key error uncorrected, the failing-storage address may designate any address within the block of storage associated with the storage key that is in error. When an error is detected in more than one location before the interruption, the failing-storage address may designate any of the failing locations. The address stored is an absolute address; that is, the value stored is the address that is used to reference storage after dynamic address translation and prefixing have been applied.

Machine-Check Extended Save Area

When the vector facility for z/Architecture is installed and bits 0-53 of real locations 4528-4535 are not all zeros, then as part of a machine check interruption, the current contents of the vector registers 0-31 are stored in a machine-check extended save area. The absolute address of the extended save area is obtained by appending 10 bits to the right of bits 0-53 of real locations 4528-4535. Storing does not occur if the address is invalid.

The extended save area has associated with it a validity bit in the machine check interruption code, bit 25 (VR). If for any reason the machine cannot store the proper information in the area, the associated validity bit is set to zero.

Figure 11-3 lists the fields that are stored, their offsets within the area, and their lengths. Bytes 512-1023 of the extended save area are unchanged.

Handling of Machine-Check Conditions

Floating Interruption Conditions

An interruption condition which is made available to any CPU in a multiprocessing configuration is called a floating interruption condition. The first CPU that accepts the interruption clears the interruption condition, and it is no longer available to any other CPU in the configuration.

Floating interruption conditions include service-signal external-interruption and I/O-interruption conditions. Two machine-check-interruption conditions, channel report pending and channel-subsystem damage, are floating interruption conditions. Additionally, floating interruption conditions include STP external-damage machine-check conditions (STP Sync Check, STP Island Condition, STP CTN Configuration Error, and STP Clock Source Error) when STP machine-check floating interruptions are enabled.

Depending on the model, some machine-check-interruption conditions associated with system recovery and warning may also be floating interruption conditions.

A floating interruption is presented to the first CPU in the configuration which is enabled for the interruption condition and can accept the interruption. A CPU cannot accept the interruption when the CPU is in the check-stop state, has an invalid prefix, is performing an unending string of interruptions due to a PSW-format error of the type that is recognized early, or is in the stopped state. However, a CPU with the rate control set to instruction step can accept the interruption when the start key is activated.

Programming Note: When a CPU enters the check-stop state in a multiprocessing configuration, the program on another CPU can determine whether a floating interruption may have been reported to the failing CPU and then lost. This can be accomplished if the interruption program places zeros in the real storage locations containing old PSWs and interruption codes after the interruption has been handled (or has
been moved into another area for later processing). After a CPU enters the check-stop state, the program on another CPU can inspect the old-PSW and interruption-code locations of the failing CPU. A nonzero value in an old PSW or interruption code indicates that the CPU has been interrupted but the program did not complete the handling of the interruption.

Floating Machine-Check-Interruption Conditions
Floating machine-check-interruption conditions are reset only by the manually initiated resets through the operator facilities. When a machine check occurs which prohibits completion of a floating machine-check interruption, the interruption condition is no longer considered a floating interruption condition, and system damage is indicated.

Floating I/O Interruptions
The detection of a machine malfunction by the channel subsystem, while in the process of presenting an I/O-interruption request for a floating I/O interruption, may be reported as channel report pending or as channel-subsystem damage. Detection of a machine malfunction by a CPU, while in the process of accepting a floating I/O interruption, is reported as system damage.

Machine-Check Masking
All machine-check interruptions are under control of the machine-check mask, PSW bit 13. In addition, some machine-check conditions are controlled by subclass masks in control register 14.

The exigent machine-check conditions (system damage and instruction-processing damage) are controlled only by the machine-check mask, PSW bit 13. When PSW bit 13 is one, an exigent condition causes a machine-check interruption. When PSW bit 13 is zero, the occurrence of an exigent machine-check condition causes the CPU to enter the check-stop state.

The repressible machine-check conditions, except channel-subsystem damage and service-processor damage, are controlled both by the machine-check mask, PSW bit 13, and by five subclass-mask bits in control register 14. If PSW bit 13 is one and one of the subclass-mask bits is one, the associated condition initiates a machine-check interruption. If a subclass-mask bit is zero, the associated condition does not initiate an interruption but is held pending. However, when a machine-check interruption is initiated because of a condition for which the CPU is enabled, those conditions for which the CPU is not enabled may be presented along with the condition which initiates the interruption. All conditions presented are then cleared.

Control register 14 contains mask bits that specify whether certain conditions can cause machine-check interruptions. It has the following format:

|   | CR | DE | EW | RM | MM | MM | ...
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td></td>
<td>35</td>
<td>36</td>
<td>37</td>
<td>38</td>
<td>39</td>
<td>40</td>
</tr>
</tbody>
</table>

Bits 35-39 of control register 14 are the subclass masks for repressible machine-check conditions. In addition, bit 32 of control register 14 is initialized to one but is otherwise ignored by the machine.

Programming Note: The program should avoid, whenever possible, operating with PSW bit 13, the machine-check mask, set to zero, since any exigent machine-check condition which is recognized during this situation will cause the CPU to enter the check-stop state. In particular, the program should avoid executing I/O instructions or allowing I/O interruptions with PSW bit 13 zero.

Channel-Report-Pending Subclass Mask
Bit 35 (CM) of control register 14 controls channel-report-pending interruption conditions. This bit is initialized to zero.

Recovery Subclass Mask
Bit 36 (RM) of control register 14 controls system-recovery interruption conditions. This bit is initialized to zero.

Degradation Subclass Mask
Bit 37 (DM) of control register 14 controls degradation interruption conditions. This bit is initialized to zero.

External-Damage Subclass Mask
Bit 38 (EM) of control register 14 controls timing-facility-damage and external-damage interruption conditions. This bit is initialized to one.
Warning Subclass Mask
Bit 39 (WM) of control register 14 controls warning interruption conditions. This bit is initialized to zero.

Machine-Check Logout

As part of the machine-check interruption, some models may place model-dependent information in the fixed-logout area. This area is 16 bytes in length and starts at real location 4864.

Summary of Machine-Check Masking

A summary of machine-check masking is given in Figure 11-5 and Figure 11-6.

<table>
<thead>
<tr>
<th>Machine-Check Condition</th>
<th>Sub-Class Mask</th>
<th>Action when CPU Disabled for Subclass</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 0 System damage</td>
<td>-</td>
<td>Check stop</td>
</tr>
<tr>
<td>Bit 1 Instruction-processing damage</td>
<td>-</td>
<td>Check stop</td>

<td>P</td>
</tr>
<tr>
<td>Bit 11 Channel-subsystem damage</td>
<td>-</td>
<td>P</td>
</tr>
</tbody>
</table>

Explanation:
- The condition does not have a subclass mask.
P Indication is held pending.
Y Indication may be held pending or may be discarded.
CM Channel-report-pending subclass mask (bit 35 of CR14).
DM Degradation subclass mask (bit 37 of CR14).
EM External-damage subclass mask (bit 38 of CR14).
RM Recovery subclass mask (bit 36 of CR14).
WM Warning subclass mask (bit 39 of CR14).

Manual Operation

The operator facilities provide functions for the manual operation and control of the machine. The functions include operator-to-machine communication, indication of machine status, control over the setting of the TOD clock, initial program loading, resets, and other manual controls for operator intervention in normal machine operation. A model may not implement all of the operator facilities described in this chapter.

A model may provide additional operator facilities which are not described in this chapter. Examples are the means to indicate specific error conditions in the equipment, to change equipment configurations, and to facilitate maintenance. Furthermore, controls covered in this chapter may have additional settings which are not described here. Such additional facilities and settings may be described in the appropriate System Library publication.

Most models provide, in association with the operator facilities, a console device which may be used as an I/O device for operator communication with the program; this console device may also be used to implement some or all of the facilities described in this chapter.

The operator facilities may be implemented on different models in various technologies and configurations. On some models, more than one set of physical representations of some keys, controls, and indicators may be provided, such as on multiple local or remote operating stations, which may be effective concurrently.

A machine malfunction that prevents a manual operation from being performed correctly, as defined for that operation, may cause the CPU to enter the check-stop state or give some other indication to the operator that the operation has failed. Alternatively, a machine malfunction may cause a machine-check-interruption condition to be recognized.

Basic Operator Facilities

Address-Compare Controls

The address-compare controls provide a way to stop the CPU when a preset address matches the address used in a specified type of main-storage reference.

One of the address-compare controls is used to set up the address to be compared with the storage address.

Another control provides at least two positions to specify the action, if any, to be taken when the address match occurs:
1. The normal position disables the address-compare operation.

2. The stop position causes the CPU to enter the stopped state on an address match. When the control is in this setting, the test indicator is on. Depending on the model and the type of reference, pending I/O, external, and machine-check interruptions may or may not be taken before entering the stopped state.

A third control may specify the type of storage reference for which the address comparison is to be made. A model may provide one or more of the following positions, as well as others:

1. The any position causes the address comparison to be performed on all storage references.
2. The data-store position causes address comparison to be performed when storage is addressed to store data.
3. The I/O position causes address comparison to be performed when storage is addressed by the channel subsystem to transfer data or to fetch a channel-command or indirect-data-address word. Whether references to the measurement block, interruption-response block, channel-path-status word, channel-report word, subchannel-status word, subchannel-information block, and operation-request block cause a match to be indicated depends on the model.
4. The instruction-address position causes address comparison to be performed when storage is addressed to fetch an instruction. The rightmost bit of the address setting may or may not be ignored. The match is indicated only when the first byte of the instruction is fetched from the selected location (which includes fetching the target instruction of an execute-type instruction).

Depending on the model and the type of reference, address comparison may be performed on virtual, real, or absolute addresses, and it may be possible to specify the type of address.

In a multiprocessing configuration, it depends on the model whether the address setting applies to one or all CPUs in the configuration and whether an address match causes one or all CPUs in the configuration to stop.

Depending on the model, the availability of address-compare controls may be limited by the use of program-event-recording (PER) controls; PER controls include bit 1 of the PSW and all bits of control registers 9, 10, and 11. The address-compare-control limitations are as follows:

- The setting of address-compare controls may be inhibited when any PER control is nonzero. In a multi-processing configuration, the setting of address-compare controls may be inhibited on all CPUs in the configuration when any PER control is nonzero on any CPU in the configuration.
- If address-compare controls have been set on a CPU, and any PER control is set to a nonzero value, the address-compare controls may be disabled; the address-compare controls may remain disabled even if the respective PER controls are all subsequently reset to zero. In a multi-processing configuration, the address-compare controls may be disabled on all CPUs in the configuration if any PER control is set to a nonzero value in any CPU in the configuration.

### Alter-and-Display Controls

The operator facilities provide controls and procedures to permit the operator to alter and display the contents of locations in storage, the storage keys, the general, floating-point, floating-point-control, vector, access, and control registers, the prefix, and the PSW.

Before alter-and-display operations may be performed, the CPU must first be placed in the stopped state. During alter-and-display operations, the manual indicator may be turned off temporarily, and the start and restart keys may be inoperative.

Addresses used to select storage locations for alter-and-display operations are real addresses. The capability of specifying logical, virtual, or absolute addresses may also be provided.

### Architectural-Mode Indicator

The architectural-mode indicator shows the architectural mode of operation (the ESA/390 mode, z/Architecture mode, or some other mode) selected by the last architectural-mode-selection operation and by
the last SIGNAL PROCESSOR set-architecture order or the last reset that determined the mode.

**Architectural-Mode-Selection Controls**

The architectural-mode-selection controls provide for the selection of either the ESA/390 architectural mode of operation or, possibly, some other architectural mode of operation. (The z/Architecture mode is selected from the ESA/390 mode by the SIGNAL PROCESSOR set-architecture order.) Depending on the model, the architectural-mode selection may be provided as part of the IML operation or may be a separate operation.

As part of the architectural-mode-selection process, all CPUs and the associated channel-subsystem components in a particular configuration are placed in the same architectural mode.

**Check-Stop Indicator**

The check-stop indicator is on when the CPU is in the check-stop state. Reset operations normally cause the CPU to leave the check-stop state and thus turn off the indicator. The manual indicator may also be on in the check-stop state.

**CPUs-per-Core Indicator**

When the multithreading facility is installed, the CPUs-per-core indicator is provided. When the multithreading facility is not enabled, the value of this indicator is one. When the multithreading facility is enabled, the value of this indicator is one more than value of the program-specified maximum thread identification last set by the SIGNAL PROCESSOR set-multithreading order.

**Operation Note:** Certain operator functions are addressed to a specific CPU, designated by a CPU address. When multithreading is enabled, the CPU address includes a core identification and a thread identification as described in “CPU-Address Identification” on page 4-63. The CPUs-per-core indicator can be used to determine which format of CPU address is needed when selecting a CPU to which operator functions are addressed.

**IML Controls**

The IML controls provided with some models perform initial machine loading (IML), which is the loading of licensed internal code into the machine. The IML operation, when provided, may be used to select the ESA/390 mode or, possibly, some other mode of operation.

When the IML operation is completed, the state of the affected CPUs, channel subsystem, main storage, and operator facilities is the same as if a power-on reset had been performed, except that the value and state of the TOD clock are not changed. The contents of expanded storage may have been cleared to zeros with valid checking-block code or may have remained unchanged, depending on the model.

The IML controls are effective while the power is on.

**Interrupt Key**

When the interrupt key is activated, an external-interruption condition indicating the interrupt key is generated. (See “Interrupt Key” on page 6-12.)

The interrupt key is effective when the CPU is in the operating or stopped state. It depends on the model whether the interrupt key is effective when the CPU is in the load state.

**Load Indicator**

The load indicator is on during CCW-type initial program loading, indicating that the CPU is in the load state. The indicator goes on for a particular CPU when the load-clear, load-clear-list-directed, load-normal or load-with-dump key is activated for that CPU and the corresponding operation is started. It goes off after the new PSW is loaded successfully. For details, see “Initial Program Loading” on page 4-61 and “Initial Program Loading” on page 17-16.

**Load-Clear Key**

Activating the load-clear key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Clear reset
is performed on the configuration. For details, see “Resets” on page 4-55 and “Initial Program Loading” on page 4-61.

The load-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

**Load-Clear-List-Directed Key**

Activating the load-clear-list-directed key causes a reset operation to be performed and list-directed initial program loading to be started using the I/O device designated by the list-directed IPL parameters. Clear reset is performed on the configuration. For details, see “Resets” on page 4-55 and “List-Directed IPL” on page 17-19.

The load-clear-list-directed key is effective when the CPU is in the operating, stopped, load, or check-stop state.

**Load-Normal Key**

Activating the load-normal key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Initial CPU reset is performed on the CPU for which the load-normal key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-55 and “Initial Program Loading” on page 4-61.

The load-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

**Load-with-Dump Key**

Activating the load-with-dump key causes a reset operation to be performed and list-directed initial program loading to be started by using the I/O devices designated by the list-directed IPL parameters. A store-status operation followed by an initial CPU reset is performed on the CPU for which the load-with-dump key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-55 and “List-Directed IPL” on page 17-19.

The load-with-dump key is effective when the CPU is in the operating, stopped, load, or check-stop state.

**Load-Unit-Address Controls**

The load-unit-address controls specify four hexadecimal digits that provide the device number used for CCW-type initial program loading. When the alternate-subchannel-set-IPL-device facility is installed the load-unit-address controls may specify an additional hexadecimal digit that provides the subchannel-set ID for CCW-type initial program loading. For details, see “Initial Program Loading” on page 4-61.

**Manual Indicator**

The manual indicator is on when the CPU is in the stopped state. Some functions and several manual controls are effective only when the CPU is in the stopped state.

**Power Controls**

The power controls are used to turn the power on and off.

The CPUs, storage, channel subsystem, operator facilities, and I/O devices may all have their power turned on and off by common controls, or they may have separate power controls. When a particular unit has its power turned on, that unit is reset. The sequence is performed so that no instructions or I/O operations are performed until explicitly specified. The controls may also permit power to be turned on in stages, but the machine does not become operational until power on is complete.

When the power is completely turned on, an IML operation is performed on models which have an IML function. A power-on reset is then initiated (see “Resets” on page 4-55). It depends on the model whether the architectural mode of operation can be selected when the power is turned on, or whether the mode-selection controls have to be used to change the mode after the power is on.
Rate Control

A model may provide the rate control, the setting of which determines the effect of the start function and the manner in which instructions are executed.

When the rate control is provided, it has at least two positions. The normal position is the process position. Another position is the instruction-step position. When the rate control is set to the process position and the start function is performed, the CPU starts operating at normal speed. When the rate control is set to the instruction-step position and the wait-state bit is zero, one instruction or, for interruptible instructions, one unit of operation is executed, and all pending allowed interruptions are taken before the CPU returns to the stopped state. When the rate control is set to the instruction-step position and the wait-state bit is one, no instruction is executed, but all pending allowed interruptions are taken before the CPU returns to the stopped state. For details, see “Stopped, Operating, Load, and Check-Stop States” on page 4-2.

The test indicator is on while the rate control is not set to the process position.

If the setting of the rate control is changed while the CPU is in the operating or load state, the results are unpredictable.

When the rate control is not provided, the CPU operates as though the rate control was in the process position, and instruction stepping is not available.

Restart Key

Activating the restart key initiates a restart interruption. (See “Restart Interruption” on page 6-54.)

The restart key is effective when the CPU is in the operating or stopped state. The key is not effective when the CPU is in the check-stop state. It depends on the model whether the restart key is effective when any CPU in the configuration is in the load state.

The effect is unpredictable when the restart key is activated while any CPU in the configuration is in the load state. In particular, if the CPU performs a restart interruption and enters the operating state while another CPU is in the load state, operations such as I/O instructions, the SIGNAL PROCESSOR instruction, and the INVALIDATE PAGE TABLE ENTRY instruction may not operate according to the definitions given in this publication.

Start Key

Activating the start key causes the CPU to perform the start function. (See “Stopped, Operating, Load, and Check-Stop States” on page 4-2.)

The start key is effective only when the CPU is in the stopped state. The effect is unpredictable when the stopped state has been entered by a reset.

Stop Key

Activating the stop key causes the CPU to perform the stop function. (See “Stopped, Operating, Load, and Check-Stop States” on page 4-2.)

The stop key is effective only when the CPU is in the operating state.

Operation Note: Activating the stop key has no effect when:
- An unending string of certain program or external interruptions occurs.
- The prefix register contains an invalid address.
- The CPU is in the load or check-stop state.

Store-Status Key

Activating the store-status key initiates a store-status operation. (See “Store Status” on page 4-62.)

The store-status key is effective only when the CPU is in the stopped state.

Operation Note: The store-status operation may be used in conjunction with a standalone dump program for the analysis of major program malfunctions. For such an operation, the following sequence would be called for:

1. Activation of the stop or system-reset-normal key
2. Activation of the store-status key (this step is unnecessary if the standalone dump program is loaded by activating the load-with-dump key)
3. Activation of the load-normal key to enter a stand-alone dump program

The system-reset-normal key must be activated in step 1 when (1) the stop key is not effective because a continuous string of interruptions is occurring, (2) the prefix register contains an invalid address, or (3) the CPU is in the check-stop state.

**System-Reset-Clear Key**

Activating the system-reset-clear key causes a clear-reset operation to be performed on the configuration. For details, see “Resets” on page 4-55.

The system-reset-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

**System-Reset-Normal Key**

Activating the system-reset-normal key causes a CPU-reset operation and a subsystem-reset operation to be performed. In a multiprocessing configuration, a CPU reset is propagated to all CPUs in the configuration. For details, see “Resets” on page 4-55.

The system-reset-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

**Test Indicator**

The test indicator is on when a manual control for operation or maintenance is in an abnormal position that can affect the normal operation of a program.

Setting the address-compare controls to the stop position or setting the rate control to the instruction-step position turns on the test indicator.

The test indicator may be on when one or more diagnostic functions under the control of DIAGNOSE are activated, or when other abnormal conditions occur.

The abnormal setting of a manual control causes the test indicator of the affected CPU to be turned on; however, in a multiprocessing configuration, the operation of other CPUs may be affected even though their test indicators are not turned on.

Depending on the model, if address-compare controls have been disabled due to bit position 1 of the PSW being set to one or any or all of control registers 9, 10, and 11 containing nonzero values, the test indicator may remain on even though the address-compare controls have been disabled.

**Operation Note:** If a manual control is left in a setting intended for maintenance purposes, such an abnormal setting may, among other things, result in false machine-check indications or cause actual machine malfunctions to be ignored. It may also alter other aspects of machine operation, including instruction execution, channel-subsystem operation, and the functioning of operator controls and indicators, to the extent that operation of the machine does not comply with that described in this publication.

**TOD-Clock Control**

When the TOD-clock control is not activated, that is, the control is set to the secure position, the state and value of the TOD clock are protected against unauthorized or inadvertent change by not permitting the instructions SET CLOCK or DIAGNOSE to change the state or value.

When the TOD-clock control is activated, that is, the control is set to the enable-set position, alteration of the clock state or value by means of SET CLOCK or DIAGNOSE is permitted. This setting is momentary, and the control automatically returns to the secure position.

If there is more than one physical representation of the TOD-clock control, the TOD clock is secure only if all TOD-clock controls in the configuration are set to the secure position.

**Wait Indicator**

The wait indicator is on when the wait-state bit in the current PSW is one. Instead of a wait indicator, a model may have a means of indicating a time-averaged value of the wait-state bit.

**Multiprocessing Configurations**

In a multiprocessing configuration, one of each of the following keys and controls is provided for each CPU:
Alter and display
Interrupt
Restart
Start
Stop
Store status.

On some models, a rate control may also be provided.

On some models, the load-clear, load-clear-list-directed, load-normal, load-with-dump, and load-unit-address keys are provided for each primary CPU in the configuration. On other models, a single load-clear, load-clear-list-directed, load-normal, and load-with-dump key are provided for the entire configuration and apply to the lowest-numbered primary online CPU that is not in the check-stop state.

There need not be more than one of each of the following keys and controls in a multiprocessing configuration: address compare, IML, power, system reset clear, system reset normal, and TOD clock.

One check-stop, manual, test, and wait indicator may be provided for each CPU. A load indicator is provided only on a primary CPU. Alternatively, a single set of indicators may be switched to more than one CPU.

There need not be more than one architectural-mode and CPUs-per-core indicator in a multiprocessing configuration.

In a system capable of reconfiguration, there must be a separate set of keys, controls, and indicators in each configuration.

---

**Multithreading Considerations**

A CPU address is used to identify the CPU to which CPU-specific operator functions are directed. These CPU-specific operator functions are enumerated in the section “Multiprocessing Configurations”, above. When multithreading is enabled (that is, when the CPUs-per-core indicator is greater than one), the CPU address comprises a core identification and a thread identification, as described in “CPU-Address Identification” on page 4-63.

Some models provide a control to select the primary CPU to be started following a load operation. On such a model, when the multithreading facility is enabled prior to the load operation, the operator designates an expanded-format CPU address as described in “CPU-Address Identification” on page 4-63. However, only the core-identification portion of the designated CPU address is meaningful; the operation is always targeted to the CPU having thread identification zero of the designated core.

On models that do not provide a control to select the primary CPU to be started following a load operation, the operation is targeted to the CPU having thread identification zero in the lowest-numbered operational core.

In either case, the targeted CPU is (a) the one upon which the initial-CPU reset is performed, and (b) the CPU that is started after the load operation is completed.

Input/Output (I/O)

The terms “input” and “output” are used to describe the transfer of data between I/O devices and main storage. An operation involving this kind of transfer is referred to as an I/O operation. The facilities used to control I/O operations are collectively called the channel subsystem. (I/O devices and their control units attach to the channel subsystem.) This chapter provides a brief description of the basic components and operation of the channel subsystem.

The Channel Subsystem

The channel subsystem directs the flow of information between I/O devices and main storage. It relieves CPUs of the task of communicating directly with I/O devices and permits data processing to proceed concurrently with I/O processing. The channel subsystem uses one or more channel paths as the communication link in managing the flow of information to or from I/O devices. As part of I/O processing, the channel subsystem also performs a path-management operation by testing for channel-path availability, chooses an available channel path, and initiates the performance of the I/O operation by the device.

Within the channel subsystem are subchannels. One subchannel is provided for and dedicated to each I/O device accessible to the program through the channel subsystem.

The multiple-subchannel-set facility is an optional facility. When it is installed, subchannels are partitioned into multiple subchannel sets, and each subchannel set may provide one dedicated subchannel to an I/O device. Depending on the model and the interface used, some I/O devices may only be allowed to be accessed via certain subchannel sets.

Each subchannel provides information concerning the associated I/O device and its attachment to the channel subsystem. The subchannel also provides information concerning I/O operations and other functions involving the associated I/O device. The subchannel is the means by which the channel subsystem provides information about associated I/O devices to CPUs, which obtain this information by executing I/O instructions. The actual number of subchannels provided depends on the model and the configuration; the maximum addressability is 0-65,535 in each subchannel set.

I/O devices are attached through control units to the channel subsystem by means of channel paths. Control units may be attached to the channel subsystem by more than one channel path, and an I/O device may be attached to more than one control unit. In all,
an individual I/O device may be accessible to the channel subsystem by as many as eight different channel paths via a subchannel, depending on the model and the configuration. The total number of channel paths provided by a channel subsystem depends on the model and the configuration; the maximum addressability is 0-255.

The performance of a channel subsystem depends on its use and on the system model in which it is implemented. Channel paths are provided with different data-transfer capabilities, and an I/O device designed to transfer data only at a specific rate (a magnetic-tape unit or a disk storage, for example) can operate only on a channel path that can accommodate at least this data rate.

The channel subsystem contains common facilities for the control of I/O operations. When these facilities are provided in the form of separate, autonomous equipment designed specifically to control I/O devices, I/O operations are completely overlapped with the activity in CPUs. The only main-storage cycles required by the channel subsystem during I/O operations are those needed to transfer data and control information to or from the final locations in main storage, along with those cycles that may be required for the channel subsystem to access the subchannels when they are implemented as part of nonaddressable main storage. These cycles do not delay CPU programs, except when both the CPU and the channel subsystem concurrently attempt to reference the same main-storage area.

Subchannel Sets

When the multiple-subchannel-set facility is installed, subchannels are partitioned into multiple subchannel sets. There may be up to four subchannel sets, each identified by a subchannel-set identifier (SSID). When the multiple-subchannel-set facility is not installed, there is only one subchannel set with an SSID of zero. When the multiple-subchannel-set facility is not enabled, only subchannel set zero is visible to the program. See “Multiple-Subchannel-Set Facility” on page 29 for more information on the multiple-subchannel-set facility.

Subchannels

A subchannel provides the logical appearance of a device to the program and contains the information required for sustaining a single I/O operation. The subchannel consists of internal storage that contains information in the form of a channel-program designation, channel-path identifier, device number, count, status indications, and I/O-interruption-subclass code, as well as information on path availability and functions pending or being performed. I/O operations are initiated with a device by the execution of I/O instructions that designate the subchannel associated with the device.

Each device is accessible by means of one subchannel in each channel subsystem to which it is assigned during configuration at installation time. The device may be a physically identifiable unit or may be housed internal to a control unit. For example, in certain disk-storage devices, each actuator used in retrieving data is considered to be a device. In all cases, a device, from the point of view of the channel subsystem, is an entity that is uniquely associated with one subchannel and that responds to selection by the channel subsystem by using the communication protocols defined for the type of channel path by which it is accessible.

On some models, subchannels are provided in blocks. On these models, more subchannels may be provided than there are attached devices. Subchannels that are provided but do not have devices assigned to them are not used by the channel subsystem to perform any function and are indicated by storing the associated device-number-valid bit as zero in the subchannel-information block of the subchannel.

The number of subchannels provided by the channel subsystem is independent of the number of channel paths to the associated devices. For example, a device accessible through alternate channel paths still is represented by a single subchannel. Each subchannel is addressed by using the following:

- a 16-bit binary subchannel number
- a two-bit SSID when the subchannel-set facility is installed

After I/O processing at the subchannel has been requested by the execution of START SUBCHANNEL, the CPU is released for other work, and the channel subsystem assembles or disassembles data and synchronizes the transfer of data bytes between the I/O device and main storage. To accomplish this, the channel subsystem maintains and updates an address and a count that describe the destination or
source of data in main storage. Similarly, when an I/O device provides signals that should be brought to the attention of the program, the channel subsystem transforms the signals into status information and stores the information in the subchannel, where it can be retrieved by the program.

Attachment of Input/Output Devices

Channel Paths

The channel subsystem communicates with I/O devices by means of channel paths between the channel subsystem and control units. A control unit may be accessible by the channel subsystem by more than one channel path. Similarly, an I/O device may be accessible by the channel subsystem through more than one control unit, each having one or more channel paths to the channel subsystem.

Devices that are attached to the channel subsystem by multiple channel paths configured to a subchannel, may be accessed by the channel subsystem using any of the available channel paths. Similarly, a device having the dynamic-reconnection feature and operating in the multipath mode can be initialized to operate such that the device may choose any of the available channel paths configured to the subchannel, when logically reconnecting to the channel subsystem to continue a chain of I/O operations.

The channel subsystem may contain more than one type of channel path. Examples of channel-path types used by the channel subsystem are the ESCON I/O interface, FICON I/O interface, FICON-converted I/O interface, and IBM System/360 and System/370 I/O interface. The term “serial-I/O interface” is used to refer to the ESCON I/O interface, the FICON I/O interface, and the FICON-converted I/O interface. The term “parallel-I/O interface” is used to refer to the IBM System/360 and System/370 I/O interface.

The ESCON I/O interface is described in the System Library publication IBM Enterprise Systems Architecture/390 ESCON I/O Interface, SA22-7202.

The FICON I/O interface is described in the ANSI standards document Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)

The IBM System/360 and System/370 I/O interface is described in the System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974.

Depending on the type of channel path, the facilities provided by the channel path, and the I/O device, an I/O operation may occur in one of three modes, frame-multiplex mode, burst mode, or byte-multiplex mode.

In the frame-multiplex mode, the I/O device may stay logically connected to the channel path for the duration of the execution of a channel program. The facilities of a channel path capable of operating in the frame-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode the information required to complete an I/O operation is divided into frames that may be interleaved with frames from I/O operations for other I/O devices. During this period, multiple I/O devices are considered to be logically connected to the channel path.

In the burst mode, the I/O device monopolizes a channel path and stays logically connected to the channel path for the transfer of a burst of information. No other device can communicate over the channel path during the time a burst is transferred. The burst can consist of a few bytes, a whole block of data, a sequence of blocks with associated control and status information (the block lengths may be zero), or status information that monopolizes the channel path. The facilities of the channel path capable of operating in the burst mode may be shared by a number of concurrently operating I/O devices.

Some channel paths can tolerate an absence of data transfer for about a half minute during a burst-mode operation, such as occurs when a long gap on magnetic tape is read. An equipment malfunction may be indicated when an absence of data transfer exceeds the prescribed limit.

In the byte-multiplex mode, the I/O device stays logically connected to the channel path only for a short interval of time. The facilities of a channel path capable of operating in the byte-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode, all I/O operations are split into short intervals of time during which only a segment of information is transferred over the channel path. During such an interval, only one device and its associated subchannel are logically connected to the channel path. The intervals associated with the con-
current operation of multiple I/O devices are sequenced in response to demands from the devices. The channel-subsystem facility associated with a subchannel exercises its controls for any one operation only for the time required to transfer a segment of information. The segment can consist of a single byte of data, a few bytes of data, a status report from the device, or a control sequence used for the initiation of a new operation.

Ordinarily, devices with high data-transfer-rate requirements operate with the channel path in the frame-multiplex mode, slower devices operate in the burst mode, and the slowest devices operate in the byte-multiplex mode. Some control units have a manual switch for setting the desired mode of operation.

An I/O operation that occurs on a parallel-I/O-interface type of channel path may occur in either the burst mode or the byte-multiplex mode depending on the facilities provided by the channel path and the I/O device. For improved performance, some channel paths and control units are provided with facilities for high-speed transfer and data streaming. See the System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974, for a description of those two facilities.

An I/O operation that occurs on a serial-I/O-interface type of channel path may occur in either the frame-multiplex mode or the burst mode. For improved performance, some control units attaching to the serial-I/O interface provide the capability to provide sense data to the program concurrent with the presentation of unit-check status, if permitted to do so by the program. (See “Concurrent Sense” on page 24.)

Depending on the control unit or channel subsystem, access to a device through a subchannel may be restricted to a single channel-path type.

The modes and features described above affect only the protocol used to transfer information over the channel path and the speed of transmission. No effects are observable by CPU or channel programs with respect to the way these programs are executed.

Control Units

A control unit provides the logical capabilities necessary to operate and control an I/O device and adapts the characteristics of each device so that it can respond to the standard form of control provided by the channel subsystem.

Communication between the control unit and the channel subsystem takes place over a channel path. The control unit accepts control signals from the channel subsystem, controls the timing of data transfer over the channel path, and provides indications concerning the status of the device.

The I/O device attached to the control unit may be designed to perform only certain limited operations, or it may perform many different operations. A typical operation is moving a recording medium and recording. To accomplish its operations, the device needs detailed signal sequences peculiar to its type of device. The control unit decodes the commands received from the channel subsystem, interprets them for the particular type of device, and provides the signal sequence required for the performance of the operation.

A control unit may be housed separately, or it may be physically and logically integrated with the I/O device, the channel subsystem, or a CPU. In the case of most electromechanical devices, a well-defined interface exists between the device and the control unit because of the difference in the type of equipment the control unit and the device require. These electromechanical devices often are of a type where only one device of a group attached to a control unit is required to transfer data at a time (magnetic-tape units or disk-access mechanisms, for example), and the control unit is shared among a number of I/O devices. On the other hand, in some electronic I/O devices, such as the channel-to-channel adapter, the control unit does not have an identity of its own.

From the programmer's point of view, most functions performed by the control unit can be merged with those performed by the I/O device. Therefore, this publication normally makes no specific mention of the control-unit function; the performance of I/O operations is described as if the I/O devices communicated directly with the channel subsystem. Reference is made to the control unit only when emphasizing a function performed by it or when describing how the sharing of the control unit among a number of devices affects the performance of I/O operations.
I/O Devices

An input/output (I/O) device provides external storage, a means of communication between data-processing systems, or a means of communication between a system and its environment. I/O devices include such equipment as magnetic-tape units, direct-access-storage devices (for example, disks), display units, typewriter-keyboard devices, printers, teleprocessing devices, and sensor-based equipment. An I/O device may be physically distinct equipment, or it may share equipment with other I/O devices.

Most types of I/O devices, such as printers, or tape devices, use external media, and these devices are physically distinguishable and identifiable. Other types are solely electronic and do not directly handle physical recording media. The channel-to-channel adapter, for example, provides for data transfer between two channel paths, and the data never reaches a physical recording medium outside main storage. Similarly, communication controllers may handle the transmission of information between the data-processing system and a remote station, and its input and output are signals on a transmission line.

In the simplest case, an I/O device is attached to one control unit and is accessible from one channel path. Switching equipment is available to make some devices accessible from two or more channel paths by switching devices among control units and by switching control units among channel paths. Such switching equipment provides multiple paths by which an I/O device may be accessed. Multiple channel paths to an I/O device are provided to improve performance or I/O availability, or both, within the system. The management of multiple channel paths to devices is under the control of the channel subsystem and the device, but the channel paths may indirectly be controlled by the program.

I/O Addressing

Four different types of I/O addressing are provided by the channel subsystem for the necessary addressing of the various components: channel-path identifiers, subchannel numbers, device numbers, and, though not visible to programs, addresses dependent on the channel-path type. When the multiple-subchannel-set facility is installed, the subchannel-set identifier (SSID) is also used in I/O addressing.

Subchannel-Set Identifier

The subchannel-set identifier (SSID) is a two-bit value assigned to each provided subchannel set.

Channel-Path Identifier

The channel-path identifier (CHPID) is a system-unique eight-bit value assigned to each installed channel path of the system. A CHPID is used to address a channel path. A CHPID is specified by the second-operand address of RESET CHANNEL PATH and used to designate the channel path that is to be reset. The channel paths by which a device is accessible are identified in the subchannel-information block (SCHIB), each by its associated CHPID, when STORE SUBCHANNEL is executed. The CHPID can also be used in operator messages when it is necessary to identify a particular channel path. A system model may provide as many as 256 channel paths. The maximum number of channel paths and the assignment of CHPIDs to channel paths depends on the system model.

Subchannel Number

A subchannel number is a 16-bit value used to address a subchannel. This value is unique within a subchannel set of a channel subsystem. The subchannel is addressed by eight I/O instructions: CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, START SUBCHANNEL, STORE SUBCHANNEL, and TEST SUBCHANNEL. All I/O functions relative to a specific I/O device are specified by the program by designating a subchannel assigned to the I/O device. Subchannels in each subchannel set are always assigned subchannel numbers within a single range of contiguous numbers. The lowest-numbered subchannel is subchannel 0. The highest-numbered subchannel of the channel subsystem has a subchannel number equal to one less than the number of subchannels provided. A maximum of 65,536 subchannels can be provided in each subchannel set. Normally, subchannel numbers are only used in communication between the CPU program and the channel subsystem.
Device Number

Each subchannel that has an I/O device assigned to it also contains a parameter called the device number. The device number is a 16-bit value that is assigned as one of the parameters of the subchannel at the time the device is assigned to the subchannel. The device number identifies a device to the program and is unique within a subchannel set of a channel subsystem.

The device number provides a means to identify a device, independent of any limitations imposed by the system model, the configuration, or channel-path protocols. The device number is used in communications concerning the device that take place between the system and the system operator. For example, the device number is entered by the system operator to designate the input device to be used for initial program loading.

**Programming Note:** The device number is assigned at device-installation time and may have any value. However, the user must observe any restrictions on device-number assignment that may be required by the control program, support programs, or the particular control unit or I/O device.

Device Identifier

A device identifier is an address, not apparent to the program, that is used by the channel subsystem to communicate with I/O devices. The type of device identifier used depends on the specific channel-path type and the protocols provided. Each subchannel contains one or more device identifiers.

For a channel path of the parallel-I/O-interface type, the device identifier is called a device address and consists of an eight-bit value. For the ESCON I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address. For the FICON I/O interface, the device identifier consists of an eight-bit control-unit-image ID and an eight-bit device address. For the FICON-converted I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address.

The device address identifies the particular I/O device (and, on the parallel-I/O interface, the control unit) associated with a subchannel. The device address may identify, for example, a particular magnetic-tape drive, disk-access mechanism, or transmission line. Any number in the range 0-255 can be assigned as a device address.

For further information about the device identifier used with a particular channel-path type, see the appropriate publication for the channel-path type.

Fibre-Channel Extensions

The fibre-channel-extensions (FCX) facility is an optional facility that provides for the formation of a channel program that is composed of a transport-control word (TCW) that designates a transport-command-control block (TCCB) and a transport-status block (TSB). The TCCB includes a transport-command area (TCA) which contains a list of up to 30 I/O commands that are in the form of device-command words (DCWs).

The FCX-bidirectional-data-transfer facility is an additional and optional facility that provides support for TCW channel programs that specify both read and write operations. Whether a device recognizes bidirectional data transfers is determined by device-dependent means.

When a device does not recognize bidirectional data transfers, a TCW and its TCCB may specify either read or a write data transfers. When a device recognizes bidirectional data transfers, a TCW and its TCCB may, depending on the device, specify both read and write data transfers. For interruptions, the TSB contains the completion status and other information related to the TCW channel program in addition to the information in the IRB.

For some devices, the list of DCWs may be extended past what will fit in the TCA. For such devices, the TCA extension (TCAX) is specified and transferred as output data. Whether a device supports TCA extensions is determined by device-dependent means.

In addition to the IRB, the TSB contains the completion status and other information related to the TCW channel program.

The FCX facility provides the ability to directly or indirectly designate any or all of the TCCB, the input data storage area, and the output data storage area.
When a storage area is designated directly, the TCW specifies the location of a single, contiguous block of storage. When a storage area is designated indirectly, the TCW designates the location of a list of one or more transport-indirect-data-address words (TIDAWs). TIDAW lists and the storage area designated by each TIDAW in a list are restricted from crossing 4K-byte boundaries.

The FCX facility also provides an interrogate operation that may be initiated by the CANCEL SUBCHANNEL instruction to determine the state of an I/O operation.

I/O-Command Words

An I/O-command word specifies a command and contains information associated with the command. When the FCX facility is installed, there are two elemental forms of I/O command words which are the channel-command word (CCW) and the device-command word (DCW).

A CCW is 8-bytes in length and specifies the command to be executed. For commands that initiate certain operations the CCW also designates the storage area associated with the operation, the count of data bytes, the action to be taken when the command completes, and other options. All I/O devices recognize CCWs.

A DCW is 8-bytes in length and specifies the command to be executed, the count of data bytes, and other options. I/O devices that support FCX recognize DCWs.

Transport Command Word (TCW)

A TCW designates a transport-command-control block (TCCB) which contains a list of commands to be transported to and executed by an I/O device. The TCW also designates the storage areas for the commands in the TCCB as well as a transport-status block (TSB) to contain the status of the I/O operation.

Channel Program Organization

When the FCX facility is not installed, there is a single form of channel program which is the CCW channel program. When the FCX facility is installed, there is an additional form of channel program which is the TCW channel program. Both forms of channel programs are described below.

CCW Channel Program

A channel program that is composed of one or more CCWs is called a CCW channel program (CCP). Such a channel program contains one or more CCWs that are logically linked and arranged for sequential execution by the channel subsystem.

Figure 13-1 shows a conceptual example of a simple CCW channel program in program storage. This channel program contains 4 CCWs and specifies the transfer of data to or from contiguous areas of storage. The first CCW designates a control command and the remaining CCWs designate the transfer of data.

![Figure 13-1. CCW Channel Program Example](image)

TCW Channel Program

A channel program that is composed of a single TCW is called a TCW channel program. A TCW designates a transport-command-control block (TCCB) that contains from 1 to 30 DCWs.

When DCWs within the TCCB are logically linked and arranged for sequential execution. For DCWs that specify control information, the TCCB also contains the control information for those commands. The TCW also designates the storage area or areas for the DCWs that specify the transfer of data from or to the device and the location of a transport-status block (TSB) for completion status. The TCCB and the storage areas for the transfer of data may be specified as either contiguous or noncontiguous storage.
Figure 13-2 shows a conceptual example of a TCW channel program in program storage. This channel program is similar to the CCW channel program in Figure 13-1. This channel program is composed of a TCW that designates a TCCB containing 4 DCWs, all of which specify the transfer of data either to or from contiguous areas of storage. The first DCW designates a control command and the remaining DCWs designate the transfer of data. The TCW also designates a TSB for completion status.

**Execution of I/O Operations**

I/O operations are initiated and controlled by information with four types of formats: the instruction START SUBCHANNEL, transport-command words, I/O-command words, and orders. The START SUBCHANNEL instruction is executed by a CPU and is part of the CPU program that supervises the flow of requests for I/O operations from other programs that manage or process the I/O data.

When START SUBCHANNEL is executed, parameters are passed to the target subchannel requesting that the channel subsystem perform a start function with the I/O device associated with the subchannel. The channel subsystem performs the start function by using information at the subchannel, including the information passed during the execution of the START SUBCHANNEL instruction, to find an accessible channel path to the device. Once the device has been selected, the execution of an I/O operation is accomplished by the decoding and execution of a CCW by the channel subsystem and the I/O device, for CCW channel programs, or for TCW channel programs, by transporting the TCCB to the I/O device by the channel subsystem and the decoding and execution of a DCW by the device. I/O-command words, and transport-command words are fetched from main storage, although the modifier bits in the command code of a CCW DCW may specify device-dependent conditions for the execution of an operation at the device.

Operations peculiar to a device, such as rewinding tape or positioning the access mechanism on a disk drive, are specified by orders that are decoded and executed by I/O devices. Orders may be transferred to the device as modifier bits in the command code of a control command, may be transferred to the device as data during a control or write operation, or may be made available to the device by other means.

**Start-Function Initiation**

CPU programs initiate I/O operations with the instruction START SUBCHANNEL. This instruction passes the contents of an operation-request block (ORB) to the subchannel.

If the ORB specifies a CCW channel program, the contents of the ORB include the subchannel key, the address of the first CCW to be executed, and a specification of the format of the CCWs. The CCW specifies the command to be executed and the storage area, if any, to be used. If the ORB specifies a TCW channel program, the contents of the ORB include the subchannel key and the address of the TCW to be executed. The TCW designates the TCCB which contains the commands to be transported to the device for execution, the storage area or areas, if any, to be used for data transfer, and the TSB to contain the status of the I/O operation.

When the ORB contents have been passed to the subchannel, the execution of START SUBCHANNEL is complete. The results of the execution of the instruction are indicated by the condition code set in the program-status word.

When facilities become available and the ORB specifies a CCW channel program, the channel subsystem fetches the first CCW and decodes it according to the format bit specified in the ORB. If the format bit is zero, format-0 CCWs are specified. If the format bit is
one, format-1 CCWs are specified. Format-0 and format-1 CCWs contain the same information, but the fields are arranged differently in the format-1 CCW so that 31-bit addresses can be specified directly in the CCW. When facilities become available and the ORB specifies a TCW channel program, the channel subsystem fetches the designated TCW and transports the designated TCCB to the device. Storage areas designated by the TCW for the transfer of data to or from the device are 64-bit addresses.

Subchannel Operation Modes
There are two modes of subchannel operation. A subchannel enters transport mode when the FCX facility is installed and the start function is set at the subchannel as the result of the execution of a START SUBCHANNEL instruction that specifies a TCW channel program. The subchannel remains in transport mode until the start function is reset at the subchannel. At all other times, the subchannel is in command mode.

Path Management
If ORB specifies a CCW channel program and the first CCW passes certain validity tests and does not have the suspend flag specified as one or if the ORB specifies a TCW channel program and the designated TCW passes certain validity tests, the channel subsystem attempts device selection by choosing a channel path from the group of channel paths that are available for selection. A control unit that recognizes the device identifier connects itself logically to the channel path and responds to its selection.

If the ORB specifies a CCW channel program, the channel subsystem sends the command-code part of the CCW over the channel path, and the device responds with a status byte indicating whether the command can be executed. The control unit may logically disconnect from the channel path at this time, or it may remain connected to initiate data transfer.

If the ORB specifies a TCW channel program, the channel subsystem uses information in the designated TCW to transfer the TCCB to the control unit. The contents of the TCCB are ignored by the channel subsystem and only have meaning to the control unit and I/O device.

If the attempted selection does not occur as a result of either a busy indication or a path-not-operational condition, the channel subsystem attempts to select the device by an alternate channel path if one is available. When selection has been attempted on all paths available for selection and the busy condition persists, the operation remains pending until a path becomes free. If a path-not-operational condition is detected on one or more of the channel paths on which device selection was attempted, the program is alerted by a subsequent I/O interruption. The I/O interruption occurs either upon execution of the channel program (assuming the device was selected on an alternate channel path) or as a result of the execution being abandoned because path-not-operational conditions were detected on all of the channel paths on which device selection was attempted.

Channel-Program Execution
If the command is initiated at the device and command execution does not require any data to be transferred to or from the device, the device may signal the end of the operation immediately on receipt of the command code. In operations that involve the transfer of data, the subchannel is set up so that the channel subsystem will respond to service requests from the device and assume further control of the operation.

An I/O operation may involve the transfer of data to or from one storage area, designated by a single CCW or TCW or to or from a number of noncontiguous storage areas. In the latter case, generally a list of CCWs is used for the execution of the I/O operation, with each CCW designating a contiguous storage area and the CCWs are coupled by data chaining. Data chaining is specified by a flag in the CCW and causes the channel subsystem to fetch another CCW upon the exhaustion or filling of the storage area designated by the current CCW. The storage area designated by a CCW fetched on data chaining pertains to the I/O operation already in progress at the I/O device, and the I/O device is not notified when a new CCW is fetched.

Provision is made in the CCW format for the programmer to specify that, when the CCW is decoded, the channel subsystem request an I/O interruption as soon as possible, thereby notifying a CPU program that chaining has progressed at least as far as that CCW in the channel program.

To complement dynamic address translation in CPUs, CCW indirect data addressing and modified CCW indirect data addressing are provided.
When the ORB specifies a CCW channel program and CCW-indirect-data addressing is used, a flag in the CCW specifies that an indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the boundary of a block of storage is reached, the list is referenced to determine the next block of storage to be used. The ORB specifies whether the size of each block of storage is 2K bytes or 4K bytes.

When the ORB specifies a CCW channel program and modified-CCW-indirect-data addressing is used, a flag in the ORB and a flag in the CCW specify that a modified-indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the count of bytes specified for a block of storage is reached, the list is referenced to determine the next block of storage to be used. Unlike when indirect data addressing is used, the block may be specified on any boundary and length up to 4K, provided a data transfer across a 4K-byte boundary is not specified.

When the ORB specifies a TCW channel program and transport-indirect-data addressing is used, flags in the TCW specify whether a transport-indirect-data-address list is to be used to designate the storage areas containing the TCCB and whether a transport-indirect-data-address list is used to designate the data storage areas associated with the DCWs in the TCCB. Each time the count of bytes specified for a block of storage is reached, the corresponding transport-indirect-data-address list is referenced to determine the next storage block to be used.

CCW indirect data addressing and modified CCW indirect data addressing permit essentially the same CCW sequences to be used for a program running with dynamic address translation active in the CPU as would be used if the CPU were operating with equivalent contiguous real storage. CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to $2^{31}$-1 independent of whether format-0 or format-1 CCWs have been specified in the ORB. Modified CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to $2^{30}$-1, independent of whether format-0 or format-1 CCWs have been specified in the ORB.

In general, the execution of an I/O operation or chain of operations involves as many as three levels of participation:

1. Except for effects due to the integration of CPU and channel-subsystem equipment, a CPU is busy for the duration of the execution of START SUBCHANNEL, which lasts until the addressed subchannel has been passed the ORB contents.

2. The subchannel is busy for a new START SUBCHANNEL from the receipt of the ORB contents until the primary interruption condition is cleared at the subchannel.

3. The I/O device is busy from the initiation of the first operation at the device until either the subchannel becomes suspended or the secondary interruption condition is placed at the subchannel. In the case of a suspended subchannel, the device again becomes busy when the execution of the suspended channel program is resumed.

**Conclusion of I/O Operations**

The conclusion of an I/O operation normally is indicated by two status conditions: channel end and device end. The channel-end condition indicates that the I/O device has received or provided all data associated with the operation and no longer needs channel-subsystem facilities. This condition is called the primary interruption condition, and the channel end in this case is the primary status. Generally, the primary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the subchannel of the I/O operation or chain of I/O operations.

The device-end signal indicates that the I/O device has concluded execution and is ready to perform another operation. This condition is called the secondary interruption condition, and the device end in this case is the secondary status. Generally, the secondary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the device of the I/O operation or chain of operations. The secondary interruption condition can occur concurrently with, or later than, the primary interruption condition.

Concurrent with the primary or secondary interruption conditions, both the channel subsystem and the I/O device can provide indications of unusual situations.

The conditions signaling the conclusion of an I/O operation can be brought to the attention of the program by I/O interruptions or, when the CPUs are dis-
abled for I/O interruptions, by programmed interrogation of the channel subsystem. In the former case, these conditions cause storing of the I/O-interruption code, which contains information concerning the interrupting source. In the latter case, the interruption code is stored as a result of the execution of TEST PENDING INTERRUPTION.

When the primary interruption condition is recognized, the channel subsystem attempts to notify the program, by means of an interruption request, that a subchannel contains information describing the conclusion of an I/O operation at the subchannel. For command-mode interruptions, the information identifies the last CCW used and may provide its residual byte count, thus describing the extent of main storage used. For transport-mode interruptions, the information identifies the current TCW and the TSB associated with the channel program that contains additional status about the I/O operation, such as residual byte count. In addition to information about the channel program, both the channel subsystem and the I/O device may provide additional indications of unusual conditions as part of either the primary or the secondary interruption condition. The information contained at the subchannel may be stored by the execution of TEST SUBCHANNEL or the execution of STORE SUBCHANNEL. This information, when stored, is called a subchannel-status word (SCSW).

**Chaining When Using a CCW Channel Program**

When the ORB specifies a CCW channel program, facilities are provided for the program to initiate the execution of a chain of I/O operations with a single START SUBCHANNEL instruction. When the current CCW specifies command chaining and no unusual conditions have been detected during the operation, the receipt of the device-end signal causes the channel subsystem to fetch a new CCW. If the CCW passes certain validity tests and the suspend flag is not specified as a one in the new CCW, execution of the new command is initiated at the device. If the CCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, and the status associated with the new CCW causes an interruption condition to be generated. If the suspend flag is specified as a one and this value is valid because of a one value in the suspend control, bit 4 of word 1 of the associated ORB, execution of the new command is not initiated, and command chaining is concluded.

Execution of the new command is initiated by the channel subsystem in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a CCW specifying command chaining are not made available to the program. When another I/O operation is initiated by command chaining, the channel subsystem continues execution of the channel program. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and the ending signals causing the termination are made available to the program.

The suspend-and-resume function provides the program with control over the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend-control bit in the ORB. The suspend function is signaled to the channel subsystem during channel-program execution when the suspend-control bit in the ORB is one and the suspend flag in the first CCW or in a CCW fetched during command chaining is one.

Suspension occurs when the channel subsystem fetches a CCW with the suspend flag validly (because of a one value of the suspend-control bit in the ORB) specified as one. The command in this CCW is not sent to the I/O device, and the device is signaled that the chain of commands is concluded. A subsequent RESUME SUBCHANNEL instruction informs the channel subsystem that the CCW that caused suspension may have been modified and that the channel subsystem must refetch the CCW and examine the current setting of the suspend flag. If the suspend flag is found to be zero in the CCW, the channel subsystem resumes execution of the chain of commands with the I/O device.

**Chaining When Using a TCW Channel Program**

When the ORB specifies a TCW channel program, facilities are also provided for the program to initiate the execution of a chain of device operations with a single START SUBCHANNEL instruction. Command chaining may be specified for those DCWs designated by a single TCW. When the current DCW specifies command chaining and no unusual conditions have been detected during the operation, recognition of the successful execution of the DCW causes the next DCW in the current TCCB to be processed.
If the next DCW passes certain validity tests, execution of a new command is initiated at the device and the DCW becomes the current DCW. If the DCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, the channel program is terminated, and the status associated with the new DCW causes an interruption condition to be generated.

Execution of the new command is initiated in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a DCW that is not the last specified DCW are not made available to the program. When another I/O operation is initiated by command chaining, execution of the channel program continues. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and status is made available to the program that identifies the unusual condition.

**Premature Conclusion of I/O Operations**

Channel-program execution may be terminated prematurely by CANCEL SUBCHANNEL, HALT SUBCHANNEL or CLEAR SUBCHANNEL. The execution of CANCEL SUBCHANNEL causes the channel subsystem to terminate the start function at the subchannel if the channel program has not been initiated at the device. When the start function is terminated by the execution of CANCEL SUBCHANNEL, the channel subsystem sets condition code 0 in response to the CANCEL SUBCHANNEL instruction. The execution of HALT SUBCHANNEL causes the channel subsystem to issue the halt signal to the I/O device and terminate channel-program execution at the subchannel. When channel-program execution is terminated by the execution of HALT SUBCHANNEL, the program is notified of the termination by means of an I/O-interruption request. When the subchannel is in command mode, the interruption request is generated when the device presents status for the terminated operation. When the subchannel is in transport mode, the interruption request is generated immediately. If, however, the halt signal was issued to the device during command chaining after the receipt of device end but before the next command was transferred to the device, the interruption request is generated after the device has been signaled. In the latter case, the device-status field of the SCSW will contain zeros. The execution of CLEAR SUBCHANNEL clears the subchannel of indications of the channel program in execution, causes the channel subsystem to issue the clear signal to the I/O device, and causes the channel subsystem to generate an I/O-interruption request to notify the program of the completion of the clear function.

**I/O Interruptions**

Conditions causing I/O-interruption requests are asynchronous to activity in CPUs, and more than one condition can occur at the same time. For I/O interruptions associated with subchannels, the conditions are preserved at the subchannels until cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL, or reset by an I/O-system reset.

When an I/O-interruption condition has been recognized by the channel subsystem and indicated at the subchannel, an I/O-interruption request is made pending for the I/O-interruption subclass specified at the subchannel. The I/O-interruption subclass for which the interruption is made pending is under programmed control through the use of MODIFY SUBCHANNEL. A pending I/O interruption may be accepted by any CPU that is enabled for interruptions from its I/O-interruption subclass. Each CPU has eight mask bits, in control register 6, that control the enablement of that CPU for each of the eight I/O-interruption subclasses, with the I/O mask, bit 6 in the PSW, being the master I/O-interruption mask for the CPU.

When an I/O interruption occurs at a CPU, the I/O-interruption code is stored in the I/O-communication area of that CPU, and the I/O-interruption request is cleared. For I/O interruptions associated with subchannels, the I/O-interruption code identifies the subchannel for which the interruption was pending. The conditions causing the generation of the interruption request associated with the subchannel may then be retrieved from the subchannel explicitly by TEST SUBCHANNEL or by STORE SUBCHANNEL.

A pending I/O-interruption request may also be cleared by TEST PENDING INTERRUPTION when the corresponding I/O-interruption subclass is enabled but the PSW has I/O interruptions disabled. For I/O interruptions associated with subchannels, a pending I/O interruption may also be cleared by TEST SUBCHANNEL when the CPU is disabled for I/O interruptions from the corresponding I/O-interruption subclass. A pending I/O-interruption request associated with a subchannel may also be cleared by CLEAR SUBCHANNEL. Both CLEAR SUBCHAN-
NEL and TEST SUBCHANNEL clear the preserved interruption condition at the subchannel as well. Normally, unless the interruption request is cleared by CLEAR SUBCHANNEL, the program issues TEST SUBCHANNEL to obtain subchannel information concerning the execution of the operation.

All the I/O instructions described here are provided for the control of channel-subsystem operations. The I/O instructions are listed in Figure 14-1 on page 14-3. All of the I/O instructions are privileged instructions.

Several I/O instructions result in the channel subsystem being signaled to perform functions asynchronous to the execution of the instructions. The description of each instruction of this type contains a section, "Associated Functions," that summarizes the asynchronous functions.

I/O-Instruction Formats

I/O instructions use the S format:

<table>
<thead>
<tr>
<th>Op Code</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>

The use of the second-operand address and general registers 1 and 2 (as implied operands) depends on the I/O instruction. Figure 14-1 on page 14-3 defines which operands are used to execute each I/O instruction. In addition, detailed information regarding operand usage appears in the description of each I/O instruction.

All I/O instructions that reference a subchannel use the contents of general register 1 as an implied operand. For these I/O instructions, general register 1 contains the subsystem-identification word (SID).

When the multiple-subchannel set (MSS) facility is installed, the format of the subsystem-identification word is as follows:

```
0 31
0 32 45 47 48 63
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 SSID1 Subchannel Number
```

Bit positions 0-31 are ignored. Bit positions 32-44 must contain zeros and bit 47 must contain 1. (Exception conditions are listed later in the section.)

Bit positions 45-46 of general register 1 contain the subchannel-set identifier (SSID) uniquely identifying a subchannel set (SS). When the multiple-subchannel-set facility is not installed, the SSID must be equal to zero. Bit positions 48-63 of general register 1 contain the binary number of the subchannel within the specified subchannel set to be used for the function specified by the instruction.

(See "Multiple-Subchannel-Set Facility" on page 17-29 for more information on SSID.)

The format of the subsystem-identification word when the MSS facility is not installed is as follows:
Bit positions 48-63 of general register 1 contain the binary number of the subchannel to be used for the function specified by the instruction. Bit positions 0-31 of general register 1 are ignored and bits 32-47 specify the binary number one.

I/O-Instruction Execution

Serialization

The execution of any I/O instruction causes a serialization and checkpoint synchronization function to occur. For a definition of the serialization of CPU operations, see “CPU Serialization” on page 128 and “Channel-Program Serialization” on page 130.

Operand Access

During the execution of an I/O instruction, the order in which fields of the operand and fields of the subchannel, if applicable, are accessed is unpredictable. It is also unpredictable whether fetch accesses are made to fields of an operand or the subchannel, as applicable, when those fields are not needed to complete the execution of the I/O instruction. (See “Relation between Operand Accesses” on page 126.)

Condition Code

During the execution of some I/O instructions, the results of certain tests are used to set one of four condition codes in the PSW. The I/O instructions for which execution can result in the setting of the condition code are listed in Figure 14-1 on page 3. The condition code indicates the result of the execution of the I/O instruction. The general meaning of the condition code for I/O instructions is given below; the meaning of the condition code for a specific instruction appears in the description of that instruction.

Condition Code 0: Instruction execution produced the expected or most probable result. (See “Deferred Condition Code (CC)” on page 9 for a description of conditions that can be encountered subsequent to the presentation of condition code 0 that result in a nonzero deferred condition code.)

Condition Code 1: Instruction execution produced the alternate or second-most-probable result, or status conditions were present that may or may not have prevented the expected result.

Condition Code 2: Instruction execution was ineffective because the designated subchannel or channel-subsystem facility was busy with a previously initiated function.

Condition Code 3: Instruction execution was ineffective because the designated element was not operational or because some condition precluded initiation of the normal function.

In situations where conditions exist that could cause more than one nonzero condition code to be set, the priority of the condition codes is as follows:

Condition code 3 has precedence over condition codes 1 and 2.

Condition code 1 has precedence over condition code 2.

Program Exceptions

The program exceptions that the I/O instructions can encounter are access, operand, privileged-operation, and specification exceptions. Figure 14-1 on page 14-3 shows the exceptions that are applicable to each of the I/O instructions. The execution of the instruction is suppressed for privileged-operation, operand, and specification exceptions. Except as indicated otherwise in the section “Special Conditions” for each instruction, the instruction ending for access exceptions is as described in “Recognition of Access Exceptions” on page 45).

Instructions

The mnemonics, format, and operation codes of the I/O instructions are given in Figure 14-1 on page 3. The figure also indicates the conditions that can cause a program interruption and whether the condition code is set.
In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For START SUBCHANNEL, for example, SSCH is the mnemonic and D₂(B₂) the operand designation.

Explanation:

* PER zero-address-detection not recognized
¢ Causes a serialization and checkpoint synchronization function.
A Access exceptions for logical addresses.
A¹ When the effective address is zero, it is not used to access storage, and no access exceptions can occur, except that access exceptions may occur during access-register translation.
B₂ B₂ field designates an access register in the access-register mode.
C Condition code is set.
G1 Instruction execution includes implied use of general register 1 as a parameter.
GM Instruction execution includes the implied use of multiple general registers.
GS Instruction execution includes the implied use of general register 1 as the subsystem-identification word.
OP Operand exception.
P Privileged-operation exception; also, restricted from transactional execution.
S S instruction format.
SP Specification exception.
ST PER storage-alteration event.

Figure 14-1. Summary of I/O Instructions

CANCEL SUBCHANNEL

XSCH [S]

The current start function, if any, is terminated at the designated subchannel if CANCEL SUBCHANNEL is applicable.

General register 1 contains a subsystem-identification word that designates the subchannel for which the current START FUNCTION, if any, is to be terminated.

If the subchannel (1) is not subchannel active, (2) is start pending, resume pending, or suspended, and (3) is performing only the start function, then the start function at the subchannel is terminated, and the subchannel is made no longer start pending, resume pending, or suspended, as appropriate. In addition, internal indications of busy are reset for the subchannel.

Condition code 0 is set to indicate that the actions described above have been taken.

If an invalid ORB field or a no-path-available condition is present for a previously initiated start function and the condition was not reported during the execution of START SUBCHANNEL, condition code 0 may
be indicated for CANCEL SUBCHANNEL provided that the subchannel is not yet status pending to report the error condition; if condition code 0 is presented, no subsequent status is generated to indicate the error condition.

During the execution of CANCEL SUBCHANNEL for a transport-mode operation, the channel subsystem may be signaled to asynchronously perform the interrogate function.

**Special Conditions**

*Condition code 1* is set, and no other action is taken, when the subchannel is status pending with any status.

*Condition code 2* is set, and no other action is taken, when CANCEL SUBCHANNEL is not applicable and the subchannel is not status pending, or when conditions exist that prevent immediate determination of internal conditions for the subchannel and the CPU has determined to end the instruction. CANCEL SUBCHANNEL is not applicable when the subchannel (1) has no function specified, (2) has a function other than the start function alone specified, (3) is not resume pending, is not start pending, and is not suspended, or (4) is subchannel active.

When the subchannel is operating in transport mode and condition code 2 is set, the CPU may signal the channel subsystem to asynchronously perform the interrogate function, and end the instruction.

*Condition code 3* is set, and no other action is taken, when the subchannel is not operational for CANCEL SUBCHANNEL. A subchannel is not operational for CANCEL SUBCHANNEL when the subchannel is not provided by the channel subsystem, has no valid device number assigned to it, or is not enabled.

CANCEL SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

**Resulting Condition Code:**

- 0 Start function canceled
- 1 Status pending
- 2 CANCEL SUBCHANNEL not applicable
- 3 Not operational

**Program Exceptions:**

- Operand
- Privileged operation
- Transaction constraint

**Programming Notes:**

1. The actions taken by CANCEL SUBCHANNEL are completed during the execution of the instruction.

   If condition code 0 is presented, there is no subsequent I/O interruption resulting from the terminated I/O operation. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device.

   Condition code 2 may be presented to indicate that the CPU has determined to end the instruction because the internal conditions of the specified subchannel cannot be immediately determined. Subsequent execution of STORE SUBCHANNEL may store an SCSW indicating that CANCEL SUBCHANNEL is applicable (i.e., the subchannel is performing the start function alone, is start pending, resume pending, or suspended, and is not subchannel-active). In such a case, the program can either recognize that the I/O operation has not been terminated and allow the operation to start or the program can retry CANCEL SUBCHANNEL in an attempt to terminate the start function. However, retrying CANCEL SUBCHANNEL does not guarantee that the instruction will end with condition code 0.

   In transport mode, condition code 2 may be presented to indicate that the CPU has determined to asynchronously signal the channel subsystem to perform the interrogate function, and end the
instruction. The LPUM must contain a nonzero value for the interrogate to be initiated.

2. Upon the completion of CANCEL SUBCHANNEL with condition code 0, the subchannel is ready to accept a new start function initiated by START SUBCHANNEL.

CLEAR SUBCHANNEL

The designated subchannel is cleared, the current start or halt function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the clear function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel to be cleared.

If a start or halt function is in progress, it is terminated at the subchannel.

The subchannel is made no longer status pending. All activity, as indicated in the activity-control field of the SCSW, is cleared at the subchannel, except that the subchannel is made clear pending. Any functions in progress, as indicated in the function-control field of the SCSW, are cleared at the subchannel, except for the clear function that is to be performed because of the execution of this instruction.

The channel subsystem is signaled to asynchronously perform the clear function. The clear function is summarized below in the section “Associated Functions” and is described in detail in “Clear Function” on page 14.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem asynchronously performs the clear function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the clear signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending. Conditions encountered by the channel subsystem that preclude issuing the clear signal to the device do not prevent the subchannel from becoming status pending (see “Clear Function” on page 14).

When the subchannel becomes status pending as a result of performing the clear function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the clear-function bit stored as one. If the channel subsystem can determine that the clear signal was issued to the device, the clear-pending bit is stored as zero in the SCSW. Otherwise, the clear-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 6.)

Measurement data is not accumulated, and device-connect time is not stored in the extended-status word for the subchannel, for a start function that is terminated by CLEAR SUBCHANNEL.

Special Conditions

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for CLEAR SUBCHANNEL. A subchannel is not operational for CLEAR SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

CLEAR SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.
Resulting Condition Code:

- Privileged operation
- Transaction constraint

HALT SUBCHANNEL

The current start function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the halt function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word that designates the subchannel to be halted.

If a start function is in progress, it is terminated at the subchannel.

The subchannel is made halt pending, and the halt function is indicated at the subchannel.

When HALT SUBCHANNEL is executed and the designated subchannel is subchannel-and-device active and status pending with intermediate status, the status-pending indication is eliminated (see the discussion of bits 24, 25, and 28 in “Activity Control (AC)” on page 14). The status-pending condition is reestablished as part of the halt function (see the section “Associated Functions” below).

The channel subsystem is signaled to asynchronously perform the halt function. The halt function is summarized below in the section “Associated Functions” and is described in detail in “Halt Function” on page 16.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem asynchronously performs the halt function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the halt signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending.

When the subchannel becomes status pending as a result of performing the halt function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the halt-function bit stored as one. If the halt signal was issued to the device, the halt-pending bit is stored as zero. Otherwise, the halt-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 6, and “Halt Function” on page 16.)

On some models, path availability is tested as part of the halt function instead of as part of the execution of the instruction. In these models, when no channel path is available for selection, the halt signal is not issued, and the subchannel is made status pending. When the status-pending condition is subsequently cleared by TEST SUBCHANNEL, the halt-pending bit is stored as one in the SCSW.

If a status-pending condition is eliminated during the execution of HALT SUBCHANNEL, then this condition is reestablished along with the other status conditions when the completion of the halt function is indicated to the program.

The halt-pending condition may not be recognized by the channel subsystem if a status-pending condition has been generated. This situation could occur, for example, when alert status is presented or generated while the subchannel is already start pending or resume pending, or when primary status is presented during the attempt to initiate the I/O operation for the first command as specified by the start function or implied by the resume function. If recognition of the status-pending condition by the channel subsystem has occurred logically prior to recognition of the halt-pending condition, the SCSW, when cleared by TEST SUBCHANNEL, has the halt-pending bit stored as one.
If measurement data is being accumulated when a start function is terminated by HALT SUBCHANNEL, the measurement data continues to be accumulated for the subchannel and reflects the extent of subchannel and device usage required, if any, while performing the currently terminated start function. The measurement data, if any, is accumulated in the measurement block for the subchannel or placed in the extended-status word, as appropriate, when the subchannel becomes status-pending with primary or secondary status. (See “Channel-Subsystem Monitoring” on page 1.)

Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending alone or is status pending with any combination of alert, primary, or secondary status.

**Condition code 2** is set, and no other action is taken, when the subchannel is busy for HALT SUBCHANNEL. The subchannel is busy for HALT SUBCHANNEL when a halt function or clear function is already in progress at the subchannel.

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for HALT SUBCHANNEL. A subchannel is not operational for HALT SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled. On some models, a subchannel is also not operational for HALT SUBCHANNEL when no channel path is available for selection by the device. (See “Channel-Path Availability” on page 13 for a description of channel paths that are available for selection.)

HALT SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

**Resulting Condition Code:**

0   Function initiated
1   Status pending with other than intermediate status
2   Busy
3   Not operational

**Program Exceptions:**

- Operand
- Privileged operation
- Transaction constraint

**Programming Note:** After the execution of HALT SUBCHANNEL, the status-pending condition indicating the completion of the halt function may be delayed for an extended period of time, for example, when the device is a magnetic-tape unit executing a rewind command.

**MODIFY SUBCHANNEL**

The information contained in the subchannel-information block (SCHIB) is placed in the program-modifiable fields at the subchannel. As a result, the program influences, for that subchannel, certain aspects of I/O processing relative to the clear, halt, resume, and start functions and certain I/O support functions.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel that is to be modified as specified by certain fields of the SCHIB. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The channel-subsystem operations that may be influenced due to placement of SCHIB information in the subchannel are:

- I/O processing (E field)
- Interruption processing (interruption parameter and ISC field)
- Path management (D, LPM, and POM fields)
• Monitoring and address-limit checking (measurement-block index, LM, and MM fields)
• Measurement-block-format control (F field)
• Extended-measurement-word-mode enable (X field)
• Concurrent-sense facility (S field)
• Measurement-block address (MBA)

Bits 0, 1, 6, and 7 of word 1, and bits 0-28 of word 6 of the SCHIB operand must be zeros, and bits 9 and 10 of word 1 must not both be ones. When the extended-I/O-measurement-block facility is installed and a format-1 measurement block is specified, bits 26-31 of word 11 must be specified as zeros. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized.

Condition code 0 is set to indicate that the information from the SCHIB has been placed in the program-modifiable fields at the subchannel, except that, when the device-number-valid bit (V) at the designated subchannel is zero, then condition code 0 is set, and the information from the SCHIB is not placed in the program-modifiable fields.

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending. (See “Status Control (SC)” on page 17.)

Condition code 2 is set, and no other action is taken, when a clear, halt, or start function is in progress at the subchannel. (See “Function Control (FC)” on page 13.)

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for MODIFY SUBCHANNEL. A subchannel is not operational for MODIFY SUBCHANNEL when the subchannel is not provided in the channel subsystem.

In word 1 of the SCHIB, bits 0, 1, 6, and 7 must be zeros and, when the address-limit-checking facility is installed, bits 9 and 10 must not both be ones. In word 6 of the SCHIB, bits 0-28 must be zeros. Otherwise an operand exception is recognized.

When the extended-I/O-measurement-block facility is installed and a format-1 measurement block is specified, bits 26-31 of word 11 must be specified as zeros; otherwise, an operand exception is recognized. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of MODIFY SUBCHANNEL is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 Function completed
1 Status pending
2 Busy
3 Not operational

Program Exceptions:

• Access (fetch, operand 2)
• Operand
• Privileged operation
• Specification
• Transaction constraint
Programming Notes:

1. If a device signals I/O-error alert while the associated subchannel is disabled, the channel subsystem issues the clear signal to the device and discards the I/O-error-alert indication without generating an I/O-interruption condition.

2. If a device presents unsolicited status while the associated subchannel is disabled, that status is discarded by the channel subsystem without generating an I/O-interruption condition. However, if the status presented contains unit check, the channel subsystem issues the clear signal for the associated subchannel and does not generate an I/O-interruption condition. This should be taken into account when the program uses MODIFY SUBCHANNEL to enable a subchannel. For example, the medium on the associated device that was present when the subchannel became disabled may have been replaced, and, therefore, the program should verify the integrity of that medium.

3. It is recommended that the program inspect the contents of the subchannel by subsequently issuing STORE SUBCHANNEL when MODIFY SUBCHANNEL sets condition code 0. Use of STORE SUBCHANNEL is a method for determining if the designated subchannel was changed or not. Failure to inspect the subchannel following the setting of condition code 0 by MODIFY SUBCHANNEL may result in conditions that the program does not expect to occur.

RESET CHANNEL PATH

RCHP [S]

'b23b' / / / / / / / / / / / / / / /
0 16 31

The channel-path-reset facility is signaled to perform the channel-path-reset function on the channel path designated by the contents of general register 1.

The format of general register 1 is as follows:

Channel-Path Identifier (CHPID): Bit positions 56-63 of general register 1 contain an unsigned binary integer that designates the channel path on which the channel-path-reset function is to be performed.

Bit positions in general register 1 that are shown as zeros, are reserved and must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

If conditions allow, the channel-path-reset facility is signaled to asynchronously perform the channel-path-reset function on the designated channel path. The channel-path-reset function is summarized below in the section “Associated Functions” and is described in detail in “Channel-Path Reset” on page 13.

Condition code 0 is set to indicate that the channel-path-reset facility has been signaled.

Associated Functions

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset facility asynchronously performs the channel-path-reset function. Certain indications are reset at all subchannels that have access to the designated channel path, and the reset signal is issued on that channel path. Any I/O functions in progress at the devices are reset, but only for the channel path on which the reset signal is received. An I/O operation or chain of I/O operations taking place in the multipath mode may be able to continue to be executed on other channel paths in the multipath group, if any. (See “Channel-Path-Reset Function” on page 80.)

The result of performing the channel-path-reset function on the designated channel path is communicated to the program by means of a channel report (see “Channel Report” on page 24).
Special Conditions

Condition code 2 is set, and no other action is taken, when, on some models, the channel-path-reset facility is busy performing the channel-path-reset function for a previous execution of the RESET CHANNEL PATH instruction.

Condition code 3 is set, and no other action is taken, when, on some models, the designated channel path is not operational for the execution of RESET CHANNEL PATH. On these models, the channel path is not operational for the execution of RESET CHANNEL PATH when the designated channel path is not physically available.

If the channel-path-reset facility is busy and the designated channel path is not physically available, it depends on the model whether condition code 2 or 3 is set.

RESET CHANNEL PATH can encounter the program exceptions described or listed below.

Bit positions 32-55 of general register 1 must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

Resulting Condition Code:

0 Function initiated
1 —
2 Not operational
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. To eliminate the possibility of a data-integrity exposure for devices that have the capability of generating unsolicited device-end status, I/O operations in progress with such devices on the channel path for which RESET CHANNEL PATH is to be executed must be terminated by the execution of either HALT SUBCHANNEL or CLEAR SUBCHANNEL. Otherwise, subsequent to receiving the reset signal, the device may present an unsolicited device end that may be interpreted by the channel subsystem as a solicited device end and cause command chaining to occur.

2. If the status-verification facility is being used and RESET CHANNEL PATH is executed without first stopping all ongoing operations associated with the channel path being reset, erroneous device-status-check conditions may be detected

RESUME SUBCHANNEL

RSCH [S]

The channel subsystem is signaled to perform the resume function at the designated subchannel.

General register 1 contains a subsystem-identification word that designates the subchannel at which the resume function is to be performed.

The subchannel is made resume pending.

Logically prior to the setting of condition code 0 and only if the subchannel is currently in the suspended state, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the resume function. The resume function is summarized below in the section “Associated Functions” and is described in detail in “Start Function and Resume Function” on page 20.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of RESUME SUBCHANNEL, the channel subsystem asynchronously performs the resume function. Except when the subchannel is subchannel active, if the execution of RESUME SUBCHANNEL results in the setting of condition code 0, performance of the resume function causes execution of a currently suspended channel program to be resumed with the associated device, provided that the suspend flag for the current CCW has been set to zero by the program. If the suspend flag remains one, execution of the channel pro-
gram remains suspended. But, if the subchannel is subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition code 0, then it is unpredictable whether execution of the current program is resumed or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status when the resume-pending condition is recognized by the channel sub-system. (See “Start Function and Resume Function” on page 20.)

Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending.

**Condition code 2** is set, and no other action is taken, when the resume function is not applicable. The resume function is not applicable when the subchannel (1) has any function other than the start function alone specified, (2) has no function specified, (3) is resume pending, or (4) does not have suspend control specified for the start function in progress.

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for the resume function. A subchannel is not operational for the resume function if the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

RESUME SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Function initiated</td>
</tr>
<tr>
<td>1</td>
<td>Status pending</td>
</tr>
<tr>
<td>2</td>
<td>Function not applicable</td>
</tr>
<tr>
<td>3</td>
<td>Not operational</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Operand
- Privileged operation
- Transaction constraint

**Programming Notes:**

1. When channel-program execution is resumed from the suspended state, the device views the resumption as the beginning of a new chain of commands. When the suspension of channel-program execution occurs and the device requires that certain commands be first or appear only once in a chain of commands (for example, direct-access-storage devices), the program must ensure that the appropriate commands in the proper sequence are fetched by the channel subsystem after channel-program execution is resumed. One way the program can ensure proper sequencing of commands at the device is by allowing the I/O interruption to occur for an intermediate interruption condition due to suspension.

   It is not reliable to notify the program that the subchannel is suspended by using the PCI flag in the CCW that contains the S flag because the PCI I/O interruption may occur before the subchannel is suspended. The SCSW would indicate that an I/O operation is in progress at the subchannel and device in this case.

   The suspend flag of the target CCW should be set to zero before RESUME SUBCHANNEL is executed; otherwise, it is possible that the resume-pending condition may be recognized and the CCW refetched while the suspend flag is still one, in which case the resume-pending condition would be reset, and the execution of the channel program would be suspended. If the suspend flag of the target CCW is set to zero before the execution of RESUME SUBCHANNEL, the channel program is not suspended, provided that the subchannel is not subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition
code 0. If condition code 0 is set while the subchannel is still subchannel active, it is unpredictable whether the resume-pending condition is recognized by the channel subsystem or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status at the time the resume-pending condition is recognized. When the subchannel is suspended, the execution of TEST SUBCHANNEL, which clears the intermediate interruption condition, also clears the indication of resume pending.

2. Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched having an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

3. Path availability is not tested during the execution of RESUME SUBCHANNEL. Instead, path availability is tested when the channel subsystem begins performance of the resume function.

4. The contents of the CCW fetched during performance of the resume function may be different from the contents of the same CCW when it was previously fetched and contained an S flag validly set to one.

**SET ADDRESS LIMIT**

```
SAL "B237" //////////////////////////////////////////////////////////
0 16 31
```

The address-limit-checking facility is signaled to use the specified address as the address-limit value, and the specified address is passed to the facility. Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for operand exception and privileged-operation exception, and then is suppressed.

When the address-limit-checking facility is installed, or the FCX facility is installed, the SET ADDRESS LIMIT instruction is not provided.

General register 1 contains the absolute address to be used as the address-limit value. The specified address must be on a 64K-byte boundary and may designate a maximum absolute storage address of 2,147,418,112 (7FFF0000 hex) regardless of whether the CPU is operating in the 24-bit, 31-bit, or 64-bit addressing mode. Bits 0-31 of general register 1 are ignored, and bit 32 must be zero.

General register 1 has the following format:

```
0 ////////////////////////////////////////////////////////// 31
0 Address-Limit Value
32 ////////////////////////////////////////////////////////// 63
```

Associated Functions

The value that is used by the address-limit-checking facility when determining whether to permit or prohibit a data access is called the address-limit value. The initial address-limit value is zero. The initial address-limit value is used by the address-limit-checking facility until the facility recognizes a signal, caused by the execution of SET ADDRESS LIMIT, to use a specified address. The recognition of this specified address as the new address-limit value occurs asynchronously with respect to the execution of SET ADDRESS LIMIT.

If address-limit checking is specified for a subchannel, then whether the specified address is used by the address-limit-checking facility, when determining whether to permit or prohibit a data access, depends on whether SET ADDRESS LIMIT was executed before, during, or after the execution of START SUBCHANNEL for that subchannel. If SET ADDRESS LIMIT is executed before START SUBCHANNEL, the specified address is used by the address-limit-checking facility. If SET ADDRESS LIMIT is executed during or after the execution of START SUBCHANNEL, it is unpredictable whether the specified address is used by the address-limit-checking facility for that particular start function. For a description of the manner in which address-limit checking is performed, see “Address-Limit Checking” on page 22.
Special Conditions

SET ADDRESS LIMIT can encounter the program exceptions described or listed below.

The address in general register 1 must be designated on a 64K byte boundary, and bit 32 of general register 1 must be zero; otherwise, an operand exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

SET CHANNEL MONITOR

SCHM [S]

Each of the measurement-block-update mode and device-connect-time-measurement mode of the channel subsystem is made either active or inactive, depending on the values of the measurement-mode-control bits in general register 1. If the measurement-mode-control bit for measurement-block update is one, the measurement-block origin and measurement-block key are passed to the channel subsystem.

General register 1 has the following format:

```
| 0 | 1 | MBK | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
|   |   |     |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
```

Ignored: Bit positions 0-31 of general register 1 are ignored.

Measurement-Block Key (MBK): Bit positions 32-35 of general register 1 contain the measurement-block key. When bit 62 is one, MBK specifies the access key that is to be used by the channel subsystem when it accesses the measurement-block area and, when the extended-I/O-measurement-block facility is installed, to access format-1 measurement blocks. Otherwise, MBK is ignored.

Measurement-Block-Update Control (M): Bit 62 of general register 1 is the measurement-mode-control bit that controls the measurement-block-update mode. When bit 62 of general register 1 is one and conditions allow, the measurement-block-update facility is signaled to asynchronously make the measurement-block-update mode active. In addition, the measurement-block-origin (MBO) address in general register 2 and the measurement-block key (MBK) in general register 1 are passed to the measurement-block-update facility.

The measurement-block origin is used to determine the location of format-0 measurement blocks; the address of format-1 measurement blocks is stored at the subchannel using MODIFY SUBCHANNEL. The measurement-block key is used to access both format-0 and format-1 measurement blocks. The asynchronous functions that are performed by the measurement-block-update facility are summarized below in the section “Associated Functions” and are described in detail in “Channel-Subsystem Monitoring” on page 1.

When bit 62 of general register 1 is zero and conditions allow, the measurement-block-update mode is made inactive if it is active or remains inactive if it is inactive. The contents of bit positions 32-35 (MBK) of general register 1 and the contents of general register 2 are ignored.

Device-Connect-Time-Measurement Control (D): Bit 63 of general register 1 is the measurement-mode-control bit (D). When bit 63 is one and conditions allow, the device-connect-time-measurement mode is made active if it is inactive or remains active if it is active. When bit 63 is zero and conditions allow, the device-connect-time-measurement mode is made inactive if it is active or remains inactive if it is inactive.

Bit positions 36-61 of general register 1 are reserved and must contain zeros; otherwise, an operand exception is recognized.

General register 2 has the following format:
**SET CHANNEL MONITOR**

**Measurement-Block-Origin (MBO) Address:**
When bit 62 (M) of general register 1 is one, bit positions 0-63 of general register 2 contain the absolute address of the measurement-block origin (MBO), which is the beginning of the measurement-block area. The MBO address is used by the channel subsystem to locate format-0 measurement blocks. The origin of the measurement-block area must be designated on a 32-byte boundary otherwise, an operand exception is recognized. When bit 62 of general register 1 is zero, the contents of general register 2 are ignored.

If the channel-subsystem timer that is used by the channel-subsystem-monitoring facilities is in the error state, the state is reset. This happens independent of the setting of the two measurement-mode-control bits. (See “Channel-Subsystem Timing” on page 2 for a description of the timing facilities.)

**Associated Functions**

When the measurement-block-update facility is signaled (by means of SET CHANNEL MONITOR) to make the measurement-block-update mode active, the functions that are performed by the facility depend on whether or not the mode is already active when the signal is generated.

If the measurement-block-update mode is inactive when the signal is generated, the mode remains inactive until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the measurement-block-update mode is made active, and the MBK that was passed when the signal was generated is used to access all measurement blocks, and the MBO that was passed when the signal was generated is used to determine the address of format-0 measurement blocks.

If the measurement-block-update mode is active when the signal is generated, the mode remains active, and the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction continue to be used to control the storing of measurement data until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the MBK and MBO associated with that signal are used instead of the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction. The SET CHANNEL MONITOR instruction does not affect the measurement-block address used for format-1 measurement blocks, but the MBK associated with the signal becomes the key used to access the measurement block.

In all above cases, the measurement-block-update facility recognizes the signal during, or subsequent to, the execution of the SET CHANNEL MONITOR instruction that caused the signal to be generated and logically prior to the performance of any start function that is initiated by the subsequent execution of START SUBCHANNEL for a subchannel that is enabled for measurement by this facility. If a subchannel that is enabled for measurement by this facility already has a start function in progress when the signal is generated, it is unpredictable when measurement data for that subchannel is stored by using the MBK and MBO associated with that signal.

While the measurement-block-update mode is active, performance measurements are accumulated for subchannels that are enabled for measurement-block update. Measurements for a subchannel are either accumulated in a single 32-byte format-0 measurement block within the measurement-block area, or a 64-byte format-1 measurement block pointed to by the measurement-block address at the subchannel. A subchannel is enabled for the measurement-block-update mode by setting the measurement-block-update-enable bit to one in the SCHIB and then executing the MODIFY SUBCHANNEL instruction for that subchannel. The measurement-block-format-control bit (F) at the subchannel specifies whether a format-0 or format-1 measurement block is stored for a subchannel when the measurement-block-update mode is active and the subchannel is enabled for measurement-block updates. When the F bit is zero, the MBO and MBI are used to determine the address of format-0 measurement blocks. When the F bit is one, the measurement-block-address field at the subchannel contains the address of the measurement block for the subchannel, and a format-1 measurement block is stored. The F bit and measurement-block-address field are modified using the MODIFY SUBCHANNEL instruction.

When the device-connect-time-measurement mode is active, measurements of the length of time that the
device is actively communicating with the channel subsystem during the execution of a channel program are accumulated for subchannels that are enabled for device-connect-time measurement. Measurements for a subchannel are provided in the extended-status word ESW of the IRB. A subchannel is enabled for device-connect-time-measurement mode by setting the device-connect-time-measurement-enable bit to one in the SCHIB and then executing MODIFY SUBCHANNEL for that subchannel.

For a more detailed description of the measurement-block-update mode, the format and contents of the measurement block, and the device-connect-time-measurement mode, see “Channel-Subsystem Monitoring” on page 1.

Special Conditions

SET CHANNEL MONITOR can encounter the program exceptions described or listed below.

Bits 36-61 of general register 1 must be zeros. When bit 62 (M) of general register 1 is one, the MBO address in general register 2 must be designated on a 32-byte boundary. Otherwise, an operand exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Note: When the channel subsystem is initialized, the measurement-block-update and device-connect-time-measurement modes are made inactive.

START SUBCHANNEL

<table>
<thead>
<tr>
<th>SSCH</th>
<th>D2(B2)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textbf{B233}</td>
<td>B2</td>
<td>D2</td>
</tr>
</tbody>
</table>

The channel subsystem is signaled to asynchronously perform the start function for the associated device, and the execution parameters that are contained in the designated ORB are placed at the designated subchannel. (See “Operation-Request Block” on page 24.)

General register 1 contains a subsystem-identification word that designates the subchannel to be started. The second-operand address is the logical address of the ORB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution parameters contained in the ORB are placed at the subchannel.

When START SUBCHANNEL is executed, the subchannel is status pending with only secondary status, and the extended-status-word-format bit (L) is zero, the status-pending condition is discarded at the subchannel.

The subchannel is made start pending, and the start function is indicated at the subchannel. If the second operand designates a command-mode ORB, the subchannel remains in command mode. If the second operand designates a transport-mode ORB, the subchannel enters transport mode. When the subchannel enters transport mode, the LPUM is set to zero if no previous dedicated allegiance exists; otherwise the LPUM is not changed.

Logically prior to the setting of condition code 0, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the start function. The start function is summarized below in the section “Associated Functions” and is described in detail in “Start Function and Resume Function” on page 20.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of START SUBCHANNEL, the channel subsystem asynchronously performs the start function.

The contents of the ORB, other than the fields that must contain all zeros, are checked for validity. On some models, the fields of the ORB that must contain zeros are checked asynchronously, instead of during the execution of the instruction. When invalid fields are detected asynchronously, the subchannel
and alert status and with deferred condition code 1 and program check indicated. (See “Program Check” on page 25.) In this situation, the I/O operation or chain of I/O operations is not initiated at the device, and the condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL. (See “Sub-channel-Status Word” on page 7).

On some models, path availability is tested asynchronously, instead of during the execution of the instruction. When no channel path is available for selection, the subchannel becomes status pending with primary and secondary status and with deferred condition code 3 indicated. The I/O operation or chain of I/O operations is not initiated at the device, and this condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL.

If conditions allow, a channel path is chosen, and execution of the channel program that is designated in the ORB is initiated. (See “Start Function and Resume Function” on page 20.)

Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending when START SUBCHANNEL is executed. On some models, condition code 1 is not set when the subchannel is status pending with only secondary status; instead, the status-pending condition is discarded.

**Condition code 2** is set, and no other action is taken, when a start, halt, or clear function is currently in progress at the subchannel (see “Function Control (FC)” on page 13).

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for START SUBCHANNEL. A subchannel is not operational for START SUBCHANNEL if the subchannel is not provided in the channel subsystem, has no valid device number associated with it, or is not enabled.

A subchannel is also not operational for START SUBCHANNEL, on some models, when no channel path is available for selection. On these models, the lack of an available channel path is detected as part of the START SUBCHANNEL execution. On other models, channel-path availability is only tested as part of the asynchronous start function.

START SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the command-mode ORB, bits 26-30 must be zeros, and, in word 2 of the command-mode ORB, bit 0 must be zero. Otherwise, on some models, an operand exception is recognized. On other models, an I/O-interruption condition is generated, indicating program check, as part of the asynchronous start function.

START SUBCHANNEL can also encounter the program exceptions listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of START SUBCHANNEL is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:**

<table>
<thead>
<tr>

</tr>
<tr>
<td>0</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>
Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for privileged operation exception and the instruction is suppressed by the machine.

A channel-path-status word of up to 256 bits is stored at the designated location.

The second-operand address is the logical address of the location where the channel-path-status word is to be stored and must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The channel-path-status word indicates which channel paths are actively communicating with a device at the time STORE CHANNEL PATH STATUS is executed. Bit positions 0-255 correspond, respectively, to the channel paths having the channel-path identifiers 0-255. Each of the 256 bits at the designated location is set to one, set to zero, or left unchanged, as follows:

- For all channel paths in the configuration that are actively communicating with devices at the time STORE CHANNEL PATH STATUS is executed, the corresponding bits are stored as ones.
- For all channel paths that are (1) provided in the system (PIM bit in the PMCW is one) and (2) in the configuration but not currently being used by the channel subsystem in actively communicating with devices, the corresponding bits are stored as zeros.
- For all channel paths that are not provided in the system (PIM bit in the PMCW is zero), the corresponding bits either are not stored or are stored as zeros.
- For all channel paths in the configuration that are in the channel-path-terminal state or are not physically available (the corresponding PAM bit in the PMCW is zero), the corresponding bits are stored as zeros.

Special Conditions

STORE CHANNEL PATH STATUS can encounter the program exceptions described or listed below.

The second operand must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL PATH STATUS is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

**Programming Notes:**

1. To ensure a consistent interpretation of channel-path-status-word bits, the program should, prior to the initial use of the area, store zeros at the location where the channel-path-status word is to be stored.

**STORE CHANNEL REPORT WORD**

A CRW containing information affecting the channel subsystem is stored at the designated location.

The second-operand address is the logical address of the location where the CRW is to be stored and must be designated on a word boundary; otherwise, a specification exception is recognized.

When a malfunction or other condition affecting channel-subsystem operation is recognized, a channel report (consisting of one or more CRWs) describing the condition is made pending for retrieval and analysis by the program. The channel report contains information concerning the identity and state of a facility following the detection of the malfunction or other condition. For a description of the channel report, the CRW, and program-recovery actions related to the channel subsystem, see “Channel-Subsystem Recovery” on page 24.

When one or more channel reports are pending, the instruction causes a CRW to be stored at the designated location and condition code 0 to be set. A pending CRW can only be stored by the execution of STORE CHANNEL REPORT WORD and, once
STORE SUBCHANNEL

STORE SUBCHANNEL

STSCH D_{j(B_2)} [S]

Control and status information for the designated subchannel is stored in the designated SCHIB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

When the extended-I/O-measurement-block facility is not installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, and three words of model-dependent information. When the extended-I/O-measurement-block facility is installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, the measurement-block-address field, and one word of model-dependent information. (See “Subchannel-Information Block” on page 2.)

The execution of STORE SUBCHANNEL does not change any information at the subchannel.

Condition code 0 is set to indicate that control and status information for the designated subchannel has been stored in the SCHIB. When the execution of STORE SUBCHANNEL results in the setting of condition code 0, the information in the SCHIB indicates a consistent state of the subchannel.

Special Conditions

Condition code 3 is set, and no other action is taken, when the designated subchannel is not operational for STORE SUBCHANNEL. A subchannel is not operational for STORE SUBCHANNEL if the subchannel is not provided in the channel subsystem.

STORE SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. If the overflow condition is encountered, one or more channel-report words have been lost. (See “Channel-Subsystem Recovery” on page 24 for details.)

2. A pending CRW can be cleared by any CPU in the configuration executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU.

Special Conditions

STORE SUBCHANNEL REPORT WORD can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of STORE SUBCHANNEL REPORT WORD is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0  CRW stored
1  Zeros stored
2  —
3  —

Program Exceptions:

• Access (store, operand 2)
• Privileged operation
• Specification
• Transaction constraint

Programming Notes:

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. Thus, each pending CRW is presented only once to the program.

When no channel reports are pending in the channel subsystem execution of STORE CHANNEL REPORT WORD causes zeros to be stored at the designated location and condition code 1 to be set.

Special Conditions

STORE SUBCHANNEL REPORT WORD can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL REPORT WORD is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0  CRW stored
1  Zeros stored
2  —
3  —

Program Exceptions:

• Access (store, operand 2)
• Privileged operation
• Specification
• Transaction constraint

Programming Notes:

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. Thus, each pending CRW is presented only once to the program.

When no channel reports are pending in the channel subsystem execution of STORE CHANNEL REPORT WORD causes zeros to be stored at the designated location and condition code 1 to be set.

Special Conditions

STORE SUBCHANNEL REPORT WORD can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL REPORT WORD is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0  CRW stored
1  Zeros stored
2  —
3  —

Program Exceptions:

• Access (store, operand 2)
• Privileged operation
• Specification
• Transaction constraint

Programming Notes:

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. Thus, each pending CRW is presented only once to the program.

When no channel reports are pending in the channel subsystem execution of STORE CHANNEL REPORT WORD causes zeros to be stored at the designated location and condition code 1 to be set.
When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SCHIB stored</td>
</tr>
<tr>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>2</td>
<td>—</td>
</tr>
<tr>
<td>3</td>
<td>Not operational</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

**Programming Notes:**

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.

2. The information that is stored in the SCHIB is obtained from the subchannel. The STORE SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.

3. STORE SUBCHANNEL may be executed at any time to sample conditions existing at the subchannel, without causing any pending status conditions to be cleared.

4. Repeated execution of STORE SUBCHANNEL without an intervening delay (for example, to determine when a subchannel changes state) should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit access of the subchannel by a channel subsystem to update the subchannel.

---

**TEST PENDING INTERRUPTION**

<table>
<thead>
<tr>
<th>TPI</th>
<th>D(B2)</th>
<th>[S]</th>
</tr>
</thead>
<tbody>
<tr>
<td>'B236'</td>
<td>B2</td>
<td>D2</td>
</tr>
</tbody>
</table>

0  | 16  | 20  | 31  |

The I/O-interruption code for a pending I/O interruption at a subchannel is stored at the location designated by the second-operand address, and the pending I/O-interruption request is cleared.

The second-operand address, when nonzero, is the logical address of the location where the two-word I/O-interruption code, consisting of words 0 and 1, is to be stored. The second-operand address must be designated on a word boundary; otherwise, a specification exception is recognized.

If the second-operand address is zero, the three-word I/O-interruption code, consisting of words 0-2, is stored at real locations 184-195. In this case, low-address protection and key-controlled protection do not apply.

In the access-register mode when the second-operand address is zero, it is unpredictable whether access-register translation occurs for access register B2. If the translation occurs, the resulting address-space-control element is not used; that is, the interruption code still is stored at real locations 184-195.

Pending I/O-interruption requests are accepted only for those I/O-interruption subclasses allowed by the I/O-interruption-subclass mask in control register 6 of the CPU executing the instruction. If no I/O-interruption requests exist that are allowed by control register 6, the I/O-interruption code is not stored, the second-operand location is not modified, and condition code 0 is set.

If a pending I/O-interruption request is accepted, the I/O-interruption code is stored, the pending I/O-interruption request is cleared, and condition code 1 is set. The I/O-interruption code that is stored is the same as would be stored if an I/O interruption had occurred. However, PSWs are not swapped as when an I/O-interruption occurs.
The I/O-interruption code that is stored during the execution of the instruction is defined as follows:

<table>
<thead>
<tr>
<th>Word</th>
<th>Subsystem-Identification Word</th>
<th>Interruption Parameter</th>
<th>Interruption-Identification Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>31</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Subsystem-Identification Word (SID):
Bits 32-63 of the SID are placed in word 0.

See “I/O-Instruction Formats” in Chapter 14.

Interruption Parameter: Word 1 contains a four-byte parameter that was specified by the program and passed to the subchannel in word 0 of the ORB or the PMCW. When a device presents alert status and the interruption parameter was not previously passed to the subchannel by an execution of START SUBCHANNEL or MODIFY SUBCHANNEL, this field contains zeros.

Interruption-Identification Word: Word 2, when stored, contains the interruption-identification word, which further identifies the source of the I/O-interruption. Word 2 is stored only when the second-operand address is zero.

The interruption-identification word is defined as follows:

A bit (A)Bit 0 of the interruption-identification word specifies the type of pending I/O-interruption request that was cleared. When bit 0 is zero, the I/O-interruption request was associated with a subchannel.

I/O-Interruption Subclass (ISC): Bit positions 2-4 of the interruption-identification word contain an unsigned binary integer, in the range 0-7, that specifies the I/O-interruption subclass associated with the subchannel for which the pending I/O-interruption request was cleared.

The remaining bit positions are reserved and stored as zeros.

Reserved: Bits 8-14 and 15-31 of word 0 and all of word 1 are reserved and stored as zeros.

Special Conditions

TEST PENDING INTERRUPTION can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of TEST PENDING INTERRUPTION is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

<table>
<thead>
<tr>
<th></th>
<th>Interruption code not stored</th>
<th>Interruption code stored</th>
<th>—</th>
<th>—</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Program Exceptions:

- Access (store, operand 2, second-operand address nonzero only)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. TEST PENDING INTERRUPTION should only be executed with a second-operand address of zero when I/O interruptions are masked off. Otherwise, an I/O-interruption code stored by the instruction may be lost if an I/O interruption occurs. The I/O-interruption code that identifies the source of an I/O interruption taken subsequent to TEST PENDING INTERRUPTION is also stored at real locations 184-195, replacing an I/O-interruption code that was stored by the instruction.

2. In the access-register mode when the second-operand address is zero, an access exception is recognized if access-register translation occurs and the access register is in error. This exception can be prevented by making the B2 field zero or by placing 00000000 hex, 00000001 hex, or any other valid contents in the access register.
Control and status information for the subchannel is stored in the designated IRB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operator address is the logical address of the IRB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The information that is stored in the IRB consists of a SCSW, an extended-status word, and an extended-control word. (See “Interruption-Response Block” on page 6.)

If the subchannel is status pending, the status-pending bit of the status-control field is stored as one. Whether or not the subchannel is status pending has an effect on the functions that are performed when TEST SUBCHANNEL is executed.

When the subchannel is status pending and TEST SUBCHANNEL is executed, information, as described above, is stored in the IRB, followed by the clearing of certain conditions and indications that exist at the subchannel as described in Figure 14-2 on page 21. If the subchannel is in transport mode, the clearing of these conditions, specifically the start function, places the subchannel in command mode. (See Figure 14-2 on page 21. If an I/O-interruption request is pending for the subchannel, the request is cleared. Condition code 0 is set to indicate that these actions have been taken.

When the subchannel is not status pending and TEST SUBCHANNEL is executed, information (as described above) is stored in the IRB, and no conditions or indications are cleared. Condition code 1 is set to indicate that these actions have been taken.

Figure 14-2 on page 21 describes which conditions and indications are cleared by TEST SUBCHANNEL when the subchannel is status pending. All other conditions and indications at the subchannel remain unchanged.

CM  Command-Mode Operation
TM  Transport-Mode Operation

* Note that the rightmost column applies to status pending when it is alone. The other four status-pending conditions result in the clearing actions given. These actions apply both when a single status-pending condition occurs and when a combination of the four status-pending conditions occurs. In the combination case, all the clearing actions of the individual cases apply.

C  Cleared.
Nm  Not reset or modified by TEST SUBCHANNEL.
Cp  The resume-, start-, halt-, clear pending, and suspended conditions are cleared.
Cs  The status-pending condition is cleared.
Nc  Not changed unless function control indicates the halt function and activity control indicates suspended. If both the halt function and suspended are indicated, conditions are cleared as for status pending alone.
Nr  Not changed unless activity control indicates suspended and function control indicates the start function with or without the halt function. If the halt function is indicated, the conditions are cleared as for status pending alone. If only the start function is indicated, the resume-pending condition and the N condition are cleared.

Note: The clearing of certain subchannel conditions, places the subchannel in command mode. A subchannel in the idle state, or with the function control bits zero is considered to be in command-mode.

Figure 14-2. Conditions and Indications Cleared at the Subchannel by TEST SUBCHANNEL

Special Conditions

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for TEST SUBCHANNEL. A subchannel is not operational for TEST SUBCHANNEL if the subchannel is...
not provided, has no valid device number associated with it, or is not enabled.

TEST SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 00001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

When the execution of TEST SUBCHANNEL is terminated on addressing and protection exceptions, the state of the subchannel is not changed.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>IRB stored; subchannel status pending</td>
</tr>
<tr>
<td>1</td>
<td>IRB stored; subchannel not status pending</td>
</tr>
<tr>
<td>2</td>
<td>—</td>
</tr>
<tr>
<td>3</td>
<td>Not operational</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification

The priority of recognition of program exceptions for the instruction is shown in Figure 14-3.

1.-7 Exceptions with the same priority as the priority of program-interruption conditions for the general case.

8.A Specification exception due to the address specified by the second operand not being on a word boundary.

8.B Access exceptions for an access to the subchannel-status-word, extended-status-word, and extended-control-word sections of the IRB designated by the second operand.

8.C Operand exception due to an invalid field in the subsystem-identification word specified in register 1.

8.D Access exceptions for an access to the extended-measurement-word section of the IRB designated by the second operand when the extended-I/O-measurement-word mode is enabled at the designated subchannel.

**Programming Notes:**

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.

2. The information that is stored in the IRB is obtained from the subchannel. The TEST SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.

3. When an I/O interruption occurs, it is the result of a status-pending condition at the subchannel, and typically TEST SUBCHANNEL is executed to clear the status. TEST SUBCHANNEL may also be executed at any other time to sample conditions existing at the subchannel.

4. Repeated execution of TEST SUBCHANNEL to determine when a start function has been completed should be avoided because there are conditions under which the completion of the start function may or may not be indicated. For example, if the channel subsystem is holding an interface-control-check (IFCC) condition in abeyance (for any subchannel) because another subchannel is already status pending, and if the start function being tested by TEST SUBCHANNEL has as the only path available for selection the channel path with the IFCC condition, then the start function may not be initiated until the status-pending condition in the other subchannel is cleared, allowing the IFCC condition to be indicated at the subchannel to which it applies.

5. Repeated execution of TEST SUBCHANNEL without an intervening delay, for example, to determine when a subchannel changes state,
should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit accessing of the subchannel by the channel subsystem. Execution of TEST SUBCHANNEL by multiple CPUs for the same subchannel at approximately the same time may have the same effect and also should be avoided.

6. The priority of I/O-interruption handling by a CPU can be modified by the execution of TEST SUBCHANNEL. When TEST SUBCHANNEL is executed and the designated subchannel has an I/O-interruption request pending, that I/O-interruption request is cleared, and the SCSW is stored, without regard to any previously established priority. The relative priority of the remaining I/O-interruption requests is unchanged.
Chapter 15. Basic I/O Functions

Some I/O instructions specify to the channel subsystem that a function is to be performed. Collectively, these functions are referred to as the basic I/O functions. The basic I/O functions are the clear, halt, resume, and channel-path-reset functions.
performed. This information is communicated to the program in the subchannel-information block during the execution of STORE SUBCHANNEL.

**Subchannel-Information Block**

The subchannel-information block (SCHIB) is the operand of the MODIFY SUBCHANNEL and STORE SUBCHANNEL instructions. The two rightmost bits of the SCHIB address are zeros, designating the SCHIB on a word boundary. The SCHIB contains three major fields: the path-management-control word (PMCW), the subchannel-status word (SCSW), and a model-dependent area. When the extended-I/O-measurement-block facility is installed the SCHIB also contains the measurement-block-address field. (Figure 15-1 on page 2 shows the format of the PMCW, and Figure 16-3 on page 8 shows the format of the command-mode SCSW and Figure 16-8 on page 34 shows the format of the transport-mode SCSW.)

STORE SUBCHANNEL is used to store the current PMCW, the SCSW, model-dependent data, and, when the extended-I/O-measurement-block facility is installed, the measurement-block-address field, for the designated subchannel. MODIFY SUBCHANNEL alters certain PMCW fields and, when the extended-I/O-measurement-block facility is installed, the measurement-block address in the subchannel. When the program needs to change the contents of one or more of the PMCW fields, the normal procedure is to (1) issue STORE SUBCHANNEL to obtain the current contents, (2) perform the required modifications to the PMCW field or the measurement-block-address field in main storage, and (3) issue MODIFY SUBCHANNEL to pass the new information to the subchannel. The SCHIB has the following format:

**Word**

<table>

Figure 15-1. PMCW Format

**Interruption Parameter:** Bit positions 0-31 of word 0 contain the interruption parameter that is stored as word 1 of the interruption code. The interruption parameter can be set to any value by START SUBCHANNEL and MODIFY SUBCHANNEL. The initial value of the interruption parameter is zero.

**I/O-Interruption-Subclass Code (ISC):** Bits 2-4 of word 1 are an unsigned binary integer, in the range 0-7, that corresponds to the bit position of the I/O-
interruption subclass-mask bit in control register 6 of each CPU in the configuration. The setting of that mask bit in control register 6 of a CPU controls the recognition of interruption requests relating to this subchannel by that CPU (see “Priority of Interruptions” on page 5). The ISC can be set to any value by MODIFY SUBCHANNEL. The initial value of the ISC is zero.

**Reserved:** Bits 0, 1, and 5-7 of word 1 are reserved and stored as zeros by STORE SUBCHANNEL. Bits 0, 1, 6, and 7 must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized. Bit 5 of word 1 is ignored when MODIFY SUBCHANNEL is executed.

**Enabled (E):** Bit 8 of word 1, when one, indicates that the subchannel is enabled for all I/O functions. When the E bit is zero, status presented by the device is not made available to the program, and I/O instructions other than MODIFY SUBCHANNEL and STORE SUBCHANNEL that are executed for the designated subchannel cause condition code 3 to be set. The E bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, all subchannels are not enabled; IPL causes the IPL I/O device to become enabled.

**Limit Mode (LM):** When the address-limit-checking facility is installed, bits 9 and 10 of word 1 define the limit mode (LM) of the subchannel. The limit mode is used by the channel subsystem when address-limit checking is invoked for an I/O operation. (See “Address-Limit Checking” on page 22.) Address-limit checking is under the control of the address-limit-checking-control bit that is passed to the subchannel in the operation-request block (ORB) during the execution of START SUBCHANNEL. (See “Address-Limit-Checking Control (A)” on page 27.)

The definitions of the LM bits, whose values are used during data transfer, are as follows:

<table>
<thead>
<tr>
<th>Bit 9</th>
<th>Bit 10</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Initialized value. No limit checking is performed for this subchannel.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Data address must be equal to or greater than the current address limit.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Data address must be less than the current address limit.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

Bit positions 9 and 10 can contain any of the first three bit combinations shown above when MODIFY SUBCHANNEL is executed. Specification of the reserved bit combination in the operand causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

When the address-limit-checking facility is not installed, bits 9-10 of word 1 may be set as described above; however, they are ignored and are not set at the specified subchannel. When bits 9-10 are not specified as described above and MODIFY SUBCHANNEL is executed, an operand exception is recognized.

**Measurement-Mode Enable (MM):** Bits 11 and 12 of word 1 enable the measurement-block-update mode and the device-connect-time-measurement mode, respectively, of the subchannel. These bits can have any value when MODIFY SUBCHANNEL is executed; initially, neither measurement mode is
enabled. The definition of each of these bits is as follows:

**Bit 11 Measurement-Block-Update Enable:**

- 0: Initialized value. The subchannel is not enabled for measurement-block update. Storing of measurement-block data does not occur.
- 1: The subchannel is enabled for measurement-block update. If the measurement-block-update mode is active, measurement data is accumulated in the measurement block at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected. (See "Measurement-Block Update" on page 2.) If the measurement-block-update mode is inactive, no measurement-block data is stored.

**Bit 12 Device-Connect-Time-Measurement Enable:**

- 0: Initialized value. The subchannel is not enabled for device-connect-time measurement. Storing of the device-connect-time interval (DCTI) in the extended-status word (ESW) does not occur.
- 1: The subchannel is enabled for device-connect-time measurement. If the device-connect-time-measurement mode is active and timing facilities are provided for the subchannel, the value of the DCTI is stored in the ESW when TEST SUBCHANNEL is executed after channel-program execution is completed or suspended at the subchannel, provided no error conditions described by subchannel logout have been detected. If the device-connect-time-measurement mode is inactive, no measurement values are stored in the ESW.

The meaning of the measurement-mode-enable bits (MM), described above, applies when the timing-facility bit for the subchannel is one. When the timing-facility bit is zero, the effect of the MM bits is changed, as described below under “Timing Facility (T)” on page 4. (For more discussion on measurement modes, see “Measurement-Block Update” on page 2 and “Device-Connect-Time Measurement” on page 10.)

**Multipath Mode (D):** Bit 13 of word 1, when one, indicates that the subchannel operates in the multipath mode when performing an I/O operation or chain of I/O operations. For proper operation in the multipath mode when more than one channel path is available for selection, the associated device must have the dynamic-reconnection feature installed and must be set up for multipath-mode operation. During performance of a start function in the multipath mode, a device is allowed to request service from the channel subsystem over any of the channel paths indicated at the subchannel as being available for selection (see “Logical-Path Mask (LPM)” on page 5 and “Path-Available Mask (PAM)” on page 7). Bit 13, when zero, indicates that the subchannel operates in single-path mode when performing an I/O operation or chain of I/O operations. In the single-path mode, the entire start function is performed by using the channel path on which the first command of the I/O operation or chain of I/O operations was accepted by the device. The D bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, the subchannel is in the single-path mode.

**Timing Facility (T):** Bit 14 of word 1, when one, indicates that the channel-subsystem-timing facility is available for the subchannel and is under the control of the two measurement-mode-enable bits (MM) and SET CHANNEL MONITOR. Bit 14, when zero, indicates that the channel-subsystem-timing facility is not available for the subchannel. When bit 14 is zero, the START SUBCHANNEL count is the only measurement data that can be accumulated in the measurement block for the subchannel. Storing of the START SUBCHANNEL count is under the control of bit 11 and SET CHANNEL MONITOR, as described above under “Measurement-Mode Enable (MM)” on page 3. Similarly, if the T bit is zero, no device-connect-time-interval (DCTI) values can be measured for the subchannel. (See “Measurement-Block Update” on page 2 and “Device-Connect-Time Measurement” on page 10.)

**Device Number Valid (V):** Bit 15 of word 1, when one, indicates that the device-number field (see below) contains a valid device number and that a device associated with this subchannel may be physically installed. Bit 15, when zero, indicates that the subchannel is not valid, there is no I/O device currently associated with the subchannel, and the contents of all other defined fields of the SCHIB are
**Device Number:** Bit positions 16-31 of word 1 contain the binary representation of the four-digit hexadecimal device number of the device that is associated with this subchannel. The device number is a system-unique parameter that is assigned to the subchannel and the associated device when the device is installed.

**Logical-Path Mask (LPM):** Bits 0-7 of word 2 indicate the logical availability of channel paths to the associated device. Each bit of the LPM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A bit set to one means that the corresponding channel path is logically available; a zero means the corresponding channel path is logically not available. When a channel path is logically not available, the channel subsystem does not use that channel path to initiate performance of any clear, halt, resume, or start function, except when a dedicated allegiance exists for that channel path. When a dedicated allegiance exists at the subchannel for a channel path, the logical availability of the channel path is ignored whenever a clear, halt, resume, or start function is performed. (See “Channel-Path Allegiance” on page 12). If the subchannel is idle, the logical availability of the channel path is ignored whenever the control unit initiates a request to present alert status to the channel subsystem. The logical availability of a channel path associated with the subchannel can be changed by setting the corresponding LPM bit in the SCHIB and then issuing MODIFY SUBCHANNEL, or by setting the corresponding LPM bit in the ORB and then issuing START SUBCHANNEL. Initially, each installed channel path is logically available.

**Path-Not-Operational Mask (PNOM):** Any of bits 8-15 of word 2, when one, indicates that a path-not-operational condition has been recognized on the corresponding channel path. Each bit of the PNOM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. Any of bits 8-15 of word 2, when zero, indicates that a path-not-operational condition has not been recognized on the corresponding channel path.

Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a PNOM of all zeros if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

**Programming Note:** The PNOM indicates those channel paths for which a path-not-operational condition has been recognized during the performance of the most recent clear, halt, resume, or start function. That is, the PNOM indicates which of the channel paths associated with the subchannel have made a transition from the operational to the not-operational state for the subchannel during the performance of the most recent clear, halt, resume, or start function. However, the transition of a channel path from the not-operational to the operational state for the subchannel is indicated in the POM. Therefore, the POM must be examined in order to determine whether any of the channel paths that are associated with a designated subchannel are operational for the subchannel.

Furthermore, while performing either a start function or a resume function, the transition of a channel path from the not-operational to the operational state for the subchannel is recognized by the channel subsystem only during the initiation sequence for the first command specified by the start function or implied by the resume function. Therefore, a channel path that is currently not operational for the subchannel can be used by the device associated with the subchannel when reconnecting to the channel subsystem in order to continue command chaining; however, the channel subsystem does not indicate a transition of
that channel path from the not-operational to the operational state for the subchannel in the POM.

</tr>
</tbody>
</table>

**Explanation:**

1. Device state as it appears on the corresponding channel path.
2. Prior to the attempted device selection during the performance of either a start function or a resume function while the subchannel is suspended, the channel subsystem clears all existing path-not-operational conditions, if any, at the designated subchannel.
3. The N bit (bit 15 of word 0 of the SCSW) is indicated to the program and the N condition is cleared at the subchannel when TEST SUBCHANNEL is executed the next time the subchannel is status pending for other than intermediate status alone provided that it is not also suspended.

**Last-Path-Used Mask (LPUM):** Bits 16-23 of word 2 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. Each bit of the LPUM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB.

For a subchannel operating in command mode, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The first command of a start or resume function is accepted by the device (see “Activity Control (AC)” on page 14).

2. The device and channel subsystem are actively communicating when the suspend function is performed for the channel program in execution.

3. Status has been accepted from the device and is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 2).

4. An interface-control-check condition has been recognized (see “Interface-Control Check” on page 29), and no subchannel-logout information is currently present in the subchannel.

For a subchannel operating in transport mode, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The path has been selected for transporting the TCCB for the operation.

2. Status has been accepted from the device and is recognized as an interruption condition. If the accepted status is an interrogate response, the LPUM may be different than that stored with primary or secondary status or both.

3. An interface-control-check has been recognized and no subchannel-logout information is currently present in the subchannel.

The LPUM field of the PMCW contains the most recent setting. For transport-mode operations the LPUM in the subchannel is set to zeros when the start function is set and no dedicated-allegiance condition exists for the subchannel.

**Path-Installed Mask (PIM):** Bits 24-31 of word 2 indicate which of the channel paths 0-7 to the I/O device are physically installed. The PIM indicates the validity of the channel-path identifiers (see below) for those channel paths that are physically installed. Each bit of the PIM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PIM bit stored as one indicates that the corresponding channel path is installed. A PIM bit stored as zero indicates that the corresponding channel path is not installed. The PIM always reflects the full complement of installed paths to the device, regardless of how the system is configured. Therefore, some of the channel paths indicated in the PIM may not be physically available in that configuration, as indicated by the bit settings in the path-available mask (see below). The initial value of the PIM indicates all the physically installed channel paths to the device.

**Measurement-Block Index (MBI):** Bits 0-15 of word 3 form an index value used by the measure-
ment-block-update facility when the measurement-block-update mode is active (see “SET CHANNEL MONITOR” on page 13.) and the subchannel is enabled for the mode (see “Measurement-Mode Enable (MM)” on page 3).

When the measurement-block index is used, five zero bits are appended on the right, and the result is added to the measurement-block-origin address designated by SET CHANNEL MONITOR. The calculated address, called the measurement-block address, designates the beginning of a 32-byte storage area where measurement data is stored. (See “Measurement Block” on page 3.) The MBI can contain any value when MODIFY SUBCHANNEL is executed; the initial value is zero.

Programming Note: The measurement-block-origin address specified by SET CHANNEL MONITOR is used as the origin address for the measurement blocks for subchannels in all subchannel sets available to the program. However, the two-byte measurement-block-index field is capable of supporting a maximum of 65,536 unique MBI values. It is the responsibility of the program to coordinate use of the measurement-block index among subchannels and subchannel sets.

Path-Operational Mask (POM): Bits 16-23 of word 3 indicate the last known operational state of the device on the corresponding channel paths. Each bit of the POM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. If the associated device appeared operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is operational for the subchannel, and the bit corresponding to the channel path in the POM is one. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is also operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as zero.

If the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel during an attempted device selection in order to perform a clear, halt, resume, or start function, then the channel subsystem recognizes a path-not-operational condition. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel.

Programming Note: The measurement-block-origin address specified by SET CHANNEL MONITOR is used as the origin address for the measurement blocks for subchannels in all subchannel sets available to the program. However, the two-byte measurement-block-index field is capable of supporting a maximum of 65,536 unique MBI values. It is the responsibility of the program to coordinate use of the measurement-block index among subchannels and subchannel sets.

Path-Operational Mask (POM): Bits 16-23 of word 3 indicate the last known operational state of the device on the corresponding channel paths. Each bit of the POM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. If the associated device appeared operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is operational for the subchannel, and the bit corresponding to the channel path in the POM is one. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is also operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as zero.

If the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel during an attempted device selection in order to perform a clear, halt, resume, or start function, then the channel subsystem recognizes a path-not-operational condition. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel.

When the channel path is not operational for the subchannel, a path-not-operational condition cannot be recognized. Moreover, a channel path that is not operational for the subchannel may be available for selection; if the channel subsystem chooses that channel path while performing a path-management operation, and if, during the attempted device selection, the device appears to be operational again on that channel path, then the state of the channel path changes from not operational for the subchannel to operational for the subchannel.

The POM can contain any value when MODIFY SUBCHANNEL is executed. Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a POM of all ones if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

Path-Available Mask (PAM): Bits 24-31 of word 3 indicate the physical availability of installed channel paths. Each bit of the PAM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PAM bit of one indicates that the corresponding channel path is physically available for use in accessing the device. A PAM bit of zero indicates that the channel path is not physically available for use in accessing the device. When a channel path is not physically available, it may, depending on the model and the extent of failure, be used during performance of the reset-channel-path function. A channel path that is physically available may become not physi-
cally available as a result of reconfiguring the system, or this may occur as a result of the performance of the channel-path-reset function. The initial value of the PAM reflects the set of channel paths by which the I/O device is physically accessible at the time of initialization.

Note: The change in the availability of a channel path affects all subchannels having access to that channel path. Whenever the setting of a PAM bit is referred to in conjunction with the availability status of a channel path, for brevity, reference is made in this chapter to a single PAM bit instead of to the respective PAM bits in all of the affected subchannels.

Channel-Path Identifiers (CHPIDs): Words 4 and 5 contain eight one-byte channel-path identifiers corresponding to channel paths 0-7 of the PIM. A CHPID is valid if the corresponding PIM bit is one. Each valid CHPID contains the identifier of a physical channel path to a control unit by which the associated I/O device may be accessed. A unique CHPID is assigned to each physical channel path in the system.

Different devices that are accessible by the same physical channel path have, in their respective subchannels, the same CHPID value. The CHPID value may, however, appear in each subchannel in different locations in the CHPID fields 0-7.

Subchannels that share an identical set of channel paths have the same corresponding PIM bits set to ones. The channel-path identifiers (CHPIDs) for these channel paths are the same and occupy the same respective locations in each SCHIB.

Reserved: Bits 0-28 of word 6 are reserved and are stored as zeros by STORE SUBCHANNEL. They must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception may be recognized.

Measurement Block Format Control (F): When the extended-I/O-measurement-block facility is installed, bit 29 of word 6 specifies the format of the measurement block to be stored when the subchannel is enabled for the measurement-block-update mode, and measurement-block-update mode is active. The bit can contain any value when MODIFY SUBCHANNEL is executed. The initial value is zero. The definition of the bit is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Measurement-Block-Format Control:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Format-0 measurement block. Specifies that a format-0 measurement block is used when performing a measurement-block update for the subchannel. The address of the 32-byte measurement block is obtained using the MBI provided by MSCH in conjunction with the MBO provided by SCHM.</td>
</tr>
<tr>
<td>1</td>
<td>Format-1 measurement block. Specifies that a format-1 measurement block is used when performing a measurement-block update for the subchannel. The address of the 64-byte format-1 measurement block is provided by MSCH.</td>
</tr>
</tbody>
</table>

If the extended-measurement-block facility is not installed, bit 29 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Extended Measurement Word Mode Enable (X): When the extended-measurement-word facility is installed and enabled, bit 30 of word 6 enables the extended-measurement-word mode for the subchannel. Initially, the extended-measurement-word mode is not enabled. The definition of the bit is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Measurement-Block-Word-Mode Enable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initialized value. The subchannel is not enabled for extended-measurement-word mode. Storing of the extended-measurement word does not occur.</td>
</tr>
<tr>
<td>1</td>
<td>The subchannel is enabled for extended-measurement-word mode. Measurement data is stored in the extended-measurement word at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected.</td>
</tr>
</tbody>
</table>

If the extended-measurement-word facility is not installed, or is installed but is not enabled, bit 30 of word 6 of the SCHIB operand must be zero when
MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**Concurrent Sense (S):** Bit 31 of word 6, when one, indicates that the subchannel is in the concurrent-sense mode. When the subchannel is in command mode and concurrent-sense mode, whenever the subchannel becomes status pending with alert status, and the status byte accepted from the device contains the unit-check indication, then the channel subsystem may attempt to retrieve sense information from the associated device and place that sense information in the extended-control word.

When the subchannel is operating in transport mode, any available sense information is provided in the TSB regardless of the setting of bit 31 of word 6.

If the concurrent-sense facility is not installed, bit 31 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**Subchannel-Status Word**
Words 7-9 of the SCHIB contain a copy of the SCSW. The format of the SCSW is described in “Subchannel-Status Word” on page 7. The SCSW is stored by the execution of either STORE SUBCHANNEL or TEST SUBCHANNEL (see “STORE SUBCHANNEL” on page 18 and “TEST SUBCHANNEL” on page 21).

**Model-Dependent Area/Measurement Block Address**
When the extended-I/O-measurement-block facility is not installed, words 10-12 of the SCHIB contain model-dependent information.

When the extended-I/O-measurement-block facility is installed, words 10-11 are defined as the measurement-block-address field. Word 12 contains model-dependent information.

When (1) the measurement-block-update mode is active (see “SET CHANNEL MONITOR” on page 13), (2) the subchannel is enabled for the mode (see “Measurement-Mode Enable (MM)” on page 3), and (3) the format-1-measurement block is specified (see “Measurement Block Format Control (F)” on page 8) at the subchannel, the measurement-block-address field contains the absolute storage address of the measurement block used by the measurement-block-update facility. The measurement-block address designates the beginning of a 64-byte storage area and must be designated on 64-byte boundary. The initial value of the measurement block address is zero.
Summary of Modifiable Fields

*Figure 15-3 on page 10 lists the initial settings for fields in a subchannel whose device-number-valid bit is one and indicates what modifies the fields.

All of the PMCW fields contain meaningful information when STORE SUBCHANNEL is executed and the designated subchannel is idle. Subchannel fields that the channel subsystem does not modify contain valid information whenever STORE SUBCHANNEL is executed, provided that the device-number-valid bit is one. The validity of the subchannel fields that are modifiable by the channel subsystem depends on the state of the subchannel at the time STORE SUBCHANNEL is executed.

*Figure 15-3. Modification of Subchannel Fields (Part 1 of 2)
Programming Notes:

1. System performance may be degraded if the LPM is not used to make channel paths for which a path-not-operational condition has been indicated in the PNOM logically not available.

2. If, during the performance of a start function, a channel path becomes not physically available because a channel-path failure has been recognized, continued performance of the start function may be precluded. That is, the program may or may not be notified, and the subchannel may remain in the subchannel-and-device-active state until cleared by the performance of the clear function.

3. If the same MBI is placed in more than one subchannel by the program, the channel-subsystem-monitoring facility updates the same locations with measurement data relating to more than one subchannel. In this case, the values stored in the measurement data are unpredictable. (See “Measurement-Block Update” on page 2.)

4. Modification of the I/O configuration (reconfiguration) may be accomplished in various ways depending on the model. If the reconfiguration procedure affects the physical availability of a channel path, then any change in availability can be detected by executing STORE SUBCHANNEL for a subchannel that has access to the channel path and by subsequently examining the PAM bits of the SCHIB.

5. The definitions of the PNOM, POM, and N bit are such that a path-not-operational condition is reported to the program only the first time the condition is detected by the channel subsystem after the corresponding POM bit is set to one. For example, if the POM bit for every channel path available for selection is one and the device appears not operational on all corresponding channel paths while the channel subsystem is attempting to initiate a start function at the device, the channel subsystem makes the subchannel status pending, with deferred condition code 3 and with the N bit stored as one. The PNOM in the SCHIB indicates the channel path or channel paths that appeared not operational, for which the corresponding POM bits have been set to zeros. The next START SUBCHANNEL causes the channel subsystem to again attempt device selection by choosing a channel path from among all of the channel paths that are available...
for selection. If device selection is not successful and all channel paths available for selection have again been chosen, deferred condition code 3 is set, but the N bit in the SCSW is zero. The POM contains zeros in at least those bit positions that correspond to the channel paths that are available for selection. (See “Channel-Path Availability” on page 13 for a description of the term “available for selection.”) When the N bit in the SCSW is zero, the PNOM is also zero.

6. If the program is to detect path-not-operational conditions, the PNOM should be inspected following the execution of TEST SUBCHANNEL (which results in the setting of condition code zero and the valid storing of the N bit as one) and preceding the performance of another start, resume, halt, or clear function at the subchannel.

**Working Allegiance**

**Working Allegiance for Subchannels Operating in Command Mode**

A subchannel has a working allegiance for a channel path when the subchannel is operating in command mode and becomes device active on that channel path. Once a working allegiance is established, the channel subsystem maintains the working allegiance at the subchannel for the channel path until either the subchannel is no longer device active or a dedicated allegiance is recognized, whichever occurs earlier. Unless a dedicated allegiance is recognized, a working allegiance for a channel path is extended to the set of channel paths that are available for selection if the device is specified to be operating in the multipath mode (that is, the multipath-mode bit is stored as one in the SCHIB). Otherwise, the working allegiance remains only for that channel path over which the start function was initiated.

Once a working allegiance is established for a channel path or set of channel paths, the working allegiance is not changed until the subchannel is no longer device active or until a dedicated allegiance is established. If the subchannel is operating in the single-path mode, a working allegiance is maintained only for a single path.

While a working allegiance exists at a subchannel, an active allegiance can occur only for a channel path for which the working allegiance is being maintained, unless the device is specified as operating in the multipath mode. When the device is specified as operating in the multipath mode, an active allegiance may also occur for a channel path that is not available for selection if the presentation of status by the device on that channel path causes an alert interruption condition to be recognized.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

**Working Allegiance for Subchannels Operating in Transport Mode**

A subchannel has a working allegiance for a channel path when the subchannel is operating in transport mode, becomes start pending, and the designated TCCB is transported over that channel path to the I/O device. Once a working allegiance is established, the channel subsystem maintains the working allegiance
at the subchannel for the channel path until a busy condition is encountered or the subchannel is made status pending with primary status. The working allegiance remains only for that channel path over which the start function was initiated.

While a working allegiance exists at a subchannel that is operating in transport mode, an active allegiance can occur only for the channel path for which the working allegiance is being maintained.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

**Active Allegiance**

A subchannel has an active allegiance established for a channel path no later than when active communication has been initiated on that channel path with an I/O device. The subchannel can have an active allegiance to only one channel path at a time. While the subchannel has an active allegiance for a channel path, the channel subsystem does not actively communicate with that device on any other channel path. When the channel subsystem accepts a no-longer-busy indication from the device that does not cause an interruption condition, this status does not constitute the initiation of active communication. An active allegiance at a subchannel for a channel path is terminated when the channel subsystem is no longer actively communicating with the I/O device on that channel path.

A working allegiance can become an active allegiance.

**Dedicated Allegiance**

If a channel path is physically available (that is, if the corresponding PAM bit is one), a dedicated allegiance may be recognized for that channel path. If a channel path is not physically available, a dedicated allegiance cannot be recognized for the corresponding channel path. The channel subsystem establishes a dedicated allegiance at the subchannel for a channel path when (1) the subchannel is operating in command mode, the subchannel becomes status pending with alert status, and device status containing the unit-check indication is present but (2) concurrent-sense information is not present at the subchannel. A dedicated allegiance is maintained until the subchannel is no longer start pending (unless it becomes suspended) or resume pending following performance of the next start function, clear function, or channel-path-reset function or the next resume function if applicable. If the subchannel becomes suspended, the dedicated allegiance remains until the resume function is initiated and the subchannel is no longer resume pending. Unless a clear or channel-path-reset function is performed, the subchannel establishes a working allegiance when the dedicated allegiance ends. This occurs when the subchannel becomes device active. While a dedicated allegiance exists at a subchannel for a channel path, only that channel path is available for selection until the dedicated-allegiance condition is cleared.

Dedicated allegiance does not apply to subchannels operating in transport mode. When a subchannel operating in transport mode becomes status pending with unit check indicated, the sense information has already been transferred from the I/O device into the TSB for the I/O operation.

A dedicated allegiance can become an active allegiance. While a dedicated allegiance exists, an active allegiance can only occur for the same channel path.

A currently existing dedicated allegiance is cleared at any subchannel having access to a channel path when the channel path becomes not physically available or whenever the device appears not operational on the channel path for which the dedicated allegiance exists.

**Channel-Path Availability**

When a channel path is not physically available, the channel subsystem does not use the channel path to perform any of the basic I/O functions except, in some cases, the channel-path-reset function and does not respond to any control-unit-initiated requests on that same channel path. If a channel path is not physically available, the condition is indicated by the corresponding path-available-mask PAM bit being zero when STORE SUBCHANNEL is executed (see "Path-Available Mask (PAM)" on page 7). Furthermore, if the channel path is not physically available for the subchannel designated by STORE SUBCHANNEL, then it is not physically available for any subchannel that has a device which is accessible by that channel path.
Unless a dedicated allegiance exists at a subchannel for the channel path, a channel path becomes available for selection if it is logically available and physically available, as indicated by the bits in the LPM and PAM corresponding to the channel path being stored as ones when STORE SUBCHANNEL is executed. If a dedicated allegiance exists at a subchannel for the channel path, only that channel path is available for selection, and the setting of the corresponding LPM bit is ignored. If the channel path is currently being used and a dedicated allegiance exists at the subchannel for the channel path, selection of the device is delayed until the channel path is no longer being used.

The availability status of the eight logical paths to the associated device described in Figure 15-4 on page 14 is determined by the hierarchical arrangement of the corresponding bit values contained in the PIM, PAM, and LPM and by existing conditions, if any, recognized by the channel subsystem.

<table>

Explanation:

1. Bit value is not meaningful.
2. If the channel path is recognized as being used in active communication with a device, the channel-path condition is described as active. Otherwise, its condition is described as inactive.
3. A PAM bit cannot have the value one when the corresponding PIM bit has the value zero.
4. If a dedicated allegiance exists to the channel path at the subchannel, the state of the bit is ignored, and the channel path is considered to be available for selection.
5. The channel path may appear to be active when a channel-path-terminal condition has been recognized.
6. Condition is not meaningful.

Figure 15-4. Path condition and Path-Availability Status for PIM, PAM, and LPM Values

### Clear Function

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem performs the clear function. Performance of the clear function consists in (1) performing a path-management operation, (2) modifying fields at the subchannel, (3) issuing the clear signal to the associated device, and (4) causing the subchannel to be made status pending, indicating the completion of the clear function.

### Clear-Function Path Management

A path-management operation is performed as part of the clear function in order to examine channel-path conditions for the associated subchannel and to attempt to choose an available channel path on which the clear signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.
2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.
3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.
4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.

### Control-Unit Type

In “Clear Function” on page 14, “Halt Function” on page 16, and “Start Function and Resume Function” on page 20, reference is made to type-1, type-2, and type-3 control units. For a description of these control-unit types, see the System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974. For the purposes of this definition, all control units attaching to a serial-I/O interface are considered type-2 control units.

---

**Control-Unit Type**

In “Clear Function” on page 14, “Halt Function” on page 16, and “Start Function and Resume Function”
5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).

6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path, provided that the following conditions do not apply:

1. A channel-path-terminal condition exists for the channel path.
2. For a parallel or ESCON channel path: Another subchannel has an active allegiance for the channel path.
   For a FICON channel path: The channel path is currently being used to actively communicate with the maximum number of subchannels that can have concurrent active communications.
3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.
4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

Clear-Function Subchannel Modification

Path-management-control indications at the subchannel are modified during performance of the clear function. Effectively, this modification occurs after the attempt to choose a channel path, but prior to the attempt to select the device to issue the clear signal. The path-management-control indications that are modified are as follows:

1. The state of all eight possible channel paths at the subchannel is set to operational for the subchannel.
2. The last-path-used indication is reset to indicate no last-used channel path.
3. Path-not-operational conditions, if any, are reset.

Clear-Function Signaling and Completion

Subsequent to the attempt to choose a channel path and the modification of the path-management-control fields, the channel subsystem, if conditions allow, attempts to select the device to issue the clear signal. (See “Clear Signal” on page 12.) Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the clear signal, and (2) whether the attempt to issue the clear signal is successful. Independent of these conditions, the subchannel is subsequently set status pending, and the performance of the clear function is complete. These conditions and their effect on the clear function are described as follows:

No Attempt Is Made to Issue the Clear Signal:
The channel subsystem does not attempt to issue the clear signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Clear-Function Path Management” on page 14.)
2. The chosen channel path is no longer available for selection.
3. A channel-path-terminal condition exists for the chosen channel path.
4. For parallel and ESCON channel paths: The chosen channel path is currently being used to actively communicate with a different device.
For FICON channel paths: The chosen channel path is currently being used to actively communicate with the maximum number of devices that can have concurrent active communications.

5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If any of the conditions above exist, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

**The Attempt to Issue the Clear Signal Is Not Successful:** When the channel subsystem attempts to issue the clear signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the clear signal.

2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the clear signal.

3. An error condition is encountered when the channel subsystem attempts to issue the clear signal.

If any of the conditions above exist and the channel subsystem either determines that the attempt to issue the clear signal was not successful or cannot determine whether the attempt was successful, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

**Programming Note:** Subsequent to the performance of the clear function, any nonzero status, except control unit end alone, that is presented to the channel subsystem by the device is passed to the program as unsolicited alert status. Unsolicited status consisting of control unit end alone or zero status is not presented to the program.

---

**Halt Function**

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem performs the halt function. Performance of the halt function consists of (1) performing a path-management operation, (2) issuing the halt signal to the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the halt function.

**Halt-Function Path Management**

A path-management operation is performed as part of the halt function to examine channel-path conditions for the associated subchannel and to attempt to choose a channel path on which the halt signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.

2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.

3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.

4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.
5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).

6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path for which the following conditions do not apply:

1. A channel-path-terminal condition exists for the channel path.
2. For a parallel or ESCON channel path: Another subchannel has an active allegiance for the channel path.
   For a FICON channel path: The channel path is currently being used to actively communicate with the maximum number of subchannels that can have concurrent active communications.
3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.
4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

Halt-Function Signaling and Completion

Subsequent to the attempt to choose a channel path, the channel subsystem, if conditions allow, attempts to select the device to issue the halt signal. (See “Halt Signal” on page 12.)

Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the halt signal, (2) whether the attempt to issue the halt signal is successful, and (3) whether the subchannel is made status pending to complete the halt function. These conditions and their effect on the halt function are described as follows:

No Attempt Is Made to Issue the Halt Signal:
The channel subsystem does not attempt to issue the halt signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Halt-Function Path Management” on page 16.)
2. The chosen channel path is no longer available for selection.
3. A channel-path-terminal condition exists for the chosen channel path.
4. The associated subchannel is status pending with other than intermediate status alone.
5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.
6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If the conditions described in items 3, 5, or 6 exist, the associated subchannel remains halt pending until those conditions no longer exist. When the conditions no longer exist (for the channel-path-terminal condition, when the condition no longer exists as a result of executing RESET CHANNEL PATH), the channel subsystem attempts to issue the halt signal to the device.
If any of the remaining conditions above exist, the subchannel remains halt pending and is set status pending, and the halt function is complete.

**The Attempt to Issue the Halt Signal Is Not Successful:** When the channel subsystem attempts to issue the halt signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the halt signal.
2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the halt signal.
3. An error condition is encountered when the channel subsystem attempts to issue the halt signal.

If the control unit or device signals a busy condition (item 1), the subchannel remains halt pending until the internal indication of busy is reset. When this event occurs, the channel subsystem again attempts to issue the halt signal to the device.

If any of the remaining conditions above exists and the channel subsystem either determines that the attempt to issue the halt signal was not successful or cannot determine whether the attempt was successful, then the subchannel remains halt pending and is set status pending, and the halt function is complete.

**The Attempt to Issue the Halt Signal Is Successful:** When the channel subsystem determines that the attempt to issue the halt signal was successful and ending status, if appropriate, has been received at the subchannel, the subchannel is no longer halt pending and is set status pending, and the halt function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated. The conditions that affect the receipt of ending status at the subchannel, and the effect of the halt signal at the device are described in the following discussion.

When the subchannel is subchannel-and-device active or only device active during the performance of the halt function, the state continues until the subchannel is made status pending because (1) the device has provided ending status or (2) the channel subsystem has determined that ending status is unavailable.

When the subchannel is operating in command mode and is idle, start pending, start pending and resume pending, suspended, or suspended and resume pending, or when the halt signal is issued during command chaining after the receipt of device end but before the next command is transferred to the device, no operation is in progress at the device, and therefore no status is generated by the device as a result of receiving the halt signal. When the subchannel is neither subchannel active, nor status pending with intermediate status, and no errors are detected during the attempt to issue the halt signal to the device, an interruption condition indicating status pending alone is generated after the halt signal is issued.

When the subchannel is operating in transport mode and is start pending, an operation may or may not be in progress at the device. Regardless of whether an operation is in progress, device status is not generated.

The effect of the halt signal at the device depends partially on the subchannel operation mode, type of device, and its state. The effect of the halt signal on a device that is not active or that is performing a mechanical operation in which data is not transferred across the channel path, such as rewinding tape or positioning a disk-access mechanism, depends upon the control-unit or device model. If the device is performing a type of operation that is unpredictable in duration or in which data is transferred across the channel path, the control unit interprets the signal as one to terminate the operation. Pending status conditions at the device are not reset. When the control unit recognizes the halt signal, it immediately ceases all communication with the channel subsystem until it has reached the normal ending point. The control unit then requests selection by the channel subsystem to present any generated status.

If the subchannel is involved in the data-transfer portion of an I/O operation, data transfer is terminated during the performance of the halt function, and the device is logically disconnected from the channel path. If the halt function is addressed to a subchannel operating in command mode, performing a chain of I/O operations, and the device has already provided channel end for the current I/O operation, the channel subsystem causes the device to be discon-
nected and command chaining or command retry to be suppressed.

If the subchannel is operating in command mode, performing a chain of I/O operations with the device, and the halt signal is issued during command chaining at a point after the receipt of device end for the previous I/O operation but before the next command is transferred to the device, the subchannel is made status pending with primary and secondary status immediately after the halt signal is issued. The device-status field of the SCSW contains zeros in this case. If the halt function is addressed to a subchannel that is operating in command mode, start pending, and the halt-pending condition is recognized before initiation of the start function, initiation of the start function is not attempted, and the subchannel becomes status pending after the device has been signaled.

If the halt function is addressed to a subchannel operating in transport mode that is start pending, the halt signal is issued as follows:

- If the TCCB has been transported to the I/O device for execution, the halt signal is issued and the subchannel becomes status pending.
- If the TCCB has not been transported to the I/O device, the TCCB is not transported and the subchannel becomes status pending.

When the subchannel is not performing an I/O operation with the associated device, the device is selected, and an attempt is made to issue the halt signal as the device responds. If the subchannel is in the device-active state, the subchannel does not become status pending until it receives the device-end status from the halted device. If the subchannel is neither subchannel-and-device active nor device active, the subchannel becomes status pending immediately after selecting the device and issuing the halt signal. The SCSW for the latter case has the status-pending bit set to one (see “Status-Pending (Bit 31)” on page 19).

The termination of an I/O operation by performing the halt function may result in two distinct interruption conditions.

The first interruption condition occurs when the device generates the channel-end condition. The channel subsystem handles this condition as it would any other interruption condition from the device, except that the command address in the associated SCSW designates the point at which the I/O operation is terminated as follows:

- When a command-mode IRB is stored, the SCSW contains the address of the last-executed CCW, plus 8, and the subchannel-status bits may reflect unusual conditions that were detected.
- When a transport-mode IRB is stored, the SCSW contains the address of the current TCW, and the subchannel-status, subchannel-extended-status, and FCX bits may reflect unusual conditions that were detected.

If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is indicated, subject to the control of the SLI flag in the current CCW when the subchannel is operating in command mode. The value in the count field of the associated SCSW is unpredictable. If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is not indicated, when the subchannel is operating in transport mode.

The second interruption condition occurs if device-end status was not presented with the channel-end interruption condition. In this situation, the subchannel-key, command-address, and count fields of the associated SCSW are not meaningful.

When HALT SUBCHANNEL terminates an I/O operation, the method of termination differs from that used upon exhaustion of count or upon detection of programming errors to the extent that termination by HALT SUBCHANNEL is not contingent on the receipt of a service request from the associated device.

Programming Notes:

1. When, after an operation is terminated by HALT SUBCHANNEL, the subchannel is status pending with primary, primary and secondary, or secondary status, the extent of data transferred as described by the count field is unpredictable.

2. When the path that is chosen by the path-management operation has a channel-path-terminal condition associated with it, the halt function remains pending until the condition no longer exists. Until the condition is cleared, the associated subchannel cannot be used to perform I/O operations, even if other channel paths become
available for selection. CLEAR SUBCHANNEL can be executed to terminate the halt-pending condition and make the subchannel usable.

---

**Start Function and Resume Function**

The start and resume functions initiate I/O operations as described below. The start function applies to subchannels operating in either command mode or transport mode. The resume function applies only to subchannels operating in command mode.

Subsequent to the execution of START SUBCHANNEL and RESUME SUBCHANNEL, the channel subsystem performs the start and resume functions, respectively, to initiate an I/O operation with the associated device. Performance of a start or resume function consists of: (1) performing a path-management operation, (2) performing an I/O operation or chain of I/O operations with the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the start function. (Completion of a start function is described in “I/O Interruptions” on page 1.) The start function initiates the execution of a channel program that is designated in the ORB, which in turn is designated as the operand of START SUBCHANNEL, in contrast to the resume function that initiates the execution of a suspended channel program, if any, beginning at the CCW that caused suspension; otherwise, the resume function is performed as if it were a start function (see “Resume-Pending (Bit 20)” on page 14).

---

**Start-Function and Resume-Function Path Management**

A path-management operation is performed by the channel subsystem during the performance of either a start or a resume function to choose an available channel path that can be used for device selection to initiate an I/O operation with that device. The actions taken are as follows:

1. **If the subchannel is currently start pending and device active**, the start function remains pending at the subchannel until the secondary status for the previous start function has been accepted from the associated device and the subchannel is made start pending alone. When the status is accepted and does not describe an alert interruption condition, the subchannel is not made status pending, and the performance of the pending start function is subsequently initiated. If the status describes an alert interruption condition, the subchannel becomes status pending with secondary and alert status, the pending start function is not initiated, deferred condition code 1 is set, and the start-pending bit remains one. If the subchannel is currently start pending alone, the performance of the start function is initiated as described below.

2. **If a dedicated allegiance exists at the subchannel for a channel path**, the channel subsystem chooses that path for device selection. If a busy condition is encountered while attempting to select the device and a dedicated allegiance exists at the subchannel, the start function remains pending until the internal indication of busy is reset for that channel path. When the internal indication of busy is reset, the performance of the pending start function is initiated on that channel path.

3. **If no channel path is available for selection and no dedicated allegiance exists in the subchannel for a channel path**, a channel path is not chosen.

4. **If all channel paths that are available for selection have been tried and one or more of them are being used to actively communicate with other devices**, or, alternatively, if the channel subsystem has encountered either a control-unit-busy or a device-busy condition on one or more of those channel paths, or a combination of those conditions on one or more of those channel paths, the start function remains pending until a channel path, control unit, or device, as appropriate, becomes available.

5. **If (1) the start function is to be initiated on a channel path with a device attached to a type-1 control unit and (2) no other device is attached to the same control unit whose subchannel has either a dedicated allegiance to the same channel path or a working allegiance to the same channel path where primary status has not been received for that subchannel, then that channel path is chosen if it is available for selection; otherwise, that channel path is not chosen. If, however, another channel path to the device is available for selection and no allegiances exist as described above, that channel path is chosen. If no other channel path is available for selection,
the start or resume function, as appropriate, remains pending until a channel path becomes available.

6. If the device is attached to a type-3 control unit, and if at least one other device is attached to the same control unit whose subchannel has a dedicated allegiance to the same channel path, another channel path that is available for selection may be chosen, or the start function remains pending until the dedicated allegiance for the other device is cleared.

7. If a channel path has been chosen and a busy indication is received during device selection to initiate the execution of the first command of a pending CCW channel program or to transport the TCCB of a pending TCW channel program, the channel path over which the busy indication is received is not used again for that device or control unit (depending on the device-busy or control-unit-busy indication received) until the internal indication of busy is reset.

8. If, during an attempt to select the device in order to initiate the execution of the first command specified for the start or implied for the resume function for a CCW channel program, or to initiate the transportation of the TCCB for a TCW channel program, (as described in action 7 above), the channel subsystem receives a busy indication, it performs one of the following actions:
   a. If the device is specified to be operating in the multipath mode and the busy indication received is device busy, then the start or resume function remains pending until the internal indication of busy is reset. (See “Multipath Mode (D)” on page 4.)
   b. If the device is specified to be operating in the multipath mode and the busy indication received is control unit busy, or if the device is specified to be operating in the single-path mode, the channel subsystem attempts selection of the device by choosing an alternate channel path that is available for selection and continues the path-management operation until either the start or the resume function is initiated or selection of the device has been attempted on all channel paths that are available for selection. If the start or resume function has not been initiated by the channel subsystem after all channel paths available for selection have been chosen, the start or resume function remains pending until the internal indication of busy is reset.
   c. If the subchannel has a dedicated allegiance, then action 2 on page 20 applies.

9. When, during the selection attempt to transfer the first command for a CCW channel program, or to transport the TCCB for a TCW channel program, the device appears not operational and the corresponding channel path is operational for the subchannel, a path-not-operational condition is recognized, and the state of the channel path changes at the subchannel from operational for the subchannel to not operational for the subchannel (see “Path-Not-Operational Mask (PNOM)” on page 5). The path-not-operational conditions at the subchannel, if any, are preserved until the subchannel next becomes clear pending, start pending, or resume pending (if the subchannel was suspended), at which time the path-not-operational conditions are cleared. If, however, the corresponding channel path is not operational for the subchannel, a path-not-operational condition is not recognized. When the device appears not operational during the selection attempt to transfer the first command or TCCB on a channel path that is available for selection, one of the following actions occurs:
   a. If a dedicated allegiance exists for that channel path, then it is the only channel path that is available for selection; therefore, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.
   b. If no dedicated allegiance exists and there are alternate channel paths available for selection that have not been tried, one of those channel paths is chosen to attempt device selection and transfer the first command for a CCW channel program, or the TCCB for a TCW channel program.
   c. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared operational on at least one of the channel paths that were tried, the start or resume function remains pending at the subchannel until a channel path, a control unit, or the device, as appropriate, becomes available.
d. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared not operational on all channel paths that were tried, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.

10. When the subchannel is active and an I/O operation is to be initiated with a device, all device selections occur according to the LPUM indication if the multipath mode is not specified at the subchannel. For example, if command chaining is specified for a CCW channel program, the channel subsystem transfers the first and all subsequent commands describing a chain of I/O operations over the same channel path.

Interrogate Function

Subsequent to the execution of CANCEL SUBCHANNEL for a subchannel operating in transport mode, the channel subsystem performs the interrogate function. Performance of the interrogate function consists of (1) transporting the designated interrogate TCCB to the I/O device, (2) storing the interrogate TSB, and (3) causing the subchannel to become intermediate status pending with interrogate-complete status indicated.

All storage accesses used to perform the interrogate operation are made as if a storage-access key of zero is used.

Interrogate-Function Path Management

The same channel path that was used to transport the TCCB for the I/O operation being interrogated is used for the interrogate function.

Interrogate TCCB Transportation and Completion

Subsequent to determining the channel path, the channel subsystem, if conditions allow, attempts to transport the interrogate TCCB. Conditions associated with the subchannel, the interrogate TCCB, and the chosen channel path, if any, affect (1) whether an attempt is made to transport the interrogate TCCB, (2) whether the attempt to transport the interrogate TCCB is successful, and (3) whether the interrogate TSB is stored. These conditions and their effect on the interrogate function are described as follows:

**No Attempt Is Made to Transport the Interrogate TCCB:** The channel subsystem does not transport the interrogate TCCB if any of the following conditions exists:

- The subchannel is status pending with primary status indicated.
- The subchannel is idle or device active only.
- The TCCB for the I/O operation being interrogated has not been transported to the device.
- Another interrogate function is already in progress on the channel path for the I/O device.
- The interrogate-TCW-address field of the TCW for the I/O operation being interrogated contains zeros.
- The channel subsystem doesn't have the resources to process the interrogate.

**The Attempt to Transport the Interrogate TCCB or Store the Interrogate TSB is Unsuccessful:** When the channel subsystem attempts to transport the interrogate TCCB, the attempt may not be successful if any of the following conditions exists:

- The interrogate-TCW address designated by the TCW of the I/O operation being interrogated designates an unavailable storage location or does not designate the interrogate TCW on a 64-byte boundary.
- The TCCB-TIDA flag is one in the flags field of the interrogate TCW and the TCCB-address field in the interrogate TCW does not designate the first TIDAW on a quadword boundary.
- The interrogate-TSB address designated by the TCW of the I/O operation being interrogated designates an unavailable storage location or does not designate the interrogate TSB on a double-word boundary.

If any of the above conditions is true, the subchannel is made status pending with program check and interrogate-failed status indicated in the subchannel-extended-status field of the IRB.
The attempt to transport the interrogate TCCB is also not successful when a device-detected program check is recognized. In this case, interrogate-failed status is also indicated in the subchannel-extended-status field of the IRB.

If the interrogate TCCB has been sent and the corresponding interrogate response is not received within a model-dependent amount of time, an interface-control check is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

**The Attempt to Transport the Interrogate TCCB is Successful:** When the channel subsystem determines that the attempt to transport the interrogate TCCB was successful and the interrogate data has been received at the subchannel before the completion of the I/O operation being interrogated, the interrogate data is stored into the interrogate TSB, and the subchannel is made status pending with intermediate status and interrogate-complete status indicated. The status related to the operation being interrogated remains unchanged.

When the channel subsystem determines that the operation being interrogated has completed before the interrogate data has been received at the subchannel, the channel subsystem waits until the interrogate data is received. When received, the interrogate data is stored into the interrogate TSB, and the subchannel is made status pending with primary status indicated. The status related to the operation being interrogated is unchanged.

**Execution of I/O Operations**

After a channel path is chosen, the channel subsystem, if conditions allow, initiates the execution of an I/O operation with the associated device. Execution of additional I/O operations may follow the initiation and execution of the first I/O operation.

For subchannels operating in command mode, the channel subsystem can execute seven types of commands: write, read, read backward, control, sense, sense ID, and transfer in channel. Each command, except transfer in channel, initiates a corresponding I/O operation. Except for periods when channel-program execution is suspended at the subchannel (see "Suspension of CCW Channel-Program Execution" on page 73), the subchannel is active from the acceptance of the first command until the primary interruption condition is recognized at the subchannel. If the primary interruption condition is recognized before the acceptance of the first command, the subchannel does not become active. Normally, the primary interruption condition is caused by the channel-end signal or, in the case of command chaining, the channel-end signal for the last CCW of the chain. (See “Primary Interruption Condition” on page 4.) The device is active until the secondary interruption condition is recognized at the subchannel. Normally, the secondary interruption condition is caused by the device-end signal or, in the case of command chaining, the device-end signal for the last CCW of the chain. (See “Secondary Interruption Condition” on page 5.)

For subchannels operating in transport mode, the channel subsystem can transport six types of commands for execution: write, read, control, sense, sense ID, and interrogate. Each command initiates a corresponding device operation. When one or more commands are transported to the I/O device in a TCCB, the subchannel remains start pending until primary status is presented.

**Programming Notes:**

In the single-path mode, all transfers of commands, data, and status for the I/O operation or chain of I/O operations occur on the channel path over which the first command was transferred to the device.

When the device has the dynamic-reconnection feature installed, an I/O operation or chain of I/O operations may be performed in the multipath mode. To operate in the multipath mode, MODIFY SUBCHANNEL must have been previously executed for the subchannel with bit 13 of word 1 of the SCHIB specified as one. (See “Multipath Mode (D)” on page 4.) In addition, the device must be set up for the multipath mode by the execution of certain model-dependent commands appropriate to that type of device. The general procedures for handling multipath-mode operations are as follows:

1. **Setup**
   a. A set-multipath-mode type of command must be successfully executed by the device on each channel path that is to be a member of the multipath group being set up; otherwise, the multipath mode of operation may give unpredictable results at the subchannel. If,
for any reason, one or more physically available channel paths to the device are not included in the multipath group, these channel paths must not be available for selection while the subchannel is operating in the multipath mode. A channel path can be made not available for selection by having the corresponding LPM bit set to zero either in the SCHIB prior to the execution of MODIFY SUBCHANNEL or in the ORB prior to the execution of START SUBCHANNEL.

b. When a set-multipath-mode type of command is transferred to a device, only a single channel path must be logically available in order to avoid alternate channel-path selection for the execution of that start function; otherwise, device-busy conditions may be detected by the channel subsystem on more than one channel path, which may cause unpredictable results for subsequent multipath-mode operations. This type of setup procedure should be used whenever the membership of a multipath group is changed.

2. Leaving the Multipath Mode

To leave the multipath mode and continue processing in the single-path mode, either of the following two procedures may be used:

a. A disband-multipath-mode type of command may be executed for any channel path of the multipath group. This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. No start function may be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that or subsequent start functions.

b. A resign-multipath-mode type of command is executed on each channel path of the multipath group (the reverse of the setup described in item 1 on page 23). This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. No start function may be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that or subsequent start functions.

### Blocking of Data

Data recorded by an I/O device is divided into blocks. The length of a block depends on the device; for example, a block can be a card, a line of printing, or the information recorded between two consecutive gaps on magnetic tape.

The maximum amount of information that can be transferred in one I/O operation is one block. An I/O operation is terminated when the associated main-storage area is exhausted or the end of the block is reached, whichever occurs first. For some operations, such as writing on a magnetic-tape unit or at an inquiry station, blocks are not defined, and the amount of information transferred is controlled only by the program.

### Operation-Request Block

The operation-request block (ORB) is the operand of START SUBCHANNEL. The ORB specifies the parameters to be used in controlling that particular start function. These parameters include the interruption parameter, the subchannel key, the address of first CCW or the TCW, operation-control bits, priority-control numbers, and a specification of the logical availability of channel paths to the designated device.

The contents of the ORB are placed at the designated subchannel during the execution of START SUBCHANNEL, prior to the setting of condition code 0. If the execution will result in a nonzero condition code, the contents of the ORB are not placed at the designated subchannel.

The two rightmost bits of the ORB address must be zeros, placing the ORB on a word boundary; otherwise, a specification exception is recognized.

When the fibre-channel-extensions (FCX) facility is installed, the channel-program-type control (B) (word
1, bit 13) of the ORB specifies the type of channel program that is designated by the ORB. When B is zero, the ORB designates a CCW channel program. When the B is one, the ORB designates a TCW channel program. Only I/O-devices that support FCX recognize TCW channel programs.

If the contents of an ORB that designates a CCW channel program are placed at the designated subchannel during the execution of START SUBCHANNEL, the subchannel remains in command mode. Thus, such an ORB is also known as a command-mode ORB. If the contents of an ORB that designates a TCW channel program are placed at the designated subchannel during execution of START SUBCHANNEL, the subchannel enters transport mode. Thus, such an ORB is also known as a transport-mode ORB.

**Command-Mode ORB**

This section describes the command-mode ORB. The term operation-request block (ORB), in this section, means an ORB in which bit 13 of word 1 (the channel-program-type control (B)) is zero.

The format of the command-mode ORB is as follows:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>

</tbody>
</table>

**Figure 15-5. Command-Mode Operation-Request Block**

The fields in the command-mode ORB are defined as follows:

**Interruption Parameter:** Bits 0-31 of word 0 are preserved unmodified in the subchannel until replaced by a subsequent START SUBCHANNEL or MODIFY SUBCHANNEL instruction. These bits are placed in word 1 of the interruption code when an I/O interruption occurs and when an interruption request is cleared by the execution of TEST PENDING INTERRUPTION.

**Subchannel Key:** Bits 0-3 of word 1 form the subchannel key for all fetching of CCWs, IDAUs, MIDAUs, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 11.

**Suspend Control (S):** Bit 4 of word 1 controls the performance of the suspend function for the channel program designated in the ORB. The setting of the S bit applies to all CCWs of the channel program designated by the ORB (see “Commands and Flags for CCWs” on page 75).

When bit 4 is one, suspend control is specified, and channel-program suspension occurs when a suspend flag set to one is detected in a CCW. When bit 4 is zero, suspend control is not specified, and the presence of a suspend flag set to one in any CCW of the channel program causes a program-check condition to be recognized.

**Streaming-Mode Control (C):** Bit 5 of word 1 controls streaming-mode enablement for subchannels configured to FICON-converted-I/O-interface channel paths during performance of the specified start function. When bit 5 is zero, the streaming mode is enabled at the subchannel. When bit 5 is one, the streaming mode is disabled at the subchannel. Bit 5 is meaningful only for subchannels configured to FICON-converted-I/O-interface channel paths and is ignored for subchannels configured to other channel-path types.

When the streaming mode is enabled, the channel path considers the first command of the designated channel program to be in progress at the associated device when the channel path receives the indication that the command has been accepted at the device. In addition, the channel path's acceptance of status, under certain conditions, is recognized by the channel path without receiving acknowledgement of status acceptance from the device.

When the streaming mode is not enabled, the channel path does not consider the first command of the designated channel program to be in progress at the associated device until the appropriate channel-path response, indicating that the device-command response or status has been accepted at the channel path, is sent to the device. In addition, when the device sends status to the channel path, the channel path considers this status to be in progress at the associated device only when a subsequent START SUBCHANNEL instruction is received.
path’s acceptance of that status is not recognized at the channel path until the channel path’s confirmation of acceptance is received and acknowledged by the device.

**Modification Control (M):** Bit 6 of word 1 specifies whether modification control is required for the channel program. When bit 6 is zero, modification control is specified. When bit 6 is one, modification control is not specified.

When modification control is specified, the channel subsystem forces command synchronization with the addressed I/O device each time a command is executed and the previously executed command has the PCI and chain-command flags set to one and the chain-data and suspend flags set to zero. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device for the current command. The channel subsystem temporarily suspends command chaining and does not fetch (or refetch) the next command-chained CCW until after normal ending status is received for the synchronizing command.

When modification control is not specified, then command synchronization is not required, and the channel subsystem may transfer commands to the I/O device without waiting for status.

The M bit is meaningful only for subchannels configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and is ignored for other subchannels configured to other channel-path types.

**Programming Notes:**

1. For FICON-I/O-interface and FICON-converted-I/O-interface channel paths, modification control provides the capability to optimize dynamically modified channel programs that use the PCI flag in the CCW to initiate channel-program modification. Specifically, it allows the program to delay the channel-subsystem fetching and transferring of commands until after status is received for the command following the command with the PCI bit set. This increases the likelihood that a program-controlled interruption will be accepted by a CPU and acted upon by the program that dynamically modifies one or more command-chained CCWs that follow the synchronizing command.

In order to increase the probability that any dynamically modified CCWs are fetched after their modification and not prior to their modification, the modifying program should be executed as soon as possible following the CPU’s acceptance of the program-controlled interruption. Additionally, the program should minimize the periods during which the configured CPUs are disabled for I/O interruptions.

For channel paths other than FICON-I/O-interface or FICON-converted-I/O-interface channel paths, command synchronization is implicit in the signaling protocol between the channel subsystem and the I/O device; therefore no explicit programming action is required to force command synchronization. Regardless, the program should still attempt to accept and process program-controlled interruptions for these channel-path types in as timely a manner as possible for the same reason as stated above.

2. In order to allow the channel subsystem to optimize the execution of channel programs for FICON-I/O-interface or FICON-converted-I/O-interface channel paths, use of the modification-control facility is discouraged except for channel programs that require dynamic modification.

**Synchronization Control (Y):** Bit 7 of word 1 specifies whether synchronization control is required for the channel program. When bit 7 is zero and the prefetch-control bit, bit 9 of word 1, is one, synchronization control is specified. When bit 7 is one and bit 9 is one, synchronization control is not specified.

When synchronization control is specified, the channel subsystem forces command synchronization with the addressed I/O device whenever the current command in execution describes an input operation and the next CCW to be fetched describes an output operation. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device when the input command is transferred. The transfer of the output command is held pending at the subchannel until normal ending status, signaling the completion of the performance of the input operation by the I/O device, is received. Upon receipt of the ending status, the channel subsystem fetches (or refetches) the data associated with the output command and transfers it to the I/O device.

When synchronization control is not specified, the channel subsystem may transfer commands of the channel program without awaiting status that would
signal the completion of the I/O operation for each command.

The Y bit is meaningful only when the subchannel is configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and the prefetch-control bit, bit 9 of word 1, is one. The Y bit is ignored for subchannels configured to other channel-path types and when the prefetch-control bit is zero.

**CCW-Format Control (F):** Bit 8 of word 1 specifies the format of the channel-command words (CCWs) that make up the channel program designated by the channel-program-address field. When bit 8 of word 1 is zero, format-0 CCWs are specified. When bit 8 is one, format-1 CCWs are specified. (See “Channel-Command Word” on page 30 for the definition of the CCW formats.)

**Prefetch Control (P):** Bit 9 of word 1 specifies whether or not unlimited prefetching of CCWs is allowed for the channel program. When bit 9 is one, unlimited prefetching of CCWs is allowed. (Unlimited prefetching of data, IDAWs, and MIDAWs, associated with the current and prefetched CCWs is always allowed.) It is model dependent whether prefetching is actually performed.

When bit 9 of word 0 is zero, no prefetching is allowed, except in the case of data chaining on output, where the prefetching of one CCW describing a data area is allowed. When bit 9 of word 0 is zero, the synchronization-control bit, bit 7 of word 1, is ignored.

Additional controls may limit the scope of prefetching.

**Initial-Status- Interruption Control (I):** Bit 10 of word 1 specifies whether or not the channel subsystem must verify to the program that the device has accepted the first command associated with a start or resume function. When the I bit is specified as one in the ORB, then, when the subchannel becomes active, indicating that the first command has been accepted for this start or resume function, the Z bit (see “Zero Condition Code (Z)” on page 12) is set to one at this subchannel, and the subchannel becomes status pending with intermediate status. Intermediate status may also be indicated in this case when the command is accepted if the first CCW contained the PCI flag set to one.

**Address-Limit-Checking Control (A):** When the address-limit-checking facility is installed, bit 11 of word 1 specifies whether or not address-limit checking is specified for the channel program. When this bit is zero, no address-limit checking is performed for the execution of the channel program, independent of the setting of the limit-mode bits in the subchannel (see “Limit Mode (LM)” on page 3). When this bit is one, address-limit checking is allowed for the channel program, subject to the setting of the limit-mode bits in the subchannel.

When the address-limit-checking facility is not installed, the address-limit-checking-control bit (A) must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**Suppress-Suspended-Interruption Control (U):** Bit 12 of word 1, when one, specifies that the channel subsystem is to suppress the generation of an intermediate interruption condition due to suspension if the subchannel becomes suspended. When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel becomes suspended during the execution of the channel program.

**Channel-Program Type Control (B):** Bit 13 of word 1 specifies the type of channel program that is designated by the channel-program-address field. When bit 13 is zero, the channel-program-address field designates a CCW channel program. When bit 13 is one, the channel-program-address field designates a TCW channel program. If the FCX facility is not installed and this bit is one, an operand exception or program-check exception is recognized.

Bit 13 also designates the layout of the ORB. When bit 13 is zero, a command-mode ORB is specified. When bit 13 is one, a transport-mode ORB is specified.

**Format-2-IDAW Control (H):** Bit 14 of word 1 specifies the format of IDAWs for CCWs that specify indirect data addressing. When bit 14 of word 1 is one, format-2 (64-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW. When bit 14 of word 1 is...
zero, format-1 (31-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW.

Programming Note: Format-2 IDAWs and MIDAWs provide the only means by which data can be transferred directly between an I/O device and storage locations with addresses greater than 2G bytes.

2K-IDAW Control (T): Bit 15 of word 1 specifies the main-storage block size for format-2-IDAW data areas. Bit 15 is meaningful only when bit 14 (format-2 IDAW control) is one and is ignored when bit 14 is zero. When bit 15 of word 1 is one, all format-2 IDAWs designate 2K-byte storage blocks. When bit 15 of word 1 is zero, all format-2 IDAWs designate 4K-byte storage blocks.

Logical-Path Mask (LPM): Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, resume, or start functions when requested by the program, except when a dedicated-allegiance condition exists for that channel path. If a dedicated-allegiance condition exists, the setting of the LPM is ignored, and a resume, start, halt, or clear function is performed by using the channel path having the dedicated allegiance.

Incorrect-Length-Suppression Mode (L): When bit 8 of word 1 is one, then bit 24 of word 1, when one, specifies the incorrect-length-suppression mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a non-zero value in bit positions 16-31, indication of an incorrect-length condition is suppressed. When bit 8 of word 1 is zero, the value of bit 24 is ignored by the channel subsystem, and the subchannel is in the incorrect-length-suppression mode.

Modified-CCW-Indirect-Data-Addressing Control (D): When the modified-CCW-indirect-data-addressing facility is installed, bit 25 of word 1 specifies whether the channel program may include CCWs that specify modified-CCW-indirect-data-address lists. When bit 25 of word 1 is one, the channel program may include CCWs that specify lists of quad-words each called a modified-CCW-indirect-data-address word (MIDAW). When bit 25 of word 1 is zero, the channel program may not include CCWs that specify modified-CCW-indirect-data-address lists.

When the modified-CCW-indirect-data-addressing facility is not installed, the modified-CCW-indirect-data-addressing control must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

ORB-Extension Control (X): Bit 31 of word 1 specifies whether the ORB is extended. When bit 31 of word 1 is zero, the ORB consists of words 0-2, and words 3-7 are ignored. When bit 31 of word 1 is one, the ORB consists of words 0-7. Words 0 and 1 are described above. Words 2-7 are described below.

Reserved: Bits 26-30 of word 1 are reserved for future use and must be set to zeros. Bit 31 of word 1 must be zero if the ORB-extension facility is not installed. Otherwise, an operand exception or program-check condition is recognized.

Channel-Program Address: Bits 1-31 of word 2 specify the absolute address of the first CCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized. If format-0 CCWs are specified by bit 8 of word 1, then bits 1-7 of word 2 also must be zeros; otherwise, a program-check condition is recognized.

The three rightmost bits of the channel-program address must be zeros, designating the CCW on a doubleword boundary; otherwise, a program-check condition is recognized.
If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular configuration, the start function is not initiated at the device. In this situation, the subchannel becomes status pending with primary, secondary, and alert status.

**Channel-Subsystem (CSS) Priority:** When bit 31 (X) of word 1 of the ORB is one, byte 0 of word 3 contains an unsigned binary integer, called the channel-subsystem-priority number, that is assigned to the designated subchannel and used to order the selection of subchannels when either a start function or a resume function is to be initiated for one or more subchannels that are start pending or resume pending.

The specified channel-subsystem-priority number can be any number in the range of 0 to 255. The numbers 0 and 255 designate the lowest and highest priorities, respectively.

Depending on the model and the configuration:

1. Fewer than 256 priority levels may be provided. For such models, the ORB-specified priority number may be ignored, and an alternative priority number may be implicitly assigned to the subchannel when the subchannel becomes start pending.

2. When bit 31 (X) of word 1 of the ORB is zero, an implicit priority number is assigned to the subchannel.

See “Channel-Subsystem-I/O-Priority Facility” on page 29 for details about how the priority number is assigned for both of these cases.

**Control-Unit (CU) Priority:** When bit 31 (X) of word 1 of the ORB is one, byte 2 of word 3 contains an unsigned binary integer, called the control-unit-priority number, that specifies, for an associated control unit attached by a FICON channel path, the priority level that is applied at the associated control unit for all I/O operations associated with the start function.

The specified control-unit-priority number can be any integer in the range of 1 to 255. The numbers 1 and 255 designate the lowest and highest priorities, respectively. The number 0 designates that no priority is assigned to the I/O operations associated with the start function. The handling of I/O operations when the priority number is 0 depends on the control-unit model.

Also depending on the control-unit model, fewer than 255 priority levels may be supported by the control unit. See the control-unit’s System Library publication for additional information regarding the range of priority numbers supported and how this priority number is used.

The specified control-unit-priority number is ignored if any of the following conditions exists:

1. Bit 31 (X) of word 1 is zero. In this case, a control-unit-priority number of 0 is transmitted in the associated outbound frames.

2. The designated subchannel is not associated with a control unit configured to a FICON channel path.

3. The associated control unit does not provide prioritized performance of I/O operations. In this case, the control-unit-priority number in the associated outbound frames is ignored at the control unit.

4. The channel-subsystem model does not provide for the transmission of the control-unit-priority number.

5. The channel-subsystem-I/O-priority facility is not operational due to an operator action.

**Reserved:** All fields in the ORB that are defined as either "0" or "Reserved" must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

**Programming Notes:**

1. Bit positions of the ORB that presently are specified to contain zeros may in the future be assigned for the control of new functions.

2. The interruption parameter may contain any information, but ordinarily the information is of significance to the program handling the I/O interruption.

**Transport-Mode ORB**

This section describes the transport-mode ORB. The term operation-request block (ORB), in this section,
means an ORB in which bit 13 of word 1 (the channel-program-type control (B)) is one.

The format of the transport-mode ORB is as follows:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interruption Parameter</td>
</tr>
<tr>
<td>1</td>
<td>Key: 0 0 0 0 0 0 0 0 0 0 1 0 0 LPM 0 0 0 0 0 0 X</td>
</tr>
<tr>

<td>6</td>
<td>Reserved</td>
</tr>
<tr>
<td>7</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

![Figure 15-6. Transport-Mode Operation-Request Block](image)

The fields in the transport-mode ORB are defined as follows:

**Interruption Parameter:**  This field has the same meaning as in the ORB that designates a CCW channel program. See “Interruption Parameter” on page 2.

**Subchannel Key:**  Bits 0-3 of word 1 form the subchannel key for all fetching of TCWs, TCCBs, TIDAWS, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 11.

All storage accesses to the TSB are made as if the subchannel key is zero.

**Reserved:**  All fields in the ORB that are defined as either “0” or “Reserved” must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

**Channel-Program Type Control (B):**  This bit has the same meaning as in the ORB that designates a CCW channel program. For the transport-mode ORB, the value of this bit is one. See “Channel-Program Type Control (B)” on page 27.

**Logical-Path Mask (LPM):**  Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, or start functions when requested by the program.

If the LPM specifies a channel path that does not support FCX, either an operand-exception or a program check may be recognized.

**ORB-Extension Control (X):**  This field has the same meaning as in the ORB that designates a CCW channel program. See “ORB-Extension Control (X)” on page 28.

**Channel-Program Address:**  Bits 1-31 of word 2 specify the absolute address of the TCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized.

The six rightmost bits of the channel-program address must be zeros, designating the TCW on a 64-byte boundary; otherwise, a program-check condition is recognized.

If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular configuration, the start function is not initiated at the device. In this situation, the subchannel becomes status pending with primary, secondary, and alert status.

**Channel-Subsystem (CSS) Priority:**  This field has the same meaning as in the ORB that designates a CCW channel program. See “Channel-Subsystem (CSS) Priority” on page 29.

**Reserved for Program Use (Rsv. for Pgm.):**  Byte 2 of word 3 is reserved for program use and is not checked or used by the channel subsystem.

**Programming Note:**  See the programming notes on page 29.

**Channel-Command Word**

The channel-command word (CCW) specifies the command to be executed and, for commands initiat-
ing certain I/O operations, it designates the storage area associated with the operation, the action to be taken whenever transfer to or from the area is completed, and other options.

A channel program consists of one or more CCWs that are logically linked such that they are fetched and executed by the channel subsystem in either a sequential or a nonsequential order. Sequential (contiguous) CCWs are linked by the use of the chain-data and chain-command flags, and nonsequential (noncontiguous) CCWs are linked by a CCW specifying the transfer-in-channel command.

As each CCW is executed, it is recognized as the current CCW. A CCW becomes current (1) when it is the first CCW of a channel program and has been fetched, (2) when, during command chaining, the new CCW is logically fetched, or (3) when, during data chaining, the new CCW takes over control of the I/O operation (see “Data Chaining” on page 61). When chaining is not specified, a CCW is no longer current after TEST SUBCHANNEL clears the start-function bit in the subchannel.

The location of the first CCW of the channel program is designated in the ORB that is the operand of START SUBCHANNEL. The first CCW is fetched subsequent to the execution of the instruction. The format of the CCWs fetched by the channel subsystem is specified by bit 8 of word 1 of the ORB. Each additional CCW in the channel program is obtained when the CCW is needed. Fetching of the CCWs by the channel subsystem does not affect those locations in main storage.

CCWs have either of two different formats, format 0 or format 1. The two formats do not differ in the information contained in the CCW, but they do differ in the size of the address and the arrangement of fields within the CCW.

The formats are defined as follows:

Format-0 CCW

<table>
<thead>
<tr>
<th>Cmd Code</th>
<th>Data Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>Flags</td>
<td>/ / / / / / /</td>
</tr>
<tr>
<td>Count</td>
<td>32 40 48 63</td>
</tr>
</tbody>
</table>

Format-1 CCW

<table>
<thead>
<tr>
<th>Cmd Code</th>
<th>Flags</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>16</td>
</tr>
<tr>
<td>Data Address</td>
<td>32 63</td>
<td></td>
</tr>
</tbody>
</table>

Flags

<table>
<thead>
<tr>
<th>C</th>
<th>C</th>
<th>L</th>
<th>S</th>
<th>P</th>
<th>I</th>
<th>D</th>
<th>K</th>
<th>M</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>34</td>
<td>36</td>
<td>38</td>
<td>40</td>
<td>42</td>
<td>44</td>
<td>46</td>
<td>48</td>
</tr>
</tbody>
</table>

Format-0 CCWs can be located anywhere in the first $2^{24}$ (16M) bytes of absolute storage, and format-1 CCWs can be located anywhere in the first $2^{31}$ (2G) bytes of absolute storage.

If indirect data addressing is specified and the format-2-IDAW-control bit is zero in the ORB associated with the CCW, then:

1. Bits 30 and 31 (format 0) or 62 and 63 (format 1) of the CCW must be zeros, designating a word boundary,
2. Bit 0 of the first entry of the indirect-data-address list must be zero.
3. The MIDA flag must be zero.

If indirect data addressing is specified and the format-2-IDAW-control bit is one in the ORB associated with the CCW, then:

1. Bits 29-31 (format 0) or bits 61-63 (format 1) of the CCW must be zeros, designating a doubleword boundary.

If modified indirect data addressing is specified, then:

1. The modified-CCW-indirect-data-addressing-control bit in the ORB must be one.
2. Bits 28-31 (format 0) or bits 60-63 (format 1) of the CCW must be zeros, designating a quadword boundary.

3. The CCW SKP and IDA flags must be zero.

4. The MIDAW count field must be greater than zero.

5. The combination of the MIDAW count and data-address fields must not specify the transfer of data across a 4K-byte boundary, unless skipping is in effect for the MIDAW.

6. Reserved bits in the first entry of the modified-CCW-indirect-data-address list must be zero.

When any of these requirements is not met, a program-check condition may be recognized (see “CCW Indirect Data Addressing” on page 66 and “Modified CCW Indirect Data Addressing” on page 68). Detection of this condition during data chaining causes the I/O device to be signaled to conclude the operation. When a failure to meet these requirements is detected during command chaining or subsequent to the execution of START SUBCHANNEL, the new operation is not initiated, and an interruption condition is generated.

The contents of bit positions 40-47 of a format-0 CCW are ignored.

The fields in the CCWs are defined as follows:

**Command Code:** Bits 0-7 (both formats) specify the operation to be performed.

**Data Address:** Bits 8-31 (format 0) or bits 33-63 (format 1) designate a location in absolute storage. The designated location is the first location referred to in the area designated by the CCW. Bit 32 of a format-1 CCW must be zero; otherwise, a program-check condition is recognized. If a byte count of zero is specified, this field is not checked.

When the MIDA flag is one, the data-address field must designate an absolute storage location that is on a quadword boundary; otherwise, a program-check condition is recognized.

See “CCW Indirect Data Addressing” on page 66 and “Modified CCW Indirect Data Addressing” on page 68 for information about the specification of data addresses greater than 2G bytes.

**Chain-Data (CD) Flag:** Bit 32 (format 0) or bit 8 (format 1), when one, specifies chaining of data. The bit causes the storage area designated by the next CCW to be used with the current I/O operation. When the CD flag is one in a CCW, the chain-command and suppress-length-indication flags (see below) are ignored.

**Chain-Command (CC) Flag:** Bit 33 (format 0) or bit 9 (format 1), when one, and when the CD flag and S flag are both zeros, specifies chaining of commands. The bit causes the operation specified by the command code in the next CCW to be initiated upon the normal completion of the current operation.

**Suppress-Length-Indication (SLI) Flag:** Bit 34 (format 0) or bit 10 (format 1) controls whether an incorrect-length condition is to be indicated to the program. When this bit is one and the CD flag is zero, the incorrect-length indication is suppressed. When both the CC and SLI flags are ones and the CD flag is zero, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified in all CCWs where suppression of the incorrect-length indication is desired.

**Skip (SKP) Flag:** Bit 35 (format 0) or bit 11 (format 1), when one, specifies the suppression of transfer of information to storage during a read, read-backward, sense ID, or sense operation. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

**Program-Controlled-Interruption (PCI) Flag:** Bit 36 (format 0) or bit 12 (format 1), when one, causes the channel subsystem to generate an intermediate interruption condition when the CCW containing the bit takes control of the I/O operation. When the PCI flag bit is zero, normal operation takes place.

**Indirect-Data-Address (IDA) Flag:** Bit 37 (format 0) or bit 13 (format 1), when one, specifies indirect data addressing. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

**Suspend (S) Flag:** Bit 38 (format 0) or bit 14 (format 1), when one, specifies suspension of channel-program execution. When valid, it causes channel-program execution to be suspended prior to the execution of the CCW containing the S flag. A one value of the S flag is valid when bit 4 of word 1 of the associated ORB is one.
**Modified-Indirect-Data-Address (MIDA) Flag:** Bit 39 (format 0) or bit 15 (format 1), when one, specifies modified indirect data addressing. This bit must be zero when the modified-CCW-indirect-data-addressing-control bit in the ORB is zero, the CCW IDA flag is one, the CCW SKP flag is one, or the channel paths associated with the subchannel do not support modified CCW indirect data addressing; otherwise, a program-check condition is recognized.

**Count:** Bits 48-63 (format 0) or bits 16-31 (format 1) specify the number of bytes in the storage area designated by the CCW.

### Transport Control Word

The transport-control word (TCW) specifies a transport-command-control block (TCCB) whose contents are to be transported to the I/O device for processing. The TCCB contains one or more device-command words (DCWs) and associated options. For a DCW that specifies a command which initiates the transfer of data (with the exception of control data contained within the TCCB), the TCW designates one or more storage areas where the data is located.

When a TCW specifies bidirectional data transfer and the designated DCWs specify write data transfers for storage areas that overlap with the storage areas for read data transfers, the results are unpredictable.

When START SUBCHANNEL is issued specifying a transport-mode ORB, the TCW designated by the ORB becomes the current TCW, the subchannel becomes start pending, and the TCCB designated by the TCW is transported to the I/O device for execution. The TCW remains the current TCW until TEST SUBCHANNEL clears the start-function indication in the subchannel.

The TCW is a 64-byte control block that is designated on a 64-byte boundary. For all operations, except for the interrogate operation, accesses to the TCW by the channel subsystem are made using the subchannel storage-access key specified in the ORB. For interrogate operations, fetch accesses to the interrogate TCW by the channel subsystem are made as if a subchannel storage-access key of zero is used. The channel subsystem does not make any store accesses to a TCW.

---

**The format of the TCW is as follows:**

<table>
<thead>
<tr>
<th>Word</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>F</td>

</tr>
<tr>
<td>9</td>
<td>Interrogate-TCW Address</td>
</tr>
</tbody>
</table>

**Format (F):** Bits 0-1 of word 0 form the TCW-format that contains a 2-bit unsigned integer value that defines the layout of the TCW. The value of this field must be zero, otherwise a program-check condition is recognized.

**Reserved:** Bits 2-7 of word 0 are reserved and must be zeros, otherwise a program-check condition is recognized.

**Reserved:** Bytes 0 and 2-3 of word 1 and words 12-14 are reserved and not checked. These fields are reserved for future extensions. Programs which place nonzero values in these fields may not operate compatibly on future models.

**Flags:** Bytes 1-3 of word 0 contain information about the TCW. The meaning of each flag bit is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-4</td>
<td>Reserved. Bits 0-4 are reserved and must be zero, otherwise a program-check condition is recognized.</td>
</tr>
</tbody>
</table>
| 5   | Input transport-indirect-data addressing (TIDA): When bit 5 is zero and bit 14 of word 1 (the R-bit) is one, the input-data-
address field designates the absolute address of the input location. When bit 5 is one and the R-bit is one, the input-data-address field designates the absolute address of a transport-indirect-data-address word (TIDAW) or the first TIDAW in a list of TIDAWS that designate the input storage location or locations, respectively.

When the R-bit is zero, bit 5 has no meaning.

6 Transport-command-control-block TIDA: When bit 6 is zero, the transport-command-control-block-address field designates the absolute address of the transport-command-control block for the TCW. When bit 6 is one, the transport-command-control-block-address field designates the absolute address of a TIDAW or list of TIDAWS that designate the location or locations, respectively, of the transport-command-control block for the TCW.

7 Output TIDA: When bit 7 is zero and bit 15 of word 1 (the W-bit) is one, the output-data-address field designates an output location in absolute storage. When bit 7 is one and the W-bit is one, the output-data-address field designates the absolute address of a TIDAW or list of TIDAWs that designate the output location or locations, respectively.

When the W-bit is zero, bit 7 has no meaning.

8-9 TIDAW format: Bits 8-9 form a 2-bit encoded field that specifies the format of TIDAWs designated by the TCW. This field must contain zeros, otherwise a program-check condition is recognized.

10-23 Reserved. Bits 10-23 are reserved and must be zero, otherwise a program-check condition is recognized.

Transport-Command-Control-Block Length (TCCBL): Bits 8-13 of word 1, with two zeros appended on the right, specify the unsigned integer whose value, when added to 20 for unidirectional data transfers or when added to 24 for bidirectional data transfers, specifies the length of the TCCB in bytes. This field, before having 20 added to it for unidirectional data transfers or before having 24 added to it for bidirectional data transfers, must specify a length that is between 12 and 244 inclusive, otherwise a program-check condition is recognized.

Note: The TCCBL is based on the FCP additional command length and does not include the TCA header (16 bytes), and the transport-count (4 bytes) in the TCA trailer for unidirectional data transfers, nor does it include the write count (4 bytes) and read count (4 bytes) in the TCA trailer for bidirectional data transfers.

Read Operations (R): When bit 14 of word 1 is one, the input count (word 11) is valid and contains a nonzero value, indicating the number of bytes to be transferred into main storage.

Write Operations (W): When bit 15 of word 1 is one, the output count (word 10) is valid and contains a nonzero value, indicating the number of bytes to be transferred from main storage.

If the R-bit and W-bit are both one and the device does not support bidirectional data transfer, and flags bit 10 is zero, a program-check condition is recognized.

If the W-bit is one and the TCW is an interrogate TCW, a program-check condition is recognized.

Output-Data Address: When bit 15 of word 1 (the W-bit) is one and bit 7 of the flags field (the output-TIDA flag) is zero, words 2-3 designate the 64-bit output location in absolute storage. When the W-bit is one and the output-TIDA flag is one, words 2-3 designate the 64-bit location in absolute storage of a TIDAW or list of TIDAWs that designate the output storage location or locations.

When the W-bit is one and the output-TIDA flag is one, words 2-3 must designate a storage location that is on a quadword boundary, otherwise a program-check condition is recognized.

When the W-bit is zero, words 2-3 have no meaning and are ignored.

Input-Data Address: When the bit 14 of word 1 (the R-bit) is one and bit 5 of the flags field (the input-TIDA flag) is zero, words 4-5 designate the 64-bit input location in absolute storage. When the R-bit is one and the input-TIDA flag is one, words 4-5 desig-
nate the location in absolute storage of a TIDAW or list of TIDAWs that designate the input storage location(s).

When the R-bit is one and the input-TIDA flag is one, words 4-5 must designate a storage location that is on a quadword boundary, otherwise a program-check condition is recognized.

When the R-bit is zero, words 4-5 have no meaning and are ignored.

Transport-Status-Block Address: Words 6-7 designate the 64-bit location in absolute storage of the transport-status block for the TCW.

Words 6-7 must designate a storage location on a doubleword boundary, otherwise a program-check condition is recognized.

Transport-Command-Control-Block Address: If the transport-command-control-block-TIDA bit (bit 6 of the flags field) is zero, words 8-9 designate 64-bit location in absolute storage of the transport-command-control block. When the transport-command-control-block-TIDA bit is zero, the transport-command-control block is specified to reside in a contiguous area of storage. If the transport-command-control-block-TIDA bit is one, words 8-9 designate the 64-bit location in absolute storage of a TIDAW or list of TIDAWs that designate the location in absolute storage of the transport-command-control block. When the transport-command-control-block-TIDA bit is one, the transport-command-control block may be specified to reside in noncontiguous areas of storage.

When the transport-command-control-block-TIDA flag is zero, words 8-9 should designate a storage location on a doubleword boundary, otherwise, degradation of performance is possible.

When the transport-command-control-block-TIDA flag is one:

- Words 8-9 must designate a storage location on a quadword boundary, otherwise a program-check condition is recognized.
- The transport-command-control-block-address and transport-command-control-block-length fields must not specify a list of TIDAWs that cross a 4K-byte boundary, otherwise a program-check condition is recognized.
- The TIDAW-transfer-in-channel (TTIC) bit should be zero in all specified TIDAWs, otherwise degradation of performance is possible.
- The first TIDAW should designate the TCCB on a doubleword boundary; otherwise, degradation of performance is possible.

Output Count: When bit 15 of word 1 (the W-bit) is one, word 10 contains the unsigned integer total count of output bytes for the TCW.

When the W-bit is one and word 10 contains zeros, a program-check condition is recognized.

When the W-bit is one:

- The output-count value, rounded upwards to the nearest multiple of 4, plus 4, should equal the value in the transport-count field in the associated TCCB for unidirectional data transfers or the value in the write-count field in the associated TCCB for bidirectional transfer, otherwise this may lead to a device-detected-program-check condition being recognized.
- The output-count value should equal the sum of the following, otherwise this may lead to a device-detected-program-check condition being recognized.
  - The sum of count field values in all of the DCWs that specify a write command.
  - The sum of the count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI. (Note that the size of a TCMI reserved field may be zero. See “Transport-Command DCW” on page 42.)
  - The count of any inserted padding and CBC bytes when flags bit 7 (the output-TIDA bit) is one as follows:
    - Four bytes for the CBC information for every TIDAW designated by the output-address field for which the insert-CBC flag bit is one.
    - The count of padding bytes added for every TIDAW designated by the output-address field for which the insert-CBC
flag bit is one. (See “Transport Indirect Data Addressing” on page 70.)

When the R-bit is one and word 11 contains zeros, a program-check condition is recognized.

When the W-bit is zero, word 10 is ignored.

**Input Count:** When bit 14 of word 1 (the R-bit) is one, word 11 contains the unsigned integer total count of input bytes for the TCW.

When the R-bit is one and word 11 contains zeros, a program-check condition is recognized.

When the R-bit is one:

- The input-count value, rounded upwards to the nearest multiple of 4, plus 4, should equal the value in the transport-count field in the associated TCCB for unidirectional transfer or the value in the read-count field in the associated TCCB for bidirectional transfer, otherwise this may lead to a device-detected-program-check condition being recognized.

- The input-count value should equal the sum of count fields in all of the DCWs that specify a read-type command in the associated TCCB and any such DCWs specified in a TCA extension, otherwise this may lead to a device-detected-program-check condition being recognized.

When the R-bit is zero, word 11 is ignored.

**Interrogate-TCW Address:** When a START SUBCHANNEL designates a TCW, word 15 of the TCW is not checked. When a CANCEL SUBCHANNEL designates a subchannel that is start pending for a TCW channel program and is not status pending, bits 1-31 of word 15 of the TCW designated by START SUBCHANNEL specify the 31-bit location in absolute storage of the interrogate-TCW that is used to initiate an interrogate operation for the subchannel. If word 15 contains zeros when CANCEL SUBCHANNEL is issued, an interrogate operation is not initiated.

When CANCEL SUBCHANNEL is issued, bit 0 of word 15 must be zero, otherwise a program-check condition is recognized with interrogate-failed status indicated. When CANCEL SUBCHANNEL is issued and bits 1-31 of word 15 do not contain zeros, bits 1-31 of word 15 must designate a storage location on a 64-byte boundary, otherwise a program-check condition is recognized with interrogate-failed status indicated.

**Transport-Command-Control Block**

The transport-command-control block (TCCB) is variable in length, contains header and trailer information, and from 1 to 30 device-command words (DCWs) that are logically linked such that they are executed by the control unit in a sequential manner.

A TCCB may reside as a single block of contiguous storage or it may reside as multiple blocks of noncontiguous storage. The TCCB-TIDA flag specifies whether the TCCB resides in contiguous storage. When the flag is zero, the TCW designates a contiguous TCCB. When the flag is one, the TCW designates one or more TIDAWs that designate the location of the TCCB in noncontiguous storage.

The transport-command-control block is designated on a doubleword boundary and has a maximum length of 264 bytes. For non-interrogate operations, fetch accesses to the TCCB by the channel subsystem are made using the subchannel storage-access key specified in the ORB. For interrogate operations, fetch accesses to the interrogate TCCB by the channel subsystem are made as if a storage-access key of zero is used. The channel subsystem does not make any store accesses to a TCCB nor does it examine its contents.
The format of the TCCB is as follows:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Transport-Command-Area Header (TCAH)</td>
</tr>
<tr>
<td>3</td>
<td>Transport-Command Area (TCA)</td>
</tr>
<tr>
<td>N</td>
<td>Transport-Command-Area Trailer (TCAT)</td>
</tr>
</tbody>
</table>

**Transport-Command-Area Header**

The transport-command-area header (TCAH) is a 16-byte control block that contains information about the transport-command area and the operations described therein. The TCAH has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Format Control</td>
</tr>
<tr>
<td>1</td>
<td>Reserved</td>
</tr>
<tr>
<td>2</td>
<td>Service-Action Code (SAC)</td>
</tr>
<tr>
<td>3</td>
<td>Priority</td>
</tr>
</tbody>
</table>

**Format Control:** Byte 0 of word 0 is the TCCB format control. The value of this field must be 7F hex, otherwise a device-detected-program-check is recognized.

**Reserved:** Byte 1 of word 0 is reserved and must contain zeros, otherwise a device-detected-program-check condition may be recognized. Bytes 2-3 of word 0, bytes 0-2 of word 1, byte 2 of word 2, and bytes 0-3 of word 3 are reserved and should contain zeros, otherwise the channel program may not operate compatibly in the future.

**Transport-Command-Area Length (TCAL):** Byte 3 of word 1 specifies an 8-bit unsigned integer whose value, when reduced by 12, specifies the length of the TCA in bytes. The specified value must be a non-zero multiple of 4 that is between 20 and 252, inclusive, otherwise a device-detected-program-check condition may be recognized.

**Service-Action Code (SAC):** Bytes 0-1 of word 2 contain an unsigned integer value that must be either 1FFE hex or 1FFF hex. The meanings of these values is device dependent.

**Priority:** Byte 3 of word 2 contains the 8-bit unsigned binary integer priority value for the TCCB. A value of zero indicates that no priority has been assigned. Valid priority values range from 1, the lowest priority, to 255, the highest priority.

**Transport-Command Area**

The transport-command area (TCA) is a variable-length area that contains from 1 to 30 device-command words (DCWs). The length of the TCA is an integral number of words.

For DCWs that specify control data, the TCA also contains the control data associated with the commands. Each DCW that specifies control data, reduces the maximum-DCW capacity by one or more DCWs, depending on the size of the command-associated data.

For DCWs that specify input or output data, the TCW specifying the TCCB designates the associated storage area or areas (see “Input-Data Address” on page 34 and “Output-Data Address” on page 34) and the DCW designates the count of bytes to transfer.

For some devices, the list of DCWs may be extended past what will fit in the TCA. For such devices, the TCA extension (TCAX) is specified and transferred as if it were output data; however, the TCAX is treated as a logical continuation of the TCA instead of transfer data. (See “Transport-Command-Area Extension” on page 45.) A TCAX is specified by the transfer-TCA-extension DCW. (See “Transfer-TCA-Extension DCW” on page 44.)

Whether a device supports TCA extensions is determined by device-dependent means.
The maximum size of the TCA is 240 bytes. The TCA has the following format:

<table>
<thead>
<tr>
<th>Word (from the beginning of the TCA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>N</td>
</tr>
</tbody>
</table>

*Figure 15-10. Transport-Command Area (TCA)*

**Device-Command Word**

A device-command word (DCW) specifies a command to be executed. For commands initiating certain I/O operations, it designates the count of bytes on which the operation is performed, the action to be taken whenever transfer to or from storage is completed, and other options. The storage area or areas associated with a DCW data-transfer operation are designated, depending on the operation specified by the command, by the input-data-address field or the output-data-address field of the TCW that designates the transport-control-block containing the DCW. Whether the input-data-address field or the output-data-address field of the TCW designates the storage directly or indirectly, by use of a TIDAW list, is specified by the input-TIDA and output-TIDA flags in the TCW, respectively.

For commands initiating control operations, the associated data immediately follows the command. If this data is not a multiple of 4 bytes, the field immediately following the data begins on the next word boundary that immediately follows the last byte of specified data. In the TCA, this field will be either the next DCW, if additional DCWs are specified, or the transport-command-area trailer, if additional DCWs are not specified. When the DCW is in a transport-command-area extension (TCAX), this field will be one of the following:

- The next DCW when additional DCWs are specified.
- The TCAX reserved area when present, and additional DCWs are not specified.
- The end of the TCAX when the TCAX reserved area is not present and additional DCWs are not specified.

As each DCW is executed and while it is executing it is recognized as the current DCW. A DCW becomes current when it is the first DCW of a channel program and has been selected by the I/O device for execution or when, during command chaining, the subsequent DCW takes over control of the I/O operation.

The first DCW to be executed is at offset zero of the TCA in the TCCB. Each additional DCW in the channel program is also in the TCA and is used when the DCW is needed by the I/O device.

The DCW is an 8-byte control block that is designated on an word boundary. The format of the DCW is as follows:

<table>
<thead>
<tr>
<th>Word</th>
<th>Cmd Code</th>
<th>Flags</th>
<th>Reserved</th>
<th>CD Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8 9 10 11</td>
<td>15</td>
<td>8 9 10 11</td>
<td>15</td>
</tr>
</tbody>
</table>

*Figure 15-11. Device-Command Word (DCW)*

**Command Code**: Bits 0-7 of word 0 specify the operation to be performed.

Whether a command is valid is device dependent and dependent on the value of the service-action-code field in the TCAH.

**Reserved**: Bits 8, 11-15, and 16-23 of word 0 are reserved and should contain zeros, otherwise the channel program may not operate compatibly in the future. When the FCX-incorrect-length-indication facility is not installed or the device does not support incorrect-length indication, bit 10 of word 0 is reserved and should contain zero, otherwise the
channel program may not operate compatibly in the future.

**Chain-Command (CC) Flag:** Bit 9 of word 0, when one, specifies the chaining of commands. When one, the bit causes the operation specified by the next DCW to be initiated upon normal completion of the current DCW. When the control-data count is zero, the next DCW immediately follows the DCW in the TCA or TCAX. When the control-data count is not zero, the next DCW immediately follows the control-data, rounded to a word boundary, specified for the DCW.

If bit 9 of word 0 is one in a DCW whose offset, plus 8, plus its control-data-count value leaves less than 8 bytes in the TCA and a TCAX is not specified, a device-detected-program-check condition may be recognized.

If bit 9 of word 0 is one in a DCW whose offset, plus 8, plus its control-data-count value leaves less than 8 bytes in the TCAX, a device-detected-program-check condition may be recognized.

If bit 9 of word 0 is zero in a DCW whose offset, plus 8, plus its control-data-count value leaves greater than 3 bytes remaining in the TCA, a device-detected-program-check condition may be recognized.

**Note:** When the chain-command flag is one, the next DCW location in the TCA or TCAX is determined by adding eight and the value in the CD-count field to the location of the current DCW and rounding upwards to the nearest word boundary. If the chain-command flag is one in a DCW in a TCA, the next DCW location is past the end of the TCA, and a TCAX is specified, the next DCW is at the beginning of the TCAX.

**Suppress-Length-Indication (SLI) Flag:** When the FCX-incorrect-length-indication facility is installed and the device supports incorrect-length indication, bit 10 of word 0 controls whether an incorrect-length condition is to be indicated to the program when the condition is recognized for the DCW in control as follows:

- When the SLI flag is one, incorrect-length indication is suppressed. When both the CC and SLI flags are ones, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified as one in all DCWs where suppression of the incorrect-length indication is desired.

  - When the SLI flag is not one, processing of the TCA is terminated (command-chaining is terminated) and the subchannel is made status pending with incorrect length indicated in the subchannel status.

When an incorrect-length condition exists for a DCW and the SLI flag in the DCW is set to zero, data transfer occurs as follows for read operations:

  - If the DCW count is greater than the amount of data available at the device for the command, the data available at the device is transferred.

  - If the DCW count is less than the amount of data available at the device for the command, only an amount of data equal to the DCW count is transferred.

When an incorrect-length condition exists for a DCW and the SLI flag in the DCW is set one, data transfer occurs as follows for read operations:

  - If the DCW count is greater than the amount of data available at the device for the command and the DCW chain-command (CC) flag is one, the following occurs in order:

    1) The data available at the device is transferred.

    2) Pad bytes of zeros are transferred until the total amount transferred is equal to the DCW count.

  - If the DCW count is greater than the amount of data available at the device for the command and the DCW chain-command (CC) flag is zero, the following occurs in order:

    1) The data available at the device is transferred.

    2) Depending on the device, either data transfer is terminated or pad bytes of zeros are transferred until the total amount transferred is equal to the DCW count.

  - If the DCW count is less than the amount of data available at the device for the com-
mand, only an amount of data equal to the DCW count is transferred.

When an incorrect-length condition exists for a DCW, data transfer occurs as follows for write operations regardless of the setting of the SLI flag:

- If the DCW count is greater than the amount of data required by the device for the command and the DCW chain-command (CC) flag is one, the following occurs in order:
  1) The data required by the device is transferred.
  2) Data continues to be transferred until the total amount transferred is equal to the DCW count. Data not required by the device is discarded.

- If the DCW count is greater than the amount of data required by the device for the command and the DCW chain-command (CC) flag is zero, the following occurs in order:
  1) The data required by the device is transferred.
  2) Data continues to be transferred until the next intermediate CBC is specified to be inserted or until the total amount transferred is equal to the DCW count. Data not required by the device is discarded.

- For write operations, if the DCW count is less than the amount of data required by the device for the command, only the amount of data specified by the DCW count is transferred.

Whether a device supports the suppression of incorrect-length indication is determined by device-dependent means.

**Control-Data (CD) Count:** When the command-code field specifies a command that requires control data, the data for the command immediately follows the DCW and byte 3 of word 0 specifies the length of the data, in bytes. If the command code specifies a command that requires control data and byte 3 of word 0 specifies a control-data count that is less than required for the command a unit-check condition is recognized. If the command code specifies a command that requires control data and byte 3 of word 0 contains zero or contains a value that specifies data past the end of the TCA or past the end of the specified TCAX, a device-detected-program-check condition is recognized.

**Count:** Word 1 specifies the 32-bit unsigned integer count of bytes in the storage area designated by the TCW for this DCW.

**Transport-Command-Area Trailer**
The transport-command-area trailer (TCAT) contains additional information about the TCCB. When uni-directional data transfer is specified (either the R-bit or the W-bit is set to one) or no data transfer is specified (both the R-bit and W-bit in the TCW are set to zero), the TCAT is two words in length. When bidirectional data transfer is specified (both the R-bit and the W-bit in the TCW are set to one), the TCAT is three words in length. The TCAT has the following format:

**Word (from the beginning of the TCA trailer)**

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reserved</td>
</tr>
<tr>
<td>1</td>
<td>Transport Count or Write Count</td>
</tr>
<tr>
<td>2</td>
<td>Not Present or Read Count</td>
</tr>
</tbody>
</table>

*Figure 15-12. Transport-Command-Area Trailer (TCAT)*

**Reserved:** Word 0 is reserved and not checked.

**Transport Count:** When uni-directional data transfer is specified, word 1 is the transport count and specifies the 32-bit unsigned integer count of total data to be transferred.

When a read operation is specified (the TCW R-bit is one), the value in the transport-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a read-type command are summed.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

When a read operation is specified, the transport-count value should be equal to the value in the TCW input-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.
When a write operation is specified (the W-bit in the TCW is one), the value in the transport-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a write command are summed.
- The count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI are added to the sum. (Note that the size of a TCMI reserved field may be zero. See “Transport-Command DCW” on page 42.)

- The total of the counts of any TIDAW-specified CBC bytes and padding bytes (see “Transport Indirect Data Addressing” on page 70) is added to the sum.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

The write-count value should be equal to the value in TCW output-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

**Write Count:** When bidirectional data transfer is specified, word 1 is the write count and specifies the 32-bit unsigned integer count of total output data to be transferred. The value in the write-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a write command are summed.

**Programming Note:** The following table summarizes the determination of the TCW input-count, output-
count, and the TCCB transport count values for unidirectional data transfers:

<table>
<thead>
<tr>
<th>Operation</th>
<th>TCW Input Count</th>
<th>TCW Output Count</th>
<th>TCAT Transport Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input operation (TCW R-bit is 1)</td>
<td>Sum of DCW count values in the TCA.</td>
<td>n/a</td>
<td>Sum of DCW count values in TCA, rounded to four,(^2) plus four(^2)</td>
</tr>
<tr>
<td>Output operation (TCW W-bit is 1), TIDAWS not used (TCW output-TIDA flag is 0)</td>
<td>n/a</td>
<td>Sum of DCW count values in TCA.</td>
<td>Sum of DCW count values in TCA, rounded to four,(^2) plus four(^2)</td>
</tr>
<tr>
<td>Output operation (TCW W-bit is 1), TIDAWS used (TCW output-TIDA flag is 1)</td>
<td>n/a</td>
<td>Sum of DCW count values in TCA and TCAX plus the size of the reserved areas in any specified TCMIs(^3), plus total of TIDAWS-specified CBC and padding bytes(^1)</td>
<td>Sum of DCW count values in TCA and TCAX, plus the size of the reserved areas in any specified TCMIs(^3), plus total of TIDAWS-specified CBC and padding bytes,(^1) rounded to four,(^2) plus four(^2)</td>
</tr>
</tbody>
</table>

Explanation:
1. See the description of the insert-CBC control in “Flags” on page 70.
2. The channel subsystem adds a CBC word to the end of the last data transported. Up to 3 padding bytes are added after the last data transported to ensure the added CBC word is on a word boundary.
3. Because of alignment requirements, the size of the reserved area in a TCI is either 0 or 4.

Figure 15-13. Determination of the TCAT Transport Count, TCW Input Count, and TCW Output Count for Uni-Directional Data Transfers

The following table summarizes the determination of the TCW input-count, output-count, and the TCCB read and write count values for bidirectional data transfers:

<table>
<thead>
<tr>
<th>Operation</th>
<th>TCW Input Count</th>
<th>TCW Output Count</th>
<th>TCAT Read Count</th>
<th>TCAT Write Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input operation (TCW R-bit is 1) and output operation (TCW W-bit is 1), TIDAWS not used (TCW output-TIDA flag is 0)</td>
<td>Sum of read DCW count values in the TCA and TCAX.</td>
<td>Sum of write DCW count values in the TCA, plus count values in DCWs that specify the transfer of TCI</td>
<td>Sum of read DCW count values in the TCA and TCAX, rounded to four,(^2) plus four(^2)</td>
<td>Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCI, rounded to four,(^2) plus four(^2)</td>
</tr>
<tr>
<td>Input operation (TCW R-bit is 1) and output operation (TCW W-bit is 1), TIDAWS used (TCW output-TIDA flag is 1)</td>
<td>Sum of read DCW count values in the TCA and TCAX.</td>
<td>Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCI, plus the size of the reserved areas in any specified TCMIs(^3), plus total of TIDAWS-specified CBC and padding bytes.(^1)</td>
<td>Sum of read DCW count values in the TCA and TCAX, rounded to four,(^2) plus four(^2)</td>
<td>Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCI, plus the size of the reserved areas in any specified TCMIs(^3), plus total of TIDAWS-specified CBC and padding bytes,(^1) rounded to four,(^2) plus four(^2)</td>
</tr>
</tbody>
</table>

Explanation:
1. See the description of the insert-CBC control in “Flags” on page 70.
2. The channel subsystem adds a CBC word to the end of the last data transported. Up to 3 padding bytes are added after the last data transported to ensure the added CBC word is on a word boundary.
3. Because of alignment requirements, the size of the reserved area in a TCI is either 0 or 4.

Figure 15-14. Determination of the TCAT Transport Count, TCW Input Count, TCAT Read Count, and TCAT Write Count for Bidirectional Data Transfers

Transport-Command DCW
A transport-command DCW specifies a transport command that performs a device-support function associated with transport-mode operations. (See “Command Code” on page 57.) A transport-command DCW may specify control data and may also specify the transfer of transport-command-meta information (TCMI).

When a transport-command DCW specifies the transfer of TCMI to a device, the TCMI is transferred as output data. The size of the TCMI is command-
dependent and is a multiple of 4. Furthermore, the TCMI may be extended by 4 reserved bytes when all of the following are true:

- The size of the TCMI is an even multiple of 4.
- TIDAWs are used to specify the output storage areas.
- The insert-CBC flag is one in the last TIDAW used to specify the storage containing the TCMI.
- The chain-command bit is one in the transport-command DCW that specifies the TCMI.
- A subsequent DCW specifies the transfer of a TCMI or output data.

Note that when a transport command specifies the transfer of a TCMI to a device and the TCMI is extended by 4 reserved bytes because all of the preceding conditions are met, the 4 reserved bytes are not included in the data-count value in the transport-command DCW but are included in the following:

- The count value in the last TIDAW used to specify the storage containing the TCMI.
- The output-count value in the TCW.
- The transport-count value in the associated TCCB for unidirectional data transfers or the write-count value in the associated TCCB for bidirectional transfer.

The following summarizes the transport-command DCWs and identifies the specific TCMI that may be transferred to the device:

<table>
<thead>
<tr>
<th>Transport-Command DCW</th>
<th>Transport-Command-Meta Information (TCMI)</th>

**Explanation:**
- (none) - The transport-command DCW does not transfer TCMI.

**Figure 15-15. Summary of Transport-Command DCWs**

**Transfer-CBC-Offset-Block DCW**

For write operations, the transfer-CBC-offset-block (TCOB) DCW specifies that a CBC-offset block (COB) is transported to the device. The content of the TCOB DCW is as follows:

- The output-TIDA flag (flags bit 7) in the TCW
- The command code contains the transfer-CBC-offset-block command which is a value of 60 hex.
- The chain-command flag is one.
- When the CD-count is not zero, the COB immediately follows the TCOB DCW in the TCA and the CD-count specifies the number of CBC offsets in the COB multiplied by 4.
- When the CD-count is zero, the COB is specified as TCMI in the output data, the location of the COB is specified by the output-data-address field in the TCW, and the count field specifies the number of CBC offsets in the COB multiplied by 4.

The incorrect-length condition is not recognized for the transfer-CBC-offset-block command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

When a TCOB DCW is used, a device-detected program check is recognized when any of the following conditions exist:

- A TCOB DCW is specified and a write operation is not specified (that is, the W-bit in the TCW is zero).
- A TCOB DCW is the only DCW in the TCA. (That is the chain-command flag in the TCOB DCW is zero.)
- A TCOB DCW is not the first DCW in the TCA.
- More than one TCOB DCW is specified
- The control-data-count field and the count field in the TCOB DCW both contain the value zero or both contain a value that is nonzero.
- The control-data-count field contains the value zero, the count field contains a value that is nonzero, but the value in the count field is not a multiple of 4.
- The count field contains the value zero, the control-data-count field contains a value that is nonzero, but the value in the control-data-count field is not a multiple of 4.

When a TCOB is used that specifies the COB in the output data, the following must be true; otherwise, a device-detected program check may be recognized:

- The count field must be one.
The insert-CBC control must be set to one in the last or only TIDAW that is used to transfer the COB when the transfer of a TCAX or output data or both is also specified.

When there is an odd number of CBC offsets in the COB, the total of the count fields in the TIDAWs used to the transfer the COB must specify the number of CBC offsets in the COB multiplied by 4. When there is an even number of CBC offsets in the COB, the total of the count fields in the TIDAWs used to the transfer the COB must specify the number of CBC offsets in the COB multiplied by 4, plus 4.

Whether a device recognizes the TCOB command is determined by device-dependent means.

CBC-Offset Block

The CBC-offset block (COB) is a variable-length control block that contains a list of 4-byte entries, each of which identifies the offset of a CBC specified by a TIDAW to be inserted in the output data. When the COB is specified in the output data, the offset of the CBC inserted by the TIDAW that specifies the transfer of the COB is not included in the COB.

Accesses to a CBC-offset block by the channel sub-system are treated as if a storage-access key of zero is used.

The COB has the following format:

<table>
<thead>
<tr>
<th>4-Byte Entry</th>
<th>CBC Offset 0</th>
<th>CBC Offset 1</th>
<th>...</th>
<th>CBC Offset N</th>
<th>Reserved</th>
</tr>
</thead>
</table>

(When the COB is in output data.)

**CBC Offsets:** Entries 0 through N contain CBC offsets. Each CBC offset is a 4-byte field containing a 32-bit unsigned integer value that specifies the relative offset, from the beginning of the output-data area, to a CBC that is specified to be inserted by a TIDAW. When a COB is in the TCA, the beginning of the output-data area is specified by the output-data-address field of the TCW. When a COB is in the output-data, the output-data area begins immediately after the COB.

**Reserved:** When a COB is specified in the TCA, or a COB is specified in the output data and there is an odd number of CBC offsets in the COB, there are no reserved bytes.

When a COB is specified in the output data and there is an even number of CBC offsets in the COB, the 4 bytes immediately following the last CBC offset are reserved and should contain zeros, otherwise unpredictable results may result.

See “Transport-Command DCW” on page 42 for the handling of reserved bytes when calculating the DCW count, TIDAW count, TCCB write-count (for bidirectional transfers) and TCCB transport count (for unidirectional data transfers).

**Programming Note:** When a device indicates that it supports the TCOB command and TIDAWs are used that specify insert-CBC, a TCOB and COB should be used; otherwise, unpredictable results or errors may result.

**Transfer-TCA-Extension DCW**

The transfer-TCA-extension (TTE) DCW specifies that the TCA is logically extended in the output data and that the TCA extension (TCAX) is transported to the device. The content of the TTE DCW is as follows:

- The command code contains the transfer-TCA-extension command which is the value of 50 hex.
- The chain-command flag is set to one.
- The CD-count is zero.
- The count specifies the length of the TCAX as a multiple of 4.

The incorrect-length condition is not recognized for the transfer-TCA-extension command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.
When a TTE DCW is used, a device-detected program check is recognized when any of the following conditions exist:

- When a TCOB DCW is not specified, the TTE DCW is not the first DCW in the TCA. When a TCOB DCW is specified, the TTE DCW is not the second DCW in the TCA.
- The TTE DCW is specified and a write operation is not specified (that is, the W-bit in the TCW is zero).
- The chain-command flag in the TTE DCW is zero.
- More than one TTE DCW is specified
- The control-data-count field in the TTE DCW does not contain zero.
- The count field contains less than 8 or a value that is not a multiple of 4.
- Any of the following are true for the TCA:
  - The TCA does not contain at least one DCW that is not a transport-command DCW.
  - The TCA contains one or more DCWs that are not transport-command DCWs and the chain-command flag in the last DCW of the TCA is zero.

Whether a device recognizes the TTE command is determined by device-dependent means.

**Programming-System Note:** When a TTE DCW is used and additional TCMI and/or output data follows the TCAX, the following should be true; otherwise, a device-detected program check may be recognized:

- The output-TIDA flag (flags bit 7) in the TCW must be one.
- When TIDAWs are used for the transfer of a TCAX and for the transfer of data, the insert-CBC control must be set to one in the last or only TIDAW that is used to transfer the TCAX. When TIDAWs are used for the transfer of only the TCAX, it is not necessary to set the insert-CBC control in the last or only TIDAW.

**Transport-Command-Area Extension**

The transport-command-area extension (TCAX) is a variable-length area that is the logical continuation of the TCA. At a minimum, the TCAX contains one DCW. The length of the TCAX is an integral multiple of 4 and is specified by the TTE DCW.

For DCWs that specify control data, the TCAX also contains the control data associated with the commands.

For DCWs that specify input or output data, the associated TCW designates the associated storage area or areas (see “Input-Data Address” on page 34 and “Output-Data Address” on page 34) and the DCW designates the count of bytes to transfer.

The maximum size of the TCAX is device dependent. The TCAX has the following format:

<table>
<thead>
<tr>
<th>4-Byte Entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>N</td>
</tr>
<tr>
<td>Y</td>
</tr>
</tbody>
</table>

**Explanation:**

The size of the TCAX is $4(Y+1)$, where $Y$ is an even number that is equal to either $N$ or $N+1$.

*Figure 15-17. Transport-Command Area Extension (TCAX)*

**Device-Command Word (DCW) or Control Data for Previous DCW:** For information about DCWs and control data, see “Device-Command Word” on page 38.

**Reserved:** When the last information in the TCAX is a DCW, the end of the DCW defines the end of the meaningful information in the TCAX. When the last information in the TCAX is control data and the control data ends on a 4-byte boundary, the end of the control data defines the end of the meaningful information in the TCAX. When the last information in the TCAX is control data and the control data does not end on a 4-byte boundary, padding bytes are appended to the control data to reach a 4-byte
boundary and the end of the padding bytes define the end of the meaningful information in the TCAX.

When the size of the meaningful information in the TCAX divided by four is an odd number, there are no reserved bytes; otherwise, the four bytes immediately following the meaningful information in the TCAX are reserved and should contain zeros, otherwise unpredictable results may result.

See “Transport-Command DCW” on page 42 for the handling of reserved bytes when calculating the DCW count, TIDAW count, TCAT write-count (for bidirectional transfers) and TCAT transport count (for unidirectional data transfers).

**Interrogate TCCB**

The interrogate TCCB is a TCCB that specifies a service-action code value of 1FFF hex, contains a TCA that is at least 8 bytes in length that specifies an interrogate DCW, and may specify a read operation.

Any data that immediately follows the interrogate DCW and is specified by a nonzero CD-count in the interrogate DCW is transported to the device and may be written to a device-dependent log. Any input data that is specified by the interrogate TCW is device-dependent data and is transferred from the I/O device.

Accesses to the interrogate TCCB by the channel subsystem are treated as if a storage-access key of zero is used.

The format of the interrogate TCA is as follows:

**Interrogate DCW**

Words 0 and 1 of the interrogate TCA contain a DCW that specifies an interrogate operation. The content of the interrogate DCW is as follows:

- The command code contains the interrogate command which is a value of 40 hex.
- The CD-count field must contain a value that is not greater than 232, otherwise a device-detected-program-check condition is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.
- With the exceptions of the command code, SLI flag, count and CD-count fields, all other fields in the DCW must contain zeros, otherwise a device-detected-program-check condition is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The incorrect-length condition is not recognized for the interrogate command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

**Interrogate Data**

If the CD-count of the interrogate DCW is greater than zero, interrogate data is specified. Since interrogate data is for device-dependent logging purposes only, interrogate data that is incorrectly specified does not cause any exception condition to be recognized. The interrogate data has the following format:

**Format:** Byte 0 of word 0 contains the unsigned integer value that defines the layout of the interrogate data. The value of this field should be zero, otherwise the I/O device may not recognize the layout of the interrogate data.
**Reason Code (RC):** Byte 1 of word 0 contains the unsigned integer value that indicates the reason the interrogate operation was initiated. The following values may be specified. The meaning of RC values is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interrogate reason not specified.</td>
</tr>
<tr>
<td>1</td>
<td>Timeout: Program-detected timeout for the operation being interrogated.</td>
</tr>
<tr>
<td>2-255</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

**Reason-Code Qualifier (RCQ):** Byte 2 of word 0 contains the unsigned integer value that indicates additional information about the reason the interrogate operation was initiated.

When the reason-code field contains the value one, the meaning of RCQ values are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interrogate reason qualifier not specified.</td>
</tr>
<tr>
<td>1</td>
<td>Primary: The timeout was specified by the primary program.</td>
</tr>
<tr>
<td>2</td>
<td>Secondary: The timeout was specified by a secondary program.</td>
</tr>
<tr>
<td>3-255</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

When the reason-code field does not contain the value one, the reason-code-qualifier field has no meaning.

**Logical-Path Mask (LPM):** Byte 3 of word 0 contains the LPM that was used when the operation being interrogated was initiated by START SUB-CHANNEL.

**Path-Available Mask (PAM):** Byte 0 of word 1 contains the value of the PAM at the time the interrogate operation is initiated.

**Path-Installed Mask (PIM):** Byte 1 of word 1 contains the value of the PAM at the time the interrogate operation is initiated.

**Timeout:** When the RC field contains the value one or two, bytes 2-3 of word 1 contain the timeout interval used by the designated program, in unsigned integer seconds.

**Flags:** Byte 0 of word 2 contains information about the interrogate. The meaning of each flag bit is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Multipath mode: This bit has the same setting as the multipath-mode bit (D) at the time the interrogate operation is initiated.</td>
</tr>
<tr>
<td>1</td>
<td>Program path recovery: The interrogate is issued during path recovery by the program.</td>
</tr>
<tr>
<td>2</td>
<td>Critical: The device is a critical device for the program.</td>
</tr>
<tr>
<td>3-7</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

**Reserved:** Bytes 1-3 of word 2 and word 3 are reserved.

**Time:** Words 4-5 contain the time the interrogate operation was initiated.

**Program Identifier:** Words 6-7 identify the program initiating the interrogate operation. The content of this field is program dependent.

**Program-Dependent Data:** Words 8-N contain program-dependent information.

**Programming Notes:**

1. It is assumed that the program will specify the value in the time field as UTC in the same form as the TOD clock.

2. If the interrogate operation does not complete within a model-dependent amount of time, an interface-control check condition is recognized, terminating the I/O operation being interrogated.

3. If a timeout value is specified and the timeout value is less than a device-dependent minimum, the I/O device may not write the interrogate data into its log.

**Transport Status Block**

When the TSB-valid bit in the IRB is one, the transport-status block (TSB) for the I/O operation may contain additional information about the completion of the associated TCW channel program. When the
the interrogate-complete (Q) bit in the IRB is one, the interrogate TSB may contain interrogate data.

The TSB is 64 bytes in length and is allocated on a doubleword boundary. Accesses to the TSB by the channel subsystem are treated as if a storage-access key of zero is used.

The format of the TSB is as follows:

<table>
<thead>
<tr>
<th>Word</th>
<th>Length</th>
<th>Flags</th>
<th>DCW Offset</th>
<th>Count</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
<td>0</td>
<td>3</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

Figures 15-20, 15-21. Transport-Status Block

Transport-Status Header (TSH)
The transport-status header is a 12-byte control block that contains information about the transport status. The format of the TSH is as follows:

<table>
<thead>
<tr>
<th>Word (from the beginning of the TSB)</th>
<th>Length</th>
<th>Flags</th>
<th>DCW Offset</th>
<th>Count</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
<td>0</td>
<td>3</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

Figures 15-20, 15-21. Transport-Status Header (TSH)

**Length:** Byte 0 of word 0 contains the unsigned binary integer length, in bytes, of the status information stored in the TSB. This length includes the TSH and the transport-status area (TSA), if present. If this value is less than 64, the difference between the length value and 64 specifies the number of bytes, at the end of the TSB, that are not used, have no meaning, and may or may not be stored.

**Flags:** Byte 1 of word 0 contains information about the TSB. The meaning of each flag bit is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>DCW-offset field valid. When bit 0 is one, the DCW-offset field contains a DCW-offset value. When bit 0 is zero, the DCW-offset field has no meaning.</td>
</tr>
<tr>
<td>1</td>
<td>Count field valid. When bit 1 is one, the count field contains a count value. When bit 1 is zero, the count field has no meaning.</td>
</tr>
<tr>
<td>2</td>
<td>Cache miss. When flag bits 4-7 specify an I/O-status TSB and bit 2 is one, one or more I/O-device cache misses occurred during the I/O operation. When flag bits 4-7 specify an I/O-status TSB and bit 2 is zero, no cache misses occurred.</td>
</tr>
<tr>
<td>3</td>
<td>Time fields valid. When flag bits 4-7 specify an I/O-status TSB and bit 3 is one, the device-time, defer-time, queue-time, device-busy-time, and device-active-only time fields in the I/O-status TSA contain time information. When flag bits 4-7 specify an I/O-status TSB and bit 3 is zero, the contents of the device-time, defer-time, queue-time, device-busy-time, and device-active-only time fields in the I/O-status TSA have no meaning.</td>
</tr>
<tr>
<td>4</td>
<td>Reserved.</td>
</tr>
<tr>
<td>5-7</td>
<td>TSA format. Bits 5-7 form a 3-bit unsigned integer that indicates the layout of the TSA as follows:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>TSA contents have no meaning: The other fields of the TSA do not contain meaningful data.</td>
</tr>
<tr>
<td>1</td>
<td>I/O Status TSA: The TSA contains ending status in addition to ending status in the IRB for the I/O operation.</td>
</tr>
<tr>
<td>2</td>
<td>Device-detected-program-check TSA: The TSA contains information describing the reason for the device-detected program check.</td>
</tr>
<tr>
<td>3</td>
<td>Interrogate TSA: The TSA contains interrogate response information.</td>
</tr>
</tbody>
</table>
** Reserved.

**DCW Offset:** When bit 0 of the flags field (the DCW-offset-field-valid bit) is one and the DCW-offset value is less than the size of the TCA, bytes 2-3 of word 0 contain the byte offset, from the beginning of the TCA to the DCW either partially or completely executed when the TSB is stored. When bit 0 of the flags field is one and the DCW-offset value is greater than or equal than the size of the TCA, the value in bytes 2-3 of word 0 minus the size of the TCA is the offset, from the beginning of the TCAX to the DCW either partially or completely executed when the TSB is stored.

If the channel program cannot be completed, this offset identifies the DCW for which processing could not be completed. Additional information in the IRB and TSB may be used for recovery purposes. When bit 0 of the flags field is zero, bytes 2-3 of word 0 have no meaning.

**Count:** When bit 1 of the flags field (the count-field-valid bit) is one, word 1 contains the residual count for the DCW designated by the DCW-offset field.

**Reserved:** Word 2 is reserved and contains zeros.

**Programming Note:** If the program sets the length and flags fields to zeros before initiating an operation, the program can determine whether the TSB contains meaningful information after the operation completes by checking that both the length and flags field contain nonzero values.

**I/O-Status TSA**

When the TSB-format field in the TSH contains one, the TSA has the following format:

<table>
<thead>
<tr>
<th>Word (from the beginning of the TSA)</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Device Time</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Defer Time</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Queue Time</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Device-Busy Time</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Device-Active-Only Time</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Additional Data</strong> (if present)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Figure 15-22. I/O-Status Transport-Status Area (TSA)*

**Device Time:** When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 0 contains the 32-bit unsigned integer total count of time intervals between when the I/O device received the information in the TCCB until the I/O device returned the information in the TSB. The resolution of the device time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 0 have no meaning.

**Defer Time:** When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 1 contains the 32-bit unsigned integer total count of time intervals that the I/O operation was temporarily delayed by the I/O device to perform device-dependent operations or other operations not associated with the current channel program. The resolution of the defer time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 1 have no meaning.

**Queue Time:** When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 2 contains the 32-bit unsigned integer total count of timer intervals that the I/O operation or portions of the operation were queued at the control unit while waiting for operations not associated with the current operation to complete. The resolution of the queue time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 2 have no meaning.

**Device-Busy Time:** When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 3 contains the 32-bit unsigned integer total count of time intervals that the I/O device was busy attempting to initiate a command. The resolution of the device-busy time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 3 have no meaning.

**Device-Active-Only Time:** When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one,
Word 4 contains the 32-bit unsigned integer total count of time between the time that the channel-end condition existed and the time that the channel-end and device-end conditions were recognized by the device. The resolution of the device-active time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 4 have no meaning.

**Additional Data:** When the length field in the TSH contains a value greater than 32, additional data has been provided by the I/O device. The count of meaningful additional-data bytes in this field is determined by subtracting 32 from the value in the length field.

When unit check is included in the device status, any additional data provided is sense data. When unit check is not included in the device status, any additional data provided is device dependent.

**Device-Detected-Program-Check TSA**

When the TSB-format field in the TSH contains two, the TSA has the following format:

<table>
<thead>
<tr>
<th>Word (from the beginning of the TSA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>4</td>
</tr>
</tbody>
</table>

**Reserved:** Bytes 0-2 of word 0 are reserved and have no meaning.

**Reason Code (RC):** Byte 3 of word 0 contains an 8-bit unsigned integer code that indicates the primary reason for the device-detected program check. The meaning of each reason code value is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No information: Byte 3 has no meaning.</td>
</tr>
</tbody>
</table>

1. **TCCB transport failure:** An invalid CBC was detected by the I/O device while transporting the TCCB. The reason-code-qualifier (RCQ) field contains additional information.

2. **Invalid CBC detected on output data:** An invalid CBC was detected while transferring output data. The RCQ field contains additional information.

3. **Incorrect TCCB length specification:** The RCQ field contains additional information.

4. **TCAH specification error:** The RCQ field contains additional information.

5. **DCW specification error:** There is an error with the DCW designated by the DCW-offset field in the TSH. The RCQ field contains additional information.

6. **Transfer-direction specification error:** The command specified by the DCW designated by the DCW-offset field in the TSH specifies a direction of data transfer that disagrees with the transfer direction specified in the TCW, or both the read-operation (R) and write-operation (W) bits in the TCW are set to one and the device does not support bidirectional data transfers. The RCQ field contains additional information.

7. **Transport-count specification error:** The RCQ field contains additional information.

8. **Two I/O operations active:** While an I/O operation is active at the device a second non-interrogate TCCB has been transported to the device for execution. The RCQ field has no meaning.

9. **CBC-offset specification error:** One or more CBC offsets in the CBC-offset block indicate that a CBC is at a location that is not recognized by the device or is not recognized for the designated DCW. The RCQ field contains additional information.
For a summary of the meanings of reason-code values and their associated reason-code-qualifier values see Figure 15-24 on page 54.

**Reason Code Qualifier (RCQ):** Words 1-4 may contain additional information about the reason for the device-detected program check as follows.

When the RC field contains the value one, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No additional information.</td>
</tr>
<tr>
<td>1</td>
<td>TCCB transport size error: The value of the TCCBL field of the TCW that was sent to the I/O device is not equivalent to the count of bytes actually transported for the TCCB.</td>
</tr>
<tr>
<td>2</td>
<td>TCCB CBC error: An invalid CBC was detected while transferring the TCCB.</td>
</tr>
<tr>
<td>3-255</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

When the RC field contains the value two, only words 0-1 of the RCQ field have meaning as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Word 0 contains the 32-bit unsigned integer offset of the first output-data byte for which the invalid CBC was detected.</td>
</tr>
<tr>
<td>1</td>
<td>Word 1 contains the 32-bit unsigned integer offset of the last byte of the last output-data word for which the invalid CBC was detected.</td>
</tr>
<tr>
<td>2</td>
<td>Reserved-field specification error: A reserved field in the TCAH does not contain zeros.</td>
</tr>
<tr>
<td>3</td>
<td>Service-action-code-field specification error: The service-action-code field in the TCAH contains an unrecognized value or a value that is incorrect for command specified by the DCW designated by the DCW-offset field in the TSH. See “Service-Action Code (SAC)” on page 37.</td>
</tr>
<tr>
<td>4-255</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

When the RC field contains the value three, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No additional information.</td>
</tr>
<tr>
<td>1</td>
<td>The value specified by the TCAL field is not 8 greater than the value specified by the TCCBL field in the TCW for the operation.</td>
</tr>
<tr>
<td>2</td>
<td>The value specified by the TCAL field is less than 20 or greater than 252.</td>
</tr>
<tr>
<td>3-255</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

When the RC field contains the value four, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>

</tr>
</tbody>
</table>

When the RC field contains the value five, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No additional information.</td>
</tr>
<tr>
<td>1</td>
<td>Reserved-field specification error: A reserved field in the DCW does not contain zeros.</td>
</tr>
</tbody>
</table>
| 2     | Flags-field command-chaining specification error: Either of the following is true:
• The chain-command flag is one and the offset of the next DCW is such that all or part of the next DCW extends past the end of the TCA or TCAX.

• The chain-command flag is zero and more than 3 unused bytes remain in the TCA or TCAX (excluding the TCAX reserved field).

• The DCW is the last DCW in the TCA, a TCAX is not specified, and the chain-command flag is one.

• The DCW is the last DCW in the TCAX and the chain-command flag is one.

See "Chain-Command (CC) Flag" on page 39.

Control-data-count-field specification error: The CD-count field specifies control data past the end of the TCA or TCAX.

See "Control-Data (CD) Count" on page 40.

TCOB location error: The TCOB DCW is not the first DCW in the TCA

TCOB duplication error: More than one TCOB DCW is specified.

TCOB multiple-count error: The control-data-count field and the count field in the TCOB DCW both specify the value zero or both specify a nonzero value.

TCOB direction error: A TCOB DCW is specified and the write-operation (W) in the TCW is zero.

TCOB chaining error: The chain-command bit in the TCOB DCW is zero.

TCOB count-specification error: Either of the following is true:

• The count field in the TCOB is zero, the control-data-count field in the TCOB DCW is nonzero, and the count field in the TCOB specifies a value that is not an even multiple of four.

• The control-data-count field in the TCOB is zero, the count field in the TCOB DCW is nonzero, and the count field in the TCOB specifies a value that is not an even multiple of four.

TTE location error: Either of the following is true:

• A TCOB DCW is not specified and the TTE DCW is not the first DCW in the TCA.

• A TCOB DCW is specified and the TTE DCW specified is not the second DCW in the TCA.

TTE duplication error: More than one TTE DCW is specified.

TTE CD-count specification error: The control-data-count field in the TTE DCW specifies a value that is not zero.

TTE count specification error: The count field in the TTE DCW specifies a value that is less than 8 or a value that is not a multiple of 4.

TTE direction error: A TTE DCW is specified and the write-operation (W) in the TCW is zero.

TTE chaining error: The chain-command bit in the TTE DCW is zero.

TCAx specification error: A TTE DCW is specified and any of the following is true:

• The TCA does not contain at least one DCW that specifies the transfer of data (that is, at least one DCW that is not a transport-command DCW).

• The TCA contains one or more DCWs that specify the transfer of data and the chain-command flag in the last DCW of the TCA is zero.

17-255 Reserved.

When the RC field contains the value six, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by
the RC field and the meaning of each RCQ value is as follows:

<table>

*Figure 15-25. Interrogate Transport-Status Area (TSA)*

**Format:** Byte of word 0 contains the unsigned integer value that defines the layout of the interrogate TSA. If the value of this field is not one, the contents of the interrogate TSA are meaningless.

**Flags:** Byte 1 of word 0 contains information about the interrogate TSA. The meaning of each flag bit is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Control-unit-state valid: When bit 0 is one, the control-unit-state field contains meaningful information. When bit 0 is zero, the control-unit-state field has no meaning.</td>
</tr>
<tr>
<td>1</td>
<td>Device-state valid: When bit 1 is one, the device-state field contains meaningful information. When bit 1 is zero, the device-state field has no meaning.</td>
</tr>
<tr>
<td>2</td>
<td>Operation-state valid: When bit 2 is one, the operation-state field contains meaningful information. When bit 2 is zero, the operation-state field has no meaning.</td>
</tr>
<tr>
<td>3-7</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

**Control-Unit State (CS):** Byte 2 of word 0 contains an 8-bit unsigned integer that indicates a current state of the control unit for the I/O device. The meaning of each value is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Busy: The control unit is busy and the device-dependent-data field may contain additional information about the busy state.</td>
</tr>
<tr>
<td>1</td>
<td>Recovery: The control unit is performing a recovery process and the device-dependent-data field may contain additional information about the recovery state.</td>
</tr>
<tr>
<td>2</td>
<td>Interrogate maximum: The control unit is executing the maximum number of interrogate operations that it supports.</td>
</tr>
<tr>
<td>3-127</td>
<td>Reserved.</td>
</tr>
<tr>
<td>128-255</td>
<td>Device-dependent meanings.</td>
</tr>
</tbody>
</table>

**Device State (DS):** Byte 3 of word 0 contains an 8-bit unsigned integer that indicates a current state of the I/O device. The meaning of this byte is:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Path-group identification: The state-dependent-information field contains information identifying a path group.</td>
</tr>
<tr>
<td>1</td>
<td>Long busy: The device is in a long-busy state. The meaning of long busy is device dependent and the device-dependent field may contain additional information about the long-busy state.</td>
</tr>
<tr>
<td>2</td>
<td>Recovery: The device is performing a recovery process and the device-dependent-data field may contain additional information about the recovery state.</td>
</tr>
<tr>
<td>3-127</td>
<td>Reserved.</td>
</tr>
<tr>
<td>128-255</td>
<td>Device-dependent meanings.</td>
</tr>
</tbody>
</table>

**Operation State (OS):** Byte 0 of word 1 contains an 8-bit unsigned integer that indicates whether an I/O operation is present at the device and, when present, the state of the operation. The meaning of this byte is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No I/O operation is present.</td>
</tr>
</tbody>
</table>
1 An I/O operation is present and executing.
2 An I/O operation is present and waiting for completion of an I/O operation that was initiated by another configuration.
3 An I/O operation is present and waiting for completion of an I/O operation that was initiated for the same device extent.
4 An I/O operation is present and waiting to perform a device-dependent operation.
5-127 Reserved.
128-255 Device-dependent meanings.

**State-Dependent Information:** Words 2-4 may contain state-dependent information. Whether this field has meaning is designated by the CS, DS, and OS fields.

The contents of this field are device dependent. When the device places one or more bytes in this field, they are left justified.

**Device-Level Identifier:** Word 5 contains a device-dependent token that identifies the implementation level of the device.

**Device-Dependent Data:** Words 6-12 contain device dependent information. Whether this field has meaning is designated by the CS, DS, and OS fields.

When the device places one or more bytes in this field, they are left justified.

**Note:**

1. An interrogate TSA is stored only in a TSB designated by an interrogate TCW.
2. If a program-check condition is recognized for an interrogate TCCB, a device-detect-program-check TSA is stored in the TSB designated by the interrogate TCW.

**Command Code**

For CCW channel programs, the command code, bit positions 0-7 of the CCW, specifies to the channel subsystem and the I/O device the operation to be performed. For TCW channel programs, the command code, bit positions 0-7 of the DCW, specifies to the I/O device the operation to be performed.

With the exception of transport commands, the two rightmost bits or, when these bits are zeros, the four rightmost bits of the command code identify the operation to the channel subsystem. The channel subsystem distinguishes among the following operations:

- Control
- Output forward (write)
- Input forward (read, sense, sense ID)
- Input backward (read backward)
- Branching (transfer in channel)
- Interrogate
- Transport

For CCW channel programs, the channel subsystem ignores the leftmost four bits of the command code in a format-0 CCW that specifies transfer-in-channel. In a format-1 CCW that specifies transfer in channel, all bits of the command code are decoded by the channel subsystem.

For CCW channel programs, commands that initiate I/O operations (write, read, read backward, control, sense, and sense ID) cause all eight bits of the command code to be transferred to the control unit.

In command codes that initiate I/O operations, the leftmost bit positions contain modifier bits. The modifier bits specify to the device how the command is to be executed. They may, for example, cause the device to compare data received during a write operation with data previously recorded, and they may specify such attributes as recording density and parity. For the control command, the modifier bits may contain the order code specifying the control function to be performed. The meaning of the modifier bits depends on the type of I/O device and is specified in the System Library publication for the device.

The command-code assignment is listed in Figure 15-26 on page 58. The symbol x indicates that the bit position is ignored; the symbol m identifi-
fies a modifier bit.

<table>

</tr>
</tbody>
</table>

**Explanation:**
- m: Modifier bit
- x: Ignored
  - May designate control data in DCWs.
  - CCW only
  - Format-0 CCW
  - Format-1 CCW
  - Format-1 CCW with any of bits 0-3 nonzero
  - DCW only

![Figure 15-26. Command-Code Assignment](image)

Whenever the channel subsystem detects an invalid command code during the initiation of command execution for a CCW channel program, the program-check-interruption condition is generated, and channel-program execution is terminated. The command code is ignored during data chaining, unless it specifies transfer in channel.

Whenever an I/O device detects an invalid command code while executing the commands in a TCCB, a device-detected-program-check condition is recognized and channel-program execution is terminated.

### Designation of Storage Area

For CCW channel programs, the main-storage area associated with an I/O operation is defined by one or more CCWs. A CCW defines an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred is specified either directly in the data-address field of the CCW or indirectly in an indirect-data-address word (IDAW) or modified-indirect-data-address word (MIDAW) designated by the data-address field of the CCW. The number of bytes contained in the storage area is specified in the count field.

For TCW channel programs the main-storage area associated with an I/O operation is designated by a TCW. A TCW designates an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred for input operations is specified either directly in the input-data-address field of the TCW or indirectly by a transport-indirect-data-address word (TIDAW) designated by the input-data-address field of the TCW. The number of bytes contained in the storage area for input operations is specified in the input-count field. The address of the first byte of data to be transferred for output operations is specified either directly in the output-data-address field of the TCW or indirectly by a TIDAW designated by the output-data-address field of the TCW. The number of bytes contained in the storage area for output operations is specified in the output-count field. In this case, the actual number of bytes in the storage area is determined by subtracting the number of any inserted padding or CBC bytes from the output-count field value. The address of the first byte of data to be transferred into the TSB is specified in the TSB-address field of the TCW. The number of bytes contained in the storage area for the TSB is dependent on the status being returned and is a maximum of 64.

In general, for write, read, control, and sense operations, storage locations are used in ascending order of addresses. As information is transferred to or from main storage, the address from the appropriate address field is incremented, and the count from the associated count field is decremented. For command-mode operations, the read-backward operation places data in storage in a descending order of addresses, and both the count and the address are decremented. When the associated count reaches zero, the storage area defined by the CCW is exhausted.

When a subchannel is operating in transport mode, the channel subsystem may take advantage of performance optimizations and access storage locations in a non-sequential order within the storage area or areas designated by the current TCW. When a transport-mode operation is concluded, the transfer of specified data, as indicated by information in the I/O-status TSB, is complete.
Any main-storage location available to the start function can be used in the transfer of data to or from an I/O device, provided that the location is not protected against that type of reference. Format-0 CCWs can be located in any available part of the first $2^{24}$ (16M) bytes of absolute storage, and format-1 CCWs and TCWs can be located in any available part of the first $2^{31}$ (2G) bytes of absolute storage, provided that, in both cases, the location is not protected against a fetch-type reference. When the channel subsystem attempts to refer to a protected location, the protection-check condition is generated, and the device is signaled to terminate the operation.

A main-storage location is available if it is available in the configuration and access to the location is not prevented by the address-limit-checking facility. CCWs, TCWs, ISDs, TSBs, and the data they address reside in main-storage locations. If a main-storage location is not available, it is said to have an invalid address.

If the channel subsystem refers to a location that is not available, the program-check condition is generated. When the first CCW or TCW designated by the channel-program address is at an unavailable location, the start function is not initiated at the device, the status portion of the SCSW is updated with the program-check indication, the subchannel becomes status pending with primary, secondary, and alert status, and deferred condition code 1 is indicated. An invalid data address, as well as any invalid CCW address detected on chaining or subsequent to the execution of START SUBCHANNEL, causes the channel subsystem to signal the device to stop, and the I/O operation is terminated. The channel subsystem sets the incorrect-length condition if the SLI flag is not one in the CCW. No data is transferred. If the device does not request data transfer, the operation proceeds to the normal ending point.

During an output operation, the channel subsystem may fetch data from main storage before the time the I/O device requests the data. Any number of bytes specified by the current CCW or TCW may be prefetched and buffered.

When data chaining during an output operation for a CCW channel program, the channel subsystem may fetch one CCW describing a data area at any time during the execution of the current CCW. If unlimited prefetching is allowed by the setting of the prefetch-control bit in the ORB CCW channel program, any number of CCWs, IDAWs, and MIDAWs and the associated data may be prefetched by the channel subsystem. When the I/O operation uses data or CCWs from locations near the end of the available storage, such prefetching may cause the channel subsystem to refer to locations that do not exist. Invalid addresses detected during prefetching do not affect the performance of the I/O operation and do not cause error indications until the operation actually attempts to use the information. If the operation is concluded by the I/O device or by the execution of HALT SUBCHANNEL or CLEAR SUBCHANNEL before the invalid information is needed, the condition is not brought to the attention of the program.

The count field in the CCW can specify any number of bytes up to 65,535. In format-0 CCWs, the count field is always nonzero unless the command code specifies transfer in channel, in which case the count field is ignored. In format-1 CCWs, the count field may contain the value zero unless data chaining is specified or the CCW is fetched while data chaining. Whenever (1) the count field in a format-1 CCW is zero, (2) data chaining is either not specified or not in effect, and (3) data transfer is requested by the device, the device is signaled to stop, and the I/O operation is terminated. The channel subsystem sets the incorrect-length condition if the SLI flag is not one in the CCW. No data is transferred. If the device does not request data transfer, the operation proceeds to the normal ending point.

If a zero byte count is contained in a format-0 CCW that does not specify transfer in channel, or if a zero byte count is contained in a format-1 CCW that specifies data chaining or was fetched while data chaining, a program-check condition is recognized, and the subchannel is made status pending with combinations of primary, secondary, and alert status as a function of the state of the subchannel and the status received from the device.

The input-count and output-count fields in the TCW can specify any number of bytes up to $2^{32} - 8$. For input operations, the input-count field is always nonzero; otherwise, a program-check condition is recognized. For output operations, the output-count field is always nonzero; otherwise, a program-check condition is recognized.

**Note:** For a description of the storage area associated with a CCW when indirect data addressing is
used, see “CCW Indirect Data Addressing” on page 66. For a description of the storage area associated with a TCW when indirect data addressing is used, see “Transport Indirect Data Addressing” on page 70.

Programming Notes:

1. Since a format-1 CCW with a count of zero is valid, the program can use the CCW count field to specify that no data be transferred to the I/O device. If the device requests a data transfer, the device is signaled to terminate data transfer. If the SLI and chain-command flags are also specified as ones, and no unusual conditions are encountered subsequent to signaling the device to terminate data transfer, the new operation is initiated upon receipt of device end from the device.

2. If the subchannel is in the incorrect-length-suppression mode, the chain-data flag in the current CCW is zero, and the operation is performed as an immediate operation, then incorrect length is not indicated, regardless of the setting of the SLI flag.

If the subchannel is in the incorrect-length-indication mode, if the chain-data flag in the current CCW is zero, and if the operation is performed as an immediate operation, then incorrect length is indicated if the count field of the current CCW specifies a nonzero value, unless suppressed by the SLI flag of the CCW; incorrect length is not indicated, however, if the count field of the CCW specifies a value of zero.

If a new CCW that has a count field of zero is fetched during data chaining or if a CCW is fetched with the chain-data flag set to one and a count field of zero, a program-check condition is recognized by the channel subsystem.

3. Since the channel-subsystem may access storage in a non-sequential manner while a subchannel is operating in transport mode, the results may be unpredictable if the program accesses the input storage area or areas designated by a TCW before primary status is indicated.

CCW Channel Program Chaining

When the channel subsystem has completed the transfer of information specified by a CCW, it can continue performing the start function by fetching a new CCW. Such fetching of a new CCW is a form of chaining, and the CCWs belonging to such a sequence are said to be chained.

Chaining takes place between CCWs located in successive doubleword locations in storage. It proceeds in an ascending order of addresses; that is, the address of the new CCW is obtained by adding 8 to the address of the current CCW. Two chains of CCWs located in noncontiguous storage areas can be coupled for chaining purposes by a transfer-in-channel command. All CCWs in a chain apply to the I/O device that is associated with the subchannel designated by the original START SUBCHANNEL instruction.

Two types of chaining are provided for CCWs: Chaining is controlled by the chain-data (CD) and chain-command (CC) flags in conjunction with the suppress-length-indication (SLI) flag in the CCW. These flags specify the action to be taken by the channel subsystem upon the exhaustion of the current CCW and upon receipt of ending status from the device, as shown in Figure 15-27 on page 61.

The specification of chaining is effectively propagated through a transfer-in-channel command. When, in the process of chaining, a transfer-in-channel command is fetched, the CCW designated by the transfer-in-channel command is used for the type of chaining specified in the CCW preceding the transfer-in-channel command.

The CD and CC flags are ignored in a format-0 CCW specifying the transfer-in-channel command. In a format-1 CCW specifying the transfer-in-channel com-
mand, the CD and CC flags must be zeros; otherwise, a program-check condition is recognized.

### Programming Note

When bit 9 of word 1 of the ORB is one, unlimited prefetching of chained CCWs (including CCWs linked by a transfer-in-channel command) by the channel subsystem is permitted. When prefetching is allowed by the ORB, no modification of the channel program should be performed after START SUBCHANNEL is executed and before the primary interruption condition for the operation has been received unless the subchannel is currently suspended and is not resume pending.

### Data Chaining

During data chaining, the new CCW fetched by the channel subsystem defines a new storage area for the original I/O operation. If the channel path is of the parallel-I/O-interface type, the performance of the operation at the I/O device is not affected. If the channel path is of the serial-I/O-interface type, then the performance of the operation at the I/O device either is not affected or, depending on the device model, may be terminated with unit-check status. When the operation at the I/O device is not affected and all data designated by the current CCW has been transferred to main storage or to the device, data chaining causes the operation to continue, using the storage area designated by the new CCW. The contents of the command-code field of the new CCW are ignored, unless they specify transfer in channel.

Data chaining is considered to occur immediately after the last byte of data designated by the current CCW has been transferred to main storage or to the device. When the last byte of the data transfer has been placed in main storage or accepted by the device, the new CCW takes over the control of the operation. If the device sends channel end after...
exhausting the count of the current CCW but before transferring any data to or from the storage area designated by the new CCW, the SCSW associated with the concluded operation pertains to the new CCW.

If programming errors are detected in the new CCW or during its fetching, the error indication is generated, and the device is signaled to conclude the operation when it attempts to transfer data designated by the new CCW. If the device signals the channel-end condition before transferring any data designated by the new CCW, program check or protection check is indicated in the SCSW associated with the termination. The contents of the SCSW pertain to the new CCW unless the address of the new CCW is invalid, the location is protected against fetching, or programming errors are detected in an intervening transfer-in-channel command. A data address referring to a nonexistent or protected area causes an error indication only after the I/O device has attempted to transfer data to or from the invalid location.

Data chaining during an input operation causes the new CCW to be fetched when all data designated by the current CCW has been placed in main storage. On an output operation, the channel subsystem may fetch the new CCW from main storage before data chaining occurs. Any programming errors in the prefetched CCW, however, do not affect the performance of the operation until all data designated by the current CCW has been transferred to the I/O device. If the device concludes the operation before all data designated by the current CCW has been transferred, the conditions associated with the prefetched CCW are not indicated to the program. Unlimited prefetching is allowed under the control of the prefetch bit specified in the ORB. (See “Prefetch Control (P)” on page 27.) When unlimited prefetching is not allowed and an output operation is specified, only one CCW describing a data area may be prefetched. If a prefetched CCW specifies transfer in channel, only one more CCW may be fetched before the exhaustion of the current CCW.

Programming Notes:

1. If the ORB does not specify unlimited prefetching, no prefetching of CCWs is performed, except in the case of data chaining on an output operation where one CCW describing a data area may be prefetched at a time.

If the ORB for the I/O operation specifies that prefetching is allowed, any number of CCWs, IDAWs, and MIDAWs and the associated data areas may be prefetched and buffered in the channel subsystem.

The same actions for signaling errors and terminating operations take place when unlimited prefetching is allowed by the ORB as when it is not allowed. However, when unlimited prefetching is specified and an error condition is detected, both the channel subsystem and the program must recognize that the points of termination at the channel subsystem and at the I/O device may be different in terms of the channel command in execution at the point of error. The channel subsystem indicates the point of termination at the channel subsystem by storing the appropriate CCW address in word 1 of the sub-channel-status word and the point of termination at the device by storing the secondary-CCW address in word 4 of the format-0 extended-status word.

When prefetching has been specified in the ORB, the result of modifications to CCWs after START SUBCHANNEL has been executed or after self-describing channel programs have been used is unpredictable. (See note 2 for the definition of self-describing channel programs.)

2. Data chaining may be used to rearrange information as it is transferred between main storage and an I/O device. Data chaining permits blocks of information to be transferred to or from non-contiguous areas of storage, and, when used in conjunction with the skipping function, data chaining allows the program to place in main storage specified portions of a block of data.

When, during an input operation, the program specifies data chaining to a location in which data has been placed under the control of the current CCW, the channel subsystem, in fetching the next CCW, fetches the new contents of the location. This is true even if the location contains the last byte transferred under the control of the current CCW. When a channel program data-chains to a CCW placed in storage by the CCW specifying data chaining, the input block is said to be self-describing. A self-describing block contains one or more CCWs that designate storage locations and counts for subsequent data in the same input block.

The use of self-describing blocks is equivalent to the use of unchecked data. An I/O data-transfer
malfunction that affects validity of a block of information is signaled only at the completion of data transfer. The error condition normally does not prematurely terminate or otherwise affect the performance of the operation. Thus, there is no assurance that a CCW read as data is valid until the operation is completed. If the CCW thus read is in error, use of the CCW in the current operation may cause subsequent data to be placed at wrong locations in main storage with resultant destruction of its contents, subject only to the control of the protection key and the address-limit-checking facility, if used.

3. When, during data chaining, a device transfers data by using the data-streaming feature, an overrun or chaining-check condition may be recognized when a small byte-count value is specified in the CCW. The minimum acceptable number of bytes that can be specified varies as a function of the system model and system activity.

**Command Chaining**

During command chaining, the new CCW fetched by the channel subsystem specifies a new I/O operation. The channel subsystem fetches the new CCW upon the receipt of the device-end signal for the current operation. If the new CCW does not have its S flag set to one and no unusual conditions are detected, the channel subsystem initiates the new operation. The presence of the S flag set to one or unusual conditions causes command chaining to be suppressed. When command chaining takes place, the completion of the current operation does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new operation is initiated only if no unusual conditions have been detected in the current operation. In particular, the channel subsystem initiates a new I/O operation by command chaining upon receipt of a status byte containing only the following bit combinations: (1) device end, (2) device end and status modifier, (3) device end and channel end, and (4) device end, channel end, and status modifier. In the first two cases, channel end is signaled before device end, with all other status bits zeros. If a condition such as attention, unit check, unit exception, incorrect length, program check, or protection check has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new CCW in this case is not fetched. The incorrect-length condition does not suppress command chaining if the current CCW has the SLI flag set to one.

An exception to sequential chaining of CCWs occurs when the I/O device presents the status-modifier condition with the device-end signal or channel-end and device-end signals. When command chaining is specified and no unusual conditions have been detected, or when command retry has been previously signaled and an immediate retry could not be performed, the combination of status-modifier and device-end bits causes the channel subsystem to alter the sequential execution of CCWs. If command chaining was specified, status modifier and device end cause the channel subsystem to fetch and chain to the CCW whose main-storage address is 16 higher than that of the CCW that specified chaining. If command retry was previously signaled and immediate retry could not be performed, the status causes the channel subsystem to command chain to the CCW whose storage address is 8 higher than that of the CCW for which retry was initially signaled.

When both command and data chaining are specified, the first CCW associated with the operation specifies the operation to be performed, and the last CCW specifies whether another operation follows.

**Programming Note:** Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. Command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device.

**TCW Channel Program Chaining**

When the I/O device has completed a control operation or the transfer of information specified by a DCW, the device can continue by executing the next DCW that is specified. Such execution of a new DCW is a form of command chaining, and the DCWs belonging to such a sequence are said to be chained.
Command chaining is controlled by the DCW chain-command (CC) flag in the DCW. This flag specifies the action to be taken upon the exhaustion of the current DCW. Chaining takes place between successive DCWs within the TCA. When a TCAX is specified, chaining also takes place between the last DCW in the TCA and the first DCW in the TCAX, and between successive DCWs within the TCAX.

When a TCCB is transported to an I/O device and selected by the device for processing, the first DCW in the TCA becomes the current DCW and is executed by the device. When the current DCW specifies command chaining and no unusual conditions have been detected during the operation, the completion of the current DCW causes the next DCW to become the current DCW and be executed by the device. The TCA offset of the next DCW is determined by adding 8, plus the value of the control-data (CD) count field of the DCW, to the TCA offset of the current DCW and rounding upwards to the next word boundary. If a TCAX is specified and the offset of the next DCW is past the end of the TCA, chaining continues with the first DCW of the TCAX whose TCAX offset is determined by subtracting the TCA length from the calculated offset. Thus, command chaining proceeds in ascending order of TCA offsets and then TCAX offsets when a TCAX is specified.

During command chaining, the new DCW executed by the device specifies a new I/O command. When command chaining takes place, the completion of the execution of the current command does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new command is initiated only if no unusual conditions have been detected in the execution of the current command. In particular, the I/O device initiates a new I/O operation by command chaining upon successful completion of the current command. If a condition such as attention, unit check, unit exception, or incorrect length has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new DCW in this case is not executed.

Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. For command-mode operations, command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device.

**Skipping**

Skipping causes the suppression of main-storage references during an I/O operation. It is defined only for read, read-backward, sense-ID, and sense operations. Skipping is controlled by the skip flag, which can be specified individually for each CCW, MIDAW, or TIDAW. When the skip flag is one, skipping occurs; when it is zero, normal operation takes place. The setting of the skip flag is ignored in all other operations.

Skipping affects only the handling of information by the channel subsystem. The operation at the I/O device proceeds normally, and information is transferred. The channel subsystem keeps updating the count but does not place the information in main storage. Chaining is not precluded by skipping. In the case of CCW data chaining, normal operation is resumed if the skip flag in the new CCW is zero.

No checking for invalid or protected data addresses takes place during skipping.

**Programming Note:** Skipping, when combined with CCW data chaining, MIDAWs, and TIDAWs, permits the program to place in main storage specified portions of a block of information from an I/O device.

**Program-Controlled Interruption**

The program-controlled-interruption (PCI) function permits the program to cause an I/O interruption during the performance of an I/O operation. The function is controlled by the PCI flag of the CCW. Neither the value of the PCI flag nor the associated interruption request affects the performance of the current operation.

The value of the PCI flag can be one either in the first CCW designated for the current start or resume func-
tion or in a CCW fetched during chaining. If the PCI flag is one in a CCW that has become current, the subchannel becomes status pending with intermediate status, and an I/O-interruption request is generated. The point at which the subchannel becomes status pending depends on the progress of the current start or resume function as follows:

1. If the PCI flag is one in the first CCW associated with a start function or a resume function, the subchannel becomes status pending with intermediate status only after the command has been accepted.

2. If the PCI flag is one in a CCW that has become current while data chaining, the subchannel becomes status pending with intermediate status after all data designated by the preceding CCW has been transferred.

3. If the PCI flag is one in a CCW that has become current while command chaining, the subchannel becomes status pending with intermediate status as that CCW becomes current.

In all cases, if the subchannel is enabled for I/O interruptions, the point of interruption depends on the current activity in the system and may be delayed. No predictable relationship exists between the point at which the interruption request is generated because of the PCI flag and the extent to which data transfer has been completed to or from the area designated by the CCW. However, all the fields within the SCSW pertain to the same instant.

An intermediate interruption condition that is made pending because of a PCI flag remains pending during chaining if not cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL. If another CCW containing a PCI flag that is one becomes current prior to the clearing of the intermediate interruption condition, only one interruption condition is preserved.

An intermediate interruption may occur while the subchannel is subchannel-and-device active with the operation specified by the CCW causing the intermediate interruption condition or with the operation specified by a CCW that has subsequently become current. If the intermediate interruption condition is not cleared prior to the conclusion of the operation or chain of operations, the condition is indicated together with the primary interruption condition at the conclusion of the operation or chain of operations. The intermediate interruption condition may be cleared by TEST SUBCHANNEL while the subchannel is subchannel active.

If the SCSW stored by TEST SUBCHANNEL indicates that the subchannel is status pending with intermediate status and the operation or chain of operations has not been concluded (that is, the activity-control field indicates subchannel-and-device active or suspended), then the CCW-address field contains an address that is 8 higher than the address of the most recent CCW to become current and have a PCI flag that is one, or the CCW-address field contains an address that is 8 higher than the address of a CCW that has subsequently become current. Unless the SCSW also contains the primary-status bit set to one, the device-status field contains zeros, and the count is unpredictable.

Subchannel-status conditions other than PCI may be indicated when the SCSW is stored. If the subchannel is not also status pending with primary status, these conditions may or may not be indicated again. If the subchannel-status condition is detected while prefetching and the operation or chain of operations is concluded before the condition affects an operation, the condition is reset and is not indicated when the subchannel subsequently becomes status pending with primary status. If the subchannel-status condition affects an operation, the condition is indicated when the subchannel becomes status pending with primary status.

If the program-controlled-interruption condition remains pending until the operation or chain of operations is concluded at the subchannel, a single interruption request exists. When TEST SUBCHANNEL is subsequently executed, the status-control field of the SCSW stored indicates both the primary interruption condition and the intermediate interruption condition, and the PCI bit of the subchannel-status field is one.

The value of the PCI flag is inspected in every CCW except for those CCWs that specify the transfer-in-channel command. The PCI flag is ignored during initial program loading.

Programming Notes:

1. The program-controlled interruption provides a means of alerting the program to the progress of chaining during an I/O operation. It permits programmed dynamic main-storage allocation.
2. A CCW with a PCI flag set to one may, if retried because of command retry, cause multiple PCI interruptions to occur. (See “Command Retry” on page 77.)

Indirect Storage Addressing

Indirect-storage addressing (ISA) allows for storage areas designated by a channel program to be specified in noncontiguous storage. Depending on the model, more than one form of ISA facility may be installed as follows:

- CCW-indirect-data (see “CCW Indirect Data Addressing” on page 66) addressing is installed in all models.
- Modified-CCW-indirect-data (see “Modified CCW Indirect Data Addressing” on page 68) addressing may also be installed in a model.
- TCW-indirect-data-addressing (see “Transport Indirect Data Addressing” on page 70) may also be installed in a model.

Indirect-Storage Designator (ISD)

Each ISA facility description includes the definition of a facility-unique indirect-storage designator (ISD) that is used to specify a block of storage to the channel subsystem. Thus, a list of ISDs may be used to designate noncontiguous storage blocks. How the location and size of a storage block are specified and whether the specification of the storage block has boundary restrictions, size restrictions, or both is dependent on the method of ISA used. The following ISDs may be used as follows:

- Format-1 and format-2 indirect-data-address word (IDAW). See “CCW Indirect Data Addressing” on page 66.
- Modified-indirect-data-address word (MIDAW), when the modified-CCW-indirect-data-addressing facility is installed. See “Modified CCW Indirect Data Addressing” on page 68.
- Transport-indirect-data-address word (TIDAW), when the fibre-channel-extensions (FCX) facility is installed. See “Transport Indirect Data Addressing” on page 70.

CCW Indirect Data Addressing

CCW indirect data addressing permits a single channel-command word to control the transfer of data that spans noncontiguous 2K-byte or 4K-byte blocks in main storage. The use of CCW indirect data addressing also allows the program to designate data addresses above 16M bytes when using format-0 CCWs or above 2G bytes when using format-1 CCWs. CCW indirect data addressing is specified by a flag in the CCW which, when one, indicates that the data address is not used to directly address data. Instead, the address points to a list of words or doublewords, called indirect-data-address words (IDAWs), each of which contains an absolute address designating a data area in main storage.

IDAWs have either of two formats, called format 1 and format 2, as determined by the format-2-IDAW control, bit 14 of word 1 of the ORB associated with the channel program being executed. When the format-2-IDAW control is zero, the IDAW is format 1 and is a word containing a 31-bit address. When the control is one, the IDAW is format 2 and is a doubleword containing a 64-bit address. The IDAW formats are as follows:

Format-1 IDAW

<table>
<thead>
<tr>
<th>0</th>
<th>Data Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>31</td>
</tr>
</tbody>
</table>

Format-2 IDAW

<table>
<thead>
<tr>
<th>0</th>
<th>Data Address (Bytes 0-3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>63</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>0</th>
<th>Data Address (Bytes 4-7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>63</td>
</tr>
</tbody>
</table>

Bit 0 (format 1) is reserved for future use and must be zero; otherwise, a program-check condition may be recognized, as described below.

A format-1 IDAW designates a data area within a 2K-byte block of main storage and is capable of addressing storage in the range of 0 to $2^{31} - 1$.

A format-2 IDAW designates a data area within a 2K-byte or 4K-byte block of main storage, as determined by the 2K-IDAW control, bit 15 of word 1 of the ORB associated with the channel program being executed, and is capable of addressing storage in the range of 0 to $2^{64} - 1$. When the 2K-IDAW-control bit is zero, each format-2 IDAW of the designated channel
program designates a 4K-byte block of main storage. When the 2K-IDAW-control bit is one, each format-2 IDAW designates a 2K-byte data-area block. All IDAWs associated with the designated channel program must have the same IDAW format, and all of those IDAWs specify the same size of storage block.

When the indirect-data-addressing bit in the CCW is one, the data-address field of the CCW designates the location of the first IDAW to be used for data transfer for the command. Additional IDAWs, if needed for completing the data transfer for the CCW, are in successive locations in storage. The number of IDAWs required for a CCW is determined by the IDAW format as specified in the ORB, by the count field of the CCW, and by the data address in the initial IDAW. When, for example, (1) the ORB specifies format-2 IDAWs with 4K-byte blocks, (2) the CCW count field specifies 8K bytes, and (3) the first IDAW designates a location in the middle of a 4K-byte block, then three IDAWs are required.

The IDAW designated by the CCW can designate any location. Data is then transferred, for read, write, control, sense ID, and sense commands, to or from successively higher storage locations or, for a read-backward command, to successively lower storage locations, until a 2K-byte block boundary (format-1 or format-2 IDAW) or a 4K-byte block boundary (format-2 IDAW) is reached. The control of data transfer is then passed to the next IDAW. The second and any subsequent IDAWs must designate, depending on the command, the first byte, or the last byte for read backward, of a 2K-byte block (format-1 or format-2 IDAW) or a 4K-byte block (format-2 IDAW). Thus, for read, write, control, sense ID, and sense commands, such format-1 IDAWs must have zeros in bit positions 21-31, and such format-2 IDAWs must have zeros in bit positions 53-63 (2K-byte blocks) or 52-63 (4K-byte blocks). For a read-backward command, such format-1 IDAWs must have ones in bit positions 21-31, and such format-2 IDAWs must have ones in bit positions 53-63 (2K-byte blocks) or 52-63 (4K-byte blocks). If any of these rules is violated, a program-check condition is recognized.

Except for the unique restrictions on the designation of the data address by the IDAW, all other actions taken for the data address, such as for protected storage and invalid addresses, and the actions taken for data prefetching are the same as when indirect data addressing is not used.

IDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of IDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that points to the IDAWs. An IDAW takes control of data transfer when the last byte has been transferred for the previous IDAW. The same actions take place as with data chaining regarding when an IDAW takes control of data transfer during an I/O operation. That is, when the count for the CCW has not reached zero, a new IDAW takes control of the data transfer when the last byte has been transferred for the previous IDAW for that CCW, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the next IDAW.

A prefetched IDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previous IDAW for that CCW. Program or access errors detected in prefetched IDAWs are not indicated to the program until the IDAW takes control of data transfer. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched IDAW or its associated key, the condition may be indicated to the program, when detected, before the IDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of an IDAW or its associated key, see “Channel-Control Check” on page 29.

Bits 1-31 (format 1) or bits 0-63 (format 2) designate the absolute storage location of the first byte to be used in the data transfer. When format-1 IDAWs are specified, the channel subsystem forms a 64-bit absolute main-storage address by appending 33 zero bits on the left of bit 1.

When the IDAW flag of the CCW is set to one and any of the following conditions occurs:

1. Format-1 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a word boundary,
2. Format-2 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a doubleword boundary,
3. The address in the CCW designates a storage location that is not physically available,
4. Access to the storage location specified by the address in the CCW is prohibited by protection, or
5. Bit 0 (format 1 only) of the first IDAW is not zero, then, depending on the model, one of the following two actions is taken independent of the setting of the skip flag (if condition 5 above is true, action 2 must be taken).

1. The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
2. The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

Modified CCW Indirect Data Addressing

Modified CCW indirect data addressing (MIDA) permits a single channel-command word to control the transfer of up to 65,535 bytes of data that spans non-contiguous blocks in main storage. Each block of main storage to be transferred may be specified on any boundary and length up to 4K bytes, provided the specified block does not cross a 4K-byte boundary. The use of modified CCW indirect data addressing requires that the program designate 64-bit data addresses.

Modified CCW indirect data addressing is controlled by a flag in the ORB and specified by a flag in the CCW which, when both are one, indicates that the CCW data address is not used to directly address data. Instead, the address points to a contiguous list of up to 256 quadwords called modified-indirect-data-address words (MIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.

Use of modified CCW indirect data addressing may be restricted to certain channel-path types. If the MIDA flag in the CCW is one, specifying the use of modified CCW indirect data addressing, and the subchannel is associated with channel paths that do not support modified CCW indirect data addressing, a program check is recognized.

The MIDAW begins on a quadword boundary and has the following format:

<table>
<thead>
<tr>
<th>Reserved</th>
<th>Flags</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Doubleword

Figure 15-28. Modified-Indirect-Data-Address Word (MIDAW)

Reserved: Bits 0-39 of the MIDAW are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

Flags: Bits 40-47 of the MIDAW contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not shown are reserved.

Bit Meaning
40 Last MIDAW: Bit 40, when one, specifies that the MIDAW is the last in the contiguous list of MIDAWs.
41 Skip: Bit 41, when one, specifies the suppression of transfer of information to main storage during a read, read-backward, sense ID, or sense operation, thus specifying that skipping is in effect. When the operation is not read, read-backward, sense ID, or sense, bit 41 is ignored and skipping is not in effect.

When skipping is in effect, no checking for invalid or protected data addresses takes place.
42 Data-transfer-interruption control: Bit 42, when one, specifies that a program-check be recognized when the device attempts to transfer data.

Count: Bits 48-63 of the MIDAW specify the number of bytes in the storage area designated by the data-address field. The count value must not be zero; otherwise a program-check condition is recognized. When skipping is in effect, the count value may be in the range of 1 - 65,535. When skipping is not in effect, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4K-block boundary; otherwise, a program-
check condition is recognized. When the count value causes the total data transfer count to exceed that specified in the CCW count field, a program-check condition is recognized.

**Data Address:** Bits 64-127 of the MIDAW designate the 64-bit address of a location in absolute storage which is the first byte of information to be transferred. If the count field specifies zero, this field is not checked.

When modified CCW indirect data addressing is specified, the data-address field of the CCW designates the location of the first MIDAW to be used for data transfer for the CCW command. Additional MIDAWs, if needed for completing the data transfer for the CCW, are fetched from successive locations in storage. The number of MIDAWs required for a CCW is determined by the count field of the CCW in relation to the count fields in the list of MIDAWs designated by the CCW. The list must not cross a 4K-byte boundary.

If a list of two or more MIDAWs is designated for a read operation, it is unpredictable in which order the MIDAW data addresses are used to transfer information into main storage. Thus, if two or more MIDAWs in a MIDAW list designate overlapping storage areas, the results are unpredictable.

MIDAWs that specify the transfer of data (MIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 - 4096 bytes, provided the MIDAW does not specify a data transfer that crosses a 4K-byte boundary; MIDAWs that specify the suppression of the transfer of data (MIDAWs for which skipping is in effect) may specify a skip count in the range of 1 - 65,535 bytes. The total number of bytes that can be transferred or skipped or both by a single MIDAW list is limited by the CCW count field, which is a maximum of 65,535 bytes. The sum of the count fields in all of the MIDAWs in the list designated by the CCW should equal the value in the count field of the CCW; otherwise, a program-check condition may be recognized.

The MIDAW designated by the CCW can designate any location. When the MIDAW skip flag is zero and the CCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is zero and the CCW specifies the read backwards command, data is then transferred to successively lower storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is one and the CCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the MIDAW count field have been skipped. When the MIDAW skip flag is one and the CCW specifies the read backwards command, skipping occurs to successively lower storage locations until the number of bytes specified by the MIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the CCW specifies a subsequent MIDAW, the control of data transfer is then passed to the next MIDAW in the list. Like the MIDAW designated by the CCW, subsequent MIDAWs may designate any location and any length, provided the MIDAW does not specify a data transfer that crosses a 4K-byte boundary; otherwise, a program-check condition is recognized.

Exception for the unique restriction on designating a valid combination of data address and count by a MIDAW and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a MIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when modified CCW indirect data addressing is not used.

MIDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of MIDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that designates the MIDAWs. Any MIDAWs that are prefetched for a CCW and are not used are discarded.

Similar to when CCW data chaining occurs, the action of transferring control from one MIDAW to the next is transparent to any attached device. A MIDAW takes control of data transfer when the last byte specified by the previous MIDAW has been transferred, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new MIDAW.

A prefetched MIDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previ-
ous MIDAW. Program or access errors detected in prefetched MIDAWs are not indicated to the program until the MIDAW takes control of data transfer, even if an attempt had been made to prefetch that data. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched MIDAW or its associated key, the condition may be indicated to the program, when detected, before the MIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a MIDAW or its associated key, see “Channel-Control Check” on page 29.

When a CCW specifies a MIDAW list and either the address in the CCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.

- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

**Transport Indirect Data Addressing**

When a designated subchannel is operating in transport mode, transport indirect data addressing (TIDA) may be used. TIDA permits a TCW to specify the transfer of data from noncontiguous blocks in main storage or to specify the transfer-command-control block (TCCB) in noncontiguous blocks of storage or both.

The use of transport indirect data addressing is controlled by flags in the TCW as follows:

When the input-TIDA flag is one in the TCW, the TCW input-data address is not used to directly address data. Instead, the TCW input-data address points to a list of transport-indirect-data-address words (TIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.

When the output-TIDA flag is one in the TCW, the TCW output-data address is not used to directly address data. Instead, the TCW output-data address points to a list of TIDAWs, each of which designates a data area in absolute storage.

When the transport-command-control-block-TIDA flag is one in the TCW, the TCW transport-command-control-block address is not used to directly address a TCCB. Instead, the TCW transport-command-control-block address points to a list of TIDAWs, each of which designates a portion of the TCCB in absolute storage.

A list of one or more TIDAWs is called a transport-indirect-data-addressing list (TIDAL).

Unless otherwise specified, TIDAWs may designate a block of main storage on any boundary and length up to 4K bytes, provided the specified block does not cross a 4K-byte boundary.

A TIDAW begins on a quadword boundary and has the following format:

```
Word   Flag       Reserved
   0       Count
   1     Address
```

*Figure 15-29. Transport-Indirect-Data-Address Word (TIDAW)*

**Flags:** Bits 0-7 of word 0 contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not described below are reserved.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Last TIDAW: Bit 0, when one, specifies that the TIDAW is the last in the contiguous list of TIDAWs.</td>
</tr>
<tr>
<td>1</td>
<td>Skip: Bit 1, when one, specifies the suppression of transfer of information to main storage during an input operation, thus specifying that skipping is in effect.</td>
</tr>
</tbody>
</table>
When the operation is an output operation, bit 1 is ignored and skipping is not in effect. When the TIDAW is being used to transport a TCCB, bit 1 is ignored and assumed to be zero.

When skipping is in effect, no checking for invalid or protected data addresses takes place.

**2** Data-transfer-interruption control: Bit 2, when one, specifies that a program-check be recognized when the TIDAW is the current TIDAW.

**3** TIDAW-transfer-in-channel (TTIC): Bit 3, when one, specifies that the TIDAW is not used to transfer data or TCCB storage. Instead, the address field designates the address of the next TIDAW to be used for the transfer of data. If bit 3 is one and the address field designates a TIDAW in which bit 3 is one, a program-check condition is recognized. If bit 3 is one and any other TIDAW flag bits are one, a program-check condition is recognized.

**4** Insert-CBC control: Bit 4, when one, specifies that the following occurs when an output operation is specified and all of the data specified by the TIDAW has been transferred:

- If the count of data bytes transferred is not a multiple of 4, up to 3 padding bytes are transferred to make the total count of data bytes, plus the count of padding bytes, a multiple of 4.
- A word of CBC information is generated and transferred to the device.

Bit 4 has no meaning for the following cases:

- When the TIDAW is being used for an input data transfer.
- When the TIDAW is being used for an output data transfer and the last-TIDAW flag, bit 0, is one.
- When the TIDAW is in a TIDAW list designated by the TCCB-address field of the TCW.

**5-7** Reserved: Bits 5-7 are reserved and must be zero, otherwise a program-check condition is recognized.

**Reserved:** Bits 8-31 are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

**Count:** Bits 32-63 specify the number of bytes to be transferred. When skipping is in effect, the count value may be in the range of 1 through \(2^{32}-8\) for a TIDAW. When skipping is not in effect and the TTIC flag, bit 3, is zero, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4K-byte block boundary; otherwise, a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the input-address field in the TCW, the count value specified in the TIDAW in which the last-TIDAW flag is one and the input-count value specified in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the output-address field in the TCW, the count value specified in the TIDAW in which the last-TIDAW flag is one and the output-count value specified in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the TCCB-address field in the TCW, the following are true:

- The count value specified in the TIDAW in which the last-TIDAW flag is one and the count of bytes specified by the TCCB-length field in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.
- If the TIDAW specifies the TCCB to cross a 4K-byte boundary, a program-check condition is recognized.
- If the specified count value is zero or is not evenly divisible by four, a program-check condition is recognized.

When the TTIC flag is zero, the count field must not be zero, otherwise a program-check condition is recognized. When the TTIC flag is one, the count field
must be zero, otherwise a program-check condition is recognized.

**Address:** Bits 64-127 of the TIDAW designate the 64-bit address of a location in absolute storage. When the TTIC flag is zero, this is the location of the first byte of information to be transferred. When the TTIC flag is one, this is the location of the next TIDAW to be used and must specify an address on a quadword boundary, otherwise a program-check condition is recognized.

**Input TIDAL:** When transport indirect data addressing is specified for input (the input-TIDA flag in the TCW is one), the input-address field of the TCW designates the location of the first TIDAW to be used for data transfer for the first DCW in the associated TCCB that specifies a data transfer command. Additional TIDAWs, if needed for completing the data transfer for the DCW or subsequent DCWs, are fetched from successive locations in storage. The number of TIDAWs required for an input TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the input-count field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4K-byte boundaries within those fragments.

The input TIDAL must not cross a 4K-byte boundary, otherwise a program-check condition is recognized.

If a list of two or more TIDAWs is designated for an input operation, it is unpredictable in which order the TIDAW data addresses are used to transfer information into main storage. Thus, if two or more TIDAWs in a TIDAW list designate overlapping storage areas, the results are unpredictable.

**Output TIDAL:** When transport indirect data addressing is specified for output (the output-TIDA flag in the TCW is one), the output-address field of the TCW designates the location of the first TIDAW to be used for data transfer for the first DCW in the associated TCCB that specifies a data transfer command. Additional TIDAWs, if needed for completing the data transfer for the DCW or subsequent DCWs, are fetched from successive locations in storage. The number of TIDAWs required for a TCW is determined by the output-count field of the TCW. The number of TIDAWs required for an output TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the output-count field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4K-byte boundaries within those fragments.

The output TIDAL must not cross a 4K-byte boundary, otherwise a program-check condition is recognized.

**TCCB TIDAL:** When transport indirect data addressing is specified for the TCCB (the transport-command-control-block-TIDA flag in the TCW is one), the transport-command-control-block-address field of the TCW designates the location of the first TIDAW to be used to designate the storage location of the TCCB. Additional TIDAWs, if needed for completing the TCCB, are fetched from successive locations in storage. The number of TIDAWs required for a TCCB TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the TCCB-length field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4K-byte boundaries within those fragments.

The TCCB TIDAL must not cross a 4K-byte boundary, otherwise a program-check condition is recognized.

**Additional Information**

TIDAWs that specify the transfer of data (TIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 through 4096 bytes, provided the TIDAW does not specify a data transfer that crosses a 4K-byte boundary.

TIDAWs that specify the suppression of the transfer of data may specify a skip count in the range of 1 through $2^{32} - 8$.

The total number of bytes that can be transferred or skipped or both by a single TIDAL is limited by the
TCW count field that applies to the TIDAL, which may be a maximum of $2^{32}$-8 bytes. If a TIDAL does not specify the same number of data bytes to be transferred as the count in the TCW for the TIDAL, or does not specify the same number of data bytes to transferred as that specified by the associated TCCB, a program-check condition may be recognized.

A TIDAW can designate any location. When the TIDAW skip flag is zero and a DCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the TIDAW count field have been transferred. When the TIDAW skip flag is one and a DCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the TIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the TCW and DCW specify a subsequent TIDAW, the control of data transfer is then passed to the next TIDAW in the list. Like the TIDAW designated by the TCW, subsequent TIDAWs may designate any location and any length, provided the TIDA does not specify a data transfer that crosses a 4K-byte boundary; otherwise, a program-check condition is recognized.

Except for the unique restriction on designating a valid combination of data address and count by a TIDAW, and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a TIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when transport indirect data addressing is not used.

TIDAWs pertaining to the current TCW may be prefetched. The number of TIDAWs that can be prefetched cannot exceed that required to satisfy the associated count in the TCW that designates the TIDAWs. Any TIDAWs that are prefetched for a TCW and are not used are discarded.

The action of transferring control from one TIDAW to the next is transparent to any attached device. A TIDAW takes control of data transfer when the last byte specified by the previous TIDAW has been transferred, this may occur even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new TIDAW.

Program or access errors when fetching or prefetching TIDAWs are indicated to the program when detected. For output operations, this may preclude transporting the TCCB to the I/O device.

When the channel subsystem detects an invalid CBC on the contents of a prefetched TIDAW or its associated key, the condition may be indicated to the program, when detected, before the TIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a TIDAW or its associated key, see “Channel-Control Check” on page 29.

When a TCW specifies a TIDAL and either the address in the TCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and any status presented by the device.

**Suspension of CCW Channel-Program Execution**

The suspend function, when used in conjunction with RESUME SUBCHANNEL, provides the program with a means to stop and restart the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend control, bit 4 of word 1 of the command-mode ORB. The suspend function is signaled when suspend control has been specified for the subchannel in the ORB and a CCW containing an S flag set to one becomes the current CCW. The flag can be indicated either in the first
CCW of the channel program or in a CCW fetched while command chaining. The S flag is not valid and causes a program-check condition to be recognized if (1) the ORB contains the suspend-control bit set to zero, or (2) the CCW is fetched while data chaining (see “Data Chaining” on page 61, concerning the handling of programming errors detected during data chaining).

Upon recognition of the suspend function, suspension of channel-program execution occurs when the CCW becomes current (see “Channel-Command Word” on page 30, for a definition of when a CCW becomes current). If suspension occurs during command chaining, the device is signaled that command chaining is no longer in effect.

RESUME SUBCHANNEL signals that the CCW that caused channel-program suspension may have been modified, that the CCW must be refetched, and that the contents of the CCW must be examined to determine the settings of the flags. If the S flag is one, execution of that CCW does not occur. If the CCW is valid and the S flag in the CCW is zero, execution is initiated (see “RESUME SUBCHANNEL” on page 10 and “Start Function and Resume Function” on page 20).

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. The device is signaled that the chain of operations has been concluded.

2. Channel-program execution is suspended at the subchannel; all prefetched IDAWs, MIDAWs, CCWs, and data are discarded; and the subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.

3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the accrued function-pending time (a function of the setting of the timing-facility bit) is added to the accumulated value in the measurement block for the subchannel. If a measurement-check condition is detected during the measurement-block update, the channel program is not started at the subchannel. The subchannel is made status pending with primary, secondary, and alert status. Deferred condition for the subchannel. (See “Channel-Subsystem Monitoring” on page 1 for more information.)

4. The subchannel is placed in the suspended state.

5. If the subchannel is not resume pending at this point, the intermediate interruption condition due to suspension is recognized if the suppress-suspended-interruption bit of the ORB is zero; otherwise, the resume function is performed.

If a measurement-check condition is detected during the measurement-block update, the channel program is terminated at the subchannel. The subchannel is made status pending with primary, secondary, and alert status, the device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 12.)

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. Channel-program execution is suspended prior to the selection of the device.

2. The subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.

3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the SSCH+RSCH count is incremented, and the accrued function-pending time (a function of the setting of the timing-facility bit) is added to the accumulated value in the measurement block for the subchannel. If a measurement-check condition is detected during the measurement-block update, the channel program is not started at the subchannel. The subchannel is made status pending with primary, secondary, and alert status. Deferred condition...
code one is set, and the start-pending bit remains set to one. The device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 12.)

4. The subchannel is placed in the suspended state.

5. If the subchannel is not resume pending at this point, the subchannel is made status pending with intermediate status due to suspension if the suppress-suspended-interruption-control bit of the ORB is zero; otherwise, the resume function is performed.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

**Programming Notes:**

1. The execution of MODIFY SUBCHANNEL and START SUBCHANNEL completes with condition code 2 set if the designated subchannel is suspended. The start function is indicated at the subchannel while the subchannel is in the suspended state.

2. In certain situations, normal resumption of the execution of a channel program that has been suspended may not be desired. Normal termination of the suspended channel-program execution may be accomplished by:
   a. Executing HALT SUBCHANNEL and designating the subchannel.
   b. Modifying the CCWs in storage such that, when channel-program execution is resumed, the command transferred to the device is a control command with all modifier bits specified as zeros (no-operation) and with the chain-command flag specified as zero; and then executing RESUME SUBCHANNEL.
   c. When an IRB indicates measurement check along with zero device status, zero subchannel status, and status pending with primary, secondary, and alert status, it may indicate that the measurement check was detected during an attempt to place the subchannel into the suspended state.

3. If the suspended interruption is suppressed, the N condition and DCTI values applicable to the preceding subchannel-active period are not made available to the program. The execution of RESUME SUBCHANNEL when the subchannel is in the suspended state causes path-not-operational conditions and the N condition to be reset to zeros. Path-not-operational conditions and the N condition are not reset when RESUME SUBCHANNEL is executed and the designated subchannel is not in the suspended state.

### Commands and Flags for CCWs

Figure 15-30 on page 75 lists the command codes for the seven CCW commands and indicates which flags are defined for each command. Except for a format-1 CCW specifying transfer in channel, the flags are ignored for all commands for which they are not defined. The flags are reserved in a format-1 CCW specifying transfer in channel and must be zeros.

**Explanation:**

- CC Chain command
- CD Chain data
- IDA Indirect data addressing
- M Modifier bit
- MIDA Modified indirect data addressing
- PCI Program-controlled interruption
- S Suspend
- SK Skip
- SLI Suppress-length indication
- X Ignored in a format-0 CCW; must be zero in a format-1 CCW

Note: Flags are ignored in a format-0 transfer-in-channel CCW and must be zeros in a format-1 transfer-in-channel CCW.

Figure 15-30. Command Codes and Flags for CCWs

All flags have individual significance, except for the following cases:
• The CC and SLI flags are ignored when the CD flag is set to one, and, for output forward operations the SK flag is ignored.

• The presence of the SLI flag is ignored for immediate operations involving format-0 CCWs, in which case the incorrect-length indication is suppressed regardless of the setting of the flag.

• The incorrect-length indication may be suppressed for immediate operations when executing a format-1 CCW, depending on the incorrect-length-suppression mode.

• The PCI flag is ignored during initial program loading. All flags, except the PCI flag, are ignored when the S flag is one.

• The MIDA flag is mutually exclusive from both the IDA and SKP flags. If the IDA or SKP flag is specified and the MIDA flag is specified, a program-check condition is recognized.

Programming Notes:

1. A malfunction that affects the validity of data transferred in an I/O operation is signaled at the end of the operation by means of unit check or channel-data check, depending on whether the device (control unit) or the channel subsystem detected the error. In order to make use of the checking facilities provided in the system, data read in an input operation should not be used until the end of the operation has been reached and the validity of the data has been checked. Similarly, on writing, the copy of data in main storage should not be destroyed until the program has verified that no malfunction affecting the transfer and recording of data was detected.

2. An error condition may be recognized and the I/O operation terminated when 256 or more chained commands are executed with a device and none of the executed commands result in the transfer of any data. When this condition is recognized, program check is indicated.

3. All CCWs that require suppression of incorrect-length indications must use the SLI flag.

Commands and Flags for DCWs

Figure 15-31 on page 76 lists the command codes for the eight DCW commands and indicates which flags are defined for each command.

Figure 15-31. Command Codes and Flags for DCWs

Branching in CCW Channel Programs

The channel subsystem provides two methods to modify the normal sequential execution of the CCWs in a channel program. One is the transfer-in-channel (TIC) command (described in “Transfer in Channel” on page 77), which can be used to loop back to a previously executed CCW, or to connect discontiguous segments of the channel program. The other method, which uses the status-modifier device-status bit (described in the publication ESA/390 Common I/O-Device Commands, SA22-7204), allows conditions at the device to cause the channel to bypass the next CCW in the channel program.
Transfer in Channel

The next CCW is fetched from the location in absolute main storage designated by the data-address field of the CCW specifying transfer in channel. The transfer-in-channel command does not initiate any I/O operation, and the I/O device is not signaled of the execution of the command. The purpose of the transfer-in-channel command is to provide chaining between CCWs not located in adjacent doubleword locations in an ascending order of addresses. The command can occur in both data and command chaining.

Bits 29-31 (format 0) or bits 61-63 (format 1) of a CCW that specifies the transfer-in-channel command must be zeros, designating a CCW on a doubleword boundary. Furthermore, a CCW specifying transfer in channel may not be fetched from a location designated by an immediately preceding transfer in channel. When either of these errors is detected or when an invalid address is designated in the transfer-in-channel command, the program-check condition is generated. When an invalid address is designated, the protection-check condition is generated. Detection of these errors during data chaining causes the operation at the I/O device to be terminated and an interruption condition to be generated, while during command chaining it causes only an interruption condition to be generated.

The contents of the second half of the format-0 CCW, bit positions 32-63, are ignored. Similarly, the contents of bit positions 0-3 of the format-0 CCW are ignored.

Bit positions 0-3 and 8-32 of the format-1 CCW must contain zeros; otherwise, a program-check condition is generated.

Command Retry

The channel subsystem has the capability to perform command retry, a procedure that causes a command to be retried without requiring an I/O interruption. This retry is initiated by the control unit presenting either of two status-bit combinations by means of a special sequence. When immediate retry can be performed, it presents a channel-end, unit-check, and status-modifier status-bit combination, together with device end. When immediate retry cannot be performed, the presentation of device end is delayed until the control unit is prepared. When device end is presented alone, the previous command is transferred again. If device end is accompanied by status modifier, command retry is not performed, and the channel subsystem command-chains to the CCW following the one for which command retry was signaled (for information on status modifier, see the publication ESA/390 Common I/O-Device Commands, SA22-7204). When the channel subsystem is not capable of performing command retry due to an error condition, or when any status bit other than device end or device end and status modifier accompanies the requested command-retry initiation, the retry is suppressed, and the subchannel becomes status pending. The SCSW stored by TEST SUBCHANNEL contains the status provided by the I/O device.

Programming Note: The following possible results of a command retry must be anticipated by the program:

1. A CCW containing a PCI may, if retried because of command retry, cause multiple PCI interruptions to occur.
2. If a CCW used in an operation is changed before that operation has been successfully completed, the results are unpredictable.

Concluding I/O Operations before Initiation

Subsequent to the execution of START SUBCHANNEL or RESUME SUBCHANNEL for a command-mode operation and before the first command is accepted, the start function can be ended at the subchannel by CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, or HALT SUBCHANNEL.
Subsequent to the execution of START SUBCHANNEL for a transport-mode operation, the start function may be ended at the subchannel by CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, or HALT SUBCHANNEL before the TCCB is transported.

For both command-mode and transport-mode operations, if the I/O operation is ended by CANCEL SUBCHANNEL, there is no subsequent interruption condition from the I/O operation, and the subchannel is available for the initiation of another start function. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device. (See also “Clear Function” on page 14 and “Halt Function” on page 16.)

---

**Concluding I/O Operations during Initiation**

After the designated subchannel has been determined to be in a state such that START SUBCHANNEL can be executed, certain tests are performed on the validity of the information specified by the program and on the logical availability of the associated device. This testing occurs during or subsequent to the execution of START SUBCHANNEL and during command chaining and command retry.

A data-transfer operation is initiated at the subchannel and device only when no programming or equipment errors are detected by the channel subsystem and when the device responds with zero status during the initiation sequence. When the channel subsystem detects or the device signals any unusual condition during the initiation of a command-mode I/O operation, the command is said to be not accepted. When the channel subsystem detects or the device signals any unusual condition during the initiation of a transport-mode I/O operation, the I/O-operation initiation is said to be not accepted. For these cases, the subchannel becomes status pending with primary, secondary, and alert status. Deferred condition code 1 is set, and the start-pending bit remains set to one.

Conditions that preclude the initiation of an I/O operation are detailed in the SCSW stored by TEST SUBCHANNEL. In this situation, the device is not started, no interruption conditions are generated subsequent to TEST SUBCHANNEL, and the subchannel is idle. The device is immediately available for the initiation of another operation, provided the command was not rejected because of the busy or not-operational condition.

When an unusual condition causes a command to be not accepted during the initiation of a command-mode I/O operation by command chaining or command retry, an interruption condition is generated, and the subchannel becomes status pending with combinations of primary, secondary, and alert status as a function of the status signaled by the device. The status describing the condition remains at the subchannel until cleared by TEST SUBCHANNEL. The conditions are indicated to the program by means of the corresponding status bits in the SCSW. A path-not-operational condition recognized during command chaining is signaled to the program by means of an interface-control-check indication. The new I/O operation at the device is not started.

START SUBCHANNEL is executed independent of its associated device. Tests on most program-specified information, on device availability and unit status, and on most error conditions are performed subsequent to the execution of START SUBCHANNEL. When any conditions are detected that preclude the performance of the start function, an interruption condition is generated by the channel subsystem and placed at the subchannel, causing it to become status pending.

---

**Immediate Conclusion of Command-Mode I/O Operations**

During the initiation of an I/O operation, the device can accept the command and signal the channel-end condition immediately upon receipt of the command code. An I/O operation causing the channel-end condition to be signaled during the initiation sequence is called an *immediate operation*. Status generated by the device for the immediate command, when command chaining is not specified and command retry is not signaled, causes the subchannel to become status pending with combinations of primary, secondary, intermediate, and alert status as a result of information specified in the ORB and CCW and status presented by the device. If the immediate operation is the first operation of the channel program, deferred
condition code 1 is set and accompanies the status indications. If intermediate status is indicated, the indication can occur only as a result of the CCW having the PCI flag set to one (see “Program-Controlled Interruption” on page 64).

Whenever command chaining is specified after an immediate operation and no unusual conditions have been detected during the operation, or when command retry occurs for an immediate operation, an interruption condition is not generated. The subsequent commands in the chain are handled normally, and, usually, the channel-end condition for the last CCW generates a primary interruption condition. If device end is signaled with channel end, a secondary interruption condition is also generated.

Whenever immediate completion of an I/O operation is signaled, no data has been transferred to or from the device, and the data address in the CCW is not checked for validity. If the subchannel is in the incorrect-length-suppression mode, incorrect length is not indicated to the program, and command chaining is performed when specified. If the subchannel is in the incorrect-length-indication mode, incorrect length and command chaining are under control of the SLI and chain-command flags. The conditions that cause the incorrect-length indication to be suppressed are summarized in Figure 15-27 on page 61.

Programming Note: I/O operations for which the entire operation is specified in the command code may be performed as immediate operations. Whether the command is executed as an immediate operation depends on the operation and type of device.

Concluding I/O Operations During Data Transfer

When the subchannel has been passed the contents of an ORB, the subchannel is said to be start pending. When a command-mode I/O operation has been initiated and the command has been accepted, the subchannel becomes subchannel-and-device active. When a transport-mode I/O operation has been initiated, the subchannel remains start pending while the TCCB is transported and executed. The subchannel remains in the respective state unless (1) the channel subsystem detects an equipment malfunction, (2) the operation is concluded by the execution of CLEAR SUBCHANNEL or HALT SUBCHANNEL, or (3) status that causes a primary interruption condition to be recognized (usually channel end) is accepted from the device.

When CCW command chaining and command retry are not specified or when chaining is suppressed because of unusual conditions, the status that is recognized as primary status causes the operation at the subchannel to be concluded and an interruption condition to be generated. The status bits in the associated SCSW indicate primary status and the unusual conditions, if any. The device can present status that is recognized as primary status at any time after the initiation of the I/O operation, and the presentation of status may occur before any data has been transferred.

For operations not involving data transfer, the device normally controls the timing of the channel-end condition. The duration of data-transfer operations may be variable and may be controlled by the device or the channel subsystem.

Excluding equipment errors and the execution of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, and RESET CHANNEL PATH instructions, the channel subsystem signals the device to conclude the performance of an I/O operation during data transfer whenever any of the following conditions occurs:

- The storage areas designated for the operation are exhausted or filled.
- A program-check condition is detected.
- A protection-check condition is detected.
- A CCW chaining-check condition is detected.
- A channel-control-check condition is detected that does not affect the control of the I/O operation.

The first of these conditions occurs when the channel subsystem has decremented the count to zero in the last CCW or current TCW associated with the operation. A count of zero indicates that the channel subsystem has transferred all information specified by the I/O operation. The other four conditions are due to errors and cause premature conclusion of data transfer. In either case, the conclusion is signaled in response to a service request from the device and causes data transfer to cease. If the device has no blocks defined for the operation (such as writing on...
magnetic tape), it concludes the operation and presents channel-end status.

For command-mode operations, the device can control the duration of an operation and the timing of channel end by blocking of data. On certain operations for which blocks are defined (such as reading on magnetic tape), the device does not present channel-end status until the end of the block is reached, regardless of whether the device has been previously signaled to conclude data transfer.

Checking for the validity of the CCW data address is performed only as data is transferred to or from main storage. When the initial data address in the CCW is invalid, no data is transferred during the operation, and the device is signaled to conclude the operation in response to the first service request. On writing, devices such as magnetic-tape units request the first byte of data before any mechanical motion is started, and, if the initial data address is invalid, the operation is terminated by the channel subsystem before the recording medium has been advanced. However, since the operation has been initiated at the device, the device presents channel-end status, causing the channel subsystem to recognize a primary interruption condition. Subsequently, the device also presents device-end status, causing the channel subsystem to recognize a secondary interruption condition. Whether a block at the device is advanced when no data is transferred depends on the type of device.

When CCW command chaining takes place, the subchannel is in the subchannel-and-device-active state from the time the first I/O operation is initiated at the device until the device presents channel-end status for the last I/O operation of the chain. The subchannel remains in the device-active state until the device presents the device-end status for the last I/O operation of the chain.

Any unusual conditions cause CCW command chaining to be suppressed and a primary interruption condition to be generated. The unusual conditions can be detected by either the channel subsystem or the device, and the device can provide the indications with channel end, control unit end, or device end. When the channel subsystem is aware of the unusual condition by the time the channel-end status for the operation is accepted, the chain is ended as if the operation during which the condition occurred were the last operation of the chain. The device-end status is recognized as a secondary interruption condition whether presented together with the channel-end status or separately. If the device presents unit check or unit exception together with either control unit end or device end as status that causes the channel subsystem to recognize the primary interruption condition, then the subchannel-and-device-active state of the subchannel is terminated, and the subchannel is made status pending with primary, secondary, and alert status. Intermediate status may also be indicated if an intermediate interruption condition previously existed at the subchannel for the initial-status-interruption condition or the PCI condition and that condition still remains pending at the subchannel. The channel-end status that was presented to the channel subsystem previously when command chaining was signaled is not made available to the program.

Channel-Path-Reset Function

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset function is performed. The performance of the function consists of: (1) issuing the reset signal on the designated channel path and (2) causing a channel report to be made pending, indicating the completion of the channel-path-reset function.
Channel-Path-Reset-Function Signaling

The channel subsystem issues the reset signal on the designated channel path. As part of this operation, the following actions are taken:

1. All internal indications associated with control-unit-busy, device-busy, and allegiance conditions for the designated channel path are reset. These indications are reset at all subchannels that have access to the designated channel path. The reset function has no other effect on subchannels, including those having I/O operations in progress.

2. If the channel path fails to respond properly to the reset signal (see “I/O-System Reset” on page 13 for a detailed description) or, because of a malfunction, the reset signal could not be issued, the channel path is made physically not available at each applicable subchannel.

3. If an I/O operation is in progress at the device and the device is actively communicating on the channel path in the performance of that I/O operation when the reset signal is received on that channel path, the I/O operation is reset, and the control unit and device immediately terminate current communication with the channel subsystem. (To avoid possible misinterpretation of unsolicited device-end status, programming measures can be taken as described in programming note 2 on page 82.)
