4. If an I/O operation is in progress in the multipath mode at the device and the device is not currently communicating over the channel path in the performance of that I/O operation when the reset signal is received, then the I/O operation may or may not be reset depending on whether another channel path is available for selection in the same multipath group for the device. If there is at least one other channel path in the multipath group for the device that is available for selection, the I/O operation is not reset. However, the channel path on which the system reset is received is removed from the current set of channel paths that form the multipath group. If the channel path on which the reset signal is received is the only channel path of a multipath group, or if the device is operating in the single-path mode, the I/O operation is reset.

5. The channel-path-reset function causes I/O operations to be terminated at the device as described above; however, I/O operations are never terminated at the subchannel by the channel-path-reset function.

If an I/O operation is in progress at the subchannel and the channel path designated for the performance of the channel-path-reset function is being used for that I/O operation, the subchannel may or may not accurately reflect the progress of the I/O operation up to that instant. The subchannel remains in the state that exists at the time the channel-path-reset function is performed until the state is changed because of some action taken by the program or by the device.

Channel-Path-Reset-Function-Completion Signaling

After the reset signal has been issued and an attempt has been made to issue the reset signal, or after it has been determined that the reset signal cannot be issued, the channel-path-reset function is completed. (See “Reset Signal” on page 12.)

As a result of the channel-path-reset function being performed, a channel report is made pending (see “Channel-Subsystem Recovery” on page 24) to report the results. If the channel path responds properly to the system-reset signal, the channel report indicates that the channel path has been initialized and is physically available for use. If the reset signal was issued but either the channel path failed to respond properly or the channel path was already not physically available at each subchannel having access to the channel path, the channel report indicates that the channel path has been initialized but is not physically available for use. If, because of a malfunction or because the designated channel path is not in the configuration, the reset signal could not be issued, the channel report indicates that the channel path has not been initialized and is not physically available for use.

Programming Notes:

1. If an I/O operation is in progress in the multipath mode when the channel-path-reset function is performed on a channel path of the multipath group, it is possible for the I/O operation to be
continued on a remaining channel path of the group.

2. When the performance of the channel-path-reset function causes the I/O operation at the device to be reset, unsolicited device-end status presented by the device, if any, may be erroneously interpreted by the channel subsystem to be chaining status and thus cause the channel subsystem to continue the chain of commands. If this situation occurs, then the device-end status is not made available to the program, and the device is selected again by the channel subsystem; however, the device may interpret the initiation sequence as the beginning of a new channel program instead of as command chaining. This possibility can be avoided by issuing CLEAR SUBCHANNEL or HALT SUBCHANNEL, designating the affected subchannels, prior to issuing RESET CHANNEL PATH.

3. The performance of the channel-path-reset function may, on some models, cause overruns to occur on other channel paths.

Even though reset is signaled on the designated channel path, by one or more devices may not have been reset because of a malfunction at a control unit or a malfunction at the physical channel path to the control unit.
When an I/O operation or sequence of I/O operations initiated by the execution of START SUBCHANNEL is ended, the channel subsystem and the device generate status conditions. The generation of these conditions can be brought to the attention of the program by means of an I/O interruption or by means of the execution of the TEST PENDING INTERRUPTION instruction. (During certain abnormal situations, these conditions can be brought to the attention of the program by means of a machine-check interruption. See “Channel-Subsystem Recovery” on page 24 for details.)

The status conditions, as well as an address and a count indicating the extent of the operation sequence, are presented to the program in the form
of a subchannel-status word (SCSW). The SCSW is stored in an interruption-response block (IRB) during the execution of TEST SUBCHANNEL. When a transport-mode IRB is stored, additional information describing the status of the operation is also stored in the transport-status block.

Normally an I/O operation is being performed until the device signals primary interruption status. Primary interruption status can be signaled during initiation of an I/O operation, or later. An I/O operation can be terminated by the channel subsystem performing a clear or halt function when it detects an equipment malfunction, a program check, a chaining check, a protection check, or an incorrect-length condition, or by performing a clear, halt, or channel-path-reset function as a result of the execution of CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH, respectively.

I/O interruptions provide a means for the CPU to change its state in response to conditions that occur at I/O devices or subchannels. These conditions can be caused by the program, by the channel subsystem, or by an external event at the device.

### Interruption Conditions

The conditions causing requests for I/O interruptions to be initiated are called I/O-interruption conditions. When an interruption condition is recognized by the channel subsystem, it is indicated at the appropriate subchannel. The subchannel is then said to be status pending. The subchannel becoming status pending causes the channel subsystem to generate an I/O-interruption request. An I/O-interruption request can be brought to the attention of the program only once.

An I/O-interruption request remains pending until it is accepted by a CPU in the configuration, is withdrawn by the channel subsystem, or is cleared by means of the execution of TEST PENDING INTERRUPTION, TEST SUBCHANNEL, or CLEAR SUBCHANNEL, or by means of subsystem reset. When a CPU accepts an interruption request and stores the associated interruption code, the interruption request is cleared. When the pending interruption is cleared by the execution of TEST PENDING INTERRUPTION, the subchannel remains status pending until the associated interruption condition is cleared when TEST SUB-CHANNEL or CLEAR SUBCHANNEL is executed or when the subchannel is reset.

An I/O-interruption condition is normally cleared by means of the execution of TEST SUBCHANNEL. If TEST SUBCHANNEL is executed, designating a subchannel that has an I/O-interruption request pending, both the interruption request and the interruption condition at the subchannel are cleared. The interruption request and the interruption condition can also be cleared by CLEAR SUBCHANNEL.

A device-end status condition generated by the I/O device and presented following the conclusion of the last I/O operation of a start function is reset at the subchannel by the channel subsystem without generating an I/O-interruption condition or I/O-interruption request if the subchannel is currently start pending and if the status contains device end either alone or accompanied by control unit end. If any other status bits accompany the device-end status bit, then the channel subsystem generates an I/O-interruption request with deferred condition code 1 indicated.

When an I/O operation is terminated because of an unusual condition detected by the channel subsystem during the command-initiation sequence, status describing the interruption condition is placed at the subchannel, causing it to become status pending. If the unusual condition is detected by the device, the device-status field of the associated SCSW identifies the condition.

When command chaining takes place, the generation of status by the device does not cause an interruption, and the status is not made available to the program.

When the channel subsystem detects any of the following interruption conditions, it initiates a request for an I/O interruption without necessarily communicating with, or having received the status byte from, the device:

- A programming error associated with the contents of the ORB passed to the subchannel by the previous execution of START SUBCHANNEL
- A suspend flag set to one in the first CCW fetched that initiates a CCW channel program execution for either START SUBCHANNEL or RESUME SUBCHANNEL, and suppress suspended interruption not specified in the command-mode ORB.
A programming error associated with the first CCW, TCW, TIDAW, TCCB fetch, data fetch, IDAW, or MIDAW.

These interruption conditions from the subchannel, except for the suspended condition, can be accompanied by other subchannel-status indications, but the device-status indications are all stored as zeros.

The channel subsystem issues the clear signal to the device when status containing unit check is presented to a subchannel that is disabled or when the device is not associated with any subchannel. However, if the presented status does not contain unit check, the status is accepted by the channel subsystem and discarded without causing the subchannel to become status pending.

An interruption condition caused by the device may be accompanied by multiple device-status conditions. Furthermore, more than one interruption condition associated with the same device can be accepted by the channel subsystem without an intervening I/O interruption. As an example, when the channel-end condition is not cleared at the device by the time device end is generated, both conditions may be cleared at the device concurrently and indicated in the SCSW together. Alternatively, channel-end status may have been previously accepted at the subchannel, and an I/O interruption may have occurred; however, the associated status-pending condition may not have been cleared by TEST SUBCHANNEL by the time device-end status was accepted at the subchannel. In this situation, the device-end status may be merged with the channel-end status without causing an additional I/O interruption. Whether an interruption condition may be merged at the subchannel with other existing interruption conditions depends upon whether the interruption condition is unsolicited or solicited.

**Unsolicited Interruption Condition:** An unsolicited interruption condition is any interruption condition that is unrelated to the performance of a clear, halt, resume, interrogate, or start function. An unsolicited interruption condition is identified at the subchannel as alert status. An unsolicited interruption condition can be generated only when the subchannel is not device active.

The subchannel and device status associated with an unsolicited interruption condition is never merged with that of any currently existing interruption condition. If the subchannel is currently status pending, the unsolicited interruption condition is held in abeyance in either the channel subsystem or the device, as appropriate, until the status-pending condition has been cleared. Whenever the subchannel is idle and zero status is presented by the device, the status is discarded.

**Solicited Interruption Condition:** A solicited interruption condition is any interruption condition generated as a direct consequence of performing or attempting to perform a clear, halt, resume, interrogate, or start function. Solicited interruption conditions include any interruption condition generated while the subchannel is either subchannel-and-device active or device active. When the subchannel is operating in transport mode, solicited interruption conditions can be generated when the subchannel is start pending. The subchannel and device status associated with a solicited interruption condition may be merged at the subchannel with that of another currently existing solicited interruption condition. Figure 16-1 on page 4 describes the interruption
condition that results from any combination of bits in the status-control field of the SCSW.

- 0 Indicates the bit stored as zero.
- 1 Indicates the bit stored as one.

*Figure 16-1. Interruption Condition for Status-Control-Bit Combinations*

**Intermediate Interruption Condition**

An intermediate interruption condition is a solicited interruption condition that indicates that an event has occurred for which the program had previously requested notification. An intermediate interruption condition is described by any of, or any combination of the following:

- solicited subchannel status
- the Z bit
- the subchannel-suspended condition
- the Q bit

An intermediate interruption condition can occur only after it has been requested by the program through the use of flags in the ORB, CCW, or a CANCEL SUBCHANNEL for a subchannel operating in transport mode that requests an interrogate operation. Depending on the state of the subchannel, the performance or suspension of the I/O operation continues, unaffected by the setting of the intermediate-status bit.

An intermediate interruption condition can be indicated only together with one of the following indications:

1. Subchannel active
2. Status pending with primary status alone
3. Status pending with primary status together with alert status or secondary status or both
4. Suspended
5. Interrogate-complete (Q-bit)

If only the intermediate-status bit and the status-pending bit of the status-control field are ones during the execution of TEST SUBCHANNEL, the device-status field is zero.

**Primary Interruption Condition**

A primary interruption condition is a solicited interruption condition that indicates the performance of the start function is completed at the subchannel. A primary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with primary status. Once the primary interruption condition is indicated at the subchannel, the channel subsystem is no longer actively participating in the I/O operation by transferring commands or data. When a subchannel is status pending with a primary interruption condition, the execution of any of the following instructions results in the setting of a nonzero condition code: HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, and START SUBCHANNEL. Once the primary interruption condition is cleared by the execution of TEST SUBCHANNEL, the subchannel accepts the START SUBCHANNEL instruction. (See “START SUB-
Secondary Interruption Condition

A secondary interruption condition is a solicited interruption condition that normally indicates the completion of an I/O operation at the device. A secondary interruption condition is also generated by the channel subsystem if the start function is terminated because a solicited alert interruption condition is recognized prior to initiating the first I/O operation at the device. A secondary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with secondary status. Once the channel subsystem has accepted status from the device that causes a secondary interruption condition to be recognized, the start function is completed at the device.

Alert Interruption Condition

An alert interruption condition is either a solicited interruption condition that indicates the occurrence of an unusual condition in a halt, resume, or start function or an unsolicited interruption condition that describes a condition unrelated to the performance of a halt, resume, or start function. An alert interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with alert status. An alert interruption condition may be generated by either the channel subsystem or the device. Nonzero alert status is always brought to the attention of the program.

Priority of Interruptions

All requests for an I/O interruption are asynchronous to any activity in any CPU, and interruption requests associated with more than one subchannel can exist at the same time. The priority of interruptions is controlled by two types of mechanisms — one establishes within the channel subsystem the priority among interruption requests from subchannels associated with the same I/O-interruption subclass, and another establishes within a given CPU the priority among requests from subchannels of different I/O-interruption subclasses. The channel subsystem requests an I/O interruption only after it has established priority among requests from its subchannels. The conditions responsible for the I/O-interruption requests associated with subchannels are preserved at the subchannels until cleared by a CPU's execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL or I/O-system reset is performed.

The assignment of priority among requests for interruption from subchannels of the same I/O-interruption subclass is in the order that the need for interruption is recognized by the channel subsystem. The order of recognition by the channel subsystem is a function of the type of interruption condition and the type of channel path. For the parallel-I/O-interface type of channel path, the order depends on the electrical position of the device on the channel path to which it is attached. (A device’s electrical position on the parallel-I/O interface is not related to its device address.)

The assignment of priority among requests for interruption from subchannels of different I/O-interruption subclasses is made by the CPU according to the numerical value of the I/O-interruption subclass codes (with zero having highest priority), in conjunction with the I/O-interruption-subclass mask in control register 6. The numerical value of the I/O-interruption-subclass code directly corresponds to the bit position in the I/O-interruption-subclass mask in control register 6 of a CPU. If, in any CPU, an I/O-interruption-subclass-mask bit is zero, then all subchannels having an I/O-interruption-subclass code numerically equal to the associated position in the mask register are said to be masked off in the respective CPU. Therefore, a CPU accepts the highest-priority I/O-interruption request from a subchannel that has the lowest-numbered I/O-interruption subclass code that is not masked off by a corresponding bit in control register 6 of that CPU. When the highest-priority interruption request is accepted by a CPU, it is cleared so that the interruption request is not accepted by any other CPU in the configuration.

The priority of interruption handling can be modified by the execution of either TEST SUBCHANNEL or CLEAR SUBCHANNEL. When either of these instructions is executed and the designated subchannel has an interruption request pending, that interruption request is cleared, without regard to any previous established priority. The relative priority of the remaining interruption requests is unchanged.
Programming Notes:

1. The I/O-interruption subclass mask is in control register 6, which has the following format:

   <!> Hex.
   
<table>
<thead>
<tr>
<th>Word</th>
<th>Subsystem-Identification Word</th>
<th>I/O-Interruption Parameter</th>
<th>I/O-Interruption-Identification Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>ISC Mask</td>
<td>Reserved</td>
<td></td>
</tr>
<tr>
<td>32</td>
<td>40</td>
<td>63</td>
<td></td>
</tr>
</tbody>
</table>

2. Control register 6 is set to all zeros during initial CPU reset.

Interruption Action

An I/O interruption can occur only when the I/O-interruption-subclass-mask bit associated with the subchannel is one and the CPU is enabled for I/O interruptions.

The interruption occurs at the completion of a unit of operation (see “Point of Interruption” on page 24). If the channel subsystem establishes the priority among requests for interruption from subchannels while the CPU is disabled for I/O interruptions, the interruption occurs immediately after the completion of the instruction enabling the CPU and before the next instruction is executed, provided that the I/O-interruption subclass-mask bit associated with the subchannel is one. Alternatively, if the channel subsystem establishes the priority among requests for interruption from subchannels while the I/O-interruption-subclass-mask bit is zero for each subchannel that is status pending, the interruption occurs immediately after the completion of the instruction that sets at least one of the I/O-interruption-subclass-mask bits to one, provided that the CPU is also enabled for I/O interruptions. This interruption is associated with the highest-priority I/O-interruption request, as established by the CPU.

If the channel subsystem has not established the priority among requests for interruption from the subchannels by the time the interruption is allowed, the interruption does not necessarily occur immediately after the completion of the instruction enabling the CPU. A delay can occur regardless of how long the interruption condition has existed at the subchannel.

The interruption causes the current PSW to be stored as the input/output old PSW at real locations 368-383 and causes the I/O-interruption code associated with the interruption to be stored at real locations 184-195 of the CPU allowing the interruption. Subsequently, a new input/output PSW is loaded from real locations 496-511 and processing resumes in the CPU state indicated by that PSW. The subchannel causing the interruption is identified by the interruption code.

The I/O-interruption code has the following format when it is stored. The code is described in “TEST PENDING INTERRUPTION” on page 19.

Hex.

<table>
<thead>
<tr>
<th>B8</th>
<th>184</th>
</tr>
</thead>
<tbody>
<tr>
<td>BC</td>
<td>188</td>
</tr>
<tr>
<td>C0</td>
<td>192</td>
</tr>
</tbody>
</table>

Programming Note: The I/O-interruption subclass code for all subchannels is set to zero by I/O-system reset. It may be set to any of the values 0-7 by the execution of MODIFY SUBCHANNEL. (The operation of the instruction is described in “MODIFY SUBCHANNEL” on page 7.)

Interruption-Response Block

The interruption-response block (IRB) is the operand of TEST SUBCHANNEL. The two rightmost bits of the IRB address are zeros, designating the IRB on a word boundary. The IRB contains three major fields: the subchannel-status word, the extended-status word, and the extended-control word. When the extended-I/O-measurement-word mode is enabled at the subchannel, the IRB contains a fourth major field, the extended-measurement word.

IRB Format

The format of the IRB stored depends upon the subchannel status. The status present at the subchannel when a TEST SUBCHANNEL instruction is executed determines whether a command-mode IRB or transport-mode IRB is stored. Bit 11 of word 0 of the IRB
is the IRB-format control bit (X). When an IRB is stored with X set to zero, a command-mode IRB is stored. (See “Command-Mode SCSW” on page 8.) When an IRB is stored with X set to one, a 3-bit format field is defined. (See “Format (FMT)” on page 35.) The format of the IRB is specified according to the table below:

<table>
<thead>
<tr>
<th>Subchannel Mode</th>
<th>Subchannel Status</th>
<th>Bit (X)</th>
<th>FMT</th>
<th>IRB Mode Stored</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Explanations:
N: Format field is not defined.
Y-0: Format field is defined and its value is 0.

Figure 16-2. Summary of IRB Format as Function of Subchannel Status

The general layout of the IRB is as follows:

The length of the subchannel-status and extended-status words is 12 bytes and 20 bytes, respectively. The length of the extended-control word is 32 bytes. When the extended-control bit, bit 14 of word 0 of the SCSW, is zero, words 8-15 of the interruption-response block may or may not be stored. The length of the extended-measurement word is 32 bytes. When the conditions for storing the extended-measurement word are not met (see “Extended-Measurement Word” on page 56), words 16-23 of the interruption-response block may or may not be stored.

Subchannel-Status Word

The subchannel-status word (SCSW) provides the program indications describing the status of a subchannel and its associated device. When a transport-mode IRB is stored, additional information describing the status of the operation and the associated device may also be stored in the transport-status block associated with the operation. If performance of a halt, resume, or start function has occurred, the SCSW may describe the conditions under which the operation was concluded.

The SCSW is stored when TEST SUBCHANNEL is executed and the designated subchannel is operational. The SCSW is placed in words 0-2 of the IRB that is designated as the TEST SUBCHANNEL operand. When STORE SUBCHANNEL is executed, the SCSW is stored in words 7-9 of the subchannel-information block (described in “Subchannel-Information Block” on page 2).

Figure 16-3 on page 8 shows the summary and contents of the command-mode SCSW.

Figure 16-3. Command-Mode SCSW Format

Figure 16-4. Command-Mode SCSW
The contents of the subchannel-status word (SCSW) depend on the state of the subchannel when the SCSW is stored. Depending on the state of the subchannel and the device, the specific fields of the SCSW may contain (1) information pertaining to the last operation, (2) information unrelated to the performance of an operation, (3) zeros, or (4) meaningless values. The following descriptions indicate when an SCSW field contains meaningful information for a command-mode IRB.

Subchannel Key
When the start-function bit, bit 17 of word 0, is one, bit positions 0-3 of word 0 contain the access key used during performance of the associated start function. These bits are identical with the key specified in bit positions 0-3 of word 1 of the ORB. The subchannel key is meaningful only when the start-function bit, bit 17 of word 0, is one.

Suspend Control (S)
When the start-function bit, bit 17 of word 0, is one, bit 4 of word 0, when one, indicates that the suspend function can be initiated at the subchannel. Bit 4 is meaningful only when bit 17 is one. If bit 17 is one and bit 4 is one, channel-program execution can be suspended if the channel subsystem recognizes an S flag set to one in a CCW. If bit 4 is zero, channel-program execution cannot be suspended, and, if an S flag set to one in a CCW is encountered, a program-check condition is recognized.

Extended-Status-Word Format (L)
When the status-pending bit, bit 31 of word 0, is one, bit 5 of word 0, when one, indicates that a format-0 ESW has been stored. A format-0 ESW is stored when an interruption condition containing any of the following indications is cleared by TEST SUBCHANNEL:

- Channel-data check
- Channel-control check
- Interface-control check
- Measurement-block-program check
- Measurement-block-data check
- Measurement-block-protection check
- Path verification required
- Authorization check
- Extended subchannel logout pending

The extended-status-word-format bit is meaningful whenever the subchannel is status pending. The extended-status information that is used to form a format-0 ESW is cleared at the subchannel by TEST SUBCHANNEL or CLEAR SUBCHANNEL.

Deferred Condition Code (CC)
When the start-function bit, bit 17 of word 0, is one and the status-pending bit, bit 31 of word 0, is also one, bits 6 and 7 of word 0 indicate the general reason that the subchannel was status pending when TEST SUBCHANNEL or STORE SUBCHANNEL was executed. The deferred condition code is meaningful when the subchannel is status pending with any combination of status and only when the start-function bit of the function-control field in the SCSW is one. The meaning of the deferred condition code for each value when the subchannel is status pending is given in Figure 16-5 on page 11.

The deferred condition code, if not zero, is used to indicate whether conditions have been encountered that preclude the subchannel becoming subchannel-and-device active while the subchannel is either start pending or suspended.

Deferred Condition Code 0: A normal I/O interruption has taken place.

Deferred Condition Code 1: Status is present in the SCSW that was presented by the associated device or generated by the channel subsystem subsequent to the setting of condition code 0 for START SUBCHANNEL or RESUME SUBCHANNEL. If only the alert-status bit and the status-pending bit of the status-control field of the SCSW are ones, the status present is not related to the execution of a channel program. If the intermediate-status bit, the primary-status bit, or both are ones, then the status is related to the execution of the channel program specified by the most recently executed START SUBCHANNEL instruction or implied by the most recently executed RESUME SUBCHANNEL instruction. (See “Immediate Conclusion of Command-Mode I/O Operations” on page 78.) If the secondary-status bit is one and the primary-status bit is zero, the status present is related to the channel program specified by the START SUBCHANNEL instruction or implied by the RESUME SUBCHANNEL instruction that preceded the most recently executed START SUBCHANNEL instruction.

Deferred Condition Code 2: This code does not occur and is reserved for future use.
Deferred Condition Code 3: An attempted device selection has occurred, and the device appeared not operational on all of the channel paths that were available for selection of the device.

A device appears not operational when it does not respond to a selection attempt by the channel subsystem. This occurs when the control unit is not provided in the system, when power is off in the control unit, or when the control unit has been logically switched off the channel path. The not-operational state is also indicated when the control unit is provided and is capable of attaching the device, but the device has not been installed and the control unit is not designed to recognize the device being selected as one of its attached devices. (See also “I/O Addressing” on page 5.)

A deferred condition code 3 also can be set by the channel subsystem if no channel paths to the device are available for selection. (See Figure 16-5 on page 11.)

Programming Notes:

1. If, during performance of a start function, the I/O device being selected is not installed or has been logically removed from the control unit, but the associated control unit is operational and the control unit recognizes the I/O device being selected as one of its I/O devices, the control unit, depending upon the model, either fails to recognize the address of the I/O device or considers the I/O device to be not ready. In the former case, a path-not-operational condition is recognized, subject to the setting of the path-operational mask. (See “Path-Operational Mask (POM)” on page 7.) In the latter case, the not-ready condition is indicated when the control unit responds to the selection and indicates unit check whenever the not-ready state precludes successful initiation of the operation at the I/O device. In this case, unit-check status is indicated in the SCSW, the subchannel becomes status pending with primary, secondary, and alert status, and with deferred condition code 1 indicated. (See the publication ESA/390 Common I/O-Device Commands, SA22-7204, for a description of unit-check status.) Refer to the System Library publication for the control unit to determine how the condition is indicated.

2. The deferred condition code is 1, and the status-control field contains the status-pending and intermediate-status bits or the status-pending, intermediate-status, and alert-status bits as ones when HALT SUBCHANNEL has been executed and the designated subchannel is suspended and status pending with intermediate status. If the alert-status bit is one, then subchannel-log-out information was generated as a result of attempting to issue the halt signal to the device.
When the start-function bit, bit 17 of word 0, is one, bit 8 of word 0 indicates the format of the CCWs associated with an I/O operation. The format bit is meaningful only when bit 17 is one. If bit 8 of word 0 is zero, format-0 CCWs are indicated. If it is one, format-1 CCWs are indicated. (See “Channel-Command Word” on page 30 for the description of the two CCW formats.)

### Prefetch (P)
When the start-function bit, bit 17 of word 0, is one, bit 9 of word 0 indicates whether or not unlimited prefetching of CCWs, IDAWs, MIDAWS, and associ-
ated data is allowed. The prefetch bit is meaningful only when bit 17 is one. If bit 9 is zero, prefetching of one CCW describing a data area is allowed during output-data-chaining operations and is not allowed during any other operations. If bit 9 is one, unlimited prefetching of CCWs, IDAWs, MIDAWS, and associated data is allowed. It is model dependent whether prefetching is actually performed for any or all of the CCWs, IDAWs, MIDAWS, and associated data that comprise the CCW channel program.

**Initial-Status-Interruption Control (I)**
When the start-function bit, bit 17 of word 0, is one, bit 10 of word 0, when one, indicates that the channel subsystem is to generate an intermediate interruption condition if the subchannel becomes subchannel active (see “Initial-Status-Interruption Control (I)” on page 27). Bit 10 of word 0, when zero, indicates that the subchannel becoming subchannel active is not to cause an intermediate interruption condition to be generated.

The program requests the intermediate interruption condition by means of the command-mode ORB. An I/O interruption that results from that request may be due to the channel subsystem performing either a start function or a resume function. (See “Zero Condition Code (Z)” on page 12 for details of the indication given by the channel subsystem when the intermediate interruption condition is cleared by TEST SUBCHANNEL.)

**Address-Limit-Checking Control (A)**
When the address-limit-checking facility is installed and the start-function bit, bit 17 of word 0, is one, bit 11 of word 0, when one, indicates that the channel subsystem has been requested by the program to perform address-limit checking, subject to the setting of the limit mode at the subchannel (see “Address-Limit-Checking Control (A)” on page 27). The address-limit-checking-control bit is meaningful only when bit 17 is one.

**IRB-Format Control (X)**
Bit 11 of word 0 is the IRB-format control bit (X). The value of this bit is zero for the command-mode IRB. See Figure 16-2 on page 7.

**Suppress-Suspended Interruption (U)**
When the start-function bit, bit 17 of word 0, is one, bit 12 of word 0, when one, indicates that the channel subsystem has been requested by the program to suppress the generation of a subchannel-suspended interruption condition when the subchannel is suspended (see “Suppress-Suspended-Interruption Control (U)” on page 27). When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel is suspended during the execution of the associated channel program. The suppress-suspended-interruption bit is meaningful only when bit 17 is one.

**Subchannel-Control Field**
The following subchannel-control-information descriptions apply to the subchannel-control field, bits 13-31 of word 0 of the SCSW.

**Zero Condition Code (Z)**
Bit 13 of word 0, when one, indicates that the subchannel has become subchannel active and the channel subsystem has recognized an initial-status-interruption condition at the subchannel. The Z bit is meaningful only when the intermediate-status bit, bit 28 of word 0, and the start-function bit, bit 17 of word 0, are both ones.

If the initial-status-interruption-control bit, bit 10 of word 1 of the command-mode ORB, is one when START SUBCHANNEL is executed, then the subchannel becoming subchannel active causes the subchannel to be made status pending with intermediate status indicating the initial-status-interruption condition. The initial-status-interruption condition remains at the subchannel until the intermediate interruption condition is cleared by the execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL. If the initial-status-interruption-control bit of the command-mode ORB is zero when START SUBCHANNEL is executed, then the subchannel becoming subchannel active does not cause an intermediate interruption condition to be generated, and the initial-status-interruption condition is not recognized.

**Extended Control (E)**
Bit 14 of word 0, when one, indicates that model-dependent information or concurrent-sense information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW, if stored, are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both.
Programming Note: During the execution of TEST SUBCHANNEL, the storing of words 0-7 of the ECW is a model-dependent function subject to the setting of bit 14 as described above. Therefore, the program should always provide sufficient storage to accommodate the storing of at least a 64-byte IRB or, when the extended-I/O-measurement-word mode is enabled at the subchannel, a 96-byte IRB.

Path Not Operational (N)

Bit 15 of word 0, when one, indicates that the N condition has been recognized by the channel subsystem. The N condition, in turn, indicates that one or more path-not-operational conditions have been recognized. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection.

The N bit is meaningful whenever the status-control field contains any of the indications listed below and at least one basic I/O function is also indicated at the subchannel:

- Status pending with any combination of primary, secondary, or alert status
- Status pending alone
- Status pending with intermediate status when the subchannel is also suspended

The N condition is reset whenever the execution of TEST SUBCHANNEL results in the setting of condition code 0 and the N bit is meaningful as described above.

Notes:

1. A path-not-operational condition does not imply a malfunctioning channel path. A malfunctioning channel path causes the generation of an error indication, such as interface-control check.

2. When a path-not-operational condition has been recognized and the subchannel subsequently becomes status pending with only intermediate status, the path-not-operational condition (a) continues to be recognized until the subchannel becomes status pending with primary status or becomes suspended and (b) is indicated by storing the path-not-operational bit as a one during the execution of TEST SUBCHANNEL. When a path-not-operational condition has been recognized and the channel-program execution subsequently becomes suspended, the path-not-operational condition does not remain pending if channel-program execution is subsequently resumed. Instead, the old indication is lost, and the path-not-operational indication, if any, pertains to the attempt by the channel subsystem to resume channel-program execution.

Function Control (FC)

The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 4). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

Start Function (Bit 17): When one, bit 17 indicates that a start function has been requested and is either pending or in progress at the subchannel. A start function is requested by the execution of START SUBCHANNEL. A start function is indicated at the subchannel when condition code 0 is set during the execution of START SUBCHANNEL. The start-function indication is cleared at the subchannel when TEST SUBCHANNEL is executed and the subchannel is either status pending alone or status pending with any combination of alert, primary, or secondary status. The start-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.
Halt Function (Bit 18): When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If the subchannel is subchannel active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least primary status indicated. If the subchannel is device active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least secondary status indicated. If the subchannel is suspended and status pending with intermediate status when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with intermediate status. If the subchannel is idle when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending alone. The halt-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. In normal operations, this function is indicated together with bit 17; that is, there is a start function either pending or in progress that is to be halted.

Clear Function (Bit 19): When one, bit 19 indicates that a clear function has been requested and is either pending or in progress at the subchannel. A clear function is requested by the execution of CLEAR SUBCHANNEL. A clear function is indicated at the subchannel when condition code 0 is set for CLEAR SUBCHANNEL (see “CLEAR SUBCHANNEL” on page 5). The clear-function indication is cleared at the subchannel when the resulting status-pending condition is cleared by TEST SUBCHANNEL.

Activity Control (AC)
The activity-control field is contained in bit positions 20-26 of the first word of the SCSW. This field indicates the current progress of a basic I/O function previously accepted at the subchannel. By using the contents of this field, the program can determine the degree of completion of the basic I/O function. The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not have been performed at the device. The activity-control bits are defined as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>Resume pending</td>
</tr>
<tr>
<td>21</td>
<td>Start pending</td>
</tr>
<tr>
<td>22</td>
<td>Halt pending</td>
</tr>
<tr>
<td>23</td>
<td>Clear pending</td>
</tr>
<tr>
<td>24</td>
<td>Subchannel active</td>
</tr>
<tr>
<td>25</td>
<td>Device active</td>
</tr>
<tr>
<td>26</td>
<td>Suspended</td>
</tr>
</tbody>
</table>

When an SCSW is stored that has the status-pending bit of the status-control field zero and all zeros in the activity-control field, the subchannel is said to be idle or in the idle state.

Note: All conditions that are represented by the bits in the function-control field and by the resume-pending, start-pending, halt-pending, clear-pending, subchannel-active, and suspended bits in the activity-control field are reset at the subchannel when TEST SUBCHANNEL is executed and the subchannel is (1) status pending alone, (2) status pending with primary status, (3) status pending with alert status, or (4) status pending with intermediate status and is also suspended.

Resume-Pending (Bit 20): When one, bit 20 indicates that the subchannel is resume pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes resume pending when condition code 0 is set for RESUME SUBCHANNEL. The point at which the subchannel is no longer resume pending is a function of the subchannel state existing when the resume-pending condition is recognized and the state of the device if channel-program execution is resumed.

If the subchannel is in the suspended state when the resume-pending condition is recognized, the CCW that caused the suspension is refetched, the setting of the suspend flag is examined, and one of the following actions is taken by the channel subsystem:

1. If the CCW suspend flag is one, the device is not selected, the subchannel is no longer resume pending, and the channel-program execution remains suspended.
2. If the CCW suspend flag is zero, the channel subsystem attempts to resume channel-program execution by performing a modified start function. The resumption of channel-program execution appears to the device as the initiation of a new channel-program execution. The resume function causes the channel subsystem to perform the path-management operation as if a new start function were being initiated, using the ORB parameters previously passed to the subchannel by START SUBCHANNEL with the exception that the channel-program address is the address of the CCW that caused the suspension of the channel-program execution.

The subchannel remains resume pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See “Start Function and Resume Function” on page 20.)

The subchannel is no longer resume pending when any of the following events occur:

a. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.

b. CLEAR SUBCHANNEL is executed.

c. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

d. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

e. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

If the subchannel is not in the suspended state when the resume-pending condition is recognized, the CCW suspend flag of the most recently fetched CCW, if any, is examined, and one of the following actions is taken by the channel subsystem:

1. If a CCW has not been fetched or the suspend flag of the most recently fetched CCW is zero, the subchannel is no longer resume pending, and the resume function is not performed.

2. If the suspend flag of the most recently fetched CCW is one, the subchannel is no longer resume pending, and the CCW is refetched. The subchannel proceeds with channel-program execution if the suspend flag of the refetched CCW is zero. The subchannel suspends channel-program execution if the suspend flag of the refetched CCW is one.

Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched that has an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

**Start-Pending (Bit 21):** When one, bit 21 indicates that the subchannel is start pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes start pending when condition code 0 is set for START SUBCHANNEL. The subchannel remains start pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See “Start Function and Resume Function” on page 20.)

The subchannel becomes no longer start pending when any of the following occurs:

1. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.

2. The subchannel becomes suspended because of a suspend flag validly set to one in the first CCW.

3. CLEAR SUBCHANNEL is executed.
4. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

**Halt-Pending (Bit 22):** When one, bit 22 indicates that the subchannel is halt pending. The channel subsystem may or may not be in the process of performing the halt function. The subchannel becomes halt pending when condition code 0 is set for HALT SUBCHANNEL. The subchannel remains halt pending when, during the performance of the halt function, the channel subsystem (1) determines that it is not possible to attempt to issue the halt signal to the device, (2) determines that the attempt to issue the halt signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the halt signal is issued to the device. (See “Halt Function” on page 16.)

The subchannel is no longer halt pending when any of the following occurs:

1. While performing the halt function, the channel subsystem determines that the halt signal has been issued to the device.
2. CLEAR SUBCHANNEL is executed.
3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.
4. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

**Clear-Pending (Bit 23):** When one, bit 23 indicates that the subchannel is clear pending. The channel subsystem may or may not be in the process of performing the clear function. The subchannel becomes clear pending when condition code 0 is set for CLEAR SUBCHANNEL. The subchannel remains clear pending when, during performance of the clear function, the channel subsystem (1) determines that it is not possible to attempt to issue the clear signal to the device, (2) determines that the attempt to issue the clear signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the clear signal is issued to the device. (See “Clear Function” on page 14.)

The subchannel is no longer clear pending when either of the following occurs:

1. While performing the clear function, the channel subsystem determines that the clear signal has been issued to the device.
2. TEST SUBCHANNEL clears the status-pending condition alone.

**Subchannel Active (Bit 24):** When one, bit 24 indicates that the subchannel is subchannel active. A subchannel is said to be subchannel active when an I/O operation is currently being performed at the subchannel. The subchannel becomes subchannel active when the first command is accepted and the start function or resume function is not immediately concluded at the subchannel. (See “Immediate Conclusion of Command-Mode I/O Operations” on page 78.)

The subchannel is no longer subchannel active when any of the following occurs:

1. The subchannel becomes suspended.
2. The subchannel becomes status pending with primary status.
3. CLEAR SUBCHANNEL is executed.
4. The device appears not operational during performance of a halt function.

The subchannel does not become subchannel active during performance of the function specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

**Device Active (Bit 25):** When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active when the first command is accepted.

The subchannel is no longer device active when any of the following occurs:

1. The subchannel becomes suspended.
2. The subchannel becomes status pending with secondary status.
3. CLEAR SUBCHANNEL is executed.
4. The device appears not operational during performance of a halt function.
If the subchannel is not start pending or if the status accepted from the device also describes an alert condition, the subchannel becomes status pending with secondary status. After the status has been accepted from the device, the device is capable of accepting a command for performing a new I/O operation. If the subchannel is start pending and the status is device end or device end with control unit end, then the channel subsystem discards the status and performs the start function for the new channel program. (See “Start Function and Resume Function” on page 20.) In this situation, the subchannel does not become status pending with the secondary interruption condition, and the status is not made available to the program.

The subchannel does not become device active during performance of the functions specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

**Suspected (Bit 26):** When one, bit 26 indicates that the subchannel is suspended. A subchannel is said to be suspended when channel-program execution is currently suspended. The subchannel becomes suspended as part of the suspend function. (See “Suspension of CCW Channel-Program Execution” on page 73.)

The subchannel is no longer suspended when any of the following occurs:

1. As part of the resume function following the execution of RESUME SUBCHANNEL when the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted for channel-end and device-end initial status, with or without status modifier, and the CCW does not specify command chaining.

2. CLEAR SUBCHANNEL is executed.

3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

4. TEST SUBCHANNEL clears intermediate status while the halt function is specified.

5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

**Programming Note:** When an SCSW is stored by STORE SUBCHANNEL or TEST SUBCHANNEL following CLEAR SUBCHANNEL but prior to the subchannel becoming status pending, and the subchannel-active bit, bit 24 of word 0, is stored as zero, this does not mean that data transfer has stopped for the device. The program cannot determine whether data transfer has stopped until the subchannel becomes status pending as a result of performing the clear function.

**Status Control (SC)**

The status-control field is contained in bit positions 27-31 of the first word of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status, the Z bit, or, in the case of the subchannel-suspended interruption, the suspended bit, bit 26. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see “Enabled (E)” on page 3) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 4); bits 27-30 are meaningful when bit 31 is one. The status-control bits are defined as follows:

**Alert Status (Bit 27):** When one (and when the status-pending bit is also one), bit 27 indicates an alert interruption condition exists. In such a case, the subchannel is said to be status pending with alert status. An alert interruption condition is recognized when alert status is present at the subchannel. Alert status may be subchannel status or device status. Alert status is status generated by either the channel subsystem or the device under any of the following conditions:

- The subchannel is idle (activity-control bits 20-26 and status-control bit 31 are zeros).
- The subchannel is start pending, and the status condition precludes initiation of the I/O operation.
- The subchannel is subchannel-and-device active, and the status condition has suppressed command chaining or would have suppressed command chaining if chaining had been specified (see “CCW Channel Program Chaining” on page 60).
- The subchannel is subchannel-and-device active, command chaining is not specified, the
execution of the channel program has just been concluded, and the status presented by the device is attempting to alter the sequential execution of commands (see the publication ESA/390 Common I/O-Device Commands, SA22-7204, for more information on the use of status modifier to alter the sequential execution of commands).

- The subchannel is device active only, and the status presented by the device is other than device end, control unit end, or device end and control unit end.
- The subchannel is suspended (bit 26 is one).

If the subchannel is start pending when an alert interruption condition is recognized, the subchannel becomes status pending with alert status, deferred condition code 1 is set, the start-pending bit remains one, and the performance of the pending I/O operation is not initiated.

When TEST SUBCHANNEL is executed and stores an SCSW with the alert-status bit and the status-pending bit as ones in the IRB, the alert interruption condition is cleared at the subchannel. The alert interruption condition is also cleared during the execution of CLEAR SUBCHANNEL.

Whenever alert status is present at the subchannel, it is brought to the attention of the program. Examples of alert status include attention, device end (which signals a transition from the not-ready to the ready state), incorrect length, program check, and unit check.

**Intermediate Status (Bit 28):** When one (and when the status-pending bit is also one), bit 28 indicates an intermediate interruption condition exists. In such a case, the subchannel is said to be status pending with intermediate status. Intermediate status can be indicated when the Z bit (of the subchannel-control field), the suspended bit (of the activity-control field), or the PCI bit (of the subchannel-status field) is one.

When the initial-status-interruption-control bit is one in the command-mode ORB, the subchannel becomes status pending with intermediate status (the Z bit indicated) only after the subchannel is subchannel active. If the subchannel does not become subchannel active, the Z condition is not generated.

When suspend control is specified and the generation of an intermediate interruption condition due to suspension is not suppressed in the command-mode ORB, then the subchannel can become status pending with intermediate status due to suspension if a CCW becomes current that contains the suspend flag set to one. When the suspend flag is specified in the first CCW of a channel program, channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit indicated) before the command in the first CCW is transferred to the device. When the suspend flag is specified in a CCW fetched during command chaining, then channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit is indicated), only after the execution of the preceding CCW is complete.

When the PCI flag is specified in a CCW, the generation of an intermediate interruption condition due to PCI depends on whether the CCW is the first CCW of the channel program. When the PCI flag is specified in the first CCW of a channel program, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after initial status is received for the first CCW of the channel program indicating the command has been accepted. When the PCI flag is specified in a CCW fetched while chaining, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after the execution of the preceding CCW is complete. If chaining occurs before an interruption condition containing PCI is cleared by TEST SUBCHANNEL, the condition is carried over to the next CCW. This carry-over occurs during both data and command chaining, and, in either case, the condition is propagated through the transfer-in-channel command.

If the subchannel is status pending with intermediate status when HALT SUBCHANNEL is executed, the intermediate interruption condition remains at the subchannel, but the interruption request, if any, is withdrawn, and the subchannel becomes no longer status-pending. The subchannel remains no longer status pending until performance of the halt function has ended. The subchannel then becomes status pending with intermediate status indicated (possibly together with any combination of primary, secondary, and alert status).

When TEST SUBCHANNEL is executed and stores an SCSW with the intermediate-status bit and the
status-pending bit as ones in the IRB, the intermediate interruption condition is cleared at the subchannel. The intermediate interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

**Primary Status (Bit 29):** When one (and when the status-pending bit is also one), bit 29 indicates a primary interruption condition exists. In such a case, the subchannel is said to be status pending with primary status. A primary interruption condition is a solicited interruption condition that indicates the completion of the start function at the subchannel. The primary interruption condition is described by the SCSW stored. When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with primary status (and secondary status) with both the subchannel-status field and the device-status field set to zero.

When TEST SUBCHANNEL is executed and stores an SCSW with the primary-status bit and the status-pending bit as ones in the IRB, the primary interruption condition is cleared at the subchannel. The primary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

**Secondary Status (Bit 30):** When one (and when the status-pending bit is also one), bit 30 indicates a secondary interruption condition exists. In such a case, the subchannel is said to be status pending with secondary status. A secondary interruption condition is a solicited interruption condition that normally indicates the completion of the I/O operation at the device. The secondary interruption condition is described by the SCSW stored.

When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with secondary status (and primary status) if the subchannel is also subchannel active) with zeros for subchannel and device status.

When TEST SUBCHANNEL is executed and stores an SCSW with the secondary-status bit as one in the IRB, the secondary interruption condition is cleared at the subchannel. The secondary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

**Status-Pending (Bit 31):** When one, bit 31 indicates that the subchannel is status pending and that information describing the cause of the interruption condition is available to the program. The subchannel becomes status pending whenever intermediate, primary, secondary, or alert status is generated. When HALT SUBCHANNEL is executed, designating a subchannel that is idle, the subchannel becomes status pending subsequent to performance of the halt function to notify the program that the halt function has been completed. When TEST SUBCHANNEL is executed, thus storing an SCSW with the status-pending bit as one in the IRB, the status-pending condition is cleared at the subchannel. The status-pending condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. When CLEAR SUBCHANNEL is executed and the designated subchannel is operational, the subchannel becomes status pending subsequent to performance of the clear function to notify the program that the clear function has been completed.

**Note:** The status-pending bit, in conjunction with the remaining bits of the status-control field, indicates the type of status condition. For example, if bits 29 and 31 are ones, the subchannel is status pending with primary status. Alternatively, if only bit 31 is one, then the subchannel is said to be status pending or status pending alone. If only bit 31 is one in the status-control field, the settings of all bits in the subchannel-status and device-status fields are unpredictable. If bit 31 is not one, then the remaining bits of the status-control field are not meaningful.

**CCW-Address Field**

Bits 1-31 of word 1 form an absolute address. The address indicated is a function of the subchannel state when the SCSW is stored, as indicated in Figure 16-6 on page 20. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the CCW-address field is usable for recovery purposes if the CCW-address field-validity flag in the ESW is one.

**Programming Note:** When a CCW address, either detected in the channel-program address (see “Channel-Program Address” on page 28) or generated during chaining, would cause the channel subsystem to fetch a CCW from a location greater than 2^{24} - 1 while format-0 CCWs are specified for the operation, the invalid address is stored in the CCW-address field of the SCSW without truncation. If the
invalid address causes the channel subsystem, while chaining, to fetch a CCW from a location greater than $2^{31} - 1$ while format-1 CCWs are specified for the operation, the rightmost 31 bits of the invalid address are stored in the CCW-address field.

Figure 16-6. (Part 3 of 4) CCW Address as Function of Subchannel State
Explanation:

The meaning of the notation used in this column is as follows:

A Alert status
I Intermediate status
P Primary status
S Secondary status
X Status Pending

The possible combination of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

0 Corresponding condition is not indicated
1 Corresponding condition is indicated
U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

A CCW becomes current when (1) it is the first CCW of a channel program and has been fetched, (2) while command chaining, the previous CCW is no longer current and the new CCW has been fetched, or (3) in the case of data chaining, the new CCW takes over control of the I/O operation (see the section "Data Chaining" in Chapter 15, "Basic I/O Functions"). If chaining is not specified or is suppressed, a CCW is no longer current and becomes the last-executed CCW when secondary status has been accepted by the channel subsystem. During command chaining, a CCW is no longer current when device-end status has been accepted or, in the case of data chaining, when the last byte of data for that CCW has been accepted.

The subchannel may also be resume pending.

The stored address is the channel-program address (in the ORB) + 8 even though it is either invalid or protected.

The stored address is the address of the current CCW + 8 even though it is either invalid or protected.

Incorrect length is indicated as a function of the setting of the suppress-length-indication flag in the current CCW (see the section "Channel-Command Word" in Chapter 15, "Basic I/O Functions").

Notes:

1. Unless the subchannel is also resume pending, the address stored is the address of the CCW that caused suspension, plus 8. Otherwise, the address stored is unpredictable.

2. The address of the CCW is given as a function of the alert status indicated. For example, if a program-check or protection-check condition is recognized, the CCW address stored is the same as for the entry for program check or protection check, respectively, in this table. Alternatively, if alert status for interface-control check or channel-control check is indicated, the CCW address stored is either the channel-program address (in the ORB) + 8 or invalid as specified by the field-validity flags in the subchannel logout. If alert status for path-verification required is indicated, the CCW address stored is the channel-program address (in the ORB) + 8.

3. Bit 21 of the subchannel-logout information, when stored as one, indicates that the address is CCW + 8 of the last-fetched CCW if the command for the CCW has not been accepted by the device. If the command has been accepted by the device at the time the error condition is recognized, then the address stored is the address of the CCW + 8 of the last-executed CCW.

Figure 16-6. (Part 4 of 4) CCW Address as Function of Subchannel State
Device-Status Field

Device-status conditions are generated by the I/O device and are presented to the channel subsystem over the channel path. The timing and causes of these conditions for each type of device are specified in the System Library publication for the device. The device-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Whenever the subchannel is status pending with intermediate status alone, the device-status field is zero. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the device-status field is usable for recovery purposes if the device-status field-validity flag in the ESW is one. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the device-status field are not meaningful.

If, within a system, the I/O device is accessible from more than one channel path, status related to channel-subsystem-initiated operations in the single-path mode (solicited status) is signaled over the initiating channel path. Devices operating in the multipath mode may signal solicited status over any channel path that belongs to the same path group as the initiating channel path. The handling of conditions not associated with I/O operations (unsolicited alert status), such as attention, unit exception, and device end due to transition from the not-ready to the ready state, depends on the type of device and condition and is specified in the System Library publication for the device.

The channel subsystem does not modify the status bits received from the I/O device. These bits appear in the SCSW as received over the channel path. For more information on the status bits received from the I/O device, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204.

Subchannel-Status Field

Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt, resume, or start function. The subchannel-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Individual bits contained in the subchannel-status field may be unpredictable even when the subchannel-status field is meaningful. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful.

Program-Controlled Interruption

An intermediate interruption condition is generated after a CCW with the program-controlled-interruption (PCI) flag set to one becomes the current CCW. The I/O interruption due to the PCI flag may be delayed an unpredictable amount of time because of masking of the interruption request or other activity in the system. (See “Program-Controlled Interruption” on page 64.) When the channel subsystem recognizes an alert interruption condition due to either a channel-control-check condition or an interface-control-check condition, then any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem.

Detection of the PCI condition does not affect the progress of the I/O operation.

Incorrect Length

Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device. Incorrect length is indicated for one of the following reasons:

**Long Block on Input:** During a read, read-backward, or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the SCSW is zero.

**Long Block on Output:** During a write or control operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the SCSW is zero.

**Short Block on Input:** The number of bytes transferred during a read, read-backward, or sense opera-
tion is insufficient to fill the main-storage areas assigned to the operation. The count in the SCSW is not zero.

Short Block on Output: The device terminated a write or control operation before all information contained in the assigned main-storage areas was transferred to the device. The count in the SCSW is not zero.

The incorrect-length indication is suppressed when the current CCW has the SLI flag set to one and the CD flag set to zero. The indication does not occur for operations rejected during the initiation sequence. The indication also does not occur for immediate operations when the count field is nonzero and the subchannel is in the incorrect-length-suppression mode. The incorrect-length indication is not meaningful when the count field of the SCSW is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the CCW is one or unless the condition occurs in an immediate operation when the subchannel is in the incorrect-length-suppression mode.

Program Check
Program check occurs when programming errors are detected by the channel subsystem. The condition can be due to the following causes:

Invalid CCW-Address Specification: The channel-program address (CPA) or the transfer-in-channel command does not designate the CCW on a double-word boundary, or bit 0 of the CPA or bit 32 of a format-1 CCW specifying the transfer-in-channel command is not zero.

Invalid CCW Address: The channel subsystem has attempted to fetch a CCW from a main-storage location that is not available. An invalid CCW address can occur because the program has designated an invalid address in the channel-program-address field of the command-mode ORB or in the transfer-in-channel command or because, on chaining, the channel subsystem attempts to fetch a CCW from an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute CCW address does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, and the absolute CCW address is greater than $2^{24} - 1$.
3. Format-1 CCWs are specified in the ORB, and the absolute CCW address is greater than $2^{31} - 1$

Invalid Command Code: There are zeros in the four rightmost bit positions of the command code in the CCW designated by the CPA or in a CCW fetched on command chaining. The command code is not tested for validity during data chaining.

Invalid Count, Format 0: A CCW, which is other than a CCW specifying transfer in channel, contains zeros in bit positions 48-63.

Invalid Count, Format 1: A CCW that specifies data chaining or a CCW fetched while data chaining contains zeros in bit positions 16-31.

Invalid IDAW-Address or MIDAW-Address Specification: Indirect data addressing or modified indirect data addressing is specified, and any of the following conditions is detected:

1. The ORB specifies format-1 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a word boundary; that is, bits 30 and 31 (format-0 CCW) or 62 and 63 (format-1 CCW) are not zeros.
2. The ORB specifies format-2 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a doubleword boundary; that is, bits 29-31 (format-0 CCW) or 61-63 (format-1 CCW) are not zeros.
3. The ORB specifies modified-CCW-indirect-data addressing, the CCW specifies modified-indirect-data addressing, and the contents of the data-address field in the CCW do not designate the first MIDAW on a quadword boundary.

Invalid IDAW or MIDAW Address: The channel subsystem has attempted to fetch an IDAW or MIDAW from a main-storage location that is not available. An invalid IDAW or MIDAW address can occur because the program has designated an invalid address in a CCW that specifies indirect data addressing or modified indirect data addressing, or because the channel subsystem, on sequentially fetching IDAWs or MIDAWs, attempts to fetch from...
an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute IDAW or MIDAW address does not correspond to a physical location.

2. Format-0 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than $2^{24} - 1$.

3. Format-1 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than $2^{31} - 1$.

**Invalid Data-Address Specification:** Bit 32 of a format-1 CCW is not zero.

**Invalid Data Address:** When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem.

1. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.

2. Use of the data address has caused the channel subsystem to attempt to wrap from zero to the maximum storage address during a read-backward operation.

3. The channel subsystem has attempted to transfer data to a storage location that is unavailable.

An invalid data address can occur because the program has designated an unavailable location in a CCW or in an IDAW or MIDAW, or because the channel subsystem, on sequentially accessing storage, attempted to access an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute address of the location does not correspond to a physical location.

2. Format-0 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than $2^{24} - 1$.

3. Format-1 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than $2^{31} - 1$.

4. Format-1 IDAWs are specified in the ORB, indirect data addressing is specified in the CCW, and the absolute address is greater than $2^{31} - 1$.

5. When the address-limit-checking facility is installed, the absolute address is outside the addressing range specified by SET ADDRESS LIMIT, and the limit mode at the subchannel is active.

**Note:** The maximum storage address is determined as a function of the CCW and IDAW formats used or MIDAWs used. When neither an IDAW nor a MIDAW is used, the maximum storage address is a function of the CCW format specified, as follows:

1. When 24-bit (format 0) CCWs are specified, the maximum storage address recognized by the channel subsystem is $2^{24} - 1$.

2. When 31-bit (format 1) CCWs are specified, the maximum storage address recognized by the channel subsystem is $2^{31} - 1$.

When an IDAW is used, the maximum storage address is a function of the IDAW format specified, as follows:

1. When 31-bit (format 1) IDAWs are specified, the maximum storage address recognized by the channel subsystem is $2^{31} - 1$.

2. When 64-bit (format 2) IDAWs are specified, the maximum storage address recognized by the channel subsystem is $2^{64} - 1$.

When a MIDAW is used, the maximum storage address recognized by the channel subsystem is $2^{64} - 1$.

**Invalid IDAW or MIDAW Specification:** When any of the following conditions is detected, an invalid IDAW specification is recognized by the channel subsystem:

1. Bit 0 of a format-1 IDAW is not zero.

2. A second or subsequent format-1 IDAW does not designate the location of the beginning byte of a 2K-byte block or, for read-backward operations, the location of the ending byte of a 2K-byte block.

3. A second or subsequent format-2 IDAW does not designate the location of the beginning byte of a 2K-byte or 4K-byte block, as required by the 2K-IDAW control in the ORB, or, for read-backward operations, the location of the ending byte of a 2K-byte or 4K-byte block.
When bit 0 of a format-1 IDAW is not zero, the subchannel is made status pending with program-check indicated only after the I/O device attempts to transfer data, just as when an invalid data address that refers to a nonexistent data area is detected. If the device ends the operation prior to the transfer of data, no error condition is reported. See “CCW Indirect Data Addressing” in Chapter 15 for additional information about the reporting of program-check conditions.

When any of the following conditions is detected, an invalid MIDAW specification is recognized by the channel subsystem:

1. One or more bits defined as reserved in the MIDAW are not zero.
2. The MIDAW count field contains zeros.
3. The combination of the MIDAW data-address and count fields specify data addresses that cross a 4K-byte block boundary, unless skipping is in effect for the MIDAW.
4. The MIDAW in control has its last-MIDAW flag set to zero and the sum of the count values of the previous MIDAWs in the MIDAW list (MIDAL) and the MIDAW in control is greater than or equal to the count value in the CCW.
5. The MIDAW in control has its last-MIDAW flag set to one and the sum of the count values in the previous MIDAWs in the MIDAL and the MIDAW in control do not equal the count value in the CCW.
6. The MIDAW in control is a second or subsequent MIDAW whose address is on a 4K-byte boundary.

**Invalid CCW, Format 0:** A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 39.

**Invalid CCW, Format 1:** A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 15, or a CCW specifying transfer in channel does not contain zeros in bit positions 0-3 and 8-31.

**Invalid Suspend Flag:** A format-0 or format-1 CCW fetched during data chaining, other than a CCW specifying transfer in channel, does not contain a zero in bit position 38 or 14, respectively. A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 38 for a format-0 CCW or bit position 14 for a format-1 CCW, and suspend control was not specified by bit 4 of word 1 of the ORB.

**Invalid MIDAW Flag:** When either of the following conditions is detected, an invalid MIDAW flag condition is recognized by the channel subsystem.

1. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing; however, modified CCW indirect data addressing was not specified by bit 25 of word 1 of the ORB.
2. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 35 (format 0) or bit 11 (format 1) of the CCW is one, specifying skip.
3. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 37 (format 0) or bit 13 (format 1) of the CCW is one, specifying indirect data addressing.
4. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and the designated subchannel is not associated with channel paths that support modified CCW indirect data addressing.

**Invalid ORB Format:** One or more reserved bit positions in the operation-request block (ORB) is not zero. (See “Operation-Request Block” on page 24 for more information.) If the incorrect-length-indication-suppression facility is not installed, then bit 24 of word 1 of the command-mode ORB must also be zero.

**Invalid Sequence:** The channel subsystem has fetched two successive CCWs both of which specify transfer in channel, or, depending on the model, a sequence of 256 or more CCWs with command chaining specified was executed by the channel subsystem and did not result in the transfer of any data to or from an I/O device.

Detection of the program-check condition during the initiation of an operation at the device causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When the condition is detected after the
I/O operation has been initiated at the device, the device is signaled to conclude the operation the next time the device requests or offers a byte of data or status. In this situation, the subchannel is made status pending as a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

**Protection Check**

Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection mechanism. Protection applies to the fetching of CCWs, IDAWs, MIDAWs, and output data and to the storing of input data. The subchannel key provided in the ORB is used as the access key for storage accesses associated with an I/O operation.

Detection of the protection-check condition during the fetching of the first CCW, IDAW, or MIDAW causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device is signaled to conclude the operation after the available data logically prior to the protection check has been transferred. However, if an access violation occurs when the channel subsystem is in the process of fetching either a new IDAW, MIDAW, or a new CCW while data chaining, and if the device signals the channel-end condition before transferring any data designated by the new CCW, IDAW or MIDAW, then the status is accepted, and the subchannel becomes status pending with primary and alert status and with protection check indicated. Other indications may accompany the protection-check indication as a function of the operation specified by the CCW, the status received from the device, and the current state of the subchannel. The protection-check condition causes command chaining and command retry to be suppressed.

**Channel-Data Check**

Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. The condition may be indicated when detected, even if the data is not used when prefetched. Channel-data check is indicated when data or the associated key has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored in the SCSW, when used in conjunction with the storage-access code and the CCW address, designates a byte location within the block of main storage in which the channel-data-check condition was recognized.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary and alert status, or with primary, secondary, and alert status, as a function of the status received from the device. The count and address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to prefetched data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.

Uncorrectable storage or key errors detected on prefetched data while the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored.
Channel-Control Check

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition includes invalid CBC on a CCW, an IDAW, a MIDAW, or the respective associated key. The condition may be indicated when an invalid CBC is detected on a prefetched CCW, IDAW, MIDAW, or the respective associated key, even if that CCW, IDAW, or MIDAW is not used.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The count and data-address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-control-check condition pertains to an invalid CBC detected on a prefetched CCW, a prefetched IDAW, a prefetched MIDAW, or the key associated with the prefetched CCW, the prefetched IDAW, or the prefetched MIDAW, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while prefetching when the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that will be stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored.

Programming Note: If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the channel-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

Interface-Control Check

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device while the subchannel is subchannel-and-device
active or device active has an invalid checking-block code.

2. The status byte received from a device while the subchannel is idle, start pending, suspended, or halt pending has an invalid checking-block code.

3. A device responded with an address other than the address designated by the channel subsystem during initiation of an operation.

4. During command chaining, the device appeared not operational.

5. A signal from an I/O device either did not occur or occurred at an invalid time or had an invalid duration.

6. The channel subsystem recognized the I/O-error-alert condition (see “I/O-Error Alert (A)” on page 50).

7. ESW bit 26, indicating device-status check, is set to one.

Detection of an interface-control check during a CCW-type IPL I/O operation on a machine that retries IPL I/O operations on an alternate channel path causes the channel subsystem to terminate operations on the current channel path and to retry the IPL I/O operation on another logically-available channel path to the designated device, if one is available, without causing the subchannel to become status-pending. (See “CCW-type IPL” on page 17 for additional information.) In all other cases and when an interface-control check has been detected for a CCW-type IPL operation on all logically-available channel paths to the designated device, detection of the interface-control-check condition causes the current operation, if any, to be terminated immediately, and the subchannel is made status pending with alert status, primary and alert status, secondary and alert status, or primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes an interface-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

If, while initiating a signaling sequence with the channel subsystem for the purpose of presenting status or transferring data, the device presents an address with invalid parity, the error condition is not made available to the program since the identity of the device and associated subchannel are unknown.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored.

**Programming Note:** If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the interface-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

**Chaining Check**

Chaining check is caused by channel-subsystem overrun during data chaining on input operations. The condition occurs when the I/O-data rate is too high for the particular resolution of data addresses. Chaining check cannot occur on output operations.
Detection of the chaining-check condition causes the I/O device to be signaled to conclude the operation. It causes command chaining to be suppressed.

**Count Field**

Bit positions 16-31 of word 2 contain the residual count. The count is to be used in conjunction with the original count specified in the last CCW and, depending upon existing conditions (see Figure 16-7 on page 32), indicates the number of bytes transferred to or from the area designated by the CCW. The count field is meaningful whenever the subchannel is status pending with primary status that consists of either (1) device status only or (2) device status together with subchannel status of incorrect length only, PCI only, or both.

In Figure 16-7 on page 32, the contents of the count field are listed for all cases where the subchannel is start pending, subchannel-and-device active, device active, suspended, or status pending.

Figure 16-7. (Part 1 of 2) Contents of Count Field in SCSW
Explanation:

In situations where more than a single condition exists because of, for example, alert status that is described by program check and unit check, the entry appearing first in the table takes precedence.

The meaning of the notation used in this column is as follows:

A  Alert status
I  Intermediate status
P  Primary status
S  Secondary status
X  Status Pending

The allowed combinations of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

0  Corresponding condition is not indicated
1  Corresponding condition is indicated
U  Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
Y  The corresponding condition is not significant and is indicated as a function of the subchannel state.

Notes:

1. The count is unpredictable unless IDAW/MIDAW check is indicated, in which case the count may not correctly reflect the number of bytes transferred to or from main storage but will (when used in conjunction with the CCW address) designate a byte location within the page in which the channel-control-check condition was recognized.

2. During a storage access, the maximum number of bytes that can be stored by a channel subsystem is model dependent. If a channel-data-check condition is recognized during that access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored when used in conjunction with the storage-access code and the CCW address designates a byte location within the page in which the channel-data-check condition was recognized.

Figure 16-9. Transport-Mode SCSW  (Continued)
The following descriptions indicate when an SCSW field contains meaningful information for a transport-mode IRB.

**Subchannel Key**
This bit has the same meaning as in the command mode SCSW. (See “Subchannel Key” on page 9).

**Reserved**
SCSW bits 4, 13, 16, 20, 24, and 26 of word 0, bits 0 of word 1, and bits 1, 8, 15, and 16-22 of word 2 are reserved and stored as zeros.

**Extended-Status-Word Format (L)**
This bit has the same meaning as in the command-mode SCSW. (See “Extended-Status-Word Format (L)” on page 9).

**Deferred Condition Code (CC)**
This field has the same meaning as in the command-mode SCSW. (See “Deferred Condition Code (CC)” on page 9).

**Format (FMT)**
Bits 8-10 of word 0 are the IRB-format field that contains a 3-bit, unsigned integer whose value specifies the layout of the IRB, when the IRB-format control bit (X), is set to one.

<table>
<thead>
<tr>
<th>FMT</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Transport-Mode IRB</td>
</tr>
<tr>
<td>1-7</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**IRB-Format Control (X)**
Bit 11 of word 0 is the IRB-format control bit. The value of this bit is one for the transport-mode IRB. (See Figure 16-2 on page 7).

**Interrogate Complete (Q)**
Bit 12 of word 0 is the interrogate-complete bit (Q). When one, Q indicates that the interrogate operation has completed successfully, and the subchannel is made status-pending with intermediate interruption status. If the pending intermediate interruption condition has not been cleared by TEST SUBCHANNEL by the time the primary interruption condition for the original interrogated operation is presented at the subchannel, both conditions may be merged and indicated together in the SCSW.

**Subchannel-Control Field**
The subchannel-control information is contained in bit positions 13-31 of the first word of the SCSW.

**Extended Control (E)**
Bit 14 of word 0, when one, indicates that model-dependent information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both. The concurrent sense information has no meaning when a transport-mode IRB is stored.

**Path Not Operational (N)**
This bit has the same meaning as in the command-mode SCSW. See “Path Not Operational (N)” on page 13.

**Function Control (FC)**
The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Function Control (FC)” on page 13). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

**Start Function (Bit 17):** This bit has the same meaning as in the command-mode SCSW. (See “Start Function (Bit 17)” on page 7).

**Halt Function (Bit 18):** When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If the subchannel is start pending or device active when HALT SUBCHANNEL is executed, then the
The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not have been performed at the device. The activity-control bits are defined as follows:

**Start Pending (Bit 21):** This bit has the same meaning as in the command-mode SCSW with the exception that the subchannel remains start pending until a primary interruption condition is generated. (See “Start-Pending (Bit 21)” on page 15).

**Halt Pending (Bit 22):** This bit has the same meaning as in the command-mode SCSW. (See “Halt-Pending (Bit 22)” on page 16).

**Clear Pending (Bit 23):** This bit has the same meaning as in the command-mode SCSW. (See “Clear-Pending (Bit 23)” on page 16).

**Device Active (Bit 25):** When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active, only when primary status is presented without secondary.

The status-control field is contained in bit positions 27-31 of word 0 of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status or the Q bit. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see “Enabled (E)” on page 3) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 4); bits 27-30 are meaningful when bit 31 is one. The status-control bits are defined as follows:

**Alert Status (Bit 27):** This bit has the same meaning as in the command-mode SCSW with the exception that a command-mode IRB is stored when alert status is presented with secondary status. (See “Alert Status (Bit 27)” on page 17).

**Intermediate Status (Bit 28):** Intermediate status can be indicated when the interrogate operation associated with the TCW is completed, and the Q-bit (interrogate-complete) is one.

**Primary Status (Bit 29):** This bit has the same meaning as in the command-mode SCSW. (See “Primary Status (Bit 29)” on page 19).

**Secondary Status (Bit 30):** This bit has the same meaning as in the command-mode SCSW. (See “Secondary Status (Bit 30)” on page 19).

**Status Pending (Bit 31):** This bit has the same meaning as in the command-mode SCSW. (See “Status-Pending (Bit 31)” on page 19).

**TCW Address Field**

Bits1-31 of word 1 form an absolute address of a TCW. The TCW address indicated is the address of the current TCW when the subchannel becomes pending with primary interruption. When the subchannel-status field indicates channel-control check, channel-data check, program check or interface-control check, the TCW-address field is usable for recov-
ery purposes if the TCW-address field-validity flag in
the ESW is one.

Status pending (1Y1Y1/AIPSX); termination occurred because of protection check detected as follows:

- On a TCW access: Address of protected TCW
- On data or an TIDAW access: Address of current TCW

Status pending (1Y1Y1/AIPSX); termination occurred because of chaining check: N/A

Status pending (YY1Y1/AIPSX); termination occurred under count control: Address of current TCW

Status pending (1Y1Y1/AIPSX); operation prematurely terminated by the device because of alert status: Address of current TCW

Status pending (YYYY1/AIPSX) after termination by HALT SUBCHANNEL and the activity-control-field bits indicated below set to ones:

- Status pending alone: Unpredictable
- Start pending: Unpredictable
- Device active and start pending: Unpredictable
- Device active: Unpredictable

Status pending (00001/AIPSX) after termination by CLEAR SUBCHANNEL: Unpredictable

Status pending (YYYY1/AIPSX); operation completed normally at the subchannel: Address of current TCW

Status pending (00011/AIPSX): Unpredictable

Status pending (10001/AIPSX): Unpredictable

Status pending (00001/AIPSX): Unpredictable

Status pending (1Y111/AIPSX); command chaining suppressed because of alert status other than channel-control check or interface-control check: N/A

Status pending (1YYY1/AIPSX) because of alert status for channel-control check or interface-control check: See note 3

Status pending (1Y1Y1/AIPSX) because of channel-data check: Address of current TCW

Status pending (1Y1Y1/AIPSX) because of channel-subsystem retry failed: Address of current TCW

**Explanation:**

1 The meaning of the notation used in this column is as follows:
   - A Alert status
   - I Intermediate status
   - P Primary status
   - S Secondary status
   - X Status Pending

---

*Figure 16-10. (Part 2 of 3) TCW Address as Function of Subchannel State (Continued)*
Device-Status Field

The device-status field is contained in bit positions 0-7 of word 2 of the SCSW. Each bit of the device-status field has the same meaning as in the command-mode SCSW. See “Device-Status Field” on page 24 for details.

Subchannel-Status Field

The subchannel-status field is contained in bit positions 8-15 of word 2 of the SCSW. Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt or start function. The subchannel-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful. The following subchannel-status conditions are described:

Incorrect Length
Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device.

When the FCX-incorrect-length-indication facility is not installed and an incorrect-length condition is detected, the processing of the transport-mode channel program is terminated with program-check status.

When the FCX-incorrect-length-indication facility is installed, the device supports incorrect-length indication, incorrect-length-indication is not being suppressed, and an incorrect-length condition is detected, incorrect length is indicated for one of the following reasons:

Long Block on Input: During a read or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the TSB header (TSH) is zero.

Long Block on Output: During a write operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the TSH is zero.
Short Block on Input: The number of bytes transferred during a read or sense operation is insufficient to fill the main-storage areas assigned to the operation. The count in the TSH is not zero.

Short Block on Output: The device terminated a write before all of the information contained in the assigned main-storage areas was transferred to the device. The count in the TSH is not zero.

The incorrect-length indication is suppressed when the current DCW has the SLI flag set to one. The incorrect-length indication is not meaningful when the count field of the TSH is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the DCW is one.

Program Check
Program check occurs when programming errors are detected by the channel subsystem. For a transport-mode operation, programming errors may also be detected by the I/O device and are reported as program checks. When a program check condition is recognized, additional information may be available in the “Subchannel-Extended-Status Qualifier (SESQ)” section of the subchannel-extended-status field when a program check is indicated.

Whenever the program-check condition pertains to the fetching of data, the failing-storage-address validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the program-check condition is generated is stored in the ESW failing-storage-address field.

A program check condition can be due to any of the following reasons:

Invalid TCW Specification: When any of the following conditions is detected, an invalid TCW specification is recognized:

1. A reserved field that is checked for zeros in the TCW does not contain zeros.
2. A nonzero value is specified in the TCW format field.
3. The read and write bits in the TCW are both one, bit 10 of the TCW flags field is zero, and either or both of the following are true.
4. The TCCB-length field in a TCW specifies a length that is less than 12 or greater than 244.

Invalid TCW-Address Specification: An invalid TCW address specification can occur because the TCW address is not designated on a 64-byte boundary.

Invalid TCW Address: The channel-subsystem has attempted to fetch a TCW from a main-storage location that is not available. An invalid TCW address can occur because the program has designated an invalid address in the TCW address field of the transport-mode ORB, when the B-bit (channel-program-type control), is one. A main-storage location is unavailable when the absolute TCW address does not correspond to a physical location.

Invalid TCW Counts: When any of the following conditions is detected by the channel subsystem, an invalid TCW byte count is recognized:

1. The write-bit is one in the TCW and the value in the TCW output-count field is zero.
2. The read-bit is one in the TCW and the value in the TCW input-count field is zero.

Invalid TSB-Address Specification: An invalid transport-status-block address specification can occur if the content of the transport-status-block-address field specified in the TCW does not designate a storage location on a doubleword boundary.

Invalid TSB Address: The channel-subsystem has attempted to store a TSB to a main-storage location that is not available. An invalid transport-status-block address can occur because the program has designated an unavailable location in a TCW, or the channel-subsystem has attempted to store the transport status to a main-storage location that is not available. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.

Invalid TCCB Address: The channel-subsystem has attempted to fetch a TCCB from a main-storage location that is not available. An invalid transport-command-control-block address can occur because
the program has designated an unavailable location in a TCW, or has specified a transport-command-control-block address and a length which caused a list of TIDAW to cross a 4K-byte when the transport-command-control-block-TIDA flag in the TCW is one. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location. **Invalid TIDAW-Address Specification:** Transport-indirect data addressing is specified, and any of the following conditions is detected:

1. A write operation is requested, the output-TIDA flag in a TCW is one, and the contents of the output-data-address field in the TCW do not designate a storage location on a quadword boundary.

2. A read operation is requested, the input-TIDA flag in a TCW is one, and the contents of the input-data-address field in the TCW do not designate a storage location on a quadword boundary.

3. The transport-command-control-block-TIDA flag in the TCW is one, and the contents of the transport-command-control-block-address do not designate a storage location on a quadword boundary.

**Invalid Data Address:** An invalid data address can occur because the program has designated an unavailable location specified by a TCW or a TIDAW. When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem:

1. The channel-subsystem has attempted to access a main-storage location that is not available. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.

2. The channel subsystem, on sequentially accessing storage for a data fetch or data store, attempted to access an unavailable location.

3. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.

**Invalid TIDAW Specification:** When the use of TIDAW is specified, an invalid TIDAW specification is recognized when any of the following conditions is detected by the channel subsystem:

1. Any of the bits defined as reserved in the TIDAW are not zero.

2. The TIDAW-transfer-in-channel flag (TTIC) in a TIDAW is one, and one or more other flag bits are also one.

3. The TTIC points to a TIDAW in which the TTIC flag is one.

4. The TIDAW count field contains zeros when the TTIC flag is zero.

5. The combination of a TIDAW data-address and count fields specify data that crosses a 4K-byte block boundary, when skipping is not in effect.

6. The count value specified in the TIDAW in which the last-TIDAW flag is one and the value for either input-count or output-count specified in a TCW did not both decrement to zero for the same byte of data transferred.

7. For a read operation only, the TIDAW in control has its data-transfer-interruption control flag set to one when data transfer was attempted by the device.

8. The TIDAW is in the TIDAW list designated by the TCCB-address field in the TCW and the count field of the TIDAW contains either a value that is zero or a value that is not evenly divisible by four.

**Invalid TIDAW Address:** The channel-subsystem has attempted to fetch a TIDAW from a main-storage location that is not available. An invalid TIDAW address can occur because the program has designated an invalid address in a TCW that specifies TIDAW addressing, or because the channel subsystem, on sequentially fetching TIDAWs, attempts to fetch from an unavailable location. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location. **Storage-Requests Limit Exceeded:** The use of TIDAWs is specified, and the model-dependent maximum number of storage requests required to satisfy the transfer of a block of data has been reached.

**Max Data-Count Exceeded:** The model-dependent maximum count of data for a single transport-control area (TCA) has been reached or exceeded for the current operation.
**Device-Detected Program Check:** Device-detected program checks are errors detected during a transport-mode operation by the I/O device and the channel-subsystem is requested to present a program-check condition. When a device-detected-program-check condition is recognized, additional information is available in the subchannel-extended-status field, and the TSB is stored with a transport-status-area format of two. (See device-detected-program check in chapter 15.)

**Protection Check**
Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection mechanism. A protection check condition is indicated as a result of a storage operation that detects any of the following errors:

1. Protection applies to the fetching of TCW.
2. Protection applies to the fetching of TCCB.
3. Protection applies to the fetching of TIDAWs.
4. Protection applies to the fetching of output data.
5. Protection applies to the storing of input data.

The subchannel key provided in the transport-mode ORB is used as the access key for storage accesses associated with an I/O operation except for the TSB store.

Detection of the protection-check condition during the fetching of a TCW, TCCB, or a TIDAW would cause the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device may be signaled to conclude the operation. Other indications may accompany the protection-check indication as a function of the operation specified by the TCW, the status received from the device, on a read operation, and the current state of the subchannel. The protection-check condition may or may not cause the execution of subsequent DCWs in a TCCB to be suppressed.

Whenever the protection-check condition pertains to the fetching of data, the failing-storage-address validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the protection-check condition is generated is stored in the ESW failing-storage-address field.

Additional information may be available in the “Subchannel-Extended-Status Qualifier (ESQ)” section of the subchannel-extended-status field when a protection check condition check is indicated.

**Channel-Data Check**
Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. Channel-data check is indicated when data has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. When a channel-data-check condition is recognized during a storage access, the channel subsystem stores the address where the storage exception is encountered.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary, secondary and alert status, as a function of the status received from the device. The TCW address field of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to the fetching of data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.
Uncorrectable storage or key errors detected during data access causes the operation to be terminated. In this case the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may be available in the “Subchannel-Extended-Status Qualifier (SESQ)” section of the subchannel-extended-status field.

**Channel-Control Check**

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition may be indicated when an invalid CBC is detected on a TCW, TIDAW, TCCB, TSB, or the respective associated key.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition may or may not be recognized by the channel subsystem.

Whenever the channel-control-check condition pertains to an invalid CBC detected on fetching a TCW or a TCCB, or a TIDAW or storing a TSB, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while fetching when the subchannel is start pending cause the operation to be terminated. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that is stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may be available in the “Subchannel-Extended-Status Qualifier (SESQ)” section of the subchannel-extended-status field.

**Interface-Control Check**

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device has an invalid checking-block code.
2. A signal from an I/O device either did not occur or occurred at an invalid time.
3. ESW bit 26, indicating device-status check, is set to one.
4. A failed interrogate function or a recovery operation.
5. The TCW residual count did not match the residual count in the response from the device.

When the channel subsystem recognizes an interface-control-check condition, any previously existing
intermediate interruption condition may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and sub-channel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel is made status pending with at least alert and primary status.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may also be available in the “Subchannel-Extended-Status Qualifier (SESQ)” section of the subchannel-extended-status field.

Channel-Subsystem Retry Failed
Channel-subsystem retry failed indicates that internal channel-subsystem conditions exist that prevent the fetching of the TCCB, a TIDAW, or data. The channel subsystem retried the fetch and the retry failed.

FCX-Status Field
The FCX-status field is contained in bit positions 16-23 of word 2 of the SCSW. This field contains channel specific status information returned by the I/O device.

**TSB Valid (Bit 23)**: Bit 23, when set to one, indicates that additional status information for the I/O operation designated by the subchannel is available in the transport-status block. When zero, the contents of the transport-status block do not contain any additional status information for the completed I/O operation.

**Subchannel-Extended-Status Field**

The subchannel-extended-status field is contained in bit positions 24-31 of word 2 of the SCSW. This field may contain information used to further qualify the reason for any of the following conditions, when indicated in the subchannel-status: interface-control check, channel-control check, channel-data check, program check, and protection check. If none of these bits are active in the subchannel-status byte, the fields of the subchannel-extended-status contain no meaningful information. When more than one condition is indicated, the interface-control check takes priority over the other conditions.

**Interrogate Failed (F)**: Bit 24 is the interrogate-failed operation bit. When set to one, the F bit indicates that an interrogate operation failed because of a program check, channel-control check, or interface-control check.

**Subchannel-Extended-Status Qualifier (SESQ)**: Bits 25-31 are the subchannel-extended-status qualifier and contain an unsigned integer value. When the subchannel-status field indicates program check, interface-control check, protection check, data check, or channel-control check, bits 25-31 may contain additional information as follows:

**Explanation:**

- **X**: Applicable
- **-**: Not applicable

**IFCC**: Interface-control check

**CCC**: Channel-control check

**CDC**: Channel-data check

**PGC**: Program check

**PTC**: Protection check

**Footnotes:**

- **a**: The failing-storage-address (FSA) field in the ESW is valid and contains the address of the TIDAW which was determined to be invalid.
- **b**: The FSA field is valid and contains the address of the current TCW.
- **c**: The FSA field is valid and contains the address of the TSB designated by the current TCW.
- **d**: The FSA field is valid and contains the address of the TCCB designated (directly or indirectly) by the TCW.
- **e**: The FSA field is valid and contains the address of the TIDAW for which the exception was detected.
- **f**: The FSA field is valid and contains the address of the input or output data designated (directly or indirectly) by the TCW.

**Note:** If the FSA field is valid for any SESQ value other than those identified by footnotes a-f, the FSA field contains the address of the current TCW.

*Figure 16-11. Subchannel-Extended Status Qualifiers (Continued)*
The extended-status word (ESW) provides additional information to the program about the subchannel and its associated device. The ESW is placed in words 3-7 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed and the subchannel designated is operational. If the subchannel is status pending or status pending with any combination of primary, secondary, intermediate, or alert status (except as noted in the next paragraph) when TEST SUBCHANNEL is executed, the ESW may have any of the following types of extended-status format:

**Format 0** Subchannel logout in word 0, an ERW in word 1, a failing-storage address or zeros in words 2 and 3, and a secondary-CCW address or zeros in word 4.

**Format 1** Zeros in bytes 0, 2, and 3 of word 0, the LPUM in byte 1 of word 0, an ERW in word 1, and zeros in words 2-4.

**Format 2** Zeros in byte 0, the LPUM in byte 1, and the device-connect time in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

**Format 3** Zeros in byte 0, the LPUM in byte 1, and unpredictable values in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

Words 0-4 of the ESW contain unpredictable values if any of the following conditions is met:

1. The subchannel is not status pending.
2. The subchannel is status pending alone, and the extended-status-word-format bit is zero.
3. The subchannel is status pending with intermediate status alone for other than the intermediate interruption condition due to suspension.

The type of extended-status format stored depends upon conditions existing at the subchannel at the time TEST SUBCHANNEL is executed. The conditions under which each of the types of formats is stored are described in the remainder of this section.

**Extended-Status Format 0**

The ESW stored by TEST SUBCHANNEL is a format-0 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is one and the subchannel is status pending with any combination of status as defined in Figure 16-12 on page 51. In this case, subchannel-logout information and an ERW are stored in the extended-status word. Subchannel logout provides detailed model-independent information relating to a subchannel and describing equipment errors detected by the channel subsystem. The information is provided to aid the recovery of an I/O operation, a device, or both. Whenever subchannel logout is provided, the error conditions relate only to the subchannel reporting the error. If I/O operations involving other subchannels have been affected by the error condition, those subchannels also provide similar subchannel-logout information. An extended-report word provides additional information relating to the cause of the malfunction.

A format-0 ESW has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Subchannel Logout</td>
</tr>
<tr>
<td>1</td>
<td>Extended-Report Word</td>
</tr>
<tr>
<td>2</td>
<td>Failing-Storage Address or ESLD</td>
</tr>
<tr>
<td>3</td>
<td>Secondary-CCW Address or Zeros</td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

**Subchannel Logout**

The subchannel logout has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ESF</td>
</tr>
<tr>
<td>1</td>
<td>LPUM</td>
</tr>

</tr>
<tr>
<td>6</td>
<td>DE</td>
</tr>
<tr>
<td>7</td>
<td>EA</td>
</tr>
<tr>
<td>8</td>
<td>SC</td>
</tr>
</tbody>
</table>

**Extended-Status Flags (ESF):** Any of bits 1-7, when one, specifies that an error-check condition has been detected by the channel subsystem. The following indications are provided in the ESF field:

**Key Check.** Bit 1, when one, indicates that the channel subsystem, when accessing data, when attempting to update the measurement block, or when attempting to fetch either a CCW, an IDAW, MIDAW, TCW, TCCB, TIDAW, or when accessing a TSB, has detected an invalid checking-block code (CBC) on the associated storage key. The channel-data-check bit, bit 12 of word 2 of the
SCSW, the measurement-block data-check bit, bit 3 of word 0 of the ESW, the CCW-check bit, bit 5 of word 0 of the ESW, or the IDAW/MIDAW-check bit, bit 6 of word 0 of the ESW, identifies the source of the key error.

**Note:** This condition may be indicated to the program when an invalid checking-block code on a key is detected but the data, CCW, IDAW, TIDAW, or MIDAW then is not used after being prefetched. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location within the storage block having the key is stored in words 2 and 3 of the ESW.

**Measurement-Block Program Check.** Bit 2, when one, indicates that the channel subsystem, in attempting to update the measurement block, has either detected an invalid absolute address when combining the measurement-block origin with the measurement-block index for this subchannel or has detected an invalid measurement-block address at the subchannel.

**Measurement-Block Data Check.** Bit 3, when one, indicates that a malfunction has been detected involving the data of the measurement block in main storage. (See “Measurement Block” on page 3.) Measurement-block data check is indicated when the measurement block is updated and an invalid checking-block code (CBC) is detected on the storage used to contain the measurement data or on the associated key. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

**Measurement-Block Protection Check.** Bit 4, when one, indicates that the channel subsystem, when attempting to update the measurement block, has been prohibited from accessing the measurement block because the storage key does not match the measurement-block key (see “Measurement Block” on page 3.) The key provided by SET CHANNEL MONITOR is used for the access of storage associated with measurement-block-update operations (see “SET CHANNEL MONITOR” on page 13.).

**Note:** Whenever any of the measurement-check conditions is indicated by bits 2-4, the channel subsystem sets the subchannel measurement-block-update-enable bit to zero, disabling the storing of measurement data for the subchannel (see “Measurement-Mode Enable (MM)” on page 3).

**CCW Check.** When a command-mode IRB is stored, bit 5, when one, indicates that an invalid CBC on the contents of the CCW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is stored as one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

When a transport-mode IRB is stored, bit 5 is reserved and set to zero.

**Note:** This condition may be indicated to the program when an invalid checking-block code on a prefetched CCW is detected but the CCW is not used. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW.

**IDAW/MIDAW Check.** When a command-mode IRB is stored, bit 6, when one, indicates that an invalid CBC on the contents of an IDAW or MIDAW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated with the device, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also one.

When a transport-mode IRB is stored, bit 6 is reserved and set to zero.

**Note:** This condition may be indicated to the program when an invalid checking-block code on the contents of a prefetched IDAW or MIDAW is detected but the IDAW or MIDAW is not used. In this case, the failing-storage-address-validity bit,
bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW. Detection of a channel-data-check condition does not cause the CCW-check and IDAW/MIDAW-check bits to be stored as ones.

Reserved. Bit 7 is stored as zero.

Last-Path-Used Mask (LPUM): Bits 8-15 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. When a command-mode IRB is stored, the bit corresponding to the channel path in use is set whenever any of the following occurs:

1. The first command of a start-subchannel function is accepted by the device (see “Activity Control (AC)” on page 14).
2. The device and channel subsystem are actively communicating when the channel subsystem performs the suspend function for the channel program in execution.
3. The channel subsystem accepts status from the device that is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 2).
4. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 29), and no subchannel-logoff information is currently present at the subchannel.

When a transport-mode IRB is stored, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The path has been selected for transporting the TCCB for the operation.
2. The channel subsystem accepts status from the device that is recognized as an interruption condition. If the accepted status is an interrogate response, the LPUM may be different than that stored with primary or secondary status, or both.
3. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 29), and no subchannel-logoff information is currently present at the subchannel.

The LPUM field contains the most recent setting and is valid whenever the ESW contains information in one of the formats 0-3 (see “Extended-Status Word” on page 47) and the SCSW is stored. When subchannel-logoff information is present in the ESW, a zero LPUM-field-validity flag indicates that the LPUM setting is not consistent with the other subchannel-logoff indications.

Ancillary Report (R): Bit 16, when one, indicates that a malfunction of a system component has occurred that has been recognized previously or that has affected the activities of multiple subchannels. When the malfunction affects the activities of multiple subchannels, an ancillary-report condition is recognized for all of the affected subchannels except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful only when a channel-control check, channel-data check, or an interface-control check is indicated in bit positions 12-14 of word 2 of the SCSW.

Depending on the model, recognition of an ancillary-report condition may not be provided or it may not be provided for all system malfunctions that affect subchannel activity. When ancillary-report recognition is not provided, bit 16 is set to zero.

Field-Validity Flags (FVF): Bits 17-21 indicate the validity of the information stored in the corresponding fields of either the SCSW or the extended-status word. When the validity bit is one, the corresponding field has been stored and is usable for recovery purposes. When the validity bit is zero, the corresponding field is not usable.

This bit-significant field has meaning when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. When these checks are not indicated, this field, as well as the termination-code and sequence-code fields, has no meaning. Furthermore, when these checks are not indicated, the last-path-used-mask, device-status, and the TCW address or the CCW-address fields are all valid. The fields are defined as follows:

17 Last-path-used mask
18 Termination code
19 Sequence code
20 Device status
CCW address or TCW address

Storage-Access Code (SA): Bits 22-23 indicate the type of storage access that was being performed by the channel subsystem at the time of error. The SA field pertains only to the access of storage for the purpose of fetching or storing data during the performance of an I/O operation. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the subchannel status. The access-code assignments are as follows:

00 Access type unknown
01 Read
10 Write
11 Read backward for a command-mode operation.

Termination Code (TC): Bits 24 and 25 indicate the type of termination that has occurred. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. The types of termination are as follows:

00 Halt signal issued
01 Stop, stack, or normal termination
10 Clear signal issued
11 Reserved

When at least one channel check is indicated in the SCSW but the termination-code-field-validity flag is zero, it is unpredictable which, if any, termination has been signaled to the device. If more than one channel-check condition is indicated in the SCSW, the device may have been signaled one or more termination codes that are the same or different. In this situation, if the termination-code-field-validity flag is one, the termination code indicates the most severe of the terminations signaled to the device. The termination codes, in order of increasing severity, are: stop, stack, or normal termination (01); halt signal issued (00); and clear signal issued (10)

Device-Status Check (D): When the status-verification facility is installed, bit 26, when one, indicates that the subchannel logout in the ESW resulted from the channel subsystem detecting device status that had valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. When the device-status-check bit is one, the interface-control-check status bit is set to one. If, additionally, bit 20 of the subchannel-logout field has been stored as one, then the status byte in error has been stored in the device-status field of the SCSW. If the status-verification facility is not installed, bit 26 is stored as zero.

Secondary Error (E): Bit 27, when one, indicates that a malfunction of a system component that may or may not have been directly related to any activity involving subchannels or I/O devices has occurred. Subsequent to this occurrence, the activity related to this subchannel and the associated I/O device was affected and caused the subchannel to be set status pending with either channel-control check or interface-control check.

I/O-Error Alert (A): Bit 28, when one, indicates that subchannel logout in the ESW resulted from the signaling of I/O-error alert. The I/O-error-alert signal indicates that the control unit or device has detected a malfunction that must be reported to the channel subsystem. The channel subsystem, in response, issues a clear signal and, except as described in the next paragraph, causes interface-control check to be set and extended-status-format-0 (logout) information to be stored in the ESW.

When I/O-error alert is signaled and the subchannel has previously been set disabled or no subchannel is associated with the device, the clear signal is issued to the device, and the I/O-error-alert indication is ignored by the channel subsystem.

Sequence Code (SC): When a command-mode IRB is stored, bits 29-31 identify the I/O sequence in progress at the time of error. The sequence code pertains only to I/O operations initiated by the execution of START SUBCHANNEL or RESUME SUBCHANNEL. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW.

When a transport-mode IRB is stored, and the validity bit corresponding to the sequence-code field is one, bits 29-31 are stored as zeros.

The sequence-code assignments are:

000 Reserved
001 A nonzero command byte has been sent by the channel subsystem, but a response has not yet been analyzed by the channel subsystem. This code is set during the initiation sequence.
Figure 16-12 defines the relationship between indications provided as subchannel-logout data and the appropriate SCSW bits.

Extended-Report Word

The extended-report word (ERW) provides information to the program describing specific conditions that may exist at the device, subchannel, or channel subsystem. The ERW is stored whenever the extended-status word is stored. When the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the extended-control bit, bit 14 of word 0 of the SCSW, are both zeros, the ERW contains all zeros. When the extended-status-word-format bit or the extended-control bit or both are ones, the ERW has the following format:

Extended-Report Word

<table>
<thead>
<tr>
<th>Subchannel-Logout Condition Indicated</th>
<th>CDC</th>
<th>CCC</th>
<th>IFCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key check</td>
<td>Y</td>
<td>Y</td>

</tr>
</tbody>
</table>

Explanation:

1. No relationship.

2. When more than one SCSW indication is signaled, the subchannel-logout conditions that are valid are the logical OR for each of the respective SCSW indications.

3. Only one measurement-block check may be indicated in a specific subchannel logout.

4. This field has a field-validity flag.

5. This field has a field-validity flag.

CCC Channel-control check.

CDC Channel-data check.

IFCC Interface-control check.

V Bit setting valid.

Reserved.

Reserved.

Reserved.
**Request Logging Only (L):** Bit 1, when one, requests that the program only record information about the condition that caused the extended-status word to be stored.

**Extended-Subchannel-Logout Pending (E):** Bit 2, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that an extended-subchannel logout is pending and that words 2-3 of the ESW contain the extended-subchannel-logout descriptor.

Bit 2 is set to zero when bit 6 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

**Authorization Check (A):** Bit 3, when one, indicates that the start or resume function was terminated because the channel subsystem has been placed in the isolated state in which pending I/O operations are not initiated and I/O operations currently being performed either are in the process of being terminated or have been terminated.

**Path Verification Required (P):** Bit 4, when one, indicates that the program must verify the identity of the device. The LPUM, when valid, indicates the channel path for which device verification is to be performed. When a valid LPUM is not available, the identity of the device must be verified for each available channel path.

**Channel-Path Timeout (T):** Bit 5, when one, indicates that, during a signaling sequence, an appropriate signal from the device did not occur within a predetermined time interval. Bit 5 is meaningful when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the interface-control-check bit, bit 14 of word 0 of the SCSW, are both ones.

**Failing-Storage-Address Validity (F):** Bit 6, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an invalid CBC on a CCW, a data location, an IDAW, a MIDAW, a TCW, TCCB, a TIDAW, a TSB or on the respective associated key and has stored, in words 2 and 3 of the ESW, the absolute address of a location associated with the invalid CBC.

Bit 6 is set to zero when bit 2 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

**Concurrent Sense (S):** When a command-mode IRB is stored, bit 7, when one, indicates that the concurrent-sense facility has placed sense information accepted from the device in the extended-control word and has stored a value, in bit positions 10-15 of the ERW, that specifies the number of sense bytes that have been stored in the extended-control word. When bit 7 is one, bit 14 of word 0 of the SCSW is also one.

When a transport-mode IRB is stored, bit 7 is reserved and set to zero.

**Concurrent-Sense Count (SCNT):** When bit 7 is one, bit positions 10-15 contain a value, in the range 1-32, that specifies the number of sense bytes stored into the extended-control word by the concurrent-sense facility. When bit 7 is zero, bit positions 10-15 contain zeros.

**Secondary-CCW-Address Validity (C):** When a command-mode IRB is stored, bit 8, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an error condition that precludes the continued performance of an I/O operation. When prefetching applies (bit 9 of word 1 of the ORB is one) and certain error conditions identified by channel-control check, channel-data check, or interface-control check are recognized by the channel subsystem, situations may exist where the termination point of execution of the channel program differs between the channel subsystem and the I/O device. To properly identify the termination points, bit 8 is set to one, and a second CCW address (secondary-CCW address) is provided in the ESW and designates the last CCW executed at the device. When the validity bit is zero for the previously mentioned errors, the channel subsystem was unable to determine the termination point of the control-unit execution, and the secondary-CCW-address field contains zeros.

Bit 8 is not set to one unless the program has permitted prefetching by setting the prefetch-control bit, bit 9 of word 1 of the ORB, to one for the channel program in execution.

When a transport-mode IRB is stored, bit 8 is reserved and set to zero.
Failing-Storage-Address Format (R): Bit 9 indicates the format of the failing-storage address when the failing-storage-address validity bit, bit 6 of the ERW, is one. When bit 6 is zero, bit 9 is not meaningful and is stored as zero. When bit 6 is one and bit 9 is zero, a format-1 failing-storage address is stored in words 2 and 3 of the ESW. When bit 6 is one and bit 9 is one, a format-2 failing-storage address is stored in words 2 and 3. See “Failing-Storage Address” below for a description of format-1 and format-2 addresses.

Failing-Storage Address
Words 2 and 3 of the extended-status contain a 24-, 31-, or 64-bit absolute address. When the failing-storage-address-validity flag, bit 6 of the ERW, is one, words 2 and 3 contain either a format-1 failing-storage address or a format-2 failing-storage address. When bit 6 is one, the failing-storage-address field designates a byte location within the invalid checking block associated with an invalid CBC for a CCW, data location, IDAW, MIDAW, TCW, TCCB, TIDAW, TSB, or their respective associated key.

When a transport-mode IRB is stored, and the failing-storage-address validity flag, bit 6 of the ERW, is one, the failing-storage address contains the absolute address associated with the reported failing condition.

When an error condition is detected and a command-mode IRB is stored, the form of the address stored in words 2 and 3 depends on the format-2-IDAW control, bit 14 of word 1 of the ORB, and on the MIDA control, bit 25 of word 1 of the ORB, as follows:

1. When the format-2-IDAW control is zero, specifying that fullword IDAWs containing 31-bit addresses are used, and the modified-CCW-indirect-data-addressing-control is zero, a format-1 address is stored, and the failing-storage-address-format bit, bit 9 of the ERW, is stored as zero.

2. When either the format-2-IDAW control is one, specifying that doubleword IDAWs containing 64-bit addresses are used, or the modified-CCW-indirect-data-addressing-control is one, or both are one, a format-2 address is stored, and the failing-storage-address-format bit is stored as one.

When an error condition is detected and a transport-mode IRB is stored, a format-2 failing-storage address is stored. A format-2 failing-storage address is stored for a transport-mode IRB when a program-check, protection check, channel-data check or channel-control check condition is indicated by the subchannel status.

When a format-1 address is stored, bits 1-31 of word 2 form the address associated with the reported error condition, and bit 0 of word 2 and all of word 3 are stored as zeros. When a format-2 address is stored, bits 0-31 of word 2 followed by bits 0-31 of word 3 form the 64-bit address associated with the reported error condition.

Extended-Subchannel-Logout Descriptor (ESLD)
When the extended-status-word-format (L) bit, bit 5 of SCSW word 0, is one and the extended-subchannel-logout pending (E) flag, bit 2 of the ERW, is one, an extended-subchannel-logout descriptor is provided in words 2-3 of the ESW. The ESLD identifies the logout and the channel path for which the extended-subchannel logout is pending.

Secondary-CCW Address
When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check and the secondary-CCW-address-validity flag, bit 8 of word 1, is one, bits 1-31 of word 4 form an absolute address of the last CCW executed by the I/O device at the point the reported check condition caused channel-program termination. When provided, the secondary-CCW address may be used for recovery purposes. When the secondary-CCW-address-validity flag is zero, this field contains zeros.

When a transport-mode IRB is stored and the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, word 4 is reserved and contains zeros.

Extended-Status Format 1
The ESW stored by TEST SUBCHANNEL is a format-1 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.
2. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:
   a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,
   b. The primary-status bit and other status-control bits, or
   c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

3. At least one of the following conditions is indicated:
   a. The device-connect-time-measurement mode is inactive.
   b. The channel-subsystem-timing facility is not available for the subchannel.
   c. The subchannel is not enabled for the device-connect-time-measurement mode.

Zeros are stored in bytes 0, 2, and 3 of word 0, and the LPUM is stored in byte 1 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

The device-connect-time-measurement mode is made inactive when SET CHANNEL MONITOR is executed and bit 31 of general register 1 is zero.

A format-1 ESW has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Zeros</th>
<th>LPUM</th>
<th>Zeros</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Last-Path-Used Mask (LPUM):** For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 49.

**Extended-Report Word (ERW):** For a definition of the ERW, see “Extended-Report Word” on page 51.

### Extended-Status Format 2

The ESW stored by TEST SUBCHANNEL is a format-2 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.
2. The channel-subsystem-timing facility is available for the subchannel.
3. The subchannel is enabled for the device-connect-time-measurement mode.
4. The device-connect-time-measurement mode is active.
5. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:
   a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,
   b. The primary-status bit and other status-control bits, or
   c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

Zeros are stored in byte 0 of word 0, the LPUM is stored in byte 1 of word 0, and the device-connect time is stored in bytes 2 and 3 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

### A format-2 ESW has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Zeros</th>
<th>LPUM</th>
<th>DCTI</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Last-Path-Used Mask (LPUM):** For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 49.

**Device-Connect-Time Interval (DCTI):** Bit positions 16-31 contain the binary count of time increments accumulated by the channel subsystem during
the time that the channel subsystem and the device were actively communicating and the subchannel was subchannel active for a command-mode operation, or start pending for a transport-mode operation. The time increment of the DCTI is 128 microseconds.

If the above conditions for the storing of the DCTI value in the ESW are met but the device-connect-time-measurement mode was made active by SET CHANNEL MONITOR subsequent to the execution of START SUBCHANNEL for this subchannel, the DCTI value stored is greater than or equal to zero and less than or equal to the correct DCTI value.

**Note:** The DCTI value stored in the ESW is the same as that used to update the corresponding measurement-block data for the subchannel if the measurement-block-update mode is in use for the subchannel. If the measurement-block-update mode for the channel subsystem is active and the subchannel is enabled for the device-connect-time-measurement mode but no DCTI value is stored in the ESW (because of the presence of subchannel-logout information), or if the DCTI is zero, then nothing is added to the corresponding measurement-block data.

**Extended-Report Word (ERW):** For a definition of the ERW, see “Extended-Report Word” on page 51.

---

**Extended-Status Format 3**

The ESW stored by TEST SUBCHANNEL is a format-3 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero and the subchannel is status pending with (1) secondary status, alert status, or both when primary status is not also present, or (2) intermediate status when the subchannel is not suspended. Zeros are stored in byte 0 of word 0, and the LPUM is stored in byte 1 of word 0. Bytes 2 and 3 of word 0 contain unpredictable values; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-3 ESW has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Zeros</th>
<th>LPUM</th>
<th>X00000000000000X</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Last-Path-Used Mask (LPUM):** For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 49.

An “X” in the format indicates the bit may be zero or one.

**Extended-Report Word (ERW):** For a definition of the ERW, see “Extended-Report Word” on page 51.

Figure 16-13 on page 55 summarizes the conditions at the subchannel under which each type of information is stored in the ESW.

---

**Subchannel Conditions When IRB is stored**

<table>
<thead>
<tr>
<th>Subchannel-Status Word</th>
<th>Path-Management-Control Word</th>
<th>Extended-Status Word (ESW), Word 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status-Control Field</td>
<td>Device-Connect-Time-Mgmt Mode</td>
<td>Device-Connect-Time-Mgmt-Mode-Enable Bit</td>
</tr>
<tr>

</tr>
<tr>
<td>****</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

**Explanation:**

- Defined to be not meaningful when X is zero.
- Bits may be zeros or ones.
- Information not relevant in this situation.
- Alert status.
- Accumulated device-connect-time-interval (DCTI) value stored in bytes 2 and 3.
- Intermediate status.
- Extended-status-word format.
- Last-path-used mask (LPUM) stored in byte 1.
- Primary status.
- Subchannel-logout information stored in word 0.
- Secondary status.
- No format defined.
- Status pending.
- Zeros are stored as zeros.

**Figure 16-13. Information Stored in ESW**
Extended-Control Word

The extended-control word, which is words 8-15 of an interruption-response block (see “Interruption-Response Block” on page 6), provides additional information to the program describing conditions that may exist at the channel subsystem, subchannel, or device. The extended-control (E) bit, bit 14 of word 0 of the SCSW, when one, indicates that model-dependent information or concurrent-sense information has been stored in the extended-control word.

The information provided in the extended-control word is as follows:

<table>
<thead>
<tr>
<th>SCSW Bits</th>
<th>ERW</th>
<th>ECW Words 0-7</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 14</td>
<td>10-15</td>
<td>0-7</td>
</tr>
<tr>
<td>0 0 0 Zeros Unpredictable</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 1 0   (1) Concurrent-sense information²</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 1 1   (1) Concurrent-sense information²</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1 0 0 Zeros Unpredictable²</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1 1 0 Zeros Model-dependent information²</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1 1 1   (1) Concurrent-sense information²</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Explanation:
1. If stored, the value of these words is unpredictable.
2. Unused bits in the model-dependent information are stored as zeros.
3. Bit positions 10-15 contain a value equal to the number of sense bytes returned.
4. Unused bytes in the concurrent-sense information are stored as zeros.
5. The combination of SCSW bit 5 as 0, SCSW bit 14 as one, and ERW bit 7 as zero does not occur.

Extended-Measurement Word

The extended-measurement word (EMW) provides I/O measurement information to the program for the most recent start or resume operation performed at the subchannel. When the extended-I/O-measurement-word facility is installed and enabled, the EMW is conditionally stored in words 16-23 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed. The EMW is stored by TEST SUBCHANNEL when all of the following conditions are met:

1. The extended-status-word-format (L) bit (bit 5, word 0 of the SCSW) is zero.
2. The channel-subsystem-timing facility is available for the subchannel, as indicated by the timing facility bit (T) at the subchannel.
3. The extended-I/O-measurement-word-mode enable bit (X) at the subchannel is one.
4. The subchannel status-control field has the status-pending bit (bit 31, word 0 of the SCSW) set to one, together with:
   a. The primary-status bit (bit 29, word 0 of the SCSW) alone, or
   b. The primary-status bit and other status-control bits, or
   c. The secondary-status bit (bit 29, word 0 of the SCSW) alone, or
   d. The intermediate-status bit (bit 28, word 0 of the SCSW) and the suspended bit (bit 26, word 0 of the SCSW).

Words 16-23 of the IRB contain unpredictable values when the extended-I/O-measurement-word facility is installed and enabled but the conditions listed above are not met.

When the extended-I/O-measurement-word facility is not installed, or the facility is installed but not enabled, words 16-23 of the IRB are not accessed by the channel subsystem.

The format of the extended-measurement word is shown below:

<table>
<thead>
<tr>
<th>Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
</tbody>
</table>

Each field in the EMW, when valid, contains a 32 bit binary count in which each increment of the count represents a value of 0.5 microseconds. A value of 00000000 hex represents a time period of zero seconds; the maximum value of FFFFFFFF hex represents approximately 35.79 minutes.
The accuracy of each of the measurement fields stored by the measurement facility is undefined and may vary depending on the resolution of timers implemented at the channel subsystem, the types of channels used to perform the operation, the capabilities of control units accessed during the operation, and the overall length of the I/O operation that was performed. The maximum value of FFFFFFFF hex is stored if a counter overflows; the program is not alerted when an overflow occurs.

Device-Connect Time: Bit positions 0-31 of word 0 contain the measured device-connect time for the operation. The device-connect time is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active for a command-mode operation, or start-pending for a transport-mode operation, and the device is actively communicating with the channel path, as defined in the section “Device-Connect Time” on page 4.

Function-Pending Time: Bit positions 0-31 of word 1 contain the SSCH- or RSCH-function-pending time for the operation. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device, as defined in the section “Function-Pending Time” on page 4.

Device-Disconnect Time: Bit positions 0-31 of word 2 contain the device-disconnect time for the operation. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel-active for a command-mode operation, or start-pending for a transport-mode operation, as defined in the section “Device-Disconnect Time” on page 5.

Control-Unit-Queuing Time: Bit positions 0-31 of word 3 contain the control-unit-queuing time for the operation. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the device is busy with an operation initiated from a different system, as defined in the section “Control-Unit-Queuing Time” on page 5.

Device-active-only time: Bit positions 0-31 of word 4 contain the device-active-only time for the operation. For a command-mode operation, device-active-only time is the sum of the time intervals when the subchannel is device-active but not subchannel-active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function, as defined in section “Device-Active-Only Time” on page 6. When a transport-mode IRB is stored, device-active-only time is the sum of the times that the I/O device was active executing device command and the time interval between when channel-end and device-end status were presented.

Device-busy time: Bit positions 0-31 of word 5 contain the device-busy time for the operation. When a command-mode IRB is stored, the device-busy time is the sum of the time intervals when the device is found to be device busy during an attempt to initiate a start function or resume function at the subchannel, as defined in the section “Device-Busy Time” on page 6. When a transport-mode IRB is stored, device-busy time is the sum of the times that the I/O device was busy attempting to initiate a command and the device busy time accumulated by the channel subsystem.

Initial Command Response Time: Bit positions 0-31 of word 6 contain the initial-command-response time for the operation. When a command-mode IRB is stored, initial-command-response time for an operation is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command. When a transport-mode IRB is stored, the initial-command-response time, is the time interval difference between when a TCCB is sent to the I/O device until the response is received from the I/O device, minus the time from when the control unit receives the TCCB until the channel subsystem receives the response from the control unit.
Chapter 17. I/O Support Functions

The I/O support functions are those functions of the channel subsystem that are not directly related to the initiation or control of I/O operations. The following I/O support functions are described in this chapter:

- Channel-subsystem monitoring
- Signals and resets
- Externally initiated functions
- Status verification
- Address-limit checking
- Configuration alert
- Incorrect-length-indication suppression
- Concurrent sense
- Channel-subsystem recovery
- I/O-priority facility
- Restore-subchannel facility
- Multiple-subchannel-set facility

Channel-Subsystem Monitoring

Monitoring facilities are provided in the channel subsystem so that the program can retrieve measured values on performance for a designated subchannel. The use of these facilities is under program control by means of the execution of the SET CHANNEL MONITOR instruction and the MODIFY SUBCHANNEL instruction.

The principal components of the channel-subsystem-monitoring facilities are the channel-subsystem-timing facility, measurement-block-update facility, and device-connect-time-measurement facility. The measurement-block-update facility and device-connect-time-measurement facility both use the channel-subsystem-timing facility but otherwise are logically distinct and operate independent of one another.
Other components of the channel-subsystem-monitoring facilities are the control-unit-queueing-measurement facility, the control-unit-defer-time facility, the device-active-only-measurement facility, the initial-command-response-measurement facility, the extended-I/O-measurement-block facility, and the extended-I/O-measurement-word facility. These enhance the measurements of the measurement-block-update facility if they are available as described in later sections, where each of the facilities that constitute the channel-subsystem-monitoring facilities is described in this chapter.

**Channel-Subsystem Timing**

The channel-subsystem-timing facility provides the channel subsystem with the capability of measuring the elapsed time required for performing several different phases of the processing of a start function initiated by START SUBCHANNEL. These elapsed-time measurements are used by both the measurement-block-update facility and the device-connect-time-measurement facility to provide subchannel performance information to the program.

While every channel subsystem has a channel-subsystem-timing facility, it may or may not be provided for use with all subchannels. Subchannels for which the facility is provided have the timing-facility bit, bit 14 of word 1, stored as one in the associated subchannel-information block. (See “Timing Facility (T)” on page 4.) If the channel-subsystem-timing facility is not provided for the subchannel, the subchannel's timing-facility bit is stored as zero.

Subchannels that do not have the channel-subsystem-timing facility provided are those for which the characteristics of the associated device, the manner in which it is attached to the channel subsystem, or the channel-subsystem resources required to support the device are such that use of the channel-subsystem-timing facility is precluded.

The channel-subsystem-timing facility consists of at least one channel-subsystem timer and the associated logic and storage required for computing and recording the elapsed-time intervals for use by the two measurement facilities. The aspects of the channel-subsystem-timing facility that are of importance to the program are described below.

**Channel-Subsystem Timer**

Each channel-subsystem timer is a binary counter that is not accessible to the program. The channel-subsystem timer provides a minimum timer resolution of 128 microseconds. A timer resolution of 1.0 microseconds is provided when FICON-I/O-interface channel paths are supported. When incrementing the channel-subsystem timer causes a carry out of the leftmost bit position, the carry is ignored, and counting continues from zero. No indications are generated as a result of the overflow.

Just as every CPU has access to a TOD clock, every channel subsystem has access to at least one channel-subsystem timer. When multiple channel-subsystem timers are provided, synchronization among these timers is also provided, creating the effect that all the timing facilities of the channel subsystem share a single timer. Synchronization among these timers may be supplied either through some TOD clock or independently by the channel subsystem.

If the TOD clocks are not synchronized, the elapsed times measured by the channel-subsystem-timing facility may have unpredictable values for some or all of the subchannels, depending on the model and on the particular channel-subsystem timer and the way the associated devices are physically attached to the system. The values are unpredictable for those devices attached to the system by separately configurable channel paths whose associated CPU TOD clocks are not synchronized.

**Synchronization:** If either the measurement-block-update mode or the device-connect-time-measurement mode is active and any of the channel-subsystem timers is found to be out of synchronization, a channel-subsystem-timer-sync check is recognized, and a channel report is generated to alert the program (see “Channel-Subsystem Recovery” on page 24). If neither of these modes is active, the lack of synchronization is not recognized.

**Measurement-Block Update**

The measurement-block-update facility provides the program with the capability of accumulating performance information for subchannels that are enabled for the measurement-block-update mode when the measurement-block-update mode is active. A subchannel is enabled for the measurement-block-update mode by setting bit 11 of word 1 of the SCHIB operand to one and then issuing MODIFY SUB-
CHANNEL. The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR when bit 62 of general register 1 is one.

When the measurement-block-update mode is active and the subchannel is enabled for the measurement-block-update mode, information is accumulated in a measurement block associated with the subchannel. A measurement block is either a 32-byte area (format-0 measurement block) or a 64-byte area (format-1 measurement block) in main storage that is associated with a subchannel for the purpose of accumulating measurement data.

For format-0 measurement blocks, the program specifies a contiguous area of absolute storage, referred to as the measurement-block area, and subdivides this area into 32-byte blocks, one block for each subchannel for which measurement data is to be accumulated. The measurement-block-update facility uses the measurement-block index contained at the subchannel in conjunction with the measurement-block origin established by the execution of SET CHANNEL MONITOR to compute the absolute address of the measurement block associated with a subchannel.

For format-1 measurement blocks, the program provides a 64-byte contiguous area of absolute storage for the subchannel. The measurement-block-update facility uses the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction.

Measurement data is stored in the measurement block associated with the subchannel each time an I/O operation or chain of I/O operations initiated by a START SUBCHANNEL instruction or RESUME SUBCHANNEL instruction is suspended or completed at the device. The completion of an I/O operation or chain of I/O operations at the device is normally determined when secondary status is accepted from the device.

The measurement data accumulated in the format-0 and format-1 measurement blocks by the measurement-block-update facility is described in the following section, “Measurement Block”.

**Measurement Block**

A measurement block is either a 32-byte area (format-0 measurement block) at a location designated by the program by its use of a measurement-block-origin address in conjunction with the measurement-block index, or a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction.

The measurement block contains the accumulated values of the measurement data described below. When the measurement-block-update mode is active and the subchannel is enabled for measurement-block update, the measurement-block-update facility accumulates the values for the measurement data that accrue during the performance of an I/O operation or chain of I/O operations initiated by START SUBCHANNEL.

When the I/O operation or chain of I/O operations is suspended or completed and no error condition is encountered, the accrued values are added to the accumulated values in the measurement block for that subchannel. If an error condition is detected and subchannel-logout information is stored in the extended-status word (ESW), the accrued values are not added to the accumulated values in the measurement block for the subchannel, and the two count fields in the measurement block are not incremented.

If (1) any of the accrued time values is detected to exceed the internal storage provided for containing these values, (2) the control unit cannot provide an accurate queuing time or defer time for the current operation, or (3) the channel subsystem successfully recovers from certain error conditions, none of the accrued values is added to the measurement block for the subchannel, and the sample count in the measurement block is not incremented, but the SSCH+RSCH count in the block is incremented.

References to the measurement block by the measurement-block-update facility, in order to accumulate measurement data at the suspension or completion of an I/O function, are single-access references and appear to be word concurrent as observed by CPUs.

The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a suspended I/O operation prior to putting the subchannel into the suspended state. The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a completed I/O operation prior to making the subchannel status pending with secondary status or, if the subchannel is start pending for a sub-
sequent operation, prior to initiating the start function.

A format-0 measurement block is stored when the measurement-block-format-control bit at the subchannel is zero; a format-1 measurement block is stored when the measurement-block-format-control bit at the subchannel is one.

The format-0 measurement block has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>SSCH+RSCH Count</th>
<th>Sample Count</th>
<th>Device-Connect Time</th>
<th>Function-Pending Time</th>
<th>Device-Disconnect Time</th>
<th>Control-Unit-Queuing Time</th>

**SSCH+RSCH Count:** Bits 0-15 of word 0 in the format-0 measurement block and bits 0-31 of word 0 in the format-1 measurement block are used as a binary counter. During the performance of a start function for which measurement-block update is active, when (1) the secondary status condition is recognized or (2) the suspend function is performed, the counter is incremented by one, and the measurement data is stored. The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs.

If the measurement-block-update mode is active and the subchannel is enabled for measuring, the SSCH+RSCH count is incremented even when the lack of measured values for an individual start function precludes the updating of the remaining fields of the measurement block or when the timing-facility bit for the subchannel is zero. The SSCH+RSCH count is not incremented if the measurement-block-update mode is inactive, if the subchannel is not enabled for the measurement-block update, or if subchannel-log-out information has been generated for the start function.

**Sample Count:** Bits 16-31 of word 0 in the format-0 measurement block and bits 0-31 of word 1 in the format-1 measurement block are used as a binary counter. During the performance of a start function, when the measurement-block-update facility obtains the accrued values of the measurement data for an individual start function, even when the measurement-block-update mode is active and the subchannel is enabled for that mode, the control unit may also signal that it was not able to accumulate an accurate queuing time. In these situations, the sample-count field is not incremented.

The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The System Library publication for the system model specifies the conditions, if any, that preclude the updating of the sample count and time-accumulation fields of the measurement block.

**Device-Connect Time:** Bit positions 0-31 of word 1 in the format-0 measurement block and bit positions 0-31 of word 2 in the format-1 measurement block contain the accumulation of measured device-connect-time intervals. The device-connect-time interval...
(DCTI) is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active and the device is actively communicating with the channel path. The device-connect time does not include the intervals when a device is logically connected to a channel path but is not actively communicating with the channel. The device reports the accumulation of time intervals when the device is logically connected but not actively communicating with the channel path as control-unit-defer time. The control-unit-defer time is not included in the device-connect-time measurement but, instead, is added to the accrued device-disconnect-time measurement for the operation.

The time intervals are stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if (1) the channel-subsystem-timing facility is not provided for the subchannel, (2) the measurement-block-update mode is inactive, or (3) any of the time values accrued for the current start function has been detected to exceed the internal storage in which it was accrued.

Accumulation of device-connect-time intervals for a subchannel and storing this data in the ESW are not affected by whether the measurement-block-update mode is active. (See “Device-Connect-Time Measurement” on page 10.)

Function-Pending Time: Bit positions 0-31 of word 2 in the format-0 measurement block and bit positions 0-31 of word 3 in the format-1 measurement block contain the accumulated SSCH- and RSCH-function-pending time. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device.

When channel-program execution is suspended because of a suspend flag in the first CCW of a channel program, the suspension occurs prior to transferring the first command to the device. In this case, the function-pending time accumulated up to that point is added to the value in the function-pending-time field of the measurement block. Function-pending time is not accrued while the subchannel is suspended. Function-pending time begins to be accrued again, in this case, when RESUME SUBCHANNEL is subsequently executed while the designated subchannel is in the suspended state.

The function-pending-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Device-Disconnect Time: Bit positions 0-31 of word 3 in the format-0 measurement block and bit positions 0-31 of word 4 in the format-1 measurement block contain the accumulated device-disconnect time. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel active. The device-disconnect time also includes the sum of control-unit-defer-time intervals reported by the device during the I/O operation.

Device-disconnect time is not accrued while the subchannel is in the suspended state. Device-disconnect time begins to be accrued again, in this case, on the first device disconnection after channel-program execution has been resumed at the device (the subchannel is again subchannel active).

The device-disconnect-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The device-disconnect time does not include the interval between the primary status condition and the secondary status condition at the end of an I/O operation when the subchannel is no longer subchannel active but the I/O device is active. If the channel subsystem provides the device-active-only measurement facility, this time is accumulated in the device-active-only-time field of the measurement block.

Control-Unit-Queuing Time: Bit positions 0-31 of word 4 in the format-0 measurement block and bit positions 0-31 of word 5 in the format-1 measurement block contain the accumulated control-unit-queuing time. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the
device is busy with an operation initiated from a different system.

Control-unit-queuing time is not accrued while the subchannel is in the suspended state. Control-unit-queuing time may be accrued for the channel program after the subchannel becomes subchannel active following a successful resumption.

The control-unit-queuing-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the control unit does not provide a queuing time.

**Device-Active-Only Time:** Bit positions 0-31 of word 5 in the format-0 measurement block and bit positions 0-31 of word 6 in the format-1 measurement block contain the accumulated device-active-only time. Device-active-only time is the sum of the time intervals when the subchannel is device active but not subchannel active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function.

Device-active-only time is not accumulated when the subchannel is device active during periods when the subchannel is active; such time is accumulated as device-connect time or device-disconnect time, as appropriate.

The device-active-only-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**Device-Busy Time:** When the extended-I/O-measurement-block facility is installed, bit positions 0-31 of word 6 in the format-0 measurement block, and bit positions 0-31 of word 7 in the format-1 measurement block contain the accumulated device-busy time. Device-busy time is the sum of the time intervals when the subchannel is device busy during an attempt to initiate a start function or resume function at the subchannel.

The device-busy-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**Initial-Command-Response Time:** Bit positions 0-31 of word 7 in the format-0 measurement block, and bit positions 0-31 of word 8 in the format-1 measurement block contain the accumulated initial-command-response time for the subchannel.

The initial-command-response time for a start or resume function is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command.

The initial-command-response time is stored at a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the initial-command-response-measurement facility is not installed.

**Control-Unit-Defer Time:** Control-unit-defer time is the sum of the time intervals measured by the control unit whenever the device is logically connected to the channel subsystem during an I/O operation but is not actively communicating with the channel because of device-dependent delays in channel-program execution. The control-unit-defer time is not stored in the measurement block as a separate measurement field but is used in the calculation of device-connect-time measurement and device-disconnect-time measurement for an operation.

Control-unit-defer time, if provided by a control unit, is accrued while the device is logically connected to the channel. The time is reported to the channel when channel-end status is presented that causes a device disconnection or terminates the I/O operation. Control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for the operation.

**Interrupt-Delay Time:** When the interrupt-delay-measurement facility is installed, bit positions 0-31 of word 9 in the format-1 measurement block contain the accumulated interrupt-delay time for the subchannel. Interrupt-delay time is the time interval from when a subchannel is made status pending with pri-
mary status to when the status is cleared by TSCH. When the interrupt-delay-measurement facility is not installed, bit positions 0-31 of word 9 in the format-1 measurement block are not updated and contain zeros.

The interrupt-delay time is accumulated in the measurement block when a measurement-block update is performed on a subsequent SSCH since the interrupt-delay time is not known when the measurement block is updated for the current SSCH. Consequently, the interrupt-delay time contains the accumulated interrupt-delay time for SSCH operations completed prior to the last completed SSCH operation.

The interrupt-delay time is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**I/O-Priority-Delay Time:** Bit positions 0-31 of word 10 in the format-1 measurement block contain the accumulated I/O-priority-delay time for the subchannel. The I/O-priority-delay time is that portion of the queue time that can be attributed to delay due to I/O-priority management performed by the control unit. The measurement applies only to TCW I/O operations and is reported in the additional data area of the TSB according to device-dependent definition. If the control unit does not support I/O-priority management or if there is no I/O-priority delay, bit positions 0-31 of word 10 in the format-1 measurement block are not updated.

The I/O-priority-delay time is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**Programming Note:** This time is a direct measurement of the effect of the software setting I/O priorities for the I/O executed at the control unit for all I/O devices. Times will vary depending if priorities are kept low for some work. Software uses the time to validate the correctness of the algorithms used for I/O priority management.

**Reserved:** The remaining words of the measurement block, along with any words associated with facilities that are not provided by the channel subsystem or the subchannel, are reserved for future use. They are not updated by the measurement-block-update facility.

**Programming Note:** It is possible for the program to fetch a portion of a measurement block immediately prior to, or during, a measurement block update by the measurement-block-update facility. To ensure that a consistent measurement block is fetched, the program should not fetch measurement data for a subchannel during the time from when a start or resume function is initiated at the subchannel until the operation is suspended or completes with secondary status.

**Measurement-Block Format**

The measurement block is stored as either a format-0 measurement block or a format-1 measurement block. The format-0 measurement block is a 32-byte area (format-0 measurement block) at a location designated by the program using the measurement-block origin in conjunction with the measurement-block index. The format-1 measurement block is a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction. The measurement-block-format-control bit at the subchannel indicates whether a format-0 or format-1 measurement block is stored when measurement-block-update mode is active and enabled at the subchannel.

**Measurement-Block Origin**

The measurement-block origin is the beginning of the measurement-block area in main storage, used to store format-0 measurement blocks. The absolute address of the measurement-block origin, specified on a 32-byte boundary, is passed in general register 2 to the measurement-block-update facility when SET CHANNEL MONITOR is executed with bit 62 of general register 1 set to one.

**Measurement-Block Address**

The measurement-block address is set at the subchannel through the execution of MODIFY SUBCHANNEL. The measurement block address specifies the absolute address of the beginning of the 64-byte area to be used for accumulating format-1 measurement-block parameters for that subchannel.

**Programming Note:** The initial value of the measurement-block address is zero. The program is
responsible for setting the measurement-block address to the proper value prior to enabling the subchannel for the measurement-block-update mode for format-1 measurement blocks and making the mode active.

**Measurement-Block Key**

Bits 32-35 of general register 1 form the four-bit access key to be used for subsequent measurement-block updates when SET CHANNEL MONITOR causes the measurement-block-update mode to be made active. The measurement-block key is passed to the measurement-block-update facility whenever the measurement-block-update mode is made active. The key is used for format-0 and format-1 measurement block updates.

**Measurement-Block Index**

The measurement-block index is set in the subchannel through the execution of MODIFY SUBCHANNEL. The measurement-block index specifies which 32-byte measurement block, relative to the measurement-block origin, is to be used for accumulating the format-0 measurement-block parameters for that subchannel. The location of the format-0 measurement block of a subchannel is computed by the measurement-block-update facility by appending five rightmost zeros to the measurement-block index of the subchannel and adding the result to the measurement-block origin. The result is the absolute address of the 32-byte format-0 measurement block for that subchannel. When the computed measurement-block address exceeds $2^{31}$, a measurement-block program-check condition is recognized, and measurement-block updating does not occur for the preceding subchannel-active period.

**Programming Note:** The initial value of the measurement-block index is zero. The program is responsible for setting the measurement-block index to the proper value prior to enabling the subchannel for the measurement-block-update mode and making the mode active. To ensure predictable results for the measured parameters in the measurement block, each subchannel for which measured parameters are to be accumulated must have a different value for its measurement-block index.

**Measurement-Block-Update Mode**

The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR with bit 62 of general register 1 set to one. If bit 62 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive. When the measurement-block-update mode is made active, the contents of general register 2 are passed to the measurement-block-update facility as the absolute address of the measurement-block origin and is used to calculate the address of format-0 measurement blocks. The measurement-block origin is not used for format-1 measurement blocks. The MBK is also passed to the measurement-block-update facility as the access key to be used when updating either format-0 or format-1 measurement blocks for each subchannel. When the measurement-block-update mode is active, the measurement-block-update facility accumulates measurements in individual measurement blocks for subchannels whose measurement-block-update-enable bit is one. (See the section “Measurement Block” on page 3 for a description of the measured parameters.)

If the measurement-block-update mode is already active when SET CHANNEL MONITOR is executed, the values for the measurement-block origin and measurement-block key that are used for a subchannel enabled for measuring by the measurement-block-update facility are dependent upon whether SET CHANNEL MONITOR is executed prior to, during, or subsequent to the execution of START SUBCHANNEL for that subchannel. If SET CHANNEL MONITOR is executed prior to START SUBCHANNEL, the current measurement-block origin and measurement-block key are in control. If SET CHANNEL MONITOR is executed during or subsequent to execution of START SUBCHANNEL, it is unpredictable whether the measurement-block origin and measurement-block key that are in control are old or current.

**Measurement-Block-Format Control**

Bit 29, word 6, of the SCHIB is the measurement-block-format-control bit. This bit provides the capability of specifying whether a format-0 or format-1 measurement block is stored on a subchannel basis. The initial value of the bit is zero. When MODIFY SUBCHANNEL is executed with the measurement-block-format-control bit in the SCHIB operand set to one, the format-1 measurement block is specified for the subchannel. If the measurement-block-update mode is active and enabled at the subchannel, the measurement-block-update facility stores a format-1 measurement-block for the subchannel, starting with the next START SUBCHANNEL issued to that sub-
channel. Similarly, if MODIFY SUBCHANNEL is ex-
ecuted with measurement-block-format-control bit of
the SCHIB operand set to zero by the program, the
measurement-block-update facility stores a format-0
measurement-block for the subchannel, starting with
the next START SUBCHANNEL issued to that sub-
channel.

Measurement-Block-Update Enable
Bit 11 of word 1 of the SCHIB is the measure-
ment-block-update-enable bit. This bit provides the capa-
bility of controlling the accumulation of measure-
ment-block parameters on a subchannel basis. The
initial value of the enable bit is zero. When MODIFY
SUBCHANNEL is executed with the enable bit set to
one in the SCHIB, the subchannel is enabled for the
measurement-block-update mode. If the measure-
ment-block-update mode is active, the measurement-
block-update facility accumulates measurement-
block parameters for the subchannel, starting with
the next START SUBCHANNEL issued to that sub-
channel. Conversely, if MODIFY SUBCHANNEL is
executed with bit 11 of word 1 of the SCHIB operand
set to zero by the program, the subchannel is dis-
abled for the measurement-block-update mode, and
no additional measurement-block parameters are
accumulated for that subchannel.

Control-Unit-Queuing Measurement
The control-unit-queuing-measurement facility allows
the channel subsystem to accept queuing times from
control units and, in conjunction with the measure-
ment-block-update facility, to accumulate those times
in the measurement block.

The System Library publication for the control-unit
model specifies its ability to supply queuing time. If a
control-unit model is capable of supplying queuing time,
the publication specifies the conditions that pre-
vent the control unit from accumulating an accurate
control-unit-queuing time.

Control-Unit-Defer Time
The control-unit-defer-time facility allows the channel
subsystem to accept defer times from control units
and, in conjunction with the measurement-block-
update facility, to modify the device-connect and
device-disconnect times reported in the measure-
ment block to reflect the defer time. The control-unit-
defer time is subtracted from the device-connect-time
measurement and is added to the device-disconnect-
time measurement reported for an I/O operation.

The System Library publication for the control-unit
model specifies its ability to supply defer time. If a
control-unit model is capable of supplying defer time,
the publication specifies the conditions that prevent
the control unit from accumulating an accurate con-

Device-Active-Only Measurement
The device-active-only-measurement facility permits
the channel subsystem to report the times that the
device is disconnected between primary status and
secondary status at the end of an I/O operation or
chain of I/O operations.

The measurement-block updates are performed at
the time that secondary status is accepted from the
I/O device, in order that the device-active time
between primary status and secondary status can be
reported.

If the subchannel is start pending when secondary
status is accepted from the I/O device and the mea-
surement-block update is to be performed, the mea-
surement-block update is performed prior to
performing the start function. If measurement-block
errors occur, they are reported to the program along
with the secondary status instead of performing the
start function.

Initial-Command-Response
Measurement
The initial-command-response-measurement facility
allows the channel subsystem to calculate initial-
command-response time for I/O operations and, in
conjunction with the measurement-block-update
facility, to accumulate those times in the measure-
ment block. The initial-command-response time is
accumulated in word 7 of the measurement block.

Time-Interval-Measurement Accuracy
On some models, when time intervals are to be mea-
sured and condition code 0 is set for START SUB-
CHANNEL (or RESUME SUBCHANNEL in the case
of a suspended subchannel), a period of latency may
occur prior to the initiation of the function-pending
time measurement. The System Library publication
for the system model specifies the mean latency
value and variance for each of the measured time
intervals.
Programming Notes:

1. Excessive delays may be encountered by the channel subsystem when attempting to update measurement data if the program is concurrently accessing the same measurement-block area. A programming convention should ensure that the storage block designated by SET CHANNEL MONITOR is made read-only while the measurement-block-update mode is active.

2. To ensure that programs written to support measurement functions are executed properly, the program should initialize all the measurement blocks to zeros prior to making the measurement-block-update mode active. Only zeros should appear in the reserved and unused words of the measurement blocks.

3. When the incrementing of an accumulated value causes a carry to be propagated out of bit position 0, the carry is ignored, and accumulating continues from zero on.

Device-Connect-Time Measurement

The device-connect-time-measurement facility provides the program with the capability of retrieving the length of time that a device is actively communicating with the channel subsystem while executing a channel program. The measured length of time that the device spends actively communicating on a channel path during the execution of a channel program is called the device-connect-time interval (DCTI). Control-unit-defer time is not included in the DCTI.

If timing facilities are provided for the subchannel, the DCTI value is passed to the program in the extended-status word (ESW) at the completion of the operation when the primary-status condition is cleared by TEST SUBCHANNEL and when TEST SUBCHANNEL clears an intermediate-status condition alone while the subchannel is suspended. The DCTI value passed in the ESW pertains to the previous subchannel-active period. The passing of the DCTI in the ESW is under program control by the SET CHANNEL MONITOR device-connect-time-measurement mode-control bit and the corresponding enable bit in the subchannel. However, the DCTI value is not stored in the ESW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout. See the section “Extended-Status Format 0” on page 47. In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 47 for the description of the logout information. If the accrued DCTI value exceeded 8.388608 seconds during the previous subchannel-active period, then the maximum value (FFFF hex) is passed in the ESW.

Device-Connect-Time-Measurement Mode

The device-connect-time-measurement mode is made active by the execution of SET CHANNEL MONITOR when bit 63 of general register 1 is one. If bit 63 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive, and DCTIs are not passed to the program. When timing facilities are provided for the subchannel, the device-connect-time-measurement mode is active, and the subchannel is enabled for the mode, the DCTI value is passed to the program in the ESW stored when TEST SUBCHANNEL (1) clears the primary-interruption condition with no logout information indicated in the SCSW (extended-status-word-format bit is zero) or (2) clears the intermediate-status condition alone while the subchannel is suspended.

If a start function is currently being executed with a subchannel enabled for the device-connect-time-measurement mode when SET CHANNEL MONITOR makes this mode active for the channel subsystem, the value of the DCTI stored under the appropriate conditions may be zero, a partial result, or the full and correct value, depending on the model and the progress of the start function at the time the mode was activated.

Provision of the DCTI value in the measurement-block area is not affected by whether the device-connect-time-measurement mode is active.

Device-Connect-Time-Measurement Enable

Bit 12 of word 1 of the SCHIB is the device-connect-time-measurement-mode-enable bit. This bit provides the program with the capability of selectively controlling the storing of DCTI values for a subchannel when the device-connect-time-measurement mode is active. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchan-
nel is enabled for the device-connect-time-measurement mode. If the device-connect-time-measurement mode is active, the device-connect-time-measurement facility begins providing DCTI values for the subchannel, starting with the next START SUB-CHANNEL issued to the subchannel. In this situation, the DCTI values are provided in the ESW (see the section “Extended-Status Format 2” on page 54). Similarly, if MODIFY SUBCHANNEL is executed with bit 12 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the device-connect-time-measurement mode, and no further DCTI values are passed to the program for that subchannel.

**Extended Measurement Word**

The extended-I/O-measurement-word facility provides the program with the capability of retrieving measurement information for a channel program. The measurement information is stored into the extended-measurement word (EMW) in the Interruption Response Block when the extended-measurement-word enable bit is one at the subchannel. See the section “Extended-Measurement Word” on page 56 in Chapter 16, “I/O Interruptions,” for the description of the extended-measurement word.

When the extended-measurement-word is enabled for the subchannel, measurement values are passed to program in the EMW when TEST SUBCHANNEL clears a primary-status condition, secondary-status condition alone, or an intermediate-status condition alone while the subchannel is suspended. The measurement values stored in the EMW pertain to the previous subchannel-active and device-active period. Measurement values are not stored in the EMW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout (see the section “Extended-Status Format 0” on page 47). In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 47 for the description of the logout information. If any of the accrued measurement values exceeded the maximum value capable of being measured during the previous subchannel-active and device-active period, then the maximum value is stored for that value in the EMW.

**Extended-Measurement-Word Enable**

Bit 30 of word 6 of the SCHIB is the extended-measurement-word enable bit. This bit provides the program with the capability of selectively controlling the storing of measurement values for a subchannel. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchannel is enabled for the extended-measurement-word and the extended-measurement-word facility begins providing measurement values for the subchannel starting with the next START SUBCHANNEL issued to the subchannel. Similarly, if MODIFY SUBCHANNEL is executed with bit 30, word 6, of the SCHIB operand set to zero by the program, the subchannel is disabled for the extended-measurement-word and no further measurement values are passed to the program for that subchannel.

**Signals and Resets**

During system operation, it may become necessary to terminate an I/O operation or to reset either the I/O system or a portion of the I/O system. (The I/O system consists of the channel subsystem plus all of the attached control units and devices.) Various signals and resets are provided for this purpose. Three signals are provided for the channel subsystem to notify an I/O device to terminate an operation or perform a reset function or both. Two resets are provided to cause the channel subsystem to reinitialize certain information contained either at the I/O device or at the channel subsystem.

**Signals**

The request that the channel subsystem initiate a signaling sequence is made by one of the following:

1. The program’s issuance of the CLEAR SUB-CHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH instruction
2. The I/O device’s signaling of I/O-error alert
3. The channel subsystem itself, upon detecting certain error conditions or equipment malfunctions

The three signals are the halt signal, the clear signal, and the reset signal.
Halt Signal
The halt signal is provided so the channel subsystem can terminate an I/O operation. The halt signal is issued by the channel subsystem as part of the halt function performed subsequent to the execution of HALT SUBCHANNEL. The halt signal is also issued by the channel subsystem when certain error conditions are encountered.

For the parallel-I/O-interface type of channel path, the halt signal results in the channel subsystem using the interface-disconnect sequence control defined in the System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974.

For the ESCON-I/O-interface type of channel path, the halt signal results in the channel subsystem using the cancel function defined in the System Library publication IBM Enterprise Systems Architecture/390 ESCON I/O Interface, SA22-7202.

For the FICON-I/O-interface type of channel path and the subchannel is operating in command-mode, the halt signal results in the channel subsystem using the cancel function defined in the ANSI standards document Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).

For the FICON-I/O-interface type of channel path with the subchannel is operating in transport mode, the halt signal results in the channel subsystem using the transport-mode abort-sequence function.

Clear Signal
The clear signal is provided so the channel subsystem can terminate an I/O operation and reset status and control information contained at the device. The clear signal is issued as part of the clear function performed subsequent to the execution of CLEAR SUBCHANNEL. The clear signal is also issued by the channel subsystem when certain error conditions or equipment malfunctions are detected by the I/O device or the channel subsystem.

For the parallel-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset sequence control defined in the System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974.

For the ESCON-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset function defined in the System Library publication IBM Enterprise Systems Architecture/390 ESCON I/O Interface, SA22-7202.

For the FICON-I/O-interface type of channel path and the subchannel is operating in command-mode, the clear signal results in the channel subsystem using the selective-reset function defined in the ANSI standards document Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).

For the FICON-I/O-interface type of channel path with the subchannel is operating in transport mode, the clear signal results in the channel subsystem using the selective-reset function.

When the subchannel is operating in command mode, if an I/O operation is in progress at the device and the device is actively communicating over a channel path in the performance of that I/O operation when a clear signal is received on that channel path, the device disconnects from that channel path upon receiving the clear signal. Data transfer and any operation using the facilities of the control unit are immediately concluded, and the I/O device is not necessarily positioned at the beginning of a block. Mechanical motion not involving the use of the control unit, such as rewinding magnetic tape or positioning a disk-access mechanism, proceeds to the normal stopping point, if possible. The device may appear busy until termination of the mechanical motion or the inherent cycle of operation, if any, whereupon it becomes available. Status information in the device and control unit is reset, but an interruption condition may be generated upon the completion of any mechanical operation.

Reset Signal
The reset signal is provided so the channel subsystem can reset all I/O devices on a channel path. The reset signal is issued by the channel subsystem as part of the channel-path-reset function performed subsequent to the execution of RESET CHANNEL PATH. The reset signal is also issued by the channel subsystem as part of the I/O-system-reset function.

For the parallel-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset sequence control defined in the System Library publication IBM System/360 and
For the ESCON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the System Library publication IBM Enterprise Systems Architecture/390 ESCON I/O Interface, SA22-7202.

For the FICON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the ANSI standards document Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).

Resets

Two resets are provided so the channel subsystem can reinitialize certain information contained at either the I/O device or the channel subsystem. The request that the channel subsystem initiate one of the reset functions is made by one of the following:

1. The program's issuance of the RESET CHANNEL PATH instruction
2. The operator's activation of a system-reset-clear or system-reset-normal key or a load-clear or load-normal key
3. The channel subsystem itself upon detecting certain error conditions or equipment malfunctions

The resets are channel-path reset and I/O-system reset.

Channel-Path Reset

The channel-path-reset facility provides a mechanism to reset certain indications that pertain to a designated channel path at all associated subchannels. Channel-path reset occurs when the channel subsystem performs the channel-path-reset function initiated by the RESET CHANNEL PATH function. (See "RESET CHANNEL PATH" on page 9.) All internal indications of dedicated allegiance, control unit busy, and device busy that pertain to the designated channel path are cleared in all subchannels, and reset is signaled on that channel path.

The receipt of the reset signal by control units attached to that channel path causes all operations in progress and all status, mode settings, and allegiance, pertaining to that channel path, of the control unit and its attached devices to be reset. (See also the description of the system-reset-signal actions in "I/O-System Reset" on page 13.)

The results of the channel-path-reset function on the designated channel path are communicated to the program by means of a subsequent machine-check-interruption condition generated by the channel subsystem (see "Channel-Subsystem Recovery" on page 24).

I/O-System Reset

The I/O-system-reset function is performed when the channel subsystem is powered on, when initial program loading is initiated manually (see "Initial Program Loading" on page 16), and when the system-reset-clear or system-reset-normal key is activated. The I/O-system-reset function cannot be initiated under program control; it must be initiated manually. I/O-system reset may fail to complete due to malfunctions detected at the channel subsystem or on a channel path. I/O-system reset is performed as part of subsystem reset, which also resets all floating interruption requests, including pending I/O interruptions. (See "Subsystem Reset" on page 60.) Detailed descriptions of the effects of I/O-system reset on the various components of the I/O system appear later in this chapter.

I/O-system reset provides a means for placing the channel subsystem and its attached I/O devices in the initialized state. I/O-system reset affects only the channel-subsystem configuration in which it is performed, including all channel-subsystem components configured to that channel subsystem. I/O-system reset has no effect on any system components that are not part of the channel-subsystem configuration that is being reset. The effects of I/O-system reset on the configured components of the channel subsystem are described in the following sections.

Channel-Subsystem State: I/O-system reset causes the channel subsystem to be placed in the initialized state, with all the channel-subsystem components in the states described in the following sections. All operations in progress are terminated and reset, and all indications of prior conditions are reset. These indications include status information, interruption conditions (but not pending interruptions), dedicated-allegiance conditions, pending channel reports, and all internal information regarding prior conditions and operations. In the initialized state, the channel subsystem has no activity in progress and is...
Control Units and Devices: I/O-system reset causes a reset signal to be sent on all configured channel paths, including those which are not physically available (as indicated by the PAM bit being zero) because of a permanent error condition detected earlier. When the reset signal is received by a control unit, control-unit functions in progress, control-unit status, control-unit allegiance, and control-unit modes for the resetting channel path are reset. Device operations in progress, device status, device allegiance, and the device mode for the resetting channel path are also reset. Control-unit and device mode, allegiance, status, and I/O functions in progress for other channel paths are not affected.

For devices that are operating in the single-path mode, an operation can be in progress for, at most, one channel path. Therefore, if the reset signal is received on that channel path, the operation in progress is reset. Devices that have the dynamic-reconnection feature and are operating in the multipath mode, however, have the capability to establish an allegiance to a group of channel paths during an I/O operation, where all the channel paths of the path group are configured to the same channel subsystem. If an operation is in progress for a device that is operating in the multipath mode and the reset signal is received on one of the channel paths of that path group, then the operation in progress is reset for the resetting channel path only. Although the operation in progress cannot continue on the resetting channel path, it can continue on the other channel paths of the path group, subject to the following restrictions:

1. If the device is actively communicating with the channel subsystem on a channel path when it receives the reset signal on that channel path, then the operation is reset unconditionally, regardless of path groups.

2. If the operation is in progress in the multipath mode but the path group consists only of the resetting channel path only. Although the operation in progress cannot continue on the resetting channel path, it can continue on the other channel paths of the path group, subject to the following restrictions:

3. Except as noted in item 2, if the operation in progress is currently in a disconnected state (device not actively communicating with the channel subsystem) or is active on another channel path of a path group, system reset has no effect upon the continued performance of the operation.

A control unit is completely reset after the reset signal has been received on all its channel paths, provided no new activity is initiated at the control unit between the receipt of the first and last reset signal. “Completely reset” means that the current operation, if any, at the control unit is terminated and that control-unit allegiance, control-unit status, and the control-unit mode, if any, are reset.

An I/O device is completely reset after the reset signal has been received on all channel paths of all control units by which the device is accessible, provided no new activity is initiated at the device between the receipt of the first and last reset signal. “Completely reset” means that the current operation, if any, at the device is terminated and that device allegiance, device status, and the device mode are reset.

In summary, system reset always causes an operation in progress to be reset for the channel path on which the reset signal is received. If the resetting channel path is the only channel path for which the operation is in progress, then the operation is completely reset. If a device is actively communicating on a channel path over which the reset signal is received, then the operation in progress is unconditionally and completely reset.

The reset signal is not received by control units and devices on channel paths from which the control unit has been partitioned. A control unit is partitioned from a channel path by means of an enable/disable switch on the control unit for each channel path by which it is accessible. Multi-tagged, unsolicited status, if any, remains pending at the control unit for such a channel path in this case. However, from the point of view of the program, the control unit and device appear to be completely reset if the reset signal is received by the control unit on all the channel paths by which it is currently accessible.

The resultant reset state of individual control units and devices is described in the System Library publication for the control unit.

Channel Paths: I/O-system reset causes a reset signal to be sent on all configured channel paths and causes the channel subsystem to be placed in the reset and initialized state, as described in the previous sections. As a result of these actions, all communication between the channel subsystem and its
attached control units and devices is terminated and the components reset, and all configured channel paths are made quiescent or are deconfigured.

**Subchannels:** I/O-system reset causes all operations on all subchannels to be concluded. Status information, all interruption conditions (but not pending interruptions), dedicated-allegiance conditions, and internal indications regarding prior conditions and operations in all subchannels are reset, and all valid subchannels are placed in the initialized state.

In the initialized state, the subchannel parameters of all valid subchannels are set to their initial values. The initial values of the following subchannel parameters are zeros:

- Interruption parameter
- I/O-interruption-subclass code (ISC)
- Enabled
- Limit mode when the address-limit-checking facility is installed
- Measurement mode
- Multipath mode
- Path-not-operational mask
- Last-path-used mask
- Measurement-block index
- Concurrent sense

The initial values of the following subchannel parameters are assigned as part of the installation procedure for the device associated with each valid subchannel:

- Timing facility
- Device number
- Logical-path mask (same value as path-installed mask)
- Path-installed mask
- Path-available mask
- Channel-path ID 0-7

The values assigned may depend upon the particular system model and the configuration; dependencies, if any, are described in the System Library publication for the system model. Programming considerations may further constrain the values assigned.

The initial value of the path-operational mask is all ones.

The device-number-valid bit is one for all subchannels having an assigned I/O device.

The initial value of the model-dependent area of the subchannel-information block is described in the System Library publication for the system model.

The initial value of the subchannel-status word and extended-status word is all zeros.

The initialized state of the subchannel is the state specified by the initial values for the subchannel parameters described above. The description of the subchannel parameters can be found in “Subchannel-Information Block” on page 2, “Subchannel-Status Word” on page 7, and “Extended-Status Word” on page 47.

**Channel-Path-Reset Facility:** I/O-system reset causes the channel-path-reset facility to be reset. A channel-path-reset function initiated by RESET CHANNEL PATH, either pending or in progress, is overridden by I/O-system reset. The machine-check-interruption condition, which normally signals the completion of a channel-path-reset function, is not generated for a channel-path-reset function that is pending or in progress at the time I/O-system reset occurs.

**Address-Limit-Checking Facility:** When the address-limit-checking facility is installed, I/O-system reset causes the address-limit-checking facility to be reset. The address-limit value is initialized to all zeros and validated.

**Channel-Subsystem-Monitoring Facilities:** I/O-system reset causes the channel-subsystem-monitoring facilities to be reset. The measurement-block-update mode and the device-connect-time-measurement mode, if active, are made inactive. The measurement-block origin and the measurement-block key are both initialized to zeros and validated.

**Pending Channel Reports:** I/O-system reset causes pending channel reports to be reset.

**Channel-Subsystem Timer:** I/O-system reset does not necessarily affect the contents of the channel-subsystem timer. In models that provide channel-subsystem-timer checking, I/O-system reset may cause the channel-subsystem timer to be validated.

**Pending I/O Interruptions:** I/O-system reset does not affect pending I/O interruptions. However, during subsystem reset, I/O interruptions are cleared concurrently with the performance of I/O-system reset. (See “Subsystem Reset” on page 60.)
Externally Initiated Functions

I/O-system reset, which is an externally initiated function, is described in “I/O-System Reset” on page 13.

Initial Program Loading

Initial program loading (IPL) provides a manual means for causing a program to be read from a designated device and for initiating the execution of that program.
Some models may provide additional controls and indications relating to IPL; this additional information is specified in the System Library publication for the model.

There are two types of IPL: CCW-type IPL and list-directed IPL. CCW-type IPL is provided by all machine configurations. List-directed IPL may be provided, depending on the model.

**CCW-type IPL**

CCW-type IPL is initiated manually by setting the load-unit-address controls to a four-digit number to designate an input device and by subsequently activating the load-clear or load-normal key.

Activating the load-clear or load-normal key sets the architectural mode to the ESA/390 mode. For ease of reference, the additional elements of the description of ESA/390 IPL are given below.

Activating the load-clear key causes a clear reset to be performed on the configuration.

Activating the load-normal key causes an initial reset to be performed on this CPU, CPU reset to be propagated to all other CPUs in the configuration, and a subsystem reset to be performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, this CPU enters the load state. This CPU does not necessarily enter the stopped state during performance of the reset. The load indicator is on while the CPU is in the load state.

Subsequently, if conditions allow, a read operation is initiated from the designated input device and associated subchannel. The read operation is performed as if a START SUBCHANNEL instruction were executed that designated (1) the subchannel corresponding to the device number specified by the load-unit-address controls and (2) an ORB containing all zeros, except for a byte of all ones in the logical-path-mask field. The ORB parameters are interpreted by the channel subsystem as follows:

- **Interruption parameter:** All zeros
- **Subchannel key:** All zeros
- **Suspend control:** Zero (suspension not allowed)
- **CCW format:** Zero
- **CCW prefetch:** Zero (prefetching not allowed)

- **Initial-status-interruption control:** Zero (no request)
- **Address-limit-checking control:** Zero (no checking), when the address-limit-checking facility is installed
- **Suppress suspended interruption:** Zero (suppression not allowed)
- **Channel-program-type control:** Zero (CCW channel program), when the FCX-facility is installed
- **Logical-path mask:** Ones (all channel paths logically available)
- **Incorrect-length-suppression mode:** Zero (ignored because format-0 CCWs are specified)
- **Channel-program address:** Absolute address 0

The first CCW to be executed is not fetched from storage. Instead, the effect is as if an implied format-0 CCW, beginning in absolute location 0 and having the following detailed format, were executed:

```
Loc.  0 00000010000000000000000000000000 4 01100000
    8 16 31
```

In the illustration above, the CCW specifies a read command with the modifier bits zeros, a data address of 0, a byte count of 24, the chain-command flag one, the suppress-invalid-length-indication flag one, the chain-data flag zero, the program-controlled-interruption (PCI) flag zero, the indirect-data-address (IDA) flag zero, and the suspend flag zero. The CCW fetched, as a result of command chaining, from location 8 or 16, as well as any subsequent CCW in the IPL sequence, is interpreted the same as a CCW in any I/O operation, except that any PCI flags that are specified in the IPL channel program are ignored.

At the time the subchannel is made start pending for the IPL read, it is also enabled, which ensures proper handling of subsequent status from the device by the channel subsystem and facilitates subsequent I/O operations using the IPL device. (Except for the subchannel used by the IPL I/O operation, each subchannel must first be made enabled by MODIFY SUBCHANNEL before it can accept a start function or any status from the device.)

When the IPL subchannel becomes status pending for the last operation of the IPL channel program, no I/O-interruption condition is generated. Instead, the
subsystem ID is stored in absolute locations 184-187, zeros are stored in absolute locations 188-191, and the subchannel is cleared of the pending status as if TEST SUBCHANNEL had been executed but without storing information usually stored in an IRB. If the subchannel-status field that would normally have been stored is all zeros and the device-status field that would normally have been stored contains only the channel-end indication, with or without the device-end indication, the IPL I/O operation is considered to be completed successfully. If the device-end status for the IPL I/O operation is provided separately after channel-end status, it causes an I/O-interruption condition to be generated.

If an interface-control check is detected during execution of the IPL channel program, some models may re-initiate the same channel program on another channel path. The other path chosen is any logically-available channel path to the designated device on which the IPL channel program has not previously been initiated during the current IPL operation. (See programming note 6 on page 19 for additional information.)

When the IPL I/O operation is completed successfully, a new PSW is loaded from absolute locations 0-7. If the PSW loading is successful and no malfunctions are recognized that preclude the completion of IPL, then the CPU leaves the load state, and the load indicator is turned off. If the rate control is set to the process position, the CPU enters the operating state, and CPU operation proceeds under control of the new PSW. If the rate control is set to the instruction-step position, the CPU enters the stopped state, with the manual indicator on, after the new PSW has been loaded.

If the IPL I/O operation or the PSW loading is not completed successfully, the CPU remains in the load state, and the load indicator remains on.

IPL does not complete when any of the following occurs

- No subchannel contains a valid device number equal to the IPL device number specified by the load-unit-address controls.
- A malfunction is detected in the CPU, main storage, or channel subsystem that precludes the completion of IPL.
- Unsolicited alert status is presented by the device subsequent to the subchannel becoming start pending for the IPL read and before the IPL subchannel becomes subchannel active. The IPL read operation is not initiated in this case.
- There were no available channel paths to the IPL device.
- On every available channel path to the IPL device, either the IPL device appeared not operational or an interface-control check was detected.
- The IPL device presented a status byte containing indications other than channel end, device end, status modifier, control unit end, control unit busy, device busy, or retry status during the IPL I/O operation. Whenever control unit end, control unit busy, or device busy is presented in the status byte, normal path-management actions are taken.
- A subchannel-status indication other than PCI was generated during the IPL I/O operation, except that on some models, detection of an interface-control check may cause the I/O operation to be retried on another available channel path to the IPL device.
- The PSW loaded from absolute locations 0-7 has a PSW-format error of the type that is recognized early.

Except in the cases of no corresponding subchannel for the device number entered or a machine malfunction, the subsystem ID of the IPL device is stored in absolute locations 184-187; otherwise, the contents of these locations are unpredictable. In all cases of unsuccessful IPL, the contents of absolute locations 0-7 are unpredictable.

Subsequent to a successful IPL, the subchannel parameters contain the normal values as if an actual START SUBCHANNEL had been executed, designating the ORB as described above.

**Programming Notes:**

1. The information read and placed at absolute locations 8-15 and 16-23 may be used as CCWs for reading additional information during the IPL I/O operation: the CCW at location 8 may specify reading additional CCWs elsewhere in storage, and the CCW at location 16 may specify the
transfer-in-channel command, causing transfer to these CCWs.

2. The status-modifier bit has its normal effect during the IPL I/O operation, causing the channel subsystem to fetch and chain to the CCW whose address is 16 higher than that of the current CCW. This applies also to the initial chaining that occurs after completion of the read operation specified by the implicit CCW.

3. The PSW that is loaded at the completion of the IPL operation may be provided by the first eight bytes of the IPL I/O operation or may be placed at absolute locations 0-7 by a subsequent CCW.

4. Activating the load-normal key implicitly specifies the use of the first 24 bytes of main storage and the eight bytes at absolute locations 184-191. Since the remainder of the IPL program may be placed in any part of storage, it is possible to preserve such areas of storage as may be helpful in debugging or recovery. The IPL program should not be placed in the low 512 bytes of storage since that area is reserved as described in a programming note under “Compatibility between z/Architecture and ESA/390” on page 31. When the load-clear key is activated, the IPL program starts with a cleared machine in a known state, except that information on external storage remains unchanged.

5. When the PSW at absolute location 0 has bit 14 set to one, the CPU is placed in the wait state after the IPL operation is completed. At that point, the load and manual indicators are off, and the wait indicator is on.

6. When the program receives control after the machine leaves the load state during IPL, the last-path-used mask (LPUM) in the subchannel-information block (SCHIB) for the IPL device should be saved. The program should use this saved LPUM as the logical-path mask (LPM) in the ORB until the program reaches the point in its initialization where it has the ability to process and recover from interface-control checks, and verify that all of the channel paths associated with the subchannel are connected to the same device.

When multiple paths are associated with the subchannel of the IPL device, it is possible that mis-cabling of one or more of the paths can cause the program initialization to proceed on different devices. This affects the integrity of the IPL process. The program should ensure that all paths are connected to the same device, but this typically is not possible before program initialization completes. Thus the use of the saved LPUM ensures that all I/O operations to the IPL device during program initialization are executed on the same device, allowing postponement of the checking of the paths.

Using the saved LPUM also helps to ensure that the channel subsystem will not select a path on which errors would prevent completion of the program initialization, since the path indicated in the LPUM has demonstrated its functionality. On some models, using the saved LPUM also ensures that the path selection will not re-select a path on which an interface-control check was detected while the machine was in the load state.

List-Directed IPL

List-directed IPL supports the use of I/O devices which are not accessed by CCWs. List-directed IPL may be provided for a logical partition or virtual machine, depending on the model and the amount of memory available to the logical partition or virtual machine. The terms logical partition and virtual machine are not defined in this publication. The term logical partition is defined in the System Library publications. The term virtual machine is defined in the virtual-machine product manuals.

List-directed IPL is initiated by activating the load-clear-list-directed or load-with-dump key. Prior to activating either of these keys, the list-directed-IPL parameters are entered using a model-dependent console. List-directed-IPL parameters include the following information:

- Information which identifies the I/O device from which a program is to be loaded. This I/O device is referred to as the load device.
- Information which identifies a location on a load device from which a program will be loaded.
- Information to be used by the program which will be loaded from the load device.

The list-directed-IPL parameters required by a specific machine and the means by which they are entered are specified in the System Library publications.
After the list-directed-IPL parameters have been entered, the load-clear-list-directed or load-with-dump key for a particular CPU is activated. In the description which follows, the term “this CPU” refers to the CPU in the configuration for which the load-clear-list-directed key was activated.

Activating the load-clear-list-directed key causes a clear reset to be performed on all of the CPUs in the configuration.

Activating the load-with-dump key causes a store-status operation to be performed on this CPU. After the store-status operation, an initial-CPU-reset operation is performed on this CPU, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, the operations listed below are performed.

- If the rate control is not in the process position, it is forced into the process position.
- If the list-directed IPL operation was initiated by activating the load-with-dump key, the contents of a model-dependent number of contiguous logical-partition or virtual-machine storage locations starting with absolute location 0 are stored in a model-dependent holding area. The data stored includes the contents of all storage locations into which the program will be loaded from the load device. See Programming Note 4 for additional information.
- The program to be loaded from the load device is loaded into logical-partition or virtual-machine storage at the locations specified on the load device.
- A system IPL-parameter block used by the machine during list-directed IPL is placed in storage in the format shown in Figure 17-2 on page 20. The absolute address of the first byte of the system IPL-parameter block is stored in absolute address locations 20-23. An XML document containing the system IPL parameters immediately follows the last byte of the system IPL-parameter block. (See “Extensible Markup Language (XML) 1.0,” available from “World Wide Web Consortium” (www.w3c.org) for information regarding XML.)

The system IPL-parameter block has the following format:

<table>
<thead>
<tr>
<th>Word</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>n</td>
</tr>
</tbody>
</table>

![Figure 17-2. System IPL-Parameter Block](image)

Bits 0-31 of word 0 of the system IPL-parameter block contains a length field. The length field contains a 32-bit binary number representing the number of bytes occupied by the system IPL-parameter block. Words 1 through n contain the system IPL parameters.

If no errors occur during the operations listed above, then if a subchannel is associated with the IPL-device, the subsystem-identification word is stored in absolute locations 184-187; otherwise zeros are stored in absolute locations 184-187. Additionally, zeros are stored in absolute locations 188-191, and a new PSW is loaded from absolute locations 0-7. If the PSW loading is successful and if no malfunctions are recognized which preclude execution of the program which was loaded from the load device, then operation proceeds under control of the new PSW.

If errors occur during the operations listed above, or if the PSW loading is not successful, then this CPU remains in the operating state. See the appropriate System Library publications for additional information.

When list-directed IPL was initiated by activating the load-clear-list-directed key, the state of the machine resources at the time when the loaded program is initiated is the same as it was immediately after the clear reset was performed except as indicated below. For a description of the state of the machine resources immediately after the clear reset was performed, see “Resets” on page 55.

- This CPU is in the operating state. The contents of the ALB and TLB for this CPU are unpredictable.
- The PSW for this CPU is set to the contents of absolute storage locations 0-7.
Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23 and 184-191. Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with this absolute address contain the system IPL-parameter block, immediately followed by an XML document containing the same system IPL parameters. If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeros; otherwise, absolute storage locations 184-191 contain zeros. The contents of all other storage locations are unpredictable.

The ACC and F bits of the storage keys associated with all main storage locations are set to zero. The R and C bits of the storage keys associated with the first 4 K-byte block of storage, the blocks of storage containing the XML document and IPL-parameter list, and the blocks of storage containing the loaded program are set to one. The R and C bits of the storage keys associated with all other blocks of storage are unpredictable.

The TOD clock is unaffected by initial-program loading.

When list-directed IPL was initiated by activating the load-with-dump key, the state of the machine resources when control is passed to the loaded program is as follows:

- The I/O system has been reset.
- The state of all CPUs in the configuration except for this CPU is the same as it was immediately after the CPUs were reset.
- This CPU is in the operating state. The contents of all registers, the ALB, and the TLB for this CPU are unpredictable.
- The PSW for this CPU is set to the contents of absolute storage locations 0-7.
- The contents of all main storage locations which were not stored in the model-dependent holding area are unchanged from the time when the load-with-dump key was activated.
- The contents of all main storage locations which were stored in the model-dependent holding area are unpredictable except as follows:
  - Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23.
  - Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with this absolute address contain the system IPL-parameter block, immediately followed by an XML document containing the system IPL parameters.
  - If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeros; otherwise, absolute storage locations 184-191 contain zeros.
- The storage keys associated with the blocks of main storage which were stored in the model-dependent holding area are unpredictable. The storage keys associated with all other blocks of main storage are in the same state as they were immediately after the CPUs were reset.
- The TOD clock is unaffected by initial-program loading.

List-directed IPL does not complete if any of the following occurs:

- A malfunction is detected in the CPU, channel subsystem, or main storage which precludes the completion of IPL.
- The list-directed IPL parameters did not contain sufficient information to identify the load device or the program on the load device.
- An I/O device designated by the list-directed-IPL parameters is not in the machine configuration.
- The I/O device designated by the list-directed-IPL parameters is a CCW-type device and is not supported by list-directed IPL.
- The I/O device appeared not operational.
• The amount of storage in the logical partition or virtual machine is insufficient to allow list-directed IPL to complete.

• The PSW to be loaded from locations 0-7 has a PSW-format error of the type that is recognized early.

Programming Notes:

1. The executable portion of the program loaded during list-directed IPL should be located in absolute storage starting at absolute storage locations 8192 and higher. This is necessary in order to avoid use of the architecturally assigned storage locations. See “Assigned Storage Locations” on page 68.

2. When the address indicated by storage locations 20-23 is above 16 MB, it is necessary for the machine to be in 31-bit addressing mode in order to access the IPL-parameter list and XML document.

3. When list-directed IPL is initiated by activation of the load-clear-list-directed key, the program loaded from the load device is typically an operating-system loader. In this case, the load device may also contain the operating system to be loaded by the operating-system loader. See the applicable operating-system manuals for additional information.

4. When list-directed IPL is initiated by activation of the load-with-dump key, the contents of storage which are affected by the IPL operation are stored in a model-dependent holding area so that they can be retrieved by the program which was loaded from the load device. The program loaded from the load device is typically an O/S-specific system dump program which stores the retrieved data onto a dump device. This process ensures that the contents of storage affected by the IPL operation are preserved for analysis during subsequent debug operations. See the applicable operating system manuals for additional information.

Reconfiguration of the I/O System

Reconfiguration of the I/O system is handled in a model-dependent manner. For example, changes may be made under program control, by using the model-dependent DIAGNOSE instruction; or manually, by using system-operator configuration controls; or by using a combination of DIAGNOSE and manual controls. The method used depends on the system model. The System Library publication for the system model specifies how the changes are made. The partitioning of channel paths because of reconfiguration is indicated by the setting of the PAM bits in the SCHIB stored when STORE SUBCHANNEL is executed (see “Path-Available Mask (PAM)” on page 7).

Status Verification

The status-verification facility provides the channel subsystem with a means of indicating that a device has presented a device-status byte that has valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. The indication provided to the program in the ESW by the channel subsystem is called device-status check. When the channel subsystem recognizes a device-status-check condition, an interface-control-check condition is also recognized. For a summary of the status combinations considered to be appropriate or inappropriate, see the System Library publications IBM Enterprise Systems Architecture/390 ESCON I/O Interface, SA22-7202, and IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974, and the ANSI standards document Fibre Channel - Single-Byte Command Code Sets-2 (FCSB-2).

Address-Limit Checking

The address-limit-checking facility may be installed on a model and when installed provides a storage-protection mechanism for I/O data accesses to storage that augments key-controlled protection. The address-limit-checking facility is not installed when the FCX facility is installed. When address-limit checking is used, absolute storage is divided into two parts by a program-controlled address-limit value. I/O data accesses can then be optionally restricted to only one of the two parts of absolute storage by the limit mode at each subchannel. The address-limit constraint applies at a higher priority than key-controlled protection, that is, I/O data accesses to the part of main storage that is protected by address-limit checking are prevented even when the subchannel key is zero or matches the key in storage. Address-
limit checking does not apply to the fetching of CCWs, IDAWs and MIDAWs.

The address-limit-checking facility consists of the following elements:

- The I/O instruction SET ADDRESS LIMIT.
- The limit mode at each subchannel.
- The address-limit-checking-control bit in the ORB.

The execution of SET ADDRESS LIMIT passes the contents of general register 1 to the address-limit-checking facility to be used as the address-limit value. Bits 32 and 48-63 of general register 1 must be zeros to designate a valid absolute address on a 64K-byte boundary; otherwise, an operand exception is recognized, and the execution of the instruction is suppressed.

The limit mode at each subchannel indicates the manner in which address-limit checking is to be performed. The limit mode is set by placing the desired value in bit positions 9 and 10 of word 1 in the SCHIB and executing MODIFY SUBCHANNEL. The settings of these bits in the SCHIB have the following meanings:

00 No limit checking (initialized value).
01 Data address must be equal to or greater than the current address limit.
10 Data address must be less than the current address limit.
11 Reserved. This combination of limit-mode bits causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

During the performance of the start function, an attempt to access an absolute storage location for data that is protected by an address limit (either high or low) is recognized as an address-limit violation, and the access is not allowed. A program-check condition is recognized, and channel-program execution is terminated, just as when an attempt is made to access an invalid address.

**Configuration Alert**

The configuration-alert facility provides a detection mechanism for devices that are not associated with a subchannel in the configuration. The configuration-alert facility notifies the program, by means of a channel report, that a device which is not associated with a subchannel has attempted to communicate with the program.

Each device must be assigned to a subchannel during an installation procedure; otherwise, the channel subsystem is unable to generate an I/O-interruption condition for the device. This is because the I/O-interruption code contains the subchannel number that identifies the particular device causing the I/O-interruption condition. When a device that is not associated with a subchannel attempts to communicate with the channel subsystem, the configuration-alert facility generates a channel report in which the unassociated device is identified. For a description of the means by which the program is notified of a pending channel report and how the information in the channel report is retrieved, see “Channel Report” on page 24.

**Incorrect-Length-Indication Suppression**

The incorrect-length-indication-suppression facility allows the indication of incorrect length for immediate operations to be suppressed in the same manner when using format-1 CCWs as when using format-0 CCWs. When the incorrect-length-indication-suppression facility is installed, bit 24 of word 1 of the ORB specifies whether the channel subsystem is to suppress the indication of incorrect length for an immediate operation when format-1 CCWs are used or whether this indication will remain under the control of the SLI flag of the current CCW (as is the case
for CCWs not executed as immediate operations). This bit provides the capability for a channel program to operate in the same manner regarding the indication of incorrect length regardless of whether format-0 or format-1 CCWs are used.

**Concurrent Sense**

The concurrent-sense facility provides a mechanism whereby sense information that is provided by the device can be presented by the channel subsystem to the program in the same command-mode IRB that contains the unit-check indication when the subchannel is in the concurrent-sense mode. The concurrent-sense mode is made active at a subchannel for which the concurrent-sense facility is applicable when MODIFY SUBCHANNEL is executed and bit 31 of word 6 of the SCHIB operand is set to one. The concurrent-sense facility is applicable to subchannels that are operating in command-mode and are associated with channel paths by which the channel subsystem can attempt to retrieve sense information from the device without requiring program intervention.

The concurrent-sense facility is not applicable when a subchannel is operating in transport mode. When a transport-mode IRB is presented that contains the unit-check indication, the associated sense information is found in the TSB for the associated TCW channel program. Therefore, the concurrent sense facility is not necessary with FCX.

**Channel-Subsystem Recovery**

The channel subsystem provides various methods for extensive detection of malfunctions and other conditions to ensure the integrity of channel-subsystem operation and to achieve automatic recovery of some malfunctions.

The method used to report a particular malfunction or other condition is dependent upon the severity of the malfunction or other condition and the degree to which the malfunction or other condition can be isolated. A malfunction or other condition in the channel subsystem may be indicated to the program by information being stored by one of the following methods:

1. Information is provided in the IRB describing a condition that has been recognized by either the channel subsystem or device that must be brought to the attention of the program. Generally, this information is made available to the program by the execution of TEST SUBCHANNEL, which is usually executed in response to the occurrence of an I/O interruption. (See “ Interruption Action” on page 6, for a definition of the information stored, as well as “ Interruptions” on page 1.)

2. Information is provided in a channel report describing a machine malfunction affecting the identified facility associated with the channel subsystem. This information is made available to the program by the execution of STORE CHANNEL REPORT WORD, which is usually executed in response to the occurrence of a machine-check interruption. (See “ Machine-Check Handling” on page 1 for a description of the machine-check-interruption mechanism and the contents of the machine-check-interruption code.)

3. Information is provided in a channel report describing a malfunction or other condition affecting a collection of channel-subsystem facilities. This information is made available to the program as indicated in item 2.

4. Information is provided in the machine-check-interruption code (MCIC) describing a malfunction affecting the continued operational integrity of the channel subsystem. (See “ Channel-Subsystem Damage” on page 17.)

5. Information is provided in the MCIC describing a malfunction affecting the continued operational integrity of a process or of the system. (See “ Instruction-Processing Damage” on page 15 and “ System Damage” on page 15.)

Channel reports are used to report malfunctions or other conditions only when the use of the I/O-interruption facility is not appropriate and in preference to reporting channel-subsystem damage, instruction-processing damage, or system damage.

**Channel Report**

When a malfunction or other condition affecting elements of the channel subsystem has been recognized, a channel report is generated. The performance of recovery actions by the program or
by external means may be required to gain recovery from the error condition. The channel report indicates the source of the channel report and the recovery state to the extent necessary for determining the proper recovery action. A channel report consists of one or more channel-report words (CRWs) that have been generated from an analysis of the malfunction or other condition. The inclusion of two or more CRWs within a channel report is indicated by the chaining flag being stored as one in all of the CRWs of the channel report except the last one in the chain.

When a channel report is made pending by the channel subsystem for retrieval and analysis by the program (by means of the execution of STORE CHANNEL REPORT WORD), a malfunction or other condition that affects the normal operation of one or more of the channel-subsystem facilities has been recognized. If the channel report that is made pending is an initial channel report, a machine-check-interruption condition is generated that indicates one or more CRWs are pending at the channel subsystem. A channel report is initial either if it is the first channel report to be generated after the most recent I/O-system reset or if no previously generated reports are pending and the last STORE CHANNEL REPORT WORD instruction that was executed resulted in the setting of condition code 1, indicating that no channel report was pending. When the machine-check interruption occurs and bit 9 of the machine-check-interruption code (channel report pending) is one, a channel report is pending. If the program clears the first CRW of a channel report before the associated machine-check interruption has occurred, some models may reset the machine-check-interruption condition, and the associated machine-check interruption does not occur. A machine-check interruption indicating that a channel report is pending occurs only if the machine-check mask (PSW bit 13) and the channel-report-pending subclass mask, bit 3 of control register 14, are both ones.

If the channel report that is made pending is not an initial channel report, a machine-check-interruption condition is not generated. The CRW that is presented to the program in response to the first STORE CHANNEL REPORT WORD instruction that is executed after a machine-check interruption may or may not be part of the initial channel report that caused the machine-check condition to be generated. A pending channel-report word is cleared by any CPU executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU. If a CRW is not pending and STORE CHANNEL REPORT WORD is executed, condition code 1 is set, and zeros are stored at the location designated by the second-operand address. During the execution of STORE CHANNEL REPORT WORD as a result of receiving a machine-check interruption, condition code 1 may be set, and zeros may be stored because (1) the related channel report has been cleared by another CPU or (2) a malfunction occurred during the generation of a channel report. In the latter case, if, during a subsequent attempt, a valid channel report can be made pending, an additional machine-check-interruption condition is generated.

When a channel report consists of multiple chained CRWs, they are presented to the program in the same order that they are placed in the chain by the channel subsystem as a result of consecutive executions of STORE CHANNEL REPORT WORD. If, for example, the first CRW of a chain is presented to the program as a result of executing STORE CHANNEL REPORT WORD, the CRW that is presented as a result of the next execution of STORE CHANNEL REPORT WORD is the second CRW of the same chain and not a CRW that is part of another channel report.

Channel reports are not presented to the program in any special order, except for channel reports whose first or only CRW indicates the same reporting-source code and the same reporting-source ID. These channel reports are presented to the program in the same order that they are generated by the channel subsystem, but they are not necessarily presented consecutively. For example, suppose the channel subsystem generates channel reports A, B, and C, in that order. The first CRW of channel reports B and C indicates the same reporting-source code and the same reporting-source ID. Channel report B is presented to the program before channel report C is presented, but channel report A may be presented after channel report B and before channel report C.

Programming Notes:

1. The information that is provided in a single CRW may be made obsolete by another CRW that is subsequently generated for the same channel-subsystem facility. Therefore, the information that is provided in one channel report should be interpreted in light of the information provided by all of the channel reports that are pending at a given instant.
2. A machine-check-interruption condition is not always generated when a channel report is made pending. The conditions that result in a machine-check-interruption condition being generated are described earlier in this section.

3. After a machine-check interruption has occurred with bit 9 of the machine-check-interruption code set to one, STORE CHANNEL REPORT WORD should be issued repeatedly until all of the pending channel reports have been cleared and condition code 1 has been set.

4. A CRW-overflow condition can occur if the program does not issue successive STORE CHANNEL REPORT WORD instructions in a timely manner after the machine-check interruption occurs.

5. The number of CRWs that can be pending at the same time is model dependent. During the existence of an overflow condition, CRWs that would have otherwise been made pending are lost and are never presented to the program.

Channel-Report Word

The channel-report word (CRW) provides information to the program that can be used to facilitate the recovery of an I/O operation, a device, or some element of the channel subsystem, such as a channel path or subchannel.

The format of the CRW is as follows:

```
   Solicited CRW (S): Bit 1, when one, indicates a solicited CRW. A CRW is considered by the channel subsystem to be solicited if it is made pending as the direct result of some action that is taken by the program. When bit 1 is zero, the CRW is unsolicited and has been made pending as the result of an action taken by the channel subsystem that is independent of the program.

   Overflow (R): Bit 2, when one, indicates that a CRW-overflow condition has been recognized since this CRW became pending and that one or more CRWs have been lost. This bit is one in the CRW that has most recently been set pending when the overflow condition is recognized. When bit 2 is zero, a CRW-overflow condition has not been recognized.

   A CRW that is part of a channel report is not made pending, even though the overflow condition does not exist, if an overflow condition prevented a previous CRW of that report from being made pending.

   Chaining (C): Bit 3, when one, and when the overflow flag is zero, indicates chaining of associated CRWs. Chaining of CRWs is indicated whenever a malfunction or other condition is described by more than a single CRW. The chaining flag is zero if the channel report is described by a single CRW or if the CRW is the last CRW of a channel report.

   The chaining flag is not meaningful if the overflow bit, bit 2, is one.

   Reporting-Source Code (RSC): Bits 4-7 identify the channel-subsystem facility that is associated with the channel report. Some facilities are further identified in the reporting-source-identification field (see below). The following combinations of bits identify the facilities:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Facility</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 1 0</td>
<td>Monitoring facility</td>
</tr>
<tr>
<td>0 0 1 1</td>
<td>Subchannel</td>
</tr>
<tr>
<td>0 1 0 0</td>
<td>Channel Path</td>
</tr>
<tr>
<td>1 0 0 1</td>
<td>Configuration-alert facility</td>
</tr>
<tr>
<td>1 0 1 1</td>
<td>Channel subsystem</td>
</tr>
</tbody>
</table>

   All other bit combinations in the reporting-source-code field are reserved.

   Ancillary Report (A): Bit 8, when one, indicates that a malfunction of a system component has occurred that was recognized previously or which has affected the activity of multiple channel-subsystem facilities. When the malfunction affects the activity of multiple channel-subsystem facilities, an ancillary-report condition is recognized for all of the affected facilities except one. This bit, when zero, indicates that this malfunction of a system component was not recognized previously. This bit is meaningful for all channel reports.

   Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions that affect chan-
nel-subsystem facilities. When ancillary-report recognition is not provided, bit 8 is set to zero.

**Error-Recovery Code (ERC):** Bits 10-15, when zero, indicate that the channel subsystem has error information regarding the channel-subsystem facility identified in the reporting-source code, and that the program can now request that information. Otherwise, bit positions 10-15 contain the error-recovery code that defines the recovery state of the channel-subsystem facility identified in the reporting-source code. This field, when used in conjunction with the reporting-source code, can be used by the program to determine whether the identified facility has already been recovered and is available for use or whether recovery actions are still required. The following error-recovery codes are defined:

<table>
<thead>
<tr>
<th>Bits</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>000000</td>
<td>Event-information pending</td>
</tr>
<tr>
<td>000001</td>
<td>Available</td>
</tr>
<tr>
<td>000010</td>
<td>Initialized</td>
</tr>
<tr>
<td>000011</td>
<td>Temporary error</td>
</tr>
<tr>
<td>000100</td>
<td>Installed parameters initialized</td>
</tr>
<tr>
<td>000101</td>
<td>Terminal</td>
</tr>
<tr>
<td>000110</td>
<td>Permanent error with facility not initialized</td>
</tr>
<tr>
<td>000111</td>
<td>Permanent error with facility initialized</td>
</tr>
<tr>
<td>001000</td>
<td>Installed parameters modified</td>
</tr>
<tr>
<td>001010</td>
<td>Installed parameters restored</td>
</tr>
</tbody>
</table>

**Explanation:**

1. Installed-parameters restored is presented only if reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility.

All other bit combinations in the error-recovery-code field are reserved.

The specific meaning of each error-recovery code depends on the particular reporting-source code that accompanies it in a CRW. The error-recovery codes are defined as follows:

- **Event-Information Pending:** Event information for the identified facility is available for retrieval by the program. This CRW does not indicate the state of the identified facility.

- **Available:** The identified facility is in the same state that the program would expect if the CRW had not been generated.

- **Initialized:** The identified facility is in the same state that existed immediately following the I/O-system reset that was part of the most recent system IPL.

- **Temporary Error:** The identified facility is not operating in a normal manner or has recognized the occurrence of an abnormal event. It is expected that subsequent actions either will restore the facility to normal operation or will record the appropriate information describing the abnormal event.

- **Installed Parameters Initialized:** This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed.

On some models that do not implement the restore-subchannel facility, or in the absence of enablement by the program of reporting of the installed-parameters-restored CRW by the restore-subchannel facility, the installed-parameters-initialized CRW may be reported as a result of the channel subsystem’s recovery of the facility designated by the reporting-source ID.

- **Terminal:** The identified facility is in a state such that an operation that was in progress can neither be completed nor terminated in the normal manner.

- **Permanent Error with Facility Not Initialized:** The identified facility is in a state of malfunction, and the channel subsystem has not caused a reset function to be performed for that facility.

- **Permanent Error with Facility Initialized:** The identified facility is in a state of malfunction, and the channel subsystem has caused or may have caused a reset function to be performed for that facility.

- **Installed Parameters Modified:** One or more parameters of the specified facility have been changed.

- **Installed Parameters Restored:** This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed from their most recent values back to their initialized values as a result of the channel subsystem’s recovery of the facility.

**Reporting-Source ID (RSID):** Bit positions 16-31 contain the reporting-source ID, which may, depending upon the condition that caused the channel report...
and the reporting-source code, either further identify
the affected channel-subsystem facility or provide
additional information describing the condition that
cased the channel report. The RSID field has the
following format as a function of the bit settings of the
reporting-source code.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

When the MSS facility is installed an additional CRW is chained to every channel report for subchannels. The content of this chained CRW is identical to the original CRW except for the RSID field. In this chained CRW, bit positions 10-11 of the RSID field contain the SSID identifying the subchannel set.

### Report-Subchannel Facility

The report-subchannel facility may be available on a model implementing z/Architecture. This facility provides the means for the channel subsystem to recover a damaged subchannel and report the recovery to the program by means of a CRW. When the facility is installed and reporting of the installed-parameters-restored CRW is enabled in the report-subchannel facility, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters restored.

In some models that do not implement the report-subchannel facility, the channel subsystem may nevertheless recover a damaged subchannel, and make a CRW pending that indicates installed-parameters initialized.

### Extended-Subchannel-Logout Facility

When the extended-subchannel-logout facility is installed and enabled, all fibre-channel (FC) channel paths can create extended-subchannel logouts, under applicable error conditions, and generate I/O interruptions that indicate such a logout is pending retrieval. The extended-subchannel logouts are stored in and retrieved from a model-dependent number of extended-subchannel-logout buffers associated with each channel path supported by the facility.

When TEST SUBCHANNEL for a subchannel that specifies an FC channel path stores an interruption-response block (IRB) containing a format-0 ESW in which the extended-subchannel-logout-pending (E) bit is 1, an extended-subchannel logout is pending for the specified subchannel. Words 2-3 of the format-0 ESW contain the extended-subchannel-logout descriptor (ESLD) that identifies the logout and the channel path for which the logout is pending.

When all the buffers for a given channel contain pending extended-subchannel logouts, the logouts will remain pending for a model-dependent time interval. If, during that time interval, a subsequent condition occurs that warrants a new extended-subchannel logout, that logout is not made and is lost. If the time interval has been exceeded and the program has not used the ESLD to retrieve a pending logout, the logout may be removed from the buffer or the buffer may be reused to contain a subsequent logout. When a logout is removed from a buffer and the buffer is not reused, the ESLD is no longer recognized as a valid logout identifier. When a buffer is reused, the ESLD may be recognized as a valid logout identifier albeit for a logout different from the logout for which the original I/O interruption was generated.
Channel-Subsystem-I/O-Priority Facility

The channel-subsystem-I/O-priority facility provides a means by which the program can establish a priority relationship, at the channel subsystem, among the subchannels that are placed into the start-pending state when START SUBCHANNEL is executed and condition code 0 is indicated. For I/O-subchannels that are configured to fibre-channel channel paths (FICON and FICON-converted channel paths), it also provides a means by which the program can establish a priority relationship for I/O operations at the fibre-channel-attached control units.

The program assigns the desired channel-subsystem priority and control-unit priority by specifying the desired priority numbers in the ORB extension when START SUBCHANNEL is executed.

The channel-subsystem-priority number specified in the ORB is used by the channel subsystem to determine the order in which start-pending and resume-pending subchannels are selected when the channel subsystem attempts to initiate a start function or a resume function. See the section “Start Function and Resume Function” on page 20 for details about these functions. In general, I/O subchannels that are in the start-pending or resume-pending state and have a higher priority number are selected for start-function or resume-function initiation by the channel subsystem before start-pending or resume-pending subchannels that have a lower priority number. The specific priority selection algorithm used by the channel subsystem for this purpose depends on the model. Additionally, the channel subsystem also applies a fairness selection algorithm in conjunction with the priority selection algorithm when selecting I/O subchannels. The specific fairness selection algorithm also depends on the model. For all models, the channel-subsystem priority and fairness selection algorithms are always applied to I/O subchannels that are either start pending or resume pending. Some models may also apply both algorithms to subchannels that are either clear pending or halt pending. See a model's System-Library publication for a description of the priority and fairness selection algorithms that the model provides and whether these algorithms are also applied to clear-pending or halt-pending subchannels.

The control-unit-priority number specified in the ORB is used by control units attached to fibre-channel channel paths in order to determine the priority of the execution of CCWs at the control unit. See “Control-Unit (CU) Priority:” on page 29 for additional information.

Number of Channel-Subsystem-Priority Levels

Depending on the model, fewer than 256 channel-subsystem-priority levels may be provided by the channel subsystem. Each priority level that the model provides is designated by an eight-bit unsigned binary integer. The lowest provided channel-subsystem-priority level is designated by the integer 0, and each succeeding higher priority level is designated by the next-higher sequential integer. For example, if the model provides 16 priority levels, they are numbered 0-15, respectively, from the lowest priority level to the highest priority level.

Multiple-Subchannel-Set Facility

The multiple-subchannel-set (MSS) facility increases the maximum number of subchannels that can be configured to a program. When the MSS facility is not provided, a single set of subchannels, in the range 0-65,535 may be provided for a program. When the MSS facility is provided, a maximum of four sets of subchannels may be provided for a program. Each subchannel set provides from one to 64K subchannels in the range 0 to 65,535. A two-bit unsigned binary integer, in the range of 0-3, called the subchannel-set identifier (SSID) is used to specify each provided subchannel set. The default subchannel set for a program is SSID 0. The initialized state of the MSS facility is disabled, in this state the MSS facility functions are not provided to programs executing in logical partitions.

When the MSS facility is provided, a subchannel is specified by a unique address formed by the concatenation of:

1. The subchannel-set identifier (SSID) of the subchannel-image set to which the designated subchannel-image is configured,

2. The subchannel number of the subchannel-image being accessed.

HFP Arithmetic

HFP Number Representation

A hexadecimal-floating-point (HFP) number consists of a sign bit, a hexadecimal fraction, and an unsigned seven-bit binary integer called the characteristic. The characteristic represents a signed exponent and is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63. The magnitude of an HFP number is the product of its fraction and the number 16 raised to the power of the exponent that is represented by its characteristic. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The fraction of an HFP number is treated as a hexadecimal number because it is considered to be multiplied by a number which is a power of 16. The name, fraction, indicates that the radix point is assumed to be immediately to the left of the leftmost fraction digit.

When an HFP operation would cause the result exponent to exceed 63, the characteristic wraps around from 0 to 127, and an HFP-exponent-underflow condition exists. The result characteristic is then too large by 128, except that a zero characteristic is produced when a true zero is forced.

A true zero is an HFP number with a zero characteristic and zero fraction. A true zero may arise as the normal result of an arithmetic operation because of the particular magnitude of the operands. For HFP operations, the result is forced to be a positive true zero when:

1. An HFP exponent underflow occurs and the HFP-exponent-underflow mask bit in the PSW is zero.
2. The result fraction of a normalized or unnormalized addition or subtraction operation is zero and the HFP-significance mask bit in the PSW is zero.
3. The operand of the CONVERT FROM FIXED instruction is zero.
4. The dividend in the DIVIDE instruction has a zero fraction.
5. The operand of the HALVE, LOAD FP INTEGER, or SQUARE ROOT instruction has a zero fraction.
6. One or both operands of a multiplication operation has a zero fraction.
When a program interruption for HFP exponent underflow occurs, a true zero is not forced; instead, the fraction and sign remain correct, and the characteristic is too large by 128. When a program interruption for HFP significance occurs, the fraction remains zero, the sign is positive, and the characteristic remains correct.

The sign of a sum, difference, product, quotient, square root, the result of CONVERT FROM FIXED, or the result of LOAD FP INTEGER with a zero fraction is positive. The sign for a zero fraction resulting from other HFP operations is established from the operand sign, the same as for nonzero fractions.

**Normalization**

A quantity can be represented with the greatest precision by an HFP number of a given fraction length when that number is normalized. A normalized HFP number has a nonzero leftmost hexadecimal fraction digit. If one or more leftmost fraction digits are zeros, the number is said to be unnormalized.

Unnormalized numbers are normalized by shifting the fraction left, one digit at a time, until the leftmost hexadecimal digit is nonzero and reducing the characteristic by the number of hexadecimal digits shifted. A number with a zero fraction cannot be normalized; either its characteristic remains unchanged or its characteristic is made zero when the result is forced to be a true zero.

Addition and subtraction with extended operands, as well as the MULTIPLY, DIVIDE, CONVERT FROM FIXED, HALVE, LOAD FP INTEGER, and SQUARE ROOT operations, are performed only with normalization. Addition and subtraction with short or long operands may be specified as either normalized or unnormalized. For all other operations, the result is produced without normalization.

With unnormalized operations, leftmost zeros in the result fraction are not eliminated. The result may or may not be in normalized form, depending upon the original operands.

In both normalized and unnormalized operations, the initial operands need not be in normalized form. The operands for multiply, divide, and square-root operations are normalized before the arithmetic process. For other normalized operations, normalization takes place when the intermediate arithmetic result is changed to the final result.

When the intermediate result of addition, subtraction, or rounding causes the fraction to overflow, the fraction is shifted right by one hexadecimal-digit position, and the value one is supplied to the vacated leftmost digit position. The fraction is then truncated to the final result length, while the characteristic is increased by one. This adjustment is made for both normalized and unnormalized operations.

Figure 18-1 on page 18-3 summarizes, for all instructions producing HFP results, the handling of zero results and whether normalization occurs for nonzero results.

**Programming Note:** Up to three leftmost bits of the fraction of a normalized number may be zeros, since the nonzero test applies to the entire leftmost hexadecimal digit.

**HFP Data Formats**

HFP numbers have a 32-bit (short) format, a 64-bit (long) format, or a 128-bit (extended) format. Numbers in the short and long formats may be designated as operands both in storage and in the floating-point registers, whereas operands having the extended format can be designated only in the floating-point registers.

In all formats, the first bit (bit 0) is the sign bit (S). The next seven bits are the characteristic. In the short and long formats, the remaining bits constitute the fraction, which consists of six or 14 hexadecimal digits, respectively.

**Explanation:**

- Not applicable.
- Floating-point-support instruction.

Y/N When the HFP-significance mask bit (PSW bit 23) is zero, a true zero is forced. When the HFP-significance mask bit is one, the characteristic remains unchanged, and a program interruption for HFP significance occurs.

*Figure 18-1. Normalization and Zero Handling for Instructions with HFP Results*
An extended HFP number has a 28-digit fraction and consists of two long HFP numbers that are called the high-order and low-order parts. The high-order part may be any long HFP number. The fraction of the high-order part contains the leftmost 14 hexadecimal digits of the 28-digit fraction. The characteristic and sign of the high-order part are the characteristic and sign of the extended HFP number. If the high-order part is normalized, the extended number is considered normalized. The fraction of the low-order part contains the rightmost 14 digits of the 28-digit fraction. The sign and characteristic of the low-order part of an extended operand are ignored.

When a result is generated in the extended format and placed in a register pair, the sign of the low-order part is made the same as that of the high-order part, and, unless the result is a true zero, the low-order characteristic is made 14 less than the high-order characteristic. The subtraction of 14 would cause the low-order characteristic to become less than zero, the characteristic is made 128 greater than its correct value. (Thus, the subtraction is performed modulo 128.) HFP exponent underflow is indicated only when the high-order characteristic underflows.

When an extended result is made a true zero, both the high-order and low-order parts are made a true zero.

The range covered by the magnitude (M) of a normalized HFP number depends on the format.

In the short format:
\[ 16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63} \]

In the long format:
\[ 16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63} \]

In the extended format:
\[ 16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63} \]

In all formats, approximately:
\[ 5.4 \times 10^{-79} \leq M \leq 7.2 \times 10^{75} \]

Although the final result of an HFP operation has six hexadecimal fraction digits in the short format, 14 fraction digits in the long format, and 28 fraction digits in the extended format, intermediate results have one additional hexadecimal digit on the right. This digit is called the guard digit. The guard digit may increase the precision of the final result because it participates in addition, subtraction, and comparison operations and in the left shift that occurs during normalization.

The entire set of HFP operations with normalized results is available for short, long, and extended operands in register-register versions; and for short and long operands in register-storage versions. Most instructions generate a result that has the same format as the source operands, except that there are multiplication operations which can generate a long product from short operands or an extended product from long operands. Other exceptions are instructions which convert operands from one floating-point format to another or between floating-point and fixed-point (binary-integer) formats.

**Programming Notes:**

1. In the absence of an HFP exponent overflow or HFP exponent underflow, the long HFP number constituting the low-order part of an extended result correctly expresses the value of the low-order part of the extended result when the characteristic of the high-order part is 14 or higher. This applies also when the result is a true zero. When the high-order characteristic is less than 14 but the number is not a true zero, the low-
order part, when considered as a long HFP number, does not express the correct characteristic value.

2. The entire fraction of an extended result participates in normalization. The low-order part alone may or may not appear to be a normalized long HFP number, depending on whether the 15th digit of the normalized 28-digit fraction is nonzero or zero.

Instructions

The HFP instructions and their mnemonics and operation codes are listed in Figure 18-2 on page 18-5. The figure indicates, in the column labeled “Characteristics”, the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All HFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the HFP instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for HFP instructions to represent operand-format length and normalization, as follows:

<table>

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CER is the mnemonic and R1,R2 the operand designation.

Programming Notes:

1. The following additional HFP instructions are available when the HFP-multiply-and-add/subtract facility is installed:
   - MULTIPLY AND ADD (MAD, MADR, MAE, MAER)
   - MULTIPLY AND SUBTRACT (MSD, MSDR, MSE, MSER)

2. The following additional HFP instructions are available when the HFP-unnormalized-extensions facility is installed:
   - MULTIPLY AND ADD UNNORMALIZED (MAY, MAYH, MAYHR, MAYL, MAYLR, MAYR)
   - MULTIPLY UNNORMALIZED (MY, MYH, MYHR, MYL, MYLR, MYR)

</table>

**Explanation:**

- $\sigma^7$ Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
- $\sigma^3$ Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
- A Access exceptions for logical addresses.
- B2 B2 field designates an access register in the access-register mode.
- C Condition code is set.
- Da AFP-register data exception.
- EO HFP-exponent-overflow exception.
- EU HFP-exponent-underflow exception.

The second operand is added to the first operand, and the normalized sum is placed at the first-operand location.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the two operands are compared, and the fraction accompanying the smaller characteristic is aligned with the other fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift until the two characteristics agree.

When a fraction is shifted right during alignment, the leftmost hexadecimal digit shifted out is retained as a guard digit. The fraction that is not shifted is considered to be extended with a zero in the guard-digit position. When no alignment shift occurs, both operands are considered to be extended with zeros in the guard-digit position. The fractions with signs are then added algebraically to form a signed intermediate sum.

The intermediate-sum fraction consists of seven (short format), 15 (long format), or 29 (extended format) hexadecimal digits, including the guard digit, and a possible carry. If a carry is present, the sum is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

If the addition produces no carry, the intermediate-sum fraction is shifted left as necessary to eliminate any leading hexadecimal zero digits resulting from the addition, provided the fraction is not zero. Zeros are supplied to the vacated rightmost digits, and the characteristic is reduced by the number of hexadecimal digits of shift. The fraction thus normalized is then truncated on the right to six (short format), 14 (long format), or 28 (extended format) hexadecimal digits. In the extended format, a characteristic is generated for the low-order part, which is 14 less than the high-order characteristic.

The sign of the sum is determined by the rules of algebra, unless all digits of the intermediate-sum fraction are zero, in which case the sign is made plus.
An HFP-exponent-overflow exception exists when a carry from the leftmost position of the intermediate-sum fraction would cause the characteristic of the normalized sum to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. For extended results, the characteristic of the low-order part remains correct.

An HFP-exponent-underflow exception exists when the characteristic of the normalized sum would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

The result fraction is zero when the intermediate-sum fraction, including the guard digit, is zero. With a zero result fraction, the action depends on the setting of the HFP-significance mask bit in the PSW. If the HFP-significance mask bit in the PSW is one, no normalization occurs, the intermediate and final result characteristics are the same, and a program interruption for HFP significance occurs. If the HFP-significance mask bit in the PSW is zero, the program interruption does not occur; instead, the result is made a positive true zero.

For AXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Result is zero</td>
</tr>
<tr>
<td>1</td>
<td>Result is less than zero</td>
</tr>
<tr>
<td>2</td>
<td>Result is greater than zero</td>
</tr>
<tr>
<td>3</td>
<td>--</td>
</tr>
</tbody>
</table>

**Program Exceptions:**

- Access (fetch, operand 2 of AE and AD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (AXR only)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the ADD NORMALIZED instruction (AE) is given in Appendix A.
2. Interchanging the two operands in an HFP addition does not affect the value of the sum.
3. The ADD NORMALIZED instruction normalizes the sum but not the operands. Thus, if one or both operands are unnormalized, precision may be lost during fraction alignment.

**ADD UNNORMALIZED**

<table>
<thead>
<tr>
<th>Mnemonic1</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUR</td>
<td>'3E'</td>
<td>Short HFP</td>
</tr>
<tr>
<td>AWR</td>
<td>'2E'</td>
<td>Long HFP</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mnemonic2</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>AU</td>
<td>'7E'</td>
<td>Short HFP</td>
</tr>
<tr>
<td>AW</td>
<td>'6E'</td>
<td>Long HFP</td>
</tr>
</tbody>
</table>

The second operand is added to the first operand, and the unnormalized sum is placed at the first-operand location.

The execution of ADD UNNORMALIZED is identical to that of ADD NORMALIZED, except that:

1. When no carry is present after the addition, the intermediate-sum fraction is truncated to the proper result-fraction length without a left shift to eliminate leading hexadecimal zeros and without the corresponding reduction of the characteristic.
2. HFP exponent underflow cannot occur.
3. The guard digit does not participate in the recognition of a zero result fraction. A zero result frac-
tion is recognized when the fraction (that is, the intermediate-sum fraction, excluding the guard digit) is zero.

**Resulting Condition Code:**

0  Result fraction zero
1  Result less than zero
2  Result greater than zero
3  --

**Program Exceptions:**

- Access (fetch, operand 2 of AU and AW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance
- Transaction constraint

**Programming Notes:**

1. An example of the use of the ADD UNNORMALIZED instruction (AU) is given in Appendix A.

2. Except when the result is made a true zero, the characteristic of the result of ADD UNNORMALIZED is equal to the greater of the two operand characteristics, increased by one if the fraction addition produced a carry, or set to zero if HFP exponent overflow occurred.

---

**COMPARE**

<th>Mnemonic3 R1,D2(X2,B2) [RX-a]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mnemonic3 Op Code Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CE  '79' Short HFP</td>
</tr>
<tr>
<td>CD  '69' Long HFP</td>
</tr>
</tbody>
</table>

The first operand is compared with the second operand, and the condition code is set to indicate the result.

The comparison is algebraic and follows the procedure for normalized subtraction, except that the difference is discarded after setting the condition code and both operands remain unchanged. When the difference, including the guard digit, is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

An HFP-exponent-overflow, HFP-exponent-underflow, or HFP-significance exception cannot occur.

For CXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Operands equal
1  First operand low
2  First operand high
3  --

**Program Exceptions:**

- Access (fetch, operand 2 of CE and CD only)
- Data with DXC 1, AFP register
- Specification (CXR only)
- Transaction constraint

**Programming Notes:**

1. Examples of the use of the COMPARE instruction (CDR) are given in Appendix A.

2. An exponent inequality alone is not sufficient to determine the inequality of two operands with the same sign, because the fractions may have different numbers of leading hexadecimal zeros.

3. Numbers with zero fractions compare equal even when they differ in sign or characteristic.
CONVERT FROM FIXED

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEFR</td>
<td>'B3B4'</td>
<td>32-bit binary-integer operand, short HFP result</td>

<td>'B3C6'</td>
<td>64-bit binary-integer operand, extended HFP result</td>
<td></td>
</tr>
</tbody>
</table>

The fixed-point second operand is converted to the HFP format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

The second operand is a signed binary integer that is located in the general register designated by \( R_2 \). A 32-bit operand is in bit positions 32-63 of the register.

The result is normalized and rounded toward zero (truncated) before it is placed at the first-operand location.

For CXFR and CXGR, the \( R_1 \) field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Specification (CXFR and CXGR)
- Transaction constraint

CONVERT TO FIXED

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEFR</td>
<td>'B3B8'</td>
<td>Short HFP operand, 32-bit binary-integer result</td>
</tr>
<tr>
<td>CFDR</td>
<td>'B3B9'</td>
<td>Long HFP operand, 32-bit binary-integer result</td>
</tr>
<tr>
<td>CFXR</td>
<td>'B3BA'</td>

</tr>
<tr>
<td>CGXR</td>
<td>'B3CA'</td>
<td>Extended HFP operand, 64-bit binary-integer result</td>
</tr>
</tbody>
</table>

The HFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by \( R_1 \). For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

The second operand is rounded to an integer value by rounding as specified by the modifier in the \( M_3 \) field:

**\( M_3 \) Effective Rounding Method**
- 0 Round toward 0
- 1 Round to nearest with ties away from 0
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward \(+\infty\)
- 7 Round toward \(-\infty\)

For details on rounding see the section “Rounding Methods” on page 9-13.

A modifier other than 0, 1, or 4-7 is invalid.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

If the rounded result would have a value exceeding the range that can be represented in the result format, the largest (in magnitude) representable num-
The number of the same sign as the source is placed at the target location, and condition code 3 is set.

HFP exponent underflow is not recognized because small values are rounded to one (with the appropriate sign) or to zero, depending on the rounding mode.

The M3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CFXR and CGXR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Source was zero  
1  Source was less than zero  
2  Source was greater than zero  
3  Special case

**Program Exceptions:**

- Data with DXC 1, AFP register  
- Specification  
- Transaction constraint

The first operand (the dividend) is divided by the second operand (the divisor), and the normalized quotient is placed at the first-operand location. No remainder is preserved.

HFP division consists in characteristic subtraction and fraction division. The operands are first normalized to eliminate leading hexadecimal zeros. The difference between the dividend and divisor characteristics of the normalized operands, plus 64, is used as the characteristic of an intermediate quotient.

All dividend and divisor fraction digits participate in forming the fraction of the intermediate quotient. The intermediate-quotient fraction can have no leading hexadecimal zeros, but a right shift of one digit position may be necessary, with this causing an increase of the characteristic by one. The fraction is then truncated to the proper result-fraction length.

An HFP-exponent-overflow exception exists when the characteristic of the final quotient would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

An HFP-exponent-underflow exception exists when the characteristic of the final quotient would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands or when the intermediate-quotient characteristic is less than zero, as long as the final quotient can be represented with the correct characteristic.
When the divisor fraction is zero, an HFP-divide exception is recognized. This includes the case of division of zero by zero.

When the dividend fraction is zero but the divisor fraction is nonzero, the quotient is made a positive true zero. No HFP exponent overflow or HFP exponent underflow occurs.

The sign of the quotient is the exclusive or of the operand signs, except that the sign is always plus when the quotient is made a positive true zero.

For DXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of DE and DD only)
- Data with DXC 1, AFP register
- HFP divide
- HFP exponent overflow
- HFP exponent underflow
- Specification (DXR only)
- Transaction constraint

**Programming Note:** Examples of the use of the DIVIDE instruction (DER) are given in Appendix A.

### HALVE

<table>
<thead>
<tr>

<th>[RR]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code</td>
<td>R&lt;sub&gt;1&lt;/sub&gt;</td>
<td>R&lt;sub&gt;2&lt;/sub&gt;</td>
</tr>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

**Mnemonic** | **Op Code** | **Operands**
---|---|---
HER | '34' | Short HFP
HDR | '24' | Long HFP

The second operand is divided by 2, and the normalized quotient is placed at the first-operand location.

The fraction of the second operand is shifted right one bit position, placing the contents of the rightmost bit position in the leftmost bit position of the guard digit, and a zero is supplied to the leftmost bit position of the fraction. The intermediate result, including the guard digit, is then normalized, and the final result is truncated to the proper length.

An HFP-exponent-underflow exception exists when the characteristic of the final result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

When the fraction of the second operand is zero, the result is made a positive true zero, and no HFP exponent underflow occurs.

The sign of the result is the same as that of the second operand, except that the sign is always plus when the quotient is made a positive true zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- HFP exponent underflow
- Transaction constraint

**Programming Notes:**

1. An example of the use of the HALVE instruction (HDR) is given in Appendix A.

2. With short and long operands, the halve operation is identical to a divide operation with the number 2 as divisor. Similarly, the result of HDR is identical to that of MD or MDR with one-half as a multiplier, and the result of HER is identical to that of MEE or MEER with one-half as a multiplier.

### LOAD AND TEST

Mnemonic2   Op Code   Operands

LTXR 'B362' Extended HFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

For short and long operands, the second operand is placed unchanged in the first-operand location.

For extended operands, the high-order sign and the entire fraction of the source are placed unchanged in the result, and the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the high-order sign bit of the source).

For LTXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LTXR only)
- Transaction constraint

Programming Note: When, for LTER and LTDR, the same register is designated as the first-operand and second-operand location, the operation is equivalent to a test without data movement.

LCXR 'B363' Extended HFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. For all operand lengths, the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the sign inverted from the source (the high-order and low-order sign bits of the result are inverted from the high-order sign bit of the source).

For LCXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LCXR only)
- Transaction constraint
LOAD FP INTEGER

<table>
<thead>
<tr>

<td>'B367'</td>
<td>Extended HFP</td>
</tr>
</tbody>
</table>

The second operand is truncated (rounded toward zero) to an integer value in the same floating-point format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

For FIXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC 1, AFP register
- Specification (FIXR only)
- Transaction constraint

**Programming Notes:**
1. LOAD FP INTEGER truncates (rounds toward zero) an HFP number to an integer value. These integers, which remain in the HFP format, should not be confused with binary integers, which use a fixed-point format.
2. If the HFP operand has a large enough exponent so that it is already an integer, the result value remains the same, except that an unnormalized operand is normalized, and an operand with a zero fraction is changed to a positive true zero.

LOAD LENGTHENED

**LOAD ROUNDED**

Mnemonic 1: \texttt{R1,R2} [RR]

<table>
<thead>
<tr>
<th>Op Code</th>
<th>0</th>
<th>8</th>
<th>12</th>
<th>15</th>
</tr>
</thead>
</table>

**Mnemonic 1 Op Code**

- LDR '35' Long HFP operand 2, short HFP operand 1
- LDXR '25' Extended HFP operand 2, long HFP operand 1

The above mnemonics are alternatives to the following older mnemonics that are less descriptive of operand lengths:

- LER '35' Long HFP operand 2, short HFP operand 1
- LRDR '25' Extended HFP operand 2, long HFP operand 1

The sign of the result is the same as the sign of the second operand. There is no normalization to eliminate leading zeros.

An HFP-exponent-overflow exception exists when shifting the fraction right would cause the characteristic to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP-exponent-underflow and HFP-significance exceptions cannot occur.

For LDXR (or LRDR) and LEXR, the \texttt{R2} field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- HFP exponent overflow
- Specification (LDXR, LEXR, LRDR)
- Transaction constraint

**Programming Note:** The sign of the rounded result is the same as the sign of the operand, even when the result is zero.

**MULTIPLY**

Mnemonic 1: \texttt{R1,R2} [RRE]

<table>
<thead>
<tr>
<th>Op Code</th>
<th>0</th>
<th>16</th>
<th>24</th>
<th>28</th>
<th>31</th>
</tr>
</thead>
</table>

**Mnemonic 1 Op Code**

- MEER 'B337' Short HFP multiplier and multiplicand, long HFP product
- MXR '26' Extended HFP multiplier and multiplicand, long HFP product
- MDER '3C' Short HFP multiplier and multiplicand, long HFP product
- MXDR '27' Extended HFP multiplier and multiplicand, long HFP product

The sign of the result is the same as the sign of the second operand. There is no normalization to eliminate leading zeros.

If rounding causes a carry out of the leftmost hexadecimal digit position of the fraction, the fraction is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

The intermediate fraction is then truncated to the proper result-fraction length. For LDR and LEXR, the result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. For LDXR, the 64-bit result is placed in a floating-point register, not a floating-point register pair.
The above mnemonic MDER is an alternative to the following older mnemonic that is less descriptive of operand lengths:
MER ‘3C’ Short HFP multiplier and multiplicand, long HFP product

Mnemonic3 R1, D2(X2, B2) [RXE]
0 8 12 16 20 32 40 47

Mnemonic3 Op Code Operands
MEE ‘ED37’ Short HFP

Mnemonic4 R1, D2(X2, B2) [RX-a]
Op Code R1 X2 B2 D2
0 8 12 16 20 31

Mnemonic4 Op Code Operands
MD ‘6C’ Long HFP
MDE ‘7C’ Short HFP multiplier and multiplicand, long HFP product
MXD ‘67’ Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDE is an alternative to the following older mnemonic that is less descriptive of operand lengths:
ME ‘7C’ Short HFP multiplier and multiplicand, long HFP product

The normalized product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The operands are first normalized to eliminate leading hexadecimal zeros. The sum of the characteristics of the normalized operands, less 64, is used as the characteristic of the intermediate product.

The fraction of the intermediate product is the exact product of the normalized operand fractions. If the intermediate-product fraction has one leading hexadecimal zero digit, the fraction is shifted left one digit position, bringing the contents of the guard-digit position into the rightmost position of the result fraction, and the intermediate-product characteristic is reduced by one. The fraction is then truncated to the proper result-fraction length.

For MDE and MDER, the multiplier and multiplicand fractions have six hexadecimal digits; the product fraction has the full 14 digits of the long format, with the two rightmost fraction digits always zeros. For MEE and MEER, the multiplier and multiplicand fractions have six digits, and the final product fraction is truncated to six digits; the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

For MD and MDR, the multiplier and multiplicand fractions have 14 digits, and the final product fraction is truncated to 14 digits. For MXD and MXDR, the multiplier and multiplicand fractions have 14 digits, with the multiplicand occupying the high-order part of the first operand; the final product fraction contains 28 digits and is an exact product of the operand fractions. For MXR, the multiplier and multiplicand fractions have 28 digits, and the final product fraction is truncated to 28 digits.

An HFP-exponent-overflow exception exists when the characteristic of the final product would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

HFP exponent overflow is not recognized when the intermediate-product characteristic is initially 128 but is brought back within range by normalization.

An HFP-exponent-underflow exception exists when the characteristic of the final product would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands, as long as the final product can be represented with the correct characteristic.
If either or both operand fractions are zero, the result is made a positive true zero, and no HFP exponent overflow or HFP exponent underflow occurs.

The sign of the product is the exclusive or of the operand signs, except that the sign is always plus when the result is made a true zero.

The \( R_1 \) field for MXD, MXDR, and MXR, and the \( R_2 \) field for MXR must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of MDE, MEE, MD, and MXD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Specification (MXD, MXDR, MXR)
- Transaction constraint

**Programming Notes:**

1. An example of the use of the MULTIPLY instruction (MDR) is given in Appendix A.
2. Interchanging the two operands in an HFP multiplication does not affect the value of the product.

**MULTIPLY AND ADD**

<tr>
<td>MAD</td>
<td>'ED3E'</td>
<td>Long HFP</td>
</tr>
</tbody>
</table>

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

\[ \text{op}_1 = \text{op}_3 \pm \text{op}_2 \]

The third and second HFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate result. The exponent and fraction of the intermediate product and intermediate result are maintained exactly. The intermediate result, if nonzero, is normalized and truncated to the operand format and then placed at the first-operand location.

The sign of the result is determined by the rules of algebra, unless the intermediate-result fraction is zero, in which case the result is made a positive true zero.

An HFP-exponent-overflow exception exists when the characteristic of the normalized result would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP exponent overflow is not recognized on intermediate values, provided the normalized result can be represented with the correct characteristic.
An HFP-exponent-underflow exception exists when the characteristic of the normalized result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

HFP exponent underflow is not recognized on input operands and intermediate values, provided the normalized result can be represented with the correct characteristic.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of MAE, MAD, MSE, MSD)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Operation (if the HFP multiply-add/subtract facility is not installed)
- Transaction constraint

**Programming Note:** MULTIPLY AND ADD (SUBTRACT) differs from MULTIPLY followed by ADD (SUBTRACT) NORMALIZED in the following ways:

1. The product is maintained to full precision, and overflow and underflow are not recognized on the product.

2. The HFP-significance exception is not recognized for MULTIPLY AND ADD (SUBTRACT).

3. ADD (SUBTRACT) NORMALIZED maintains only a single guard digit and does not prenormalize input operands; thus, in some cases, an unnormalized input operand may cause loss of precision in the result. MULTIPLY AND ADD (SUBTRACT) maintains the entire intermediate sum (difference), which is normalized before the truncation operation is performed; thus, unnormalized operands do not cause any additional loss of precision.

4. On most models, the execution time of MULTIPLY AND ADD (SUBTRACT) is less than the combined execution time of MULTIPLY followed by ADD (SUBTRACT) NORMALIZED. The performance of MULTIPLY AND ADD (SUBTRACT) may be severely degraded in the case of unnormalized input operands.

</tbody>
</table>

The second and third HFP operands are multiplied, forming an intermediate product; the first operand (addend) is then added algebraically to the intermediate product to form an intermediate sum; the intermediate-sum fraction is truncated on the left or on the right, if need be, to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R1 field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

The MULTIPLY AND ADD UNNORMALIZED operations may be summarized as:

\[ t_1 \leftarrow op_2 \cdot op_3 + op_1 \]

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-
order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting in the subsequent addition.

In all cases, the first operand is located in the floating-point register designated by the R₁ field and the first-operand fraction has 14 digits.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the intermediate product and the addend are compared. If the characteristics are equal, no alignment is required. If the characteristic of the addend is smaller than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift. If the characteristic of the addend is larger than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a left shift, with its characteristic decreased by one for each hexadecimal digit of shift. Shifting continues until the two characteristics agree. All hexadecimal digits shifted out are preserved and participate in the subsequent addition.

After alignment, the fractions with signs are then added algebraically to form a signed intermediate sum. The fraction of the intermediate sum is maintained exactly. The intermediate-sum fraction is not inspected for leading hexadecimal zero digits and is not shifted. Only those 28 hexadecimal digits of the intermediate-sum fraction which are aligned with the 28 hexadecimal digits of the intermediate-product fraction are used as the fraction of the intermediate extended-result.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

The sign of the result is determined by the rules of algebra, unless the entire intermediate-sum fraction is zero, in which case the sign of the result is made positive.

For MAY and MAYR, the entire intermediate extended result is placed in the floating-point register-pair designated by the R₁ field; the R₁ field may designate either the lower-numbered or higher-numbered register of a floating-point-register pair. For MAYH and MAYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R₁ field and the low-order part is discarded. For MAYL and MAYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R₁ field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of MAYH, MAY, and MAYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Transaction constraint

**Programming Notes:**

1. While performance of MULTIPLY AND ADD may be severely degraded for the case of unnormalized input operands, this is not the case for MULTIPLY AND ADD UNNORMALIZED.

2. MULTIPLY AND ADD UNNORMALIZED can be used to efficiently perform multiple precision arithmetic on numbers of any arbitrary size. This is accomplished by organizing the numbers into big digits of 52 bits each, with each big digit maintained as an integer in the HFP long format. Using a radix of $2^{52}$ and big digits which can hold up to 56 bits provides a redundant representation. This redundant representation permits multiplication and addition using a “carry save” technique and permits maximum utilization of the floating-point pipeline.
3. By setting the multiplier to an integer value of 1 with the proper characteristic, the multiplicand can be scaled by any power of 16 and then added to the addend. This permits, for example, adding the “carry” from one stage of a multiplication to the “sum” of the next stage to the left. In the same manner, the “sum” of one stage can be scaled to be added to the “carry” of the stage to the right.

4. In the first round of a multiply and accumulate, the step of clearing the accumulated value to zero, may be avoided by using the MULTIPLY UNNORMALIZED instead of MULTIPLY AND ADD UNNORMALIZED.

5. For additional notes concerning the unnormalized operations see the programming notes under the MULTIPLY UNNORMALIZED instruction.

The second and third HFP operands are multiplied, forming an intermediate product, which, in turn, is used to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R1 field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting as the fraction of the intermediate extended result.

The sign of the result is the exclusive or of the operand signs, including the case when the result fraction is zero.

For MY and MYR, the entire intermediate extended result is placed in the floating-point-register pair designated by the R1 field. For MYH and MYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R1 field and the low-order part is discarded. For MYL and MYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R1 field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

The R1 field for MY and MYR must designate a valid floating-point-register pair. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.
Program Exceptions:

- Access (fetch, operand 2 of MYH, MY, and MYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Specification (MY and MYR)
- Transaction constraint

Programming Notes:

1. The formal definition of Long HFP numbers is in terms of a 14-digit fraction and a signed exponent in "excess-64 notation". But, without change in function, these numbers can also be described as having a 14-digit integer and a signed exponent in “excess-78 notation”. When using the unnormalized instructions, the programmer may find it more convenient to consider these values in the later terms rather than the former. Thus, in these terms, MULTIPLY UNNORMALIZED multiplies two 14-digit integers to produce a 28-digit integer result. The characteristic of the low-order part is the sum of the operand characteristics less 78 and the high-order characteristic is set 14 larger than the low-order part. When considered as described above, MULTIPLY UNNORMALIZED provides the exact 28-digit integer product of two 14-digit integers.

2. Rather than using MY (or MYR) to provide the entire 28-digits in a floating-point-register pair, the programmer may find it more convenient to issue two separate instructions, MYH and MYL (or MYHR and MYLR), to place the high-order part and low-order part in any floating-point register. It is expected that on most machines, the performance of these two approaches is essentially the same.

3. The MULTIPLY UNNORMALIZED instruction format designates three operand locations and can be used to produce a product without overlaying the source operands. In many cases this saves an extra load.

0 & 12 & 16 & 20 & 32 & 40 \\
0 & 16 & 20 & 24 & 28 & 31 \\
0 & 20 & 24 & 28 & 32 & 40 \\
0 & 24 & 28 & 32 & 36 & 40 \\
0 & 28 & 32 & 36 & 40 & 47 \\
\end{array}
\]

- SQER 'B245' Short HFP
- SQDR 'B244' Long HFP
- SQXR 'B336' Extended HFP
- SOE 'ED34' Short HFP
- SQD 'ED35' Long HFP

The normalized and rounded square root of the second operand is placed at the first-operand location.

When the fraction of the second operand is zero, the sign and characteristic of the second operand are ignored, and the operation is completed by placing a positive true zero at the first-operand location.

If the second operand is less than zero, an HFP-square-root exception is recognized.

If the second operand is normalized and greater than zero, the characteristic, fraction, and sign of the result are produced as follows:

- The result characteristic is one-half of the sum of the operand characteristic and either 64, if the operand characteristic is even, or 65, if it is odd.
- If the operand characteristic is odd, the operand fraction is shifted right one digit position, the rightmost digit entering the guard-digit position.
- An intermediate-result fraction is produced by computing without rounding the square root of the operand fraction, after any right shift as described. The intermediate-result fraction consists of the 29 most significant hexadecimal digits of the square-root result in the extended format, 15 in the long format, or seven in the short format, where all three formats include a guard digit on the right.
- A one is added to the leftmost bit of the guard digit of the intermediate result, any carry is prop-
agated to the left, and the guard digit is dropped to produce the result fraction.

- The result sign is made plus.

If the second operand is unnormalized and greater than zero, the operand is first normalized. The operation then proceeds as for normalized operands.

For SQXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of SQE and SQD only)
- Data with DXC 1, AFP register
- HFP square root
- Specification (SQXR only)
- Transaction constraint

**Programming Notes:**

1. The use of the SQUARE ROOT instruction with short operands (SQER) is illustrated by the examples in the following table:

<table>
<thead>
<tr>
<th>Operand (hex)</th>
<th>Decimal Value</th>
<th>Result (hex)</th>
<th>Decimal Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>42 190000</td>
<td>25.0</td>
<td>41 500000</td>
<td>5.0</td>
</tr>
<tr>
<td>40 400000</td>
<td>0.250</td>
<td>40 800000</td>
<td>0.50</td>
</tr>
<tr>
<td>40 800000</td>
<td>0.50</td>
<td>40 B504F3</td>
<td>0.7071...</td>
</tr>
<tr>
<td>41 800000</td>
<td>8.0</td>
<td>41 2D413D</td>
<td>2.8284...</td>
</tr>
</tbody>
</table>

2. The result fraction is correctly normalized without any further left or right shifts of the intermediate-result fraction and without any further exponent adjustment. Rounding cannot cause a carry out of the leftmost digit.

3. Although a characteristic greater than 127 or less than zero may temporarily be generated during the operation, the result characteristic is always within the representable range, and no HFP exponent overflow or underflow occurs.

Specifically, the smallest nonzero operand in the long format consists of a one bit, preceded on the left by 63 zeros. This operand is an unnormalized number with a value of $16^{-78}$, and its square root is $16^{-39}$. The normalized representation of this result has a characteristic of 26 (decimal). Similarly, the square root of the largest representable operand has a characteristic of 96 (decimal). The instruction, therefore, cannot produce a nonzero result with a characteristic outside the range of 26 to 96.

### Subtract Normalized

**Mnemonic1**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
</table>

**Mnemonic2**

| Op Code | R1 | X2 | B2 | D2 |

The second operand is subtracted from the first operand, and the normalized difference is placed at the first-operand location.

The execution of SUBTRACT NORMALIZED is identical to that of ADD NORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

For SXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

| 0  | Result is zero |
| 1  | Result is less than zero |
| 2  | Result is greater than zero |
| 3  | -- |

**Program Exceptions:**

- Access (fetch, operand 2 of SE and SD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (SXR only)
- Transaction constraint

Binary-Floating-Point Facility

The binary-floating-point (BFP) facility provides instructions to operate on binary (radix-2) floating-point data.

BFP provides a number of important advantages over hexadecimal floating point (HFP):

- Greater precision and exponent range (except for numbers in the short format where HFP has the greater range).
- Automatic rounding to the nearest value for all arithmetic operations. There are directed-rounding options that may be used instead.
- Special entities of “infinity” and “Not-a-Number” (NaN), which are accepted and handled by arithmetic operations in a reasonable fashion. They provide better defaults for exponent overflow and invalid operations (such as division of zero by zero). This allows most programs to continue running without hiding such errors and without using specialized exception handlers.
- Exponent underflow gives “subnormal” numbers as the default, which provides more consistent results than the abrupt result of zero produced by the HFP instructions.
- The greater exponent range makes exponent overflow and underflow in correctly written programs very unlikely, so that programmers may often be able to ignore these conditions.
- Both mask and flag bits are provided for all IEEE exceptions. The mask bits enable or disable interruptions. When interruptions are disabled, the flag bits keep track of exceptions during execution so that warning messages may be issued.
- Programs can be migrated from and to workstations and other systems using different architectures and still give consistent results, provided that floating-point operations on the other sys-
tems also conform to ANSI/IEEE Standard 754-2008 (see Reference [17.] on page xxviii). This does not mean, however, that bit-wise compatible results can be guaranteed, because the standard allows implementation flexibility, especially in the presence of exceptions.

Programming Note: The bit representation of the BFP data formats in storage is defined to be left-to-right in a manner that is uniform for all numeric operands in the z/Architecture architecture. Although the format diagrams in ANSI/IEEE Standard 754-2008 appear to use the same left-to-right bit sequence, the standard only defines the meaning of the bits without specifying how they appear in storage; the storage arrangement is left to the implementation. Several implementations in fact use other sequences; this may affect programs which are dependent on the bit representation of floating-point data in storage.

Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. The FPC register is described in the section “Floating-Point-Control (FPC) Register” on page 9-9. An overview of the FPC register is shown in Figure 9-5 on page 9-9. Details are shown in Figure 9-6 on page 9-9, Figure 9-7 on page 9-10, and in Figure 9-8 on page 9-10. (In Figure 9-6 on page 9-9, the abbreviations “IM” and “SF” are based on the terms “inter-ruption mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

BFP Arithmetic

BFP Data Formats

Binary-floating-point data may be represented in any of three formats: short, long, or extended.

<table>
<thead>
<tr>
<th>BFP Short Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>S Exponent+127</td>
</tr>
<tr>
<td>Fraction (23 bits)</td>
</tr>
<tr>
<td>0 1</td>
</tr>
<tr>
<td>9 31</td>
</tr>
</tbody>
</table>

Figure 19-1. BFP Short Format (4 bytes)

When an operand in the BFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

<table>
<thead>
<tr>
<th>BFP Long Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>S Exponent + 1023</td>
</tr>
<tr>
<td>Fraction (52 bits)</td>
</tr>
<tr>
<td>0 1</td>
</tr>
<tr>
<td>12 31</td>
</tr>
</tbody>
</table>

Figure 19-2. BFP Long Format (8 bytes)

When an operand in the BFP long format is loaded into a floating-point register, it occupies the entire register.

<table>
<thead>
<tr>
<th>BFP Extended Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>S Exponent + 16383</td>
</tr>
<tr>
<td>Fraction (112 bits)</td>
</tr>
<tr>
<td>0 1</td>
</tr>
<tr>
<td>16 31</td>
</tr>
</tbody>
</table>

Figure 19-3. BFP Extended Format (16 bytes)

An operand in the BFP extended format occupies a register pair. The sign and biased exponent are in the leftmost 16 bits of the lower-numbered register of the pair and are followed by the leftmost 48 bits of the fraction. The rightmost 64 bits of the fraction are in the higher-numbered register of the pair.

The properties of the three formats are tabulated in Figure 19-4 on page 19-3.

Biased Exponent

For each format, the bias that is used to allow all exponents to be expressed as unsigned numbers is shown in the Figure 19-4 on page 19-3. Biased exponents are similar to the characteristics of the HFP format, except that special meanings are attached to
biased exponents of all zeros and all ones, which are discussed in the section “Classes of BFP Data” on page 19-4.

**Significand**

In each format, the binary point of a BFP number is considered to be to the left of the leftmost fraction bit. To the left of the binary point there is an implied unit bit, which is considered to be one for normal numbers and zero for zeros and subnormal numbers. The fraction with the implied unit bit appended on the left is the significand of the number.

The value of a normal BFP number is the significand multiplied by the radix 2 raised to the power of the unbiased exponent. The value of a subnormal BFP number is the significand multiplied by the radix 2 raised to the power of the minimum exponent.

A value of one in the rightmost bit position of the significand in each format is sometimes referred to as one ulp (unit in the last place).

**Values of Nonzero Numbers**

The values of nonzero numbers in the various formats are shown in Figure 19-5.

---

<table>
<thead>
<tr>
<th>Property</th>
<th>Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format length (bits)</td>
<td>Short</td>
<td>32</td>
</tr>

<tr>
<td>Nmin</td>
<td></td>
<td>$1.2 \times 10^{-38}$</td>
</tr>
<tr>
<td>Dmin</td>
<td></td>
<td>$1.4 \times 10^{-45}$</td>
</tr>
</tbody>
</table>

**Explanation:**

- Value is approximate.
- Dmin Smallest (in magnitude) representable subnormal number.
- Nmax Largest (in magnitude) representable finite number.
- Nmin Smallest (in magnitude) representable normal number.

Figure 19-4. Summary of BFP Data Formats

Figure 19-5. Values of Nonzero Numbers

<table>
<thead>
<tr>
<th>Number Class</th>
<th>Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>Short</td>
<td>$±2^{32} \times (1.f)$</td>

<td>Long</td>
<td>$±2^{128} \times (0.f)$</td>
</tr>
<tr>
<td></td>
<td>Extended</td>
<td>$±2^{128} \times (0.f)$</td>
</tr>
</tbody>
</table>

**Explanation:**

- e Biased exponent (shown in decimal).
- f Fraction (in binary).

Programming Note: ANSI/IEEE Standard 754-2008 specifies minimum requirements for the extended format but does not include details. The BFP extended format meets these requirements, far exceeding them in the area of precision.
Classes of BFP Data

There are six classes of BFP data, which include numeric and related nonnumeric entities. Each data item consists of a sign, an exponent, and a significand. The exponent is biased such that all biased exponents are nonnegative unsigned numbers and the minimum biased exponent is zero. The significand consists of an explicit fraction and an implicit unit bit to the left of the binary point. The sign bit is zero for plus and one for minus.

All nonzero finite numbers permitted by a given format have a unique BFP representation. There are no unnormalized numbers, which numbers might allow multiple representations for the same values, and there are no unnormalized arithmetic operations. Tiny numbers of a magnitude below the minimum normal number in a given format are represented as subnormal numbers, but those values are also represented uniquely. The implied unit bit of a normal number is one, and that of a subnormal number or a zero is zero.

The six classes of BFP data are summarized in Figure 19-6 on page 19-4.

### Zeros
Zeros have a biased exponent of zero and a zero fraction. The implied unit bit is zero. A +0 is distinct from -0, except that comparison treats them as equal.

### Subnormal Numbers
Subnormal numbers are numbers which are smaller than the smallest normal number and greater than zero in magnitude. They have a biased exponent of zero and a nonzero fraction. The biased exponent is treated arithmetically as if it were one, which causes the exponent to be the minimum exponent. The implied unit bit is zero. (In ANSI/IEEE Standard 754-2008, subnormal numbers were called “denormalized numbers”.)

### Normal Numbers
Normal numbers have a biased exponent greater than zero but less than all ones. The implied unit bit is one, and the fraction may have any value. (In some early documentation, normal numbers were called “normalized numbers”.)

### Infinities
An infinity is represented by a biased exponent of all ones and a zero fraction. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons, +∞ compares greater than any finite number, and -∞ compares less than any finite number.

### Signaling and Quiet NaNs
A NaN (not-a-number) entity is represented by a biased exponent of all ones and a nonzero fraction. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the leftmost fraction bit: zero for the SNaN and one for the QNaN. A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a leftmost fraction bit of one, with the remaining fraction bits being set to zeros.

Normally, QNaNs are just propagated during computations so that they will remain visible at the end. An

| Signaling NaN   | ±    | All ones        | —         | F0=0, Fr

**Explanation:**

- Does not apply.
- The unit bit is implied.
- The biased exponent is treated arithmetically as if it had the value one.
- F0 Leftmost bit of fraction.
- Fr Remaining bits of fraction.
- NaN Not-a-number.

Figure 19-6. Classes of BFP Data

The instruction TEST DATA CLASS may be used to determine the class of a BFP operand.
SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by setting the leftmost fraction bit to one, and the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

**Programming Notes:**

1. The program can generate and assign meanings to any nonzero fraction values of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format may truncate significant bits on the right.

2. ANSI/IEEE Standard 754-2008 requires SNaNs to signal the invalid-operation exception for the arithmetic, comparison, and conversion operations that are part of the standard, but it makes it an implementation option whether copying an SNaN without a change of format signals the exception. In the appendix, the standard also makes it an implementation option whether SNaNs should signal the invalid-operation exception for the recommended functions of copying the sign, reversing the sign, and testing the data class of a datum.

The above functions generally correspond to the instructions LOAD, LOAD COMPLEMENT, LOAD NEGATIVE, LOAD POSITIVE, and TEST DATA CLASS. These instructions do not signal the invalid-operation exception but, instead, treat SNaNs like any other data; giving an exception would be disruptive when the intention is to include SNaNs. TEST DATA CLASS does not give an exception since it is the instruction with which to test for the presence of SNaNs.

3. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option permitted by ANSI/IEEE Standard 754-2008.

4. Load-type instructions which change the precision signal the invalid-operation exception when the operand is an SNaN, as this is required by ANSI/IEEE Standard 754-2008.

---

**BFP-Format Conversion**

BFP format conversion is described in the section “IEEE Same-Radix Format Conversion” on page 9-23.

**BFP Rounding**

BFP rounding is described in the section “IEEE Rounding” on page 9-13.

**BFP Comparison**

BFP comparison is described in the section “IEEE Comparison” on page 9-24.

**Remainder**

The instruction DIVIDE TO INTEGER produces two floating-point results, an exact integer quotient and the corresponding remainder. The remainder is defined as follows:

Let

\[ a = \text{Dividend} \]
\[ b = \text{Divisor} \]
\[ q = \text{Exact quotient} (a \div b) \]
\[ r = \text{Remainder} \]

in the selected floating-point format. Then

\[ r = a - b \cdot n \]

where \( n \) is an integer. If \( q \) is an integer, then \( n \) equals \( q \). Otherwise, \( n \) is obtained by rounding \( q \) according to a final-quotient-rounding method.

When the final-quotient-rounding method is round to nearest with ties to even or round toward zero, the remainder is exact for any finite dividend and any nonzero divisor. The remainder cannot overflow.

If the integer quotient has a value that lies outside the range of the operand format, a scaled result is provided.

In certain cases where the number of bits in the integer quotient exceeds or may exceed the maximum number of bits provided in the precision of the operand format, partial results are produced, and more
than one execution of the instruction is required to obtain the final result; this may be done with a simple instruction loop.

Partial results are produced when the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient. This situation exists when the precise quotient is greater than $2^P$, where $P$ is the precision of the operand format, and the remainder is not zero. When the remainder is zero, then the quotient is an integer, and the number of bits required to represent the quotient is never more than the precision of the target.

**Programming Note:** The remainder result of DIVIDE TO INTEGER with a final-quotient-rounding method of round to nearest with ties to even corresponds to the `Remainder` function in ANSI/IEEE Standard 754-2008. This function is similar to the `MOD` function found in some languages and to the mathematical `modulo` function, but they are not the same. They differ in the definition of $n$:

- **Remainder** $n$ is $q$ rounded to nearest with ties to even.
- **modulo** $n$ is $q$ rounded toward $-\infty$.
- **MOD** $n$ is $q$ rounded toward 0.

Another important difference is that implementations of modulo and MOD may put range restrictions on the result because they may simply use the DIVIDE instruction and accept its range restrictions.

The MOD definition provides an exact result, as does Remainder, but the modulo definition may result in rounding errors.

The differences between the various methods may be illustrated by the simple example of computing $a$ divided by $b$ to obtain an integer quotient $n$, where $a$ is a series of integers, and $b$ is +4 or -4. Figure 19-7 shows the results for the three definitions.

</tr>
</tbody>
</table>

**Explanation:**
- $a$ Dividend.
- $b$ Divisor.
- $n$ Integer quotient.
- $r$ Result (Remainder, MOD, or modulo).

*Figure 19-7. Comparison of Remainder with MOD and Modulo*

The result of Remainder lies in the range of zero to one-half the divisor, inclusive, in magnitude. A zero result is defined to have the sign of the dividend. A zero divisor is invalid.
The modulo and MOD results can both be computed from the Remainder result; the reverse may not be true, because of rounding errors and, depending on the implementation, range restrictions.

An extreme example of the rounding error that can occur with the modulo definition is the following, where the result is restricted to two significant decimal digits:

\[
\text{modulo}(0.01,-95) = -94.99, \text{ which rounds to } -95 \\
\text{Remainder}(0.01,-95) = 0.01
\]

The properly rounded modulo result is completely wrong since it is equal to the divisor instead of being smaller in magnitude. The Remainder result is exact and can be used to compute the theoretical result of modulo.

Remainder is included as an arithmetic operation because of its usefulness in argument reduction when computing elementary transcendental functions. Thus, \( \text{SIN}(X) \) can be computed to full precision for any value of \( X \) in degrees by first reducing the argument to \( \text{Remainder}(X,360) \).

**IEEE Exceptions**

The IEEE exceptions for the BFP instructions are described in the section “IEEE Exceptions” on page 9-18.
## Summary of Rounding And Range Actions

<td>Overflow</td>
<td>(+\infty^1)</td>
</tr>
</tbody>
</table>

**Explanation:**

1. This situation cannot occur.
2. The rounded value, in the extreme case, may be \(N_{min}\). In this case, the exceptions are underflow, inexact and incremented.
3. The nontrap result \(r\) is considered to have been incremented.
4. The exact-zero-difference case applies only to ADD, SUBTRACT, MULTIPLY AND ADD, and MULTIPLY AND SUBTRACT. For all other BFP operations, a zero result is detected by inspection of the source operands without use of the \(R(v)\) function.
5. The denormalized value. The value derived when the precise intermediate value (\(v\)) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note \(^*\), this is a subnormal number.
6. The precision-rounded value. The value derived when the precise intermediate value (\(v\)) is rounded to the precision of the target, but assuming an unbounded exponent range.
7. Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, \(v\) is the source value (\(a\)).
8. Smallest (in magnitude) representable subnormal number in the target format.
9. Largest (in magnitude) representable finite number in the target format.
10. Smallest (in magnitude) representable normal number in the target format.

---

Figure 19-8. Action for \(R(v)\): Rounding and Range Function (Part 1 of 2)
Concise descriptions of the results produced by many of the BFP instructions are made by means of figures which contain columns and rows representing all possible combinations of BFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 19-10 on page 19-11.

**Explanation:**
- The results do not depend on this condition or mask bit.
- This condition is true by virtue of the state of some condition to the left of this column.
- The IEEE-inexact-exception control (X|C|) is defined only if the floating-point extension facility is installed.
- Scale factor. For overflow, \( v = 2^{+}\). For underflow, \( v = 2^{-}\). The unsigned scaling exponent (\( \alpha \)) depends on the type of operation and operand format. For all BFP operations except LOAD ROUNDED, \( \alpha \) depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For LOAD ROUNDED, \( \alpha \) depends on the source format, and is 512 for long and 8192 for extended.
- The precision-rounded value. The value derived when the precise intermediate value (\( v \)) is rounded to the precision of the target, but assuming an unbounded exponent range.
- Nontrap result as defined in Part 1 of this figure.
- Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
- Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-10 on page 19-11.
- IEEE overflow flag, FPC 1.2.
- IEEE underflow flag, FPC 1.3.
- IEEE inexact flag, FPC 1.4.
- The value \( x \) is placed at the target operand location. For all operations except BFP LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

**Figure 19-8. Action for R(\( v \)): Rounding and Range Function (Part 2 of 2)**
Data-Exception Codes (DXC) and Abbreviations

Figure 19-9 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols “Xi:” and “Xz:” that are used in the figures. Bits 0-4 (i, z, o, u, and x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 of byte 2 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

Explanation:
1. The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.
2. The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 19-10 on page 19-11 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)
Instructions

The BFP instructions and their mnemonics and operation codes are listed in Figure 19-11 on page 19-12.

The figure indicates, in the column labeled “Characteristics”, the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All BFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the BFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a BFP-instruction data exception, DXC 2, is recognized.

Mnemonics for the BFP instructions are distinguished from the corresponding HFP instructions by a B in the mnemonic. Mnemonics for the BFP instructions have an R as the last letter or the letter next to the last letter when the instruction is in the RRE or RRF format. Mnemonics for the BFP instructions have an A as the last letter when the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction. Certain letters are used for BFP instructions to represent operand-format length, as follows:

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CEBR is the mnemonic and R1,R2 the operand designation.

Programming Note: The floating-point extension facility includes the following BFP features:

- The following new BFP instructions are added:
  - CONVERT FROM LOGICAL (CXLFBFR, CDLFBFR, CELFBFR, CXLGBFR, CDLGBFR, and CELGBFR).
  - CONVERT TO LOGICAL (CLFXBR, CLFDBR, CLFEBFR, CLGXBR, CLGDBR, and CLGEBR)
- One new value of the effective rounding method field is assigned to support the round to prepare for shorter precision rounding method for CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER.
- An IEEE-inexact-exception control (XxC) is added to CONVERT TO FIXED and LOAD FP INTEGER.
• An effective rounding method field and an IEEE-inexact-exception control (XxC) are added to CONVERT FROM FIXED and LOAD ROUNDED.

**Explanation:**

- $c^{0}$: Restricted from transactions execution when the effective allow-floating-point-operation control is zero.
- $c^{9}$: Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
- A: Access exceptions for logical addresses.
- B2: B2 field designates an access register in the access-register mode.
- C: Condition code is set.
- Db: BFP-instruction data exception.
- F: Floating-point extension facility
- N: Instruction is new in z/Architecture as compared to ESA/390.
- RRD: RRD instruction format.
- RRE: RRE instruction format.
- RRF: RRF instruction format.
- RXE: RXE instruction format.
- RXF: RXF instruction format.
- SP: Specification exception.
- Xi: IEEE invalid-operation exception.
- Xo: IEEE overflow exception.
- Xu: IEEE underflow exception.
- Xx: IEEE inexact exception.
- Xz: IEEE division-by-zero exception.

AEB 'ED0A' Short BFP
ADB 'ED1A' Long BFP

The second operand is added to the first operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward \(-\infty\), in which method the sign is minus.
- The sign of the sum \(x\) plus \(x\) is the sign of \(x\), even when \(x\) is zero.

If one operand is an infinity and the other is a finite number, the result is that infinity. If both operands are infinities of the same sign, the result is the same infinity. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 19-13 on page 19-16 for a detailed description of the results of this instruction. (Figure 19-12 is referred to by Figure 19-13.)

For AXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

<table>
<thead>
<tr>
<th>Value of Result ( r )</th>

</tr>
</thead>
<tbody>
<tr>
<td>( r = 0 )</td>
<td>0</td>
</tr>
<tr>
<td>( r &lt; 0 )</td>
<td>1</td>
</tr>
<tr>
<td>( r &gt; 0 )</td>
<td>2</td>
</tr>
</tbody>
</table>

**IEEE Exceptions:**

- Invalid operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**

- Access (fetch, operand 2 of AEB and ADB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (AXBR only)
- Transaction constraint

**Programming Note:** Interchanging the two operands in a BFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.
### Results for ADD (a+b) when Second Operand (b) Is

#### Explanation:

- The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- Condition code is set to n.
- Condition code is set according to the resultant sum. See Figure 19-12 on page 19-15.
- Default NaN.
- Subnormal number.
- Normal number.
- Rounding and range action is performed on the value v. See Figure 19-8 on page 19-8.
- Exact zero-difference result. See Figure 19-8 on page 19-8.
- The value x is placed at the target operand location.
- IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

</tbody>
</table>

Mnemonic2 Op Code Operands
CEB 'ED09' Short BFP
CDB 'ED19' Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

\[ +\infty \text{ compares greater than any finite number, and all finite numbers compare greater than } -\infty. \] Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interrupt for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-14 on page 19-18 for a detailed description of the results of this instruction.

For CXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of CEB and CDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (CXBR only)
- Transaction constraint

Programming Notes:

1. COMPARE may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to not recognize an exception when the result is unordered due to a QNaN.

2. ANSI/IEEE Standard 754-2008 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTH-ENED may be used before COMPARE to convert the shorter operand to the same format as the longer.
COMPARE AND SIGNAL

Mnemonic2 Op Code Operands
KEB 'ED08' Short BFP
KDB 'ED18' Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus, QNaN operands are treated as if they were SNaNs.

See Figure 19-16 on page 19-19 for a detailed description of the results of this instruction.

For KXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of KEB and KDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (KXBR only)
- Transaction constraint

Programming Notes:

1. COMPARE AND SIGNAL may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to recognize an exception when the result is unordered due to a QNaN.
2. ANSI/IEEE Standard 754-2008 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTH-ENED may be used before COMPARE AND SIGNAL to convert the shorter operand to the same format as the longer.

**Explanation:**

ccn Condition code is set to n.
C(a:b) Basic compare results. See Figure 19-15 on page 19-18
\(\text{Fn}\) Finite nonzero number (includes both subnormal and normal).
\(\text{Xi}\): IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

**Figure 19-16. Results: COMPARE AND SIGNAL**

**CONVERT FROM FIXED**

<table>
<thead>
<tr>
<th>Mnemonic1 Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEFBR 'B394'</td>
<td>32-bit binary-integer operand, short BFP result</td>
</tr>
<tr>
<td>CDFBR 'B395'</td>
<td>32-bit binary-integer operand, long BFP result</td>
</tr>
<tr>
<td>CXFBR 'B396'</td>
<td>32-bit binary-integer operand, extended BFP result</td>
</tr>
<tr>
<td>CEGBR 'B3A4'</td>
<td>64-bit binary-integer operand, short BFP result</td>
</tr>
<tr>
<td>CDGBR 'B3A5'</td>
<td>64-bit binary-integer operand, long BFP result</td>
</tr>
<tr>
<td>CXGBR 'B3A6'</td>
<td>64-bit binary-integer operand, extended BFP result</td>
</tr>
</tbody>
</table>

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by \(R_2\). A 32-bit operand is in bit positions 32-63 of the register.

When the floating-point extension facility is installed, the converted result is rounded by rounding as specified by the modifier in the \(M_3\) field:

- **\(M_3\) Effective Rounding Method**
  - 0 According to current BFP rounding mode
  - 1 Round to nearest with ties away from 0
  - 3 Round to prepare for shorter precision
  - 4 Round to nearest with ties to even
  - 5 Round toward 0
6  Round toward $+\infty$
7  Round toward $-\infty$

An M₃ modifier other than 0, 1, or 3-7 is invalid. The M₃ field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M₃ modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a value of zero, the converted result is rounded according to the current BFP rounding mode. When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a nonzero value, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

When the floating-point extension facility is installed, bit 1 of the M₄ field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, then it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For CXFBR, CXFBRA, CXGBR, and CXGBRA, the R₁ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact (CEFBR, CEFBRA, CDGBR, CDGBRA, CEGBR, CEGBRA)

**Program Exceptions:**
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

**Programming Note:** Unassigned bits in the M₄ field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

Xi: T(dNaN) | T(dNaN) | T(-0) | T(+0) | R(±a) | T(+∞) | T(a) | Xi: T(a*) |

Explanation:

- This situation cannot occur.
- The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- The operand is extended to the longer format by appending zeros on the right before it is placed at the target operand location.
- The NaN is shortened to the target format by truncating the rightmost bits.
- Default NaN.
- Finite nonzero number (includes both subnormal and normal).
- Rounding and range action is performed on the value v. See Figure 19-8 on page 19-9.
- The value a is converted to the precise intermediate value floating-point number v, and then action R(v) is performed.
- The value x is placed in the target operand location.
- IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-17. Results: Single-Operand Instructions

CONVERT FROM LOGICAL

Mnemonic | R1,M3,R2,M4 | [RRF-e]
---|---|---
0 | 16 20 24 28 31

Op Code | M3 | M4 | R1 | R2
---|---|---|---|---
CELFB = 'B390' 32-bit binary-integer operand, short BFP result
CDLFBR = 'B391' 32-bit binary-integer operand, long BFP result
CXLFBR = 'B392' 32-bit binary-integer operand, extended BFP result
CELGBR = 'B3A0' 64-bit binary-integer operand, short BFP result
CDLGBR = 'B3A1' 64-bit binary-integer operand, long BFP result
CXLGBR = 'B3A2' 64-bit binary-integer operand, extended BFP result

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is an unsigned binary integer that is located in the general register designated by R2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded by rounding as specified by the modifier in the M4 field:

M3 Effective Rounding Method
0 According to current BFP rounding mode
1 Round to nearest with ties away from 0
3 Round to prepare for shorter precision
4 Round to nearest with ties to even
5 Round toward 0
6 Round toward +∞
7 Round toward -∞

An M3 modifier other than 0, 1, or 3-7 is invalid.

When the M3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The M3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CXLFBR and CXLGBR, the R1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Bit 1 of the M4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is
zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

The result always has a plus sign.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact (CELFBR, CDLGBR, CELGBR)

**Program Exceptions:**
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed)
- Specification
- Transaction constraint

**Programming Notes:**
1. Unassigned bits in the M₄ field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future
2. Using either the round toward 0 or the round toward $-\infty$ rounding method produces the same result.

</tr>
</tbody>
</table>

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R₁. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M₃ field:

**M₃ Effective Rounding Method**
- 0 According to current BFP rounding mode
- 1 Round to nearest with ties away from 0
- 3 Round to prepare for shorter precision
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward $+\infty$
- 7 Round toward $-\infty$

An M₃ modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M₃ modifier of 3 is also invalid.

When the M₃ modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.
When the floating-point extension facility is installed, bit 1 of the M₄ field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-18 for a detailed description of the results of this instruction.

Figure 19-18. Results: CONVERT TO FIXED
If the M₃ field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M₃ field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

For CFXBR, CFXBRA, CGXBR and CGXBRA, the R₂ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

| 0 | Source was zero |
| 1 | Source was less than zero |
| 2 | Source was greater than zero |
| 3 | Special case |

**IEEE Exceptions:**

- Invalid operation
- Inexact

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

**Programming Note:** Unassigned bits in the M₄ field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.
CONVERT TO LOGICAL

Mnemonic | R1 R2 M3 M4 | [RRF-e]
---|---|---
Op Code | M3 M4 R1 R2

0 | 16 20 24 28 31

Mnemonic | Op Code | Operands
---|---|---
CLFEBR | 'B39C' | Short BFP operand, 32-bit binary-integer result
CLFDBR | 'B39D' | Long BFP operand, 32-bit binary-integer result
CLFXBR | 'B39E' | Extended BFP operand, 32-bit binary-integer result
CLGEBR | 'B3AC' | Short BFP operand, 64-bit binary-integer result
CLGDBR | 'B3AD' | Long BFP operand, 64-bit binary-integer result
CLGXBR | 'B3AE' | Extended BFP operand, 64-bit binary-integer result

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is an unsigned binary integer that is placed in the general register designated by R1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M3 field. When the M3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

Bit 1 of the M4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

The M3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CLFXBR and CLGXBR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

See Figure 19-19 for a detailed description of the results of this instruction.

**Resulting Condition Code:**

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

**IEEE Exceptions:**

Explanation:

- The results do not depend on this condition or mask bit.
- † This condition is true by virtue of the state of some condition to the left of this column.
- † Result differs from DFP CONVERT TO LOGICAL. The DFP instruction combines two cases as it does not recognize inexact for this case and does not test the inexact mask.
- ccn Condition code is set to n.
- f The value n converted to a fixed-point result.
- n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
- MU Maximum unsigned number representable in the target fixed-point format.
- PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. Figure 19-10 on page 19-11.
- SFi IEEE invalid-operation flag, FPC 1.0.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The value x is placed at the target operand location.

Mnemonic2 Op Code Operands
DEB "ED0D" Short BFP
DDB "ED1D" Long BFP

The first operand (the dividend) is divided by the second operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If the divisor is nonzero and both the dividend and divisor are finite numbers, the first operand is divided by the second operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 19-20 on page 19-27 for a detailed description of the results of this instruction.

For DXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Explanation:
- The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- Finite nonzero number (includes both subnormal and normal).
- R(v) Rounding and range action is performed on the value v. See Figure 19-8 on page 19-8.
- T(x) The value x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
- Xz: IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

IEEE Exceptions:
- Underflow
- Inexact

Figure 19-20. Results: DIVIDE

**IEEE Exceptions:**
- Invalid operation
- Division by zero
- Overflow
Program Exceptions:

- Access (fetch, operand 2 of DEB and DDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (DXBR only)
- Transaction constraint

DIVIDE TO INTEGER

Mnemonic R₃,R₃,R₂,M₄ [RRF-b]

Op Code R₃ M₄ R₁ R₂

Mnemonic Op Code Operands
DIEB 'B353' Short BFP
DIDB 'B35B' Long BFP

The first operand (the dividend) is divided by the second operand (the divisor). An integer quotient in BFP form is produced and placed at the third-operand location. The remainder replaces the dividend at the first-operand location. The first, second, and third operands must be in different registers. The condition code indicates whether partial or final results have been produced.

The remainder result is

\[ r = a - b \cdot n \]

where \( a \) is the dividend, \( b \) the divisor, and \( n \) an integer obtained by rounding the precise quotient

\[ q = a \div b. \]

The first-operand result is \( r \) with the sign determined by the above expression. The third-operand result is \( n \) with a sign that is the exclusive or of the dividend and divisor signs.

If the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient, then a partial quotient and partial remainder are formed. (In all other cases, a final quotient and final remainder are formed.) This partial quotient \( n \) and the corresponding partial remainder

\[ r = a - b \cdot n \]

are used as the results. The sign of a partial remainder is the same as the sign of the dividend. The sign of a partial quotient is the exclusive or of the dividend and divisor signs.

If the remainder is zero, then the precise quotient is an integer and can be represented exactly in the precision of the quotient.

The \( M₄ \) field, called the modifier field, specifies rounding of the final quotient. This rounding is called the “final-quotient-rounding method” as contrasted to the “current BFP rounding mode” specified by the BFP rounding-mode bits in the FPC register. The final quotient is rounded according to the final-quotient-rounding method. The final-quotient-rounding method affects only the final quotient; partial quotients are rounded toward zero.

Since the partial quotient is rounded toward zero, the partial remainder is always exact. For the final-quotient-rounding methods of round toward 0, round to nearest with ties to even, and round to nearest with ties away from 0, the final remainder is exact. For the final-quotient-rounding methods of round toward +∞ and round toward −∞, the final remainder may not be exact.

The final quotient is rounded to an integer by rounding as specified by the modifier in the \( M₄ \) field:

\[ M₄ \text{ Final-Quotient-Rounding Method} \]

0 According to current BFP rounding mode
1 Round to nearest with ties away from 0
3 Round to prepare for shorter precision
4 Round to nearest with ties to even
5 Round toward 0
6 Round toward +∞
7 Round toward −∞

When the floating-point extension facility is installed, a modifier of 2 and 8-15 is invalid. If the floating-point extension facility is not installed, a modifier of 2-3 and 8-15 is invalid.

When the modifier field is zero, rounding of the final quotient is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

Underflow is recognized only on the final remainder, not on the partial remainder.
For the final-quotient-rounding methods of round toward \( +\infty \), round toward \( -\infty \), and round to prepare for shorter precision, the final remainder may not be exact. When, in these cases, the final remainder is inexact, it is rounded according to the current BFP rounding mode specified in the FPC register.

The sign of a zero quotient is the exclusive or of the divisor and dividend signs.

A zero remainder has the sign of the dividend.

See Figure 19-21 on page 19-29 for a detailed description of the results of this instruction.

If the quotient exponent is greater than the largest exponent that can be represented in the operand format, the correct remainder or partial remainder still is produced, and the third-operand result is the correct value, but with the exponent reduced by 192 or 1536 for short or long operands, respectively. The condition code indicates this out-of-range condition.

If the \( M_4 \) field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the \( M_4 \) field designates the invalid value \( 3 \), it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

The \( R_1 \), \( R_2 \), and \( R_3 \) fields must designate different registers; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

- 0 Remainder final; normal quotient
- 1 Remainder final; quotient overflow or \( \text{NaN} \)
- 2 Remainder partial; normal quotient
- 3 Remainder partial; quotient overflow

**IEEE Exceptions:**

- Invalid operation
- Underflow
- Inexact

**Explanation:**

1. The results do not depend on this condition or mask bit.
2. This condition is true by virtue of the state of some condition to the left of this column. That is, when $|q| < 2^P$, there cannot be a quotient overflow; the cases of remainder is zero, tiny, or inexact are mutually exclusive; and when $r$ is exact, it is not incremented.
3. Underflow is not recognized for a partial remainder.
4. Each entry of this column is derived from the entries of the two left columns, and helps determine the specific rounding method used in some columns on the right and determine the resulting condition code setting.
5. Scale factor. For overflow, $\Psi = 2^{+\alpha}$. For underflow, $\Psi = 2^{-\alpha}$. The unsigned scaling exponent ($\alpha$) depends on the operand format and is 192 for short and 1536 for long.
6. The absolute value of $q$, where $q$ is the precise intermediate value of $a \cdot b$ before rounding, assuming unbounded precision and unbounded exponent range.
7. Condition code is set to 0 (remainder final; normal quotient).
8. Condition code is set to 1 (remainder final; quotient overflow).
9. Condition code is set to 2 (remainder partial; normal quotient).
10. Condition code is set to 3 (remainder partial; quotient overflow).
11. Integer quotient. $n = q$, rounded toward 0 for partial results and rounded according to the final-quotient-rounding method for final results. The sign of the integer quotient, including the cases of partial and final, scaled value, and zero, is the exclusive or of the signs of the dividend ($a$) and divisor ($b$).
12. Remainder. $r = a \cdot b \cdot n$. A partial remainder is always exact; no rounding is necessary. The sign of a partial remainder is always the same as the sign of the dividend ($a$). A final remainder is rounded according to the current BFP rounding mode (if necessary) specified in the FPC register. The sign of a zero remainder is the same as the sign of the dividend ($a$). The sign of a nonzero final remainder is determined by the rules of algebra.
13. Precision of the operand, which depends on the target format: $P = 24$ for short and 53 for long.
14. Program interruption for data exception, condition $c$, with DXC of $h$ in hex. See Figure 19-10 on page 19-11.
15. IEEE invalid-operation flag, FPC 1.0.
16. IEEE underflow flag, FPC 1.3.
17. IEEE inexact flag, FPC 1.4.
18. Results $r$ (the remainder) and $n$ (the integer quotient) are placed in target operands 1 and 3, respectively.

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

**Programming Notes:**

1. The Remainder operation, as defined in ANSI/IEEE Standard 754-2008, is produced by issuing DIVIDE TO INTEGER in an iterative loop, with the $M_4$ field set to 4.
2. The rounding specifications of round to nearest with ties to even, round toward 0, and round toward \(-\infty\) permit the instruction to be used directly to produce the Remainder, MOD, and modulo functions, respectively.

3. When DIVIDE TO INTEGER is used in an iterative loop, all quotients are produced in BFP format but may be considered as portions of a multiple-precision fixed-point number.

4. In the case when the resulting remainder is subnormal, ANSI/IEEE Standard 754-2008 requires that if traps are implemented and the underflow mask is one, then an underflow trap must occur. To accomplish this, DIVIDE TO INTEGER recognizes underflow on the final remainder but not on the partial remainder. Since in all cases when underflow exists on the partial remainder it will also exist on the final remainder, recognizing underflow on only the final remainder avoids two underflow traps to be reported for what ANSI/IEEE Standard 754-2008 considers a single Remainder operation.

**LOAD AND TEST**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>R1, R2</th>
<th>[RRE]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code</td>
<td>R1</td>
<td>R2</td>
</tr>
</tbody>
</table>

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is placed unchanged at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For LTXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**LOAD COMPLEMENT**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>LCEBR</td>
<td>'B303'</td>
<td>Short BFP</td>
</tr>
<tr>
<td>LCDBR</td>
<td>'B313'</td>
<td>Long BFP</td>
</tr>
<tr>
<td>LTXBR</td>
<td>'B343'</td>
<td>Extended BFP</td>
</tr>
</tbody>
</table>

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is inverted for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LTXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

| 0 | Result is zero |
| 1 | Result is less than zero |
| 2 | Result is greater than zero |
| 3 | Result is a NaN |

**IEEE Exceptions:**

- Invalid operation

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LTXBR only)
- Transaction constraint

**Programming Note:** LOAD AND TEST signals invalid operation when the operand is an SNaN. TEST DATA CLASS may be used to test an operand if signaling is not desired.
**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 2, BFP instruction
- Specification (LCXBR only)
- Transaction constraint

**Programming Note:** LOAD COMPLEMENT does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

### LOAD FP INTEGER

<table>
<thead>
<tr>
<th>Mnemonic1</th>
<th>Op Code</th>
<th>R1, R2, M3</th>
<th>[RRF-e]</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIEBR</td>
<td>'B357'</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FIDBR</td>
<td>'B35F'</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FIXBR</td>
<td>'B347'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mnemonic2</th>
<th>Op Code</th>
<th>R1, R2, M3, M4</th>
<th>[RRF-e]</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIEBRA</td>
<td>'B357'</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FIDBRA</td>
<td>'B35F'</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FIXBRA</td>
<td>'B347'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M3 field:

**M3 Effective Rounding Method**
- 0: According to current BFP rounding mode
- 1: Round to nearest with ties away from 0
- 2: Round to prepare for shorter precision
- 3: Round to nearest with ties to even
- 4: Round toward 0
- 5: Round toward \(+\infty\)
- 6: Round toward \(-\infty\)

An M3 modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M3 modifier of 3 is also invalid.

When the M3 modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

In the absence of an interruption, if the second operand is an infinity or a QNaN, the result is that operand; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

When the floating-point extension facility is installed, bit 1 of the M4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-22 on page 19-33 for a detailed description of the results of this instruction.

If the M3 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M3 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

For FIXBRA and FIXBRA, the R fields must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Inexact

**Program Exceptions:**
- Data with DXC 2, BFP instruction
Programming Notes:

1. **LOAD FP INTEGER** rounds a BFP number to an integer value. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.

2. If the BFP operand is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.

3. Unassigned bits in the M4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

| Operand (a) | Is n Inexact (n≠a) | Inv.-Op. Mask (FPC 0.0) | IEEE Inexact Exception Control (XxC)² | Inexact Mask (FPC 0.4) | Is n Incremented (|n|>|a|) | Results |

| QNaN        | No                 | –                       | –                                     | –                      | –                         | T(a)    |
| SNaN        | No¹                | 0                       | –                                     | –                      | –                         | T( a*), SFx<1 |
| SNaN        | No¹                | 1                       | –                                     | –                      | –                         | PIDy(08) |

Explanation:

- The results do not depend on this condition or mask bit.
- The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- This condition is true by virtue of the state of some condition to the left of this column.
- XxC is defined only if the Floating-point extension facility is installed.
- The value derived when the source value, a, is rounded to a floating-point integer using the effective rounding mode.
- Fn Finite nonzero number (includes both subnormal and normal).
- PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-10 on page 19-11.
- SFi IEEE invalid-operation flag, FPC 1.0.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The value x is placed at the target operand location.

*Figure 19-22. Results: LOAD FP INTEGER*
LOAD NEGATIVE

The second operand is converted to a longer format, and the result is placed at the first-operand location.

When the second operand is a finite number, the value of the second operand is placed in the target format. The exponent of the second operand is converted to the corresponding exponent in the result format, and the fraction is extended by appending zeros on the right.

If the second operand is an infinity, the result is an infinity of the same sign. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

The sign of the result is the same as the sign of the source.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For LXDB, LXDBR, LXEB, and LXEBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Result is zero</td>
</tr>
<tr>
<td>1</td>
<td>Result is less than zero</td>
</tr>
<tr>
<td>2</td>
<td>--</td>
</tr>
<tr>
<td>3</td>
<td>Result is a NaN</td>
</tr>
</tbody>
</table>

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LNXBR only)
- Transaction constraint

Programming Note: LOAD NEGATIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.
LOAD POSITIVE

Mnemonic | R1, R2 | [RRE]
----------|--------|------

<table>
<thead>
<tr>
<th>Op Code</th>

LPEBR     | 'B300'  | Short BFP
LPDBR     | 'B310'  | Long BFP
LPXBR     | 'B340'  | Extended BFP

The second operand is placed at the first-operand location with the sign bit made zero.

The sign bit is made zero, and the rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LPXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0  Result is zero
1  --
2  Result is greater than zero
3  Result is a NaN

IEEE Exceptions:  None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LPXBR only)
- Transaction constraint

Programming Note: LOAD POSITIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

<th>M3</th>
<th>M4</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>24</td>
<td>28</td>
<td>31</td>
</tr>
</tbody>
</table>

Mnemonic2 | Op Code | Operands
-----------|---------|------
LEDBRA    | 'B344'  | Long BFP source, short BFP target, short or long BFP result
LDXBR     | 'B345'  | Extended BFP source, long BFP target, long or extended BFP result
LEXBRA    | 'B346'  | Extended BFP source, short BFP target, short or extended BFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

When the floating-point extension facility is installed, the second operand, if a finite number, is rounded by rounding as specified by the modifier in the M3 field:

M3 Effective Rounding Method
0  According to current BFP rounding mode
1  Round to nearest with ties away from 0
3  Round to prepare for shorter precision
4  Round to nearest with ties to even
5  Round toward 0
6  Round toward +\infty
7  Round toward -\infty

An M3 modifier other than 0, 1, or 3-7 is invalid. The M3 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.
When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a value of zero, the second operand is rounded according to the current BFP rounding mode. When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a nonzero value, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

In the absence of IEEE-trap action for overflow or underflow, the result is in the format and length of the target. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. For LEDBR, LEDBRA, LEXBR and LEXBRA, the result has at most 23 significand fraction bits; for LDXBR and LDXBRA, the result has at most 52 significand fraction bits.

A short-format result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. A long-format result is placed in a floating-point register, and the other register of the floating-point register pair, if any, remains unchanged. An extended-format result is placed in a floating-point register pair.

The sign of the result is the same as the sign of the second operand.

When the floating-point extension facility is installed, bit 1 of the M4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bit 21 of the instruction is zero, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bit 21 of the instruction is one, then it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For LDXBR, LDXBRA, LEXBR, and LEXBRA, the R1 and R2 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

**Programming Notes:**
1. The sign of the rounded result is the same as the sign of the operand, even when the result is zero.
2. The R1 field for LDXBR, LDXBRA, LEXBR, and LEXBRA must designate a valid floating-point-register pair since in certain cases the result is in the extended format. In normal operation for LDXBR, LDXBRA, LEXBR and LEXBRA, the result format is long or short, respectively, and this result replaces the leftmost 32 bits or 64 bits of the target-register pair. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by placing a result in the extended format at the target location. Thus, the program must take into account the fact that these instructions sometimes update both registers of the pair.
3. Unassigned bits in the M4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.
MULTIPLY

Mnemonic1  R1, R2  [RRE]

Op Code  [ ]  R1  R2

0  16  24  28  31

Mnemonic1  Op Code  Operands
MEEBR  'B317'  Short BFP
MDBR  'B31C'  Long BFP
MXBR  'B34C'  Extended BFP
MDEBR  'B30C'  Short BFP multiplier and multiplicand, long BFP product
MXDBR  'B307'  Long BFP multiplier and multiplicand, extended BFP product

Mnemonic2  R1, D2(X2, B2)  [RXE]

Op Code  [ ]  R1  X2  B2  D2

0  8  12  16  20  32  40  47

Mnemonic2  Op Code  Operands
MEEB  'ED17'  Short BFP
MDB  'ED1C'  Long BFP
MDEB  'ED0C'  Short BFP multiplier and multiplicand, long BFP product
MXDB  'ED07'  Long BFP multiplier and multiplicand, extended BFP product

The product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

The two BFP operands, if finite numbers, are multiplied, forming an intermediate product. For MDEB, MDEBR, MXDB, and MXDBR, the intermediate product is converted to the longer target format; the result cannot overflow or underflow and is exact. For MDB, MDBR, MEEB, MEEBR, and MXBR, the result is rounded to the operand format according to the current BFP rounding mode. For MEEB and MEEBR, the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

If one operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 19-23 on page 19-38 for a detailed description of the results of this instruction.

The R1 field for MXDB, MXDBR, and MXBR, and the R2 field for MXBR, must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code:  The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Underflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Inexact (MDB, MDBR, MEEB, MEEBR, MXBR)

Program Exceptions:

- Access (fetch, operand 2 of MDEB, MEEB, MDB, and MXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (MXDB, MXDBR, MXBR)
- Transaction constraint

Programming Note: Interchanging the two operands in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

**Mnemonic1** | **R_{1},R_{2},R_{3}** | **[RRD]**
---|---|
**Op Code** | **R_{1}** | **////** | **R_{3}** | **R_{2}**

**Mnemonic1 Op Code** | **Operands**
---|---
MAEBR | 'B30F' | Short BFP
MSDBR | 'B31F' | Long BFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

\[ \text{op}_1 = \text{op}_2 \times \text{op}_3 \pm \text{op}_1 \]

When the operands are finite numbers, the third and second BFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode and then placed at the first-operand location. The exponent and fraction of the intermediate product are maintained exactly; rounding and range checking occur only on the intermediate sum.

See Figure 19-24 for a detailed description of the results of MULTIPLY AND ADD. The results of MUL-
MULTIPLY AND SUBTRACT are the same, except that the first operand, if numeric, participates in the operation with its sign bit inverted. When the first operand is a NaN, it participates in the operation with its sign bit unchanged.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**
- Access (fetch, operand 2 of MAEB, MADB, MSEB, MSDB)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Transaction constraint

**Programming Note:** MULTIPLY AND ADD and MULTIPLY AND SUBTRACT produce a precise intermediate value, and a single rounding operation is performed after the addition or subtraction. This definition is consistent with the Power architecture, and, in certain applications, can be used to great advantage, especially in algorithms used in math libraries.

**Mnemonic2 Op Code Operands**

SQEB 'ED14' Short BFP
SQDB 'ED15' Long BFP

The square root of the second operand is placed at the first-operand location.

The result rounded according to the current BFP rounding mode is placed at the first-operand location.

If the second operand is a positive finite number, the result is the square root of that number with a plus sign. If the operand is a zero of either sign, the result is a zero of the same sign. If the operand is +\(\infty\), the result is +\(\infty\).

If the second operand is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For SQXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Inexact

</thead>
</table>

**Mnemonic2 Op Code Operands**

SEB 'ED0B' Short BFP
SDB 'ED1B' Long BFP

The second operand is subtracted from the first operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the second operand, if numeric, participates in the operation with its sign bit inverted. When the second operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 19-13 on page 19-16 for the detailed results of ADD.

For SXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

**IEEE Exceptions:**
• Invalid operation
• Overflow
• Underflow
• Inexact

**Program Exceptions:**

- Access (fetch, operand 2 of SEB and SDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SXBR only)
- Transaction constraint

**TEST DATA CLASS**

</tbody>
</table>

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of BFP data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 19-25, BFP operands are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

<table>

Figure 19-25. Second-Operand-Address Bits for TEST DATA CLASS

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TCXB, the R1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0  Selected bit is 0 (no match)
1  Selected bit is 1 (match)
2  --
3  --

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Specification (TCXB only)
- Transaction constraint

**Programming Notes:**

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.
2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, DFP TEST DATA CLASS uses bits 54 and 55 for subnormal number, and bits 56 and 57 for normal number.

Decimal-Floating-Point Facility

The decimal-floating-point (DFP) facility provides instructions to operate on decimal (radix-10) floating-point data. The facility was designed in cooperation with the IEEE floating-point working group.

Additionally, this facility was designed to support a common library for various systems. This facility in both the z/architecture and Power architectures supports the same data formats, the same rounding methods, the same functions, and the same exceptions.

DFP has a number of important characteristics:
The DFP computational model, a high-level overview of the computational steps, is described in the section "IEEE Computational Operations" of Chapter 9, "Floating-Point Overview and Support Instructions." Detailed definitions of rounding methods and IEEE exceptions supported by DFP are also described in the section.

**DFP Arithmetic**

**Finite Floating-Point Number**

A finite floating-point number has three components: a sign, an exponent, and a significand. The magnitude of a finite number is the product of significand multiplied by the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

**Cohort**

Finite decimal-floating-point (DFP) numbers are not necessarily normalized; that is, the leftmost significand digit may be zero. This allows some values to have multiple representations; each with a different combination of the significand and the exponent. The set of different representations for a value of the same sign is called a cohort; and each representation in a cohort is called a cohort member. A positive zero and a negative zero have the same value but are in different cohorts.

**Quantum**

For a DFP finite number, the magnitude of a value of one in the rightmost digit position of the significand is called the quantum. Each cohort member of a cohort uses a different quantum to represent the same value. Regardless of whether the left-units view or right-units view is taken, the quantum of a cohort member is the same.

**Preferred Quantum**

For operations that produce a DFP result, when, in the absence of a trap overflow or a trap underflow, the delivered value is a finite number, a value, called the preferred quantum, is defined to select a cohort member to represent the delivered value. The preferred quantum for each of these operations is shown in Figure 20-4 on page 20-9. When the delivered value is exact, the preferred quantum depends on the

---

- It produces results consistent with decimal arithmetic as taught in elementary school.
- It recognizes the quantum of a finite number, maintains quantum information through arithmetic operations, and provides special operations to extract, compare, and adjust the quantum.
- It provides greater exponent range than hexadecimal-floating-point (HFP) and binary-floating-point (BFP) while maintaining comparable precision.
- It provides greater precision and better space efficiency than provided by the decimal-arithmetic instructions and the packed-decimal format as described in Chapter 8, “Decimal Instructions.”
- It supports IEEE flags, exceptions, and special entities of “infinity” and “Not-a-Number” (NaN).
- It supports eight automatic rounding methods. For DFP computational instructions, an explicit rounding method can be specified in a modifier field in the instruction.
- It facilitates production of DFP results with a precision other than any supported format precision and with the effect of single rounding.
- It provides operations for conversion between fixed-point and DFP formats.
- It provides operations for conversion between packed-decimal and DFP formats.
- It provides three-operand nondestructive arithmetic operations by permitting different target-operand registers from source-operand registers.

The DFP facility uses the same 16 floating-point registers as those used by HFP and BFP. A set of radix-independent floating-point-support instructions can be used to load, store, or change the sign of a DFP operand. These instructions are defined in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP facility uses the same floating-point-control (FPC) register as that used by BFP. The bits of the FPC register are often referred to as, for example, FPC1.0, meaning bit 0 of byte 1 of the register. The description of the FPC register, including the DFP-rounding-mode field, and the instructions that operate on the FPC register are provided in Chapter 9, “Floating-Point Overview and Support Instructions.”

---

**Finite decimal-floating-point (DFP) numbers are not necessarily normalized; that is, the leftmost significand digit may be zero. This allows some values to have multiple representations; each with a different combination of the significand and the exponent. The set of different representations for a value of the same sign is called a cohort; and each representation in a cohort is called a cohort member. A positive zero and a negative zero have the same value but are in different cohorts.**
operation. When the delivered value is inexact, the preferred quantum is the smallest quantum of the cohort members, unless otherwise stated.

**Scaled Preferred Quantum**

For operations that produce a DFP result, when a trap overflow or a trap underflow occurs, a scaled preferred quantum is used to select a cohort member to represent the delivered value. The scaled preferred quantum is obtained by scaling the preferred quantum using the same scale factor as that used to obtain the delivered value.

**Delivered Quantum**

Normally, when the delivered value is a finite number, the result is selected from the cohort for the delivered value in the target format. However, in case of a trap overflow or trap underflow for LOAD ROUNDED, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format.

In the absence of a trap overflow or trap underflow, if the delivered value is a finite number, the cohort member with the quantum closest to the preferred quantum is selected.

In case of a trap overflow or trap underflow, the cohort member with the quantum closest to the scaled preferred quantum is selected.

**Special Quantum-Handling Operations**

Special operations are provided to handle the quantum: COMPARE BIASED EXPONENT can be used to compare two quanta; EXTRACT BIASED EXPONENT can be used to determine the quantum of a finite number; and QUANTIZE can be used to adjust the quantum of a finite number.

**Programming Notes:**

1. Many financial applications and commercial databases use scaled integer representation of decimal data. Calculations are carried out by using integer arithmetic and scaling factors are tracked separately; the scaling factor is often an attribute of a column in the database.

This computational model can be supported by DFP by allowing the integer part of decimal data to map into the significand with a right-units view and the scaling factor to map into the quantum.

2. The term coefficient is used in some other documents to mean an integer value in significand; that is, significand in right-units view.

**DFP Data Formats**

Decimal-floating-point data may be represented in any of three data formats: short, long, or extended.

The contents of each data format represent encoded information. Special codes are assigned to distinguish finite numbers from NaNs and infinities.

For finite numbers, a biased exponent is used in the format. For each format, a different bias is used for right-units-view (RUV) exponents from that for left-units-view (LUV) exponents. The biased exponents are unsigned numbers and all biases are shown in Figure 20-3 on page 20-6. The biased exponent is encoded with the leftmost digit (LMD) of the significand in the combination field. The remaining digits of the significand are encoded in the encoded trailing-significand field.

**DFP Short Format**

When an operand in the DFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

**DFP Long Format**

When an operand in the DFP long format is loaded into a floating-point register, it occupies the entire register.
An operand in the DFP extended format occupies a register pair. The leftmost 64 bits occupy the entire lower-numbered register of the pair and the rightmost 64 bits occupy the entire higher-numbered register.

The properties of the three formats are tabulated in Figure 20-3 on page 20-6.

**Sign**
The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

**Combination**
For finite numbers, this field contains the biased exponent and the leftmost digit of the significand; for NaNs and infinities, this field contains codes to identify them.

When bits 1-5 of the format are in the range of 00000 - 11101, the operand is a finite number. The two leftmost bits of the biased exponent and the leftmost digit of the significand are encoded in bits 1-5 of the format. Bit 6 through the end of the combination field contain the rest of the biased exponent.

When bits 1-5 of the format field are 11110, the operand is an infinity. All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity. A nonzero value in the reserved field is accepted in a source infinity; the reserved field is set to zero in a resultant infinity.

When bits 1-5 of the format are 11111, the operand is a NaN and bit 6, called the SNaN bit, further distinguishes QNaN from SNaN. If bit 6 is zero, then it is QNaN; otherwise, it is SNaN. All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN. A nonzero value in the reserved field is accepted in a source NaN; the reserved field is set to zero in a resultant NaN.

Figure 20-1 summarizes the encoding and layout of the combination field. In the figure, the biased exponent of a finite number is the concatenation of two parts: (1) two leftmost bits are derived from bits 1-5 of the format, and (2) the remaining bits in the combination field. For example, if the combination field of the DFP short format contains 10101010101 binary, it represents a biased exponent of 10010101 binary and a leftmost significand digit of 5.

Figure 20-1. The Combination Field
### Encoded Trailing Significand
This field contains an encoded decimal number, which represents digits in the trailing significand. The trailing significand contains all significand digits, except the leftmost digit. For infinities, nonzero trailing-significand digits are accepted in a source infinity; all trailing-significand digits in a resultant infinity are set to zeros, unless otherwise stated. For NaNs, this field contains diagnostic information called the payload.

The encoded trailing-significand field is a multiple of 10-bit blocks called declets. The number of declets depends on the format. Each declet represents three decimal digits in a 10-bit value. This is described in the section, “Densely Packed Decimal (DPD)” on page 20-57.

### Values of Finite Numbers
The values of finite numbers in the various formats are shown in Figure 20-2.

#### Figure 20-1. The Combination Field (Continued)

<table>
<thead>
<tr>
<th>Bits</th>
<th>Bit</th>
<th>Type</th>
<th>Biased Exponent</th>
<th>LMD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>11111</td>
<td>1</td>
<td>NaN</td>
<td>--</td>
<td>--</td>
</tr>
</tbody>
</table>

**Explanation:**
- `--` Not applicable.
- `|` Concatenation.
- `1` All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity.
- `2` All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN.
- LMD Leftmost digit of the significand.
- `m` Bit 6 is a part of the remaining biased exponent.
- RBE Remaining biased exponent. It includes all bits in the combination field to the right of bit 5 of the format.
- `r` Bit 6 is a reserved bit for infinity.

#### Figure 20-2. Values of Finite Numbers

**Programming Note:** The RUV exponent, Q, is related to the LUV exponent, E, as follows:

\[ Q = E - p + 1 \]

where \( p \) is the format precision.

### Significand
Hereafter, the term significand is used to mean the following:

1. For finite numbers, the significand contains all trailing significand digits padded on the left with the leftmost digit of significand derived from the combination field.

2. For infinities and NaNs, the significand contains all trailing significand digits padded on the left with a zero digit.

### DFP Significant Digits
For a finite number, the DFP significant digits begin with the leftmost nonzero significand digit and end with the rightmost significand digit.

For a finite number, the number of DFP significant digits is the difference of subtracting the number of leading zeros from the format precision. The number of leading zeros is the number of zeros in the significand to the left of the leftmost nonzero digit.

**Programming Note:** The number of DFP significant digits of the value zero is zero.
Canonical Declets

The trailing significand digits in a DFP data format are encoded by representing three decimal digits with a 10-bit declet. Of the 1024 possible declets, 1000 canonical declets are produced in resultant DFP operands, and 24 noncanonical declets are not produced as DFP results. Both canonical and noncanonical declets are accepted in source DFP operands. The encoding of a canonical declet or noncanonical declet is described in the section, “Densely Packed Decimal (DPD)” on page 20-57.

DFP Canonical Data

A finite number is canonical when all declets are canonical declets.

An infinity is canonical when the reserved field is zero and all digits in the trailing significand are zeros.

A NaN is canonical when the reserved field is zero and all declets are canonical declets.

Programming Note: To ensure compatibility with future extensions and interchangeability between software routines, only DFP canonical data should be used.

Classes of DFP Data

There are six classes of DFP data: zero, subnormal number, normal number, infinity, signaling NaN, and quiet NaN. The zero, subnormal number, and normal number data classes are collectively called finite numbers. The instruction TEST DATA CLASS may be used to determine the class of a DFP operand.

Zeros

Zeros have a zero significand and any representable value in the biased exponent. A +0 is distinct from a -0 and zeros with different biased exponents are distinct, except that comparison treats them as equal.

Subnormal Numbers

Subnormal numbers are numbers which are smaller than Nmin and larger than zero in magnitude.

</tr>
<tr>
<td>Nmin</td>
<td>(1 \times 10^{-95})</td>
</tr>
<tr>
<td>Dmin</td>
<td>(1 \times 10^{-101})</td>
</tr>
</tbody>
</table>

Explanation:

Dmin Smallest (in magnitude) subnormal number.
Nmax Largest (in magnitude) normal number.
Nmin Smallest (in magnitude) normal number.

Figure 20-3. Summary of DFP Formats
Normal Numbers
Normal numbers are numbers whose magnitude is between Nmin and Nmax inclusively.

Infinities
An infinity is represented by 11110 binary in bits 1-5 of the data format. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons, \( +\infty \) compares greater than any finite number, and \( -\infty \) compares less than any finite number. All \( +\infty \) are compared equal and all \( -\infty \) are compared equal.

Signaling and Quiet NaNs
A NaN (Not-a-Number) is represented by 11111 binary in bits 1-5 of the data format. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from a quiet NaN (QNaN) by bit 6, the SNaN bit, of the data format: zero for the QNaN and one for the SNaN. A special QNaN, called the default QNaN, is supplied as the nontrap result for an IEEE-invalid-operation exception; it has a plus sign, and the SNaN bit, the reserved field, and the payload are set to zeros.

Normally, source QNaNs are canonicalized to become the resultant QNaN that has the same sign and payload as the source during operations so that they will remain visible at the end. (See the section “Canonicalization” on page 20-7 for details.) An SNaN operand causes an IEEE invalid-operation exception, unless otherwise stated. When the exception is recognized for a SNaN, the nontrap result is the corresponding QNaN, which is produced by setting the SNaN bit in the source SNaN to zero and then the converted QNaN is canonicalized, and the IEEE-invalid-operation flag (FPC 1.0) is set to one.

Canonicalization
For operations that are defined to produce a DFP result, the result placed at the target operand location is canonical, unless otherwise stated.

Programming Notes:
1. The following instructions may produce a noncanonical infinity as the result:
   - INSERT BIASED EXPONENT
   - LOAD LENGTHENED
   - LOAD ROUNDED
   - SHIFT SIGNIFICAND LEFT
   - SHIFT SIGNIFICAND RIGHT

Infinities produced as a DFP result have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. However, the infinity produced by the above instructions does not necessarily have zeros in all digits in the trailing significand. Such an infinity is not canonical.

2. Only canonical operands should be used, as it is possible that some libraries or software routines reject noncanonical operands.

3. Except for INSERT BIASED EXPONENT, if only canonical source operands are used, the result is canonical. INSERT BIASED EXPONENT may produce a noncanonical result even if all source operands are canonical. Special precautions should be taken to avoid producing a noncanonical result from INSERT BIASED EXPONENT.

DFP-Format Conversion
DFP format conversion is described in the section “IEEE Same-Radix Format Conversion” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Rounding
DFP rounding is described in the section “IEEE DFP Rounding” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Comparison
DFP comparison is described in the section “IEEE Comparison” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Formatting Instructions
A set of instructions are provided to compose and decompose DFP data. These instructions do not recognize any IEEE exceptions. They are:

- CONVERT FROM PACKED
Conversion of data between character strings in an external format and the DFP format may be performed in several steps. At certain steps, for finite numbers, the significand is kept in the packed-decimal format and the biased exponent in the fixed-point format. See Chapter 8, “Decimal Instructions,” for a detailed description of the zoned and packed-decimal formats.

It takes 17 packed-decimal digits to hold the 16 significand digits and one sign of a long DFP format; it takes 35 packed-decimal digits for an extended DFP format. To facilitate the conversion, the significand is divided into pieces and only one piece contains the sign. Each piece fits into a register or a register pair, and each piece is converted separately. To support this piecemeal conversion, two formats, signed-packed-decimal and unsigned-packed-decimal, are used to hold the pieces.

To facilitate the conversion between packed-decimal format data in memory and the DFP format, the CONVERT FROM PACKED and CONVERT TO PACKED instructions are provided. It takes up to 9 bytes to hold the 16 significand digits and one sign digit of a long DFP format. It takes up to 18 bytes to hold the 34 significand digits and one sign digit for an extended DFP format. Any unused digits in a packed-decimal format operand of CONVERT FROM PACKED must be zero.

For a zoned-decimal format, it takes 16 bytes to hold the 16 significand digits and one sign digit of a long DFP format; it takes 34 bytes for an extended DFP format. To facilitate the conversion, the CONVERT FROM ZONED and CONVERT TO ZONED instructions are provided.

Signed-Packed-Decimal Format
In the signed-packed-decimal format, each byte contains two 4-bit decimal digits (D), except for the rightmost byte, which contains a 4-bit sign (S) to the right of a 4-bit decimal digit.

When a signed-packed-decimal operand resides in a general register (GR), the operand is 64 bits (15 digits and sign), as shown below.

<table>
<thead>
<tr>
<th>D</th>
<th>D</th>
<th>D</th>
<th>D</th>
<th>D</th>

When a signed-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair and the rightmost 64 bits occupy the odd-numbered register, as shown below.

| D | D | D | D | D | D | D | D | D | D | D | D | D | D | D |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0 | 4 | 8 | 12 | 16 | 20 | 24 | 28 | 32 | 36 | 40 | 44 | 48 | 52 | 56 | 60 | 63

Unsigned-Packed-Decimal Format
In the unsigned-packed-decimal format, each byte contains two 4-bit decimal digits (D) and there is no sign.

When an unsigned-packed-decimal operand resides in a general register, the operand is 64 bits (16 digits), as shown below.

<table>
<thead>
<tr>
<th>D</th>
<th>D</th>
<th>D</th>
<th>D</th>
<th>D</th>
<th>D</th>

</thead>
</table>
| 0 | 4 | 8 | 12 | 16 | 20 | 24 | 28 | 32 | 36 | 40 | 44 | 48 | 52 | 56 | 60 | 63

Zoned-Decimal Format
In the unsigned zoned-decimal format, each byte contains two fields, a zone field in the leftmost four bit positions and a decimal digit in the rightmost four bit positions. The signed zoned-decimal format is similar to the unsigned zoned-decimal format except that the...
zone field of the rightmost byte instead contains a 4-bit sign. A zoned-decimal operand is a storage operand. See “Zoned Format” on page 8-1 for more details.

**IEEE Exceptions**

The IEEE exceptions for the DFP instructions are described in the section “IEEE Exceptions” on page 9-18. This also includes the quantum exception.

Explanation:
---
- This situation cannot occur.
- The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.
- The nontrap result r is considered to have been incremented.
- d The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.
- g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
- v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value.
- EZD Exact zero difference. The case applies only to ADD and SUBTRACT. For all other DFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.
- Dmin Smallest (in magnitude) representable subnormal number in the target format.
- Nmax Largest (in magnitude) representable finite number in the target format.
- Nmin Smallest (in magnitude) representable normal number in the target format.
- RNTA Round to nearest with ties away from 0.
- RNTZ Round to nearest with ties to even.
- RFS Round to prepare for shorter precision.
- RM Round toward -\infty.
- RP Round toward +\infty.
- RZ Round toward 0.

**Explanation:**

— The results do not depend on this condition or mask bit.
1 This condition is true by virtue of the state of some condition to the left of this column.
2 The quantum exception mask bit and the quantum exception control are defined only when the floating-point extension facility is installed.
3 This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum-exception mask bit and the quantum-exception control.
\(\Psi\) Scale factor. For overflow, \(\Psi=2^\alpha\). For underflow, \(\Psi=2^{-\alpha}\). The unscaled scaling exponent (\(\alpha\)) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED, \(\alpha\) depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED, \(\alpha\) depends on the source format and is 192 for long and 3072 for extended.
\(g\) The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
\(r\) Nontrap result as defined in Part 1 of this figure.
\(v\) Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
\(PIDc(h)\) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-15.
\(PIDq(04)\) DXC 04 is defined only when the floating-point extension facility is installed.
\(QX\) Quantum exception. This exception is defined only when the floating-point extension facility is installed.
\(SFo\) IEEE overflow flag, FPC 1.2.
\(SFq\) Quantum-exceptio status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed.
\(SFu\) IEEE underflow flag, FPC 1.3.
\(SFx\) IEEE inexact flag, FPC 1.4.
\(T(x)\) The value x is placed at the target operand location.
\(Tw(x)\) The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

**Explanation:**

The results do not depend on this condition or mask bit.

1. This condition is true by virtue of the state of some condition to the left of this column.
2. This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum-exception mask bit and the quantum-exception control.
3. This condition is true by virtue of the state of some condition to the left of this column.

**Legend:**

- **tr**, **v**: Non-trap result as defined in Part 1 of this figure.
- **XEC**: Programm interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-15.
- **PIDc(h)**: DXC 04 is defined only when the floating-point extension facility is installed.
- **QU**: Quantum exception. This exception is defined only when the floating-point extension facility is installed.
- **SFo**: IEEE overflow flag, FPC 1.2.
- **SFq**: Quantum-exception status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed.
- **SFu**: IEEE underflow flag, FPC 1.3.
- **SFx**: IEEE inexact flag, FPC 1.4.
- **T(x)**: The value x is placed at the target operand location.
- **Tw(x)**: The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

**Explanation:**

— The results do not depend on this condition or mask bit.

1 This condition is true by virtue of the state of some condition to the left of this column.

2 The quantum exception mask bit and the quantum exception control are defined only when the floating-point extension facility is installed.

3 This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum exception mask bit and the quantum exception control.

\(\Psi\) Scale factor. For overflow, \(\Psi=2^{12}\). For underflow, \(\Psi=2^{-12}\). The unsigned scaling exponent (\(\alpha\)) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED, \(\alpha\) depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED, \(\alpha\) depends on the source format and is 192 for long and 3072 for extended.

\(g\) The precision-rounded value. The value derived when the precise intermediate value (\(v\)) is rounded to the precision of the target, but assuming an unbounded exponent range.

\(r\) Nontrap result as defined in Part 1 of this figure.

\(v\) Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-15.

PIDq(04) DXC 04 is defined only when the floating-point extension facility is installed.

QX Quantum exception. This exception is defined only when the floating-point extension facility is installed.

SFo IEEE overflow flag, FPC 1.2.

SFq Quantum-exception status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed

SFu IEEE underflow flag, FPC 1.3.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand location.

Tw(x) The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 20-6. (Part 3 of 3) Rounding and Range Actions
Result Figures

Concise descriptions of the results produced by many of the DFP instructions are made by means of figures which contain columns and rows representing all possible combinations of DFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross-reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 20-8 on page 20-15.

Data-Exception Codes (DXC) and Abbreviations

Figure 20-7 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols “Xi:” and “Xz:” that are used in the figures. Bits 0-4 (i,z,o,u,x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 (y) of byte 2 is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

When the floating-point extension facility is installed, bit 5 of DXC also has a second meaning. When DXC bits 0-4 are zero, DXC bit 5 is the quantum-exception trap flag and corresponds to the quantum-exception mask IMq and its status flag SFq.

Figure 20-8 on page 20-15 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)

Explanation:

1. The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.

2. The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 20-7. IEEE Exception and Flag Abbreviations
The Decimal-Floating-Point (DFP) instructions and their mnemonics and operation codes are listed in Figure 20-9 on page 20-16.

The figure indicates, in the column labeled “Characteristics,” the instruction format, when the condition code is set, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All DFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the DFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a DFP-instruction data exception, DXC 3, is recognized.

Mnemonics for the DFP instructions are distinguished from corresponding HFP or BFP instructions by a T in the mnemonic. Mnemonics for the DFP instructions have an R as the last letter or the letter next to the last letter when the instruction is in the RRE or RRF format. Mnemonics for the DFP instructions have an A as the last letter when the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction. Certain letters are used for DFP instructions to represent operand format and operand-format length, as follows:

E Short
F Thirty-two-bit fixed point
G Sixty-four-bit fixed point
D Long
P Packed
X Extended
Z Zoned

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (long), for example, CDTR is the mnemonic and R1,R2 the operand designation.

**Programming Notes:**

1. The floating-point extension facility includes the following:
   - The following new DFP instructions:
     - CONVERT FROM FIXED (CXFTR, CDFTR)
     - CONVERT FROM LOGICAL (CXLGTR, CDLGT, CXLFR, CDLFR)
     - CONVERT TO FIXED (CFXTR, CFDT)
     - CONVERT TO LOGICAL (CLGXTR, CLGDTR, CLFXT, CLFDTR)
   - All reserved values in the effective rounding method field and a quantum-exception control (XqC) are assigned for LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND.
   - All reserved values in the effective rounding method field are assigned for CONVERT TO FIXED.
   - An IEEE-inexact-exception control (XxC) is added to CONVERT TO FIXED and LOAD ROUNDED.
   - An effective rounding method field and a quantum-exception control (XqC) are added to ADD, DIVIDE, MULTIPLY, and SUBTRACT.
   - An effective rounding method field, an IEEE-inexact-exception control (XxX), and a quantum-exception control (XxC) are added to CONVERT FROM FIXED.

Explanation:

$\sigma^7$ Restricted from transactional execution when the effective allow-floating-point-operation control is zero.

Figure 20-9. Summary of Decimal Instructions (Part 2 of 3)
The third operand is added to the second operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format and the rounded value is then placed at the result location.

When the floating-point extension facility is installed, the intermediate sum is rounded by rounding as specified by the modifier in the $M_4$ field:

- 0: According to the current DFP rounding mode
- 1: Round to nearest with ties away from 0
- 2: According to the current DFP rounding mode
- 3: Round to prepare for shorter precision
- 4: Round to nearest with ties to even
When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate sum is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero, as follows:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward \(-\infty\), in which method the sign is minus.
- The sign of the sum \(x + x\) is the sign of \(x\), even when \(x\) is zero.

If one operand is an infinity and the other is a finite number, the result is an infinity with the sign of the source infinity. If both operands are infinities of the same sign, the result is an infinity with the same sign. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-11 on page 20-20 for a detailed description of the results of this instruction. (Figure 20-10 is referred to by Figure 20-11.)

For AXTR and AXTRA, the R fields designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

**IEEE Exceptions:**

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (AXTR and AXTRA only)
- Transaction constraint

*Figure 20-10. Condition Code for Resultant Sum*

**Programming Notes:**

1. Interchanging the two operands in a DFP addition does not affect the value of the sum when
the result is numeric. This is not true, however, when both operands are QNaNs; or when both operands are SNaNs and the IEEE invalid-operation mask bit in the FPC register is zero, in these cases, the result is the canonical QNaN derived from the second operand.

2. For ADD or SUBTRACT, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the smaller quantum of the two source operands.

</tbody>
</table>

Explanation:
* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
cccn Condition code is set to n.
ccrs Condition code is set according to the resultant sum. See Figure 20-10 on page 20-19.
dNaN Default NaN.
Nn Normal number.
R(v) Rounding and range action is performed on the value v. See Figure 20-5 on page 20-10. The result is canonical.
Rezd Exact zero-difference result. See Figure 20-5 on page 20-10.
Dn Subnormal number.
T(x) The canonical result x is placed at the target operand location.
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-11. Results: ADD

COMPARE

| Mnemonic | Op Code |  |  |
|----------|---------|  |  |
| R1, R2   | 1111111 | R1 | R2 |

The first operand is compared with the second operand, and the condition code is set to indicate the result.
If both operands are finite numbers, the comparison is algebraic and follows the procedure for DFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

$+\infty$ compares greater than any finite number, and all finite numbers compare greater than $-\infty$. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 20-12 on page 20-21 for a detailed description of the results of this instruction.

For CXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

<td>24</td>
</tr>
</tbody>
</table>

Mnemonic Op Code Operands
KDTR 'B3E0' Long DFP
KXTR 'B3E8' Extended DFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus QNaN operands are treated as if they were SNaNs.

See Figure 20-14 on page 20-22 for a detailed description of the results of this instruction.

For KXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

- 0 Operands equal
- 1 First operand low
- 2 First operand high
- 3 Operands unordered

**IEEE Exceptions:**

- Invalid operation

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (KXTR only)
- Transaction constraint

**Figure 20-14. Results: COMPARE AND SIGNAL**

Mnemonic Op Code Operands
CEDTR 'B3F4' Long DFP
CEXTR 'B3FC' Extended DFP

The biased exponent of the first operand is compared with the biased exponent of the second operand, and the condition code is set to indicate the result.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-15 on page 20-23 for a detailed description of the results of this instruction.

For CEXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.
**Resulting Condition Code:**

0  Biased exponents equal
1  First-operan biased exponent low
2  First-operan biased exponent high
3  Unordered

**IEEE Exceptions:**  None.

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CEXTR only)
- Transaction constraint

</thead>
<tbody>
<tr>
<td>CDGTRA</td>
<td>'B3F1'</td>
<td>64-bit binary integer source, long DFP result</td>
</tr>
<tr>
<td>CXGTRA</td>
<td>'B3F9'</td>
<td>64-bit binary integer source, extended DFP result</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDFTTR</td>
<td>'B951'</td>
<td>32-bit binary integer source, long DFP result</td>
</tr>
<tr>
<td>CXTTR</td>
<td>'B959'</td>
<td>32-bit binary integer source, extended DFP result</td>
</tr>
</tbody>
</table>

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by \( R_2 \). A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded and then the rounded value is placed at the first-operand location.

When the floating-point extension facility is installed, the converted result is rounded by rounding as specified by the modifier in the \( M_3 \) field:

**M_3 Effective Rounding Method**

0  According to the current DFP rounding mode
1  Round to nearest with ties away from 0
2  According to the current DFP rounding mode
3  Round to prepare for shorter precision
4  Round to nearest with ties to even
5  Round toward 0
6  Round toward +∞
7  Round toward −∞
8  Round to nearest with ties to even
9  Round toward 0
10 Round toward +∞
11 Round toward −∞
12 Round to nearest with ties away from 0
13 Round to nearest with ties toward 0
14 Round away from 0
15 Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.
If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 16-19 of the instruction contain a value of zero, the converted result is rounded according to the current DFP rounding mode; if bits 16-19 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

When the delivered value is exact, the preferred quantum is one; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 on page 20-41 for a detailed description of the results of this instruction.

When the floating-point extension facility is installed, bit 1 of the M₄ field is the IEEE-inexact-exception control (XxC), and bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 20-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

For CXGTR, CXGTRA, and CXFTR, the R₃ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

An operation exception is recognized if the DFP facility is not installed. For CDFTR and CXFTR, the operation exception is also recognized if the floating-point extension facility is not installed.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact (CDGTR and CDGTRA only)
- Quantum (CDGTR and CDGTRA only, if the floating-point extension facility is installed)

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CXGTR, CXGTRA, and CXFTR only)
- Transaction constraint

**Programming Note:** Unassigned bits in the M₄ field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

### CONVERT FROM LOGICAL

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDLGTR 'B952'</td>
<td>64-bit binary-integer source, long DFP result</td>
<td></td>
</tr>
<tr>
<td>CXLGTR 'B95A'</td>
<td>64-bit binary-integer source, extended DFP result</td>
<td></td>
</tr>
<tr>
<td>CDLFTR 'B953'</td>
<td>32-bit binary-integer source, long DFP result</td>
<td></td>
</tr>
<tr>
<td>CXLFTR 'B95B'</td>
<td>32-bit binary-integer source, extended DFP result</td>
<td></td>
</tr>
</tbody>
</table>

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is an unsigned binary integer that is located in the general register designated by R₂. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded to an integer value by rounding as specified by the modifier in the M₃ field:

**M₃ Effective Rounding Method**
- 0: According to the current DFP rounding mode
- 1: Round to nearest with ties away from 0
- 2: According to the current DFP rounding mode
- 3: Round to prepare for shorter precision
- 4: Round to nearest with ties to even
- 5: Round toward 0
- 6: Round toward +∞
- 7: Round toward −∞
- 8: Round to nearest with ties to even
- 9: Round toward 0
When the modifier field is zero or two, rounding is
controlled by the current DFP rounding mode speci-
fied in the FPC register. When the field is 1, or 3-15,
rounding is performed as specified by the modifier,
regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-excep-
tion control (XqC) is one and recognition of the quan-
tum exception is suppressed; if the modifier field is 1-
7, the quantum-exception control is zero and recogni-
tion of the exception is not suppressed.

Bit 1 of the M4 field is the IEEE-inexact-exception
control (XxC). Bits 0, 2, and 3 are ignored. If XxC is
zero, recognition of IEEE-inexact exception is not
suppressed; if XxC is one, recognition of the exception
is suppressed.

The result always has a plus sign.

When the delivered value is exact, the preferred
quantum is one; when the delivered value is inexact,
the preferred quantum is the smallest quantum.

The result placed at the first-operand location is
canonical.

See Figure 20-24 on page 20-41 for a detailed
description of the results of this instruction.

For CXLGTR and CXLFR, the R1 field must desig-
nate a valid floating-point-register pair; otherwise, a
specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact (CDLGTR only)
- Quantum (CDLGTR only)

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is
  not installed)
- Specification (CXLGTR and CXLFR only)
- Transaction constraint

**Programming Notes:**
1. Unassigned bits in the M4 field are reserved for
   future extensions and should be set to zeros;
   otherwise, the program may not operate compat-
   ibly in the future.

2. Using either the round toward 0 or the round
toward \(-\infty\) rounding method produces the same
result; using either the round away from 0 or the
round toward \(+\infty\) rounding method produces the
same result.

**CONVERT FROM PACKED**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Rd(Dx),L2,B2,M3</th>
<th>[RSL-b]</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDPT</td>
<td>‘EDAE’</td>
<td>Packed source, long DFP result</td>
</tr>
<tr>
<td>CXPT</td>
<td>‘EDAF’</td>
<td>Packed source, extended DFP result</td>
</tr>
</tbody>
</table>

The second operand in the packed-decimal format is
converted to the DFP format, and the result is placed
at the first-operand location.

The preferred quantum is one, and the delivered
value is always represented with the preferred quan-
tum.

The result placed at the first-operand location is
canonical.

For CXPT the length in bytes of the second operand
is 1-18, corresponding to a length code in L2 of 0-17.
For CDPT the length in bytes of the second operand
is 1-9, corresponding to a length code in L2 of 0-8.
See Figure 20-17 for valid L2 values along with the
corresponding number of digits converted.

The M3 field has the following format:
The bits of the $M_3$ field are defined as follows:

- **Sign-Control (S):** Bit 0 of the $M_3$ field is the sign control (S). When the S bit is zero, the second operand does not have a sign field and the sign bit of the DFP first-operand result is set to zero.

When the S bit is one, the second operand contains a sign field in the rightmost four bit positions of the rightmost byte. The sign bit of the DFP first-operand result is set to zero when the sign field of the second operand indicates a positive value, or when the ignore-sign-digit control is one. The sign bit of the DFP first-operand result is set to one when the sign field of the second operand indicates a negative value and the ignore-sign-digit control is zero.

- **Reserved:** Bits 1-2 of the $M_3$ field are reserved.

- **Ignore-Sign-Digit Control (I):** Bit 3 of the $M_3$ field is the ignore-sign-digit control (I). When the I bit is zero, no special action is taken. When the I bit is one, the sign field of the second operand is ignored, it is not checked for invalid digits, and the sign bit of the DFP first-operand result is set to zero. When the S-bit is zero, the I bit is ignored.

**Special Conditions**

When an invalid digit or sign code is detected in the second operand, or an unused digit is not zero, a general-operand data exception is recognized. If the sign control and the ignore-sign-digit control are one, no sign code checking is performed on the sign digit. A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CDPT, the $L_2$ field is greater than 8
- For CXPT, the $R_1$ field designates an invalid floating-point-register pair, or the $L_2$ field is greater than 17

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (Fetch operand 2)
- Data with DXC 0, general operand

- Data with DXC 3, DFP instruction
- Operation (if the DFP packed-conversion facility is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. Depending on the model, for CXPT, when the $L_2$ field specifies 16 or 17 (meaning 32-34 digits), performance may be significantly worse than if shorter lengths are specified.

2. When trying to convert 16 packed digits and a sign digit for CDPT, a $L_2$ value of 8 should be used and the S bit in the $M_3$ field should be set to one. When trying to convert 34 packed digits and a sign digit for CXPT an $L_2$ value of 17 should be used and the S bit in the $M_3$ field should be set to one. In both of these cases, bits 0-3 of the first byte of the second operand should be zero; otherwise, a general-operand data exception will occur.

<td>32</td>
<td>36</td>
<td>40</td>
<td>47</td>
</tr>
</tbody>
</table>

Mnemonic Op Code Operands
CDZT ‘EDAA’ Zoned source, long DFP result
CXZT ‘EDAB’ Zoned source, extended DFP result

The second operand in the zoned format is converted to the DFP format, and the result is placed at the first-operand location.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

The length in bytes of the second operand is 1-34 for CXZT, corresponding to a length code in \( L_2 \) of 0-33. The length in bytes of the second operand is 1-16 for CDZT, corresponding to a length code in \( L_2 \) of 0-15.

The \( M_3 \) field has the following format:

\[
\begin{array}{cccc}
S & / & / & \n\end{array}
\]

0 1 2 3

The bits of the \( M_3 \) field are defined as follows:

- **Sign-Control (S):** Bit 0 of the \( M_3 \) field is the sign control (S). When zero, the second operand does not have a sign field and the sign bit of the DFP first-operand result is set to zero. When one, the second operand is signed. That is, the leftmost four bit positions of the rightmost byte are a sign. The sign bit of the DFP first-operand result is set to zero when the sign field indicates a positive value and one when the sign field indicates a negative value.

- **Reserved:** Bits 1-3 of the \( M_3 \) field are ignored.

**Special Conditions:**

When an invalid digit or sign code is detected in the second operand, a general-operand data exception is recognized.

A specification exception is recognized, and the operation is suppressed, when any of the following is true:

- For CDZT, the \( L_2 \) field is greater than or equal to 16.
- For CXZT, the \( R_1 \) field designates an invalid floating-point-register pair, or the \( L_2 \) field is greater than or equal to 34.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (Fetch operand 2)
- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP zoned-conversion facility is not installed)
- Specification
- Transaction constraint

**Programming Notes:**

1. When an ASCII second operand is specified, bit 0 of the \( M_3 \) field must be zero, otherwise a general-operand data exception is recognized. That is, a sign value of 0011 binary is not a valid sign.

2. Depending on the model, for CXZT, when the \( L_2 \) field specifies 32 or 33 (meaning 33 or 34 digits), performance may be significantly worse than if shorter lengths are specified.

3. Bits 1-3 of the \( M_3 \) field should be set to zeros, otherwise the program may not operate compatibly in the future.

CONVERT TO FIXED

Mnemonic: \( R_1, M_3, R_2 \) [RRF-e]

<table>
<thead>
<tr>
<th>Op Code</th>
<th>M_3</th>
<th>// //</th>
<th>R_1</th>
<th>R_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 16</td>
<td>20</td>
<td>24</td>
<td>28</td>
<td>31</td>
</tr>
</tbody>
</table>

Mnemonic Op Code Operands
CGDTR ‘B3E1’ Long DFP source, 64-bit binary-integer result
CGXTR ‘B3E9’ Extended DFP source, 64-bit binary-integer result
The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R1. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M3 field:

<table>
<thead>
<tr>
<th>M3</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>1</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>2</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>3</td>
<td>Round to prepare for shorter precision</td>
</tr>
<tr>
<td>4</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>5</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>6</td>
<td>Round toward +∞</td>
</tr>
<tr>
<td>7</td>
<td>Round toward -∞</td>
</tr>
<tr>
<td>8</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>9</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>10</td>
<td>Round toward +∞</td>
</tr>
<tr>
<td>11</td>
<td>Round toward -∞</td>
</tr>
<tr>
<td>12</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>13</td>
<td>Round to nearest with ties toward 0</td>
</tr>
<tr>
<td>14</td>
<td>Round away from 0</td>
</tr>
<tr>
<td>15</td>
<td>Round to prepare for shorter precision</td>
</tr>
</tbody>
</table>

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the M3 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the floating-point extension facility is installed, bit 1 of the M4 field is the IEEE-inexact-exception control (XxC), and bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 20-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 20-18 for a detailed description of the results of this instruction.

For CGXTR, CGXTRA, and CFXTR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

An operation exception is recognized if the DFP facility is not installed. For CFDTR, CFDTRA, CFXTR, and CFXTRA the operation exception is also recognized if the floating-point extension facility is not installed.

**Resulting Condition Code:**

**Explanation:**

— The results do not depend on this condition or mask bit.

1 This condition is true by virtue of the state of some condition to the left of this column.

2 XxC is defined only when the floating-point extension facility is installed.

ccn Condition code is set to n.

† Result differs from BFP CONVERT TO FIXED. The BFP instruction recognizes inexact for this case and takes different actions depending on the inexact mask. The DFP implementation is intended to be more in keeping with the spirit of the IEEE standard.

f The value n converted to a fixed-point result.

n The value derived when the source value (b) is rounded to a floating-point integer using the effective rounding method.

MN Maximum negative number representable in the target fixed-point format.

MP Maximum positive number representable in the target fixed-point format.

PiDc(h) Program interruption for data exception, condition c, with DXC of h in hex. Figure 20-8 on page 20-15

SFi IEEE invalid-operation flag, FPC 1.0.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand location.

---

*Figure 20-18. Results: CONVERT TO FIXED*

</tbody>
</table>

The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is an unsigned binary integer that is placed in the general register designated by R1. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M3 field:

<table>
<thead>
<tr>
<th>M3</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>1</td>

</tr>
<tr>
<td>14</td>
<td>Round away from 0</td>
</tr>
<tr>
<td>15</td>
<td>Round to prepare for shorter precision</td>
</tr>
</tbody>
</table>

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

Bit 1 of the M4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

See Figure 20-19 for a detailed description of the results of this instruction.

For CLGXTR and CLFXTR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

CONVERT TO PACKED

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPDT</td>
<td>EDAC</td>
<td>Long DFP source, packed result</td>
</tr>
<tr>
<td>CPXT</td>
<td>‘EDAD’</td>
<td>Extended DFP source, packed result</td>
</tr>
</tbody>
</table>

The significand digits of the DFP first operand and the sign bit of the first operand are converted to the packed format. The exponent in the combination field is ignored. The specified number of rightmost bytes of packed digits are placed at the second-operand location.

If there are not enough significand digits to fill all of the packed bytes, zero digits are appended to the significand as leftmost digits.

The number of bytes containing rightmost significant digits of the converted first operand is specified by L₂. The length in bytes of the second operand is 1-18 for
The M₃ field has the following format:

```
S / P  F
0 1 2 3
```

The bits of the M₃ field are defined as follows:

- **Sign Control (S):** Bit 0 of the M₃ field is the sign control (S). When S is zero, the second operand does not have a sign field. When S is one, the second operand has a sign field. That is, the rightmost four bit positions of the rightmost byte are a sign.

- **Reserved:** Bit 1 of the M₃ field is reserved and should be zero.

- **Plus-Sign-Code Control (P):** Bit 2 of the M₃ field is the plus-sign-code control (P). When P is zero, the plus sign is encoded as 1100 binary. When P is one, the plus sign is encoded as 1111 binary. When the S bit is zero, the P bit is ignored.

- **Force-Plus-Zero Control (F):** Bit 3 of the M₃ field is the force-plus-zero control (F). When F is zero and a signed value of negative zero results, no action is taken. When F is one and the absolute value of the result placed in the second operand location is zero, the result is set to indicate a positive zero with the sign code specified by the P bit. When the S bit is zero, the F bit is ignored.

**Special Conditions**

The operation is performed for any first operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

If the first operand is an infinity or a NaN, a zero digit is appended as the leftmost digit (LMD) of the significand, thereby conceptually forming the effective significand to be converted. The specified number of rightmost effective significand digits and the sign bit are converted to the packed format, the result is placed at the second-operand location, and execution completes with condition code 3.

For any type of first operand, including an infinity and a NAN, when one or more leftmost nonzero digits of the significand are lost because the second operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

A specification exception is recognized, and the operation is suppressed, when any of the following is true:

- For CPDT, the L₂ field is greater than 8.
- For CPXT, the R₁ field designates an invalid floating-point-register pair, or the L₂ field is greater than 17.

**Resulting Condition Code:**

0  Source is zero  
1  Source is not special and is less than zero  
2  Source is not special and is greater than zero  
3  Source is special which is infinity, QNaN, SNaN, or a partial result

**Program Exceptions:**

- Access (Store operand 2)  
- Data with DXC 3, DFP instruction  
- Decimal overflow  
- Operation (if the DFP packed-conversion facility is not installed)  
- Specification  
- Transaction constraint

**Programming Notes:**

1. If the number of significant digits of a significand exceeds the specified number, one or more leftmost digits of the significand are ignored except for the detection of a decimal overflow exception.

2. A completion with condition code 0 indicates that the absolute value of the first operand is zero.
CONVERT TO SIGNED PACKED

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSBTR</td>
<td>'B3E3'</td>
<td>Long DFP source, 64-bit signed-packed-decimal result in GR</td>
</tr>
<tr>
<td>CSXTR</td>
<td>'B3EB'</td>
<td>Extended DFP source, 128-bit signed-packed-decimal result in GRs</td>
</tr>
</tbody>
</table>

Rightmost significand digits of the DFP second operand are converted to the signed-packed-decimal format, and the result is placed at the first-operand location.

For CSBTR, the rightmost 15 digits in the trailing significand and the sign bit of the second operand are converted to a 64-bit result (15 4-bit decimal digits and a 4-bit sign); for CSXTR, the rightmost 31 digits in the trailing significand and the sign bit of the second operand are converted to a 128-bit result (31 4-bit decimal digits and a 4-bit sign). The sign of the result is the sign of the second operand.

Bit 3 of the M4 field is the plus sign-code selection bit. When the bit is zero, the plus sign is encoded as 1100; when the bit is one, the plus sign is encoded as 1111. Bits 0-2 are ignored.

The result is placed in the general register or general-register pair designated by R1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CSXTR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CSXTR only)

CONVERT TO UNSIGNED PACKED

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUDTR</td>
<td>'B3E2'</td>
<td>Long DFP source, 64-bit unsigned-packed-decimal result in GR</td>
</tr>
<tr>
<td>CUXTR</td>
<td>'B3EA'</td>
<td>Extended DFP source, 128-bit unsigned-packed-decimal result in GRs</td>
</tr>
</tbody>
</table>

Rightmost significand digits of the DFP second operand are converted to the unsigned-packed-decimal format, and the result is placed at the first-operand location.

For CUDTR, 16 significand digits of the second operand are converted to a 64-bit result (16 4-bit decimal digits). If the second operand is an infinity or NaN, the 15 digits in the trailing significand are padded with a zero digit on the left to form a 16 significand digits.

For CUXTR, the rightmost 32 digits in the trailing significand of the second operand are converted to a 128-bit result (32 4-bit decimal digits).

The result is placed in the general register or general-register pair designated by R1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CUXTR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.
**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CUXTR only)
- Transaction constraint

## CONVERT TO ZONED

### Mnemonic

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L₂</th>
<th>B₂</th>
<th>D₂</th>
<th>R₁</th>
<th>M₃</th>
<th>Op Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>R₁,D₂(L₂,B₂),M₃</td>
<td>[RSL-b]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Op Code

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Op Code</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CZDT</td>
<td>‘EDA8’</td>
<td>Long DFP source, zoned result</td>
</tr>
<tr>
<td>CZXT</td>
<td>‘EDA9’</td>
<td>Extended DFP source, zoned result</td>
</tr>
</tbody>
</table>

The specified number of rightmost significand digits of the DFP first operand and the sign bit of the first operand are converted to the zoned format, and the result is placed at the second-operand location. The exponent in the combination field is ignored.

The number of rightmost significand digits of the first operand to be converted is specified by L₂. The length in bytes of the second operand is 1-34 for CZXT, corresponding to a length code in L₂ of 0-33, meaning 1-34 digits. The length in bytes of the second operand is 1-16 for CZDT, corresponding to a length code in L₂ of 0-15, meaning 1-16 digits.

The M₃ field has the following format:

```
SZPF
0 1 2 3
```

The bits of the M₃ field are defined as follows:

- **Sign Control (S):** Bit 0 of the M₃ field is the sign control (S). When S is zero, the second operand does not have a sign field, and the zone field is set as determined by the Z bit. When S is one, the second operand has a sign field. That is, the leftmost four bit positions of the rightmost byte are a sign.

- **Zone Control (Z):** Bit 1 of the M₃ field is the zone control (Z). When Z is zero, each zone field of the second operand is stored as 1111 binary, except that the zone field of the rightmost byte is set to the sign when the S bit is one. When Z is one, each zone field of the second operand is stored as 0011 binary, except that the zone field of the rightmost byte is set to the sign when the S bit is one.

- **Plus-Sign-Code Control (P):** Bit 2 of the M₃ field is the plus-sign-code control (P). When P is zero, the plus sign is encoded as 1100 binary. When P is one, the plus sign is encoded as 1111 binary.

When the S bit is zero, the P bit is ignored and assumed to be zero. The zone of the rightmost digit is set as determined by the Z bit.

- **Force-Plus-Zero Control (F):** Bit 3 of the M₃ field is the force-plus-zero control (F). When F is zero, no action is taken. When F is one and the absolute value of the result placed at the second-operand location is zero, the sign of the result is set to indicate a plus value with the sign code specified by the P bit.

When the S bit is zero, the F bit is ignored and assumed to be zero.

### Special Conditions

The operation is performed for any first operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

If the first operand is an infinity or a NaN, a zero digit is assumed to be the leftmost digit (LMD) of the significand, thereby conceptually forming the effective significand to be converted. The specified number of rightmost effective-significand digits and the sign bit are converted to the zoned format, the result is placed at the second-operand location, and execution completes with condition code 3.

For any type of first operand, including an infinity, and a NaN, when one or more leftmost nonzero digits of the significand are lost because the second-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; non-zero digits must have been lost during the operation.

A specification exception is recognized, and the operation is suppressed, when any of the following is true:

---

20-35
• For CZDT, the L₂ field is greater than or equal to 16, meaning 17 or more digits.
• For CZXT, the R₁ field designates an invalid floating-point-register pair, or the L₂ field is greater than or equal to 34, meaning 35 or more digits.

**Resulting Condition Code:**

0 Source is zero  
1 Source is less than zero  
2 Source is greater than zero  
3 Infinity, QNaN, SNaN, Partial result

**Program Exceptions:**

• Access (Store operand 2)  
• Data with DXC 3, DFP instruction  
• Decimal overflow  
• Operation (if the DFP zoned-conversion facility is not installed)  
• Specification  
• Transaction constraint

**Programming Notes:**

1. An ASCII zoned-decimal operand may be stored as signed when the S bit is one. This is entirely up to the program as ASCII representations are usually unsigned and positive with no concept of a rightmost zone being used as a sign.

2. If the number of significant digits of a significand exceeds the specified number, one or more leftmost digits of the significand are ignored.

3. Depending on the model, for CZXT, when the L₂ field specifies 32 or 33 (meaning 33 or 34 digits), performance may be significantly worse than if shorter lengths are specified.

4. A completion with condition code 0 indicates that the absolute value of the first operand is zero.

**DIVIDE**

<table>
<thead>
<tr>
<th>Mnemonic1</th>

<tbody>
<tr>
<td>DDTR 'B3D1'</td>
<td>Long DFP</td>
</tr>
<tr>
<td>DXTR 'B3D9'</td>
<td>Extended DFP</td>
</tr>
</tbody>
</table>

The second operand (the dividend) is divided by the third operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If divisor is nonzero and both the dividend and divisor are finite numbers, the second operand is divided by the third operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format and the rounded value is then placed at the first-operand location.

When the floating-point extension facility is installed, the intermediate quotient is rounded by rounding as specified by the modifier in the M₄ field:

<table>
<thead>
<tr>
<th>M₄</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>1</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>2</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>3</td>
<td>Round to prepare for shorter precision</td>
</tr>
<tr>
<td>4</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>5</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>6</td>
<td>Round toward +∞</td>
</tr>
<tr>
<td>7</td>
<td>Round toward -∞</td>
</tr>
<tr>
<td>8</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>9</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>10</td>
<td>Round toward +∞</td>
</tr>
<tr>
<td>11</td>
<td>Round toward -∞</td>
</tr>
<tr>
<td>12</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>13</td>
<td>Round to nearest with ties toward 0</td>
</tr>
<tr>
<td>14</td>
<td>Round away from 0</td>
</tr>
<tr>
<td>15</td>
<td>Round to prepare for shorter precision</td>
</tr>
</tbody>
</table>

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-
7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate quotient is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

When the dividend is a finite number and the divisor is infinity, then a value of zero with zero significant and zero biased exponent is produced.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

When the delivered value is exact, the preferred quantum is the quantum of the dividend divided by the quantum of the divisor; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

If the divisor is zero but the dividend is nonzero and finite, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinite, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 20-20 on page 20-37 for a detailed description of the results of this instruction.

For DXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (DXTR and DXTRA only)
- Transaction constraint

<td>X: T(b*)</td>
</tr>
</tbody>
</table>

**Explanation:**
- The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- dNaN Default NaN.
- Fn Nonzero finite number (includes both subnormal and normal numbers).
- R(x) Rounding and range action is performed on the value x. See Figure 20-5 on page 20-10. The result is canonical.
- T(x) The canonical result x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
- Xz: IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.
- zt A value of zero with zero significant and zero biased exponent.

Figure 20-20. Results: DIVIDE
Programming Note: For DIVIDE, when the delivered value is inexact, the preferred quantum is the smallest quantum which is not always the same quantum as that closest to the quantum of the dividend divided by the quantum of the divisor.

For example, with the short data format, when \( 5000001 \times 10^{-7} \) is divided by \( 400 \times 10^0 \), the smallest quantum for the delivered value is \( 1 \times 10^{-8} \). However, the quantum that is closest to the quantum of the dividend divided by the quantum of the divisor is \( 1 \times 10^{-7} \).

**EXTRACT BIASED EXPONENT**

<table>

<td>Extended DFP source, 64-bit binary-integer result</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The biased exponent of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the biased exponent of the second operand is placed at the first-operand location. When the second operand is an infinity, QNaN, or SNaN, a special value is placed at the first-operand location.

The result is a 64-bit signed binary integer that is placed in the general register designated by R1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-21 for a detailed description of the results of this instruction.

For EEXTR, the R2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (EEXTR only)
- Transaction constraint

**EXTRACT SIGNIFICANCE**

<table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

The number of DFP significant digits of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the result is set to the number of DFP significant digits of the second operand. When the second operand is an infinity, QNaN, or SNaN, the result is set to -1, -2, or -3, respectively.

The result is a 64-bit signed binary integer that is placed in the general register designated by R1.

See Figure 20-22 for a detailed description of the results of this instruction.

**Second-operand data**

</tr>
</thead>
<tbody>
<tr>
<td>IEDTR</td>
<td>'B3F6'</td>
<td>Long DFP</td>
</tr>
<tr>
<td>IEXTR</td>
<td>'B3FE'</td>
<td>Extended DFP</td>
</tr>
</tbody>
</table>

A DFP operand is produced by combining the requested biased exponent with the sign bit and the significand of the DFP third operand, and the result is placed in the first-operand location.

The value of the requested biased exponent is a 64-bit signed binary integer and is located in the general register designated by R₂.

When the value of the requested biased exponent is in the range between zero and the maximum biased exponent, inclusively, for the target format, the result is a finite number. The biased exponent of the result is set to the value of the requested biased exponent; the significand of the result is set to the significand of the third operand. If the third operand is an infinity or NaN, the significand of the third operand contains the digits in the trailing significand of the third operand padded with a zero digit on the left.

When the value of the requested biased exponent is -1, the result is an infinity. The reserved field of the result is set to zero; the trailing significand of the result is set to the trailing significand of the third operand.

When the value of the requested biased exponent is equal to -2, less than -3, or greater than the maximum biased exponent for the target format, the result is a QNaN; when the value of the requested biased exponent is -3, the result is an SNaN. When a NaN is produced as the result, the reserved field of the result is set to zero, and the trailing significand of the result is set to the trailing significand of the third operand.

The sign of the result is the same as the sign of the third operand.

The preferred quantum is the quantum that corresponds to the requested biased exponent. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the third operand are zeros, then the result is a canonical infinity; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

See Figure 20-23 for a detailed description of the results of this instruction.

This operation is performed for any requested biased exponent and any third operand without causing an IEEE exception.

For IEXTR, the R₁ and R₃ fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (IEXTR only)
- Transaction constraint

**Programming Note:** Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand...
field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

LOAD AND TEST

Mnemonic R1,R2 [RRE]

<table>

<tr>
<td>Mnemonic</td>
<td>LTXTR</td>
<td>'B3DE'</td>
<td>Extended DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is canonicalized before it is placed at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN.

The preferred quantum is the quantum of the second operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 for a detailed description of the results of this instruction.

For LTXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

**IEEE Exceptions:**

- Invalid operation

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LTXTR only)
- Transaction constraint

</tr>
</tbody>
</table>

**Explanation:**

- The results do not depend on this condition.
- * The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- 1 The operand is extended to the longer format by appending zeros on the left before it is placed at the target operand location.
- 2 The operand is shortened to the target format by truncating the leftmost digits.
- Fn Nonzero finite number (includes both subnormal and normal).
- N(±∞) The resultant infinity has the reserved field set to zero and has canonical declets in the encoded trailing-significand field. The result is not considered canonical unless all digits in the trailing significand are zeros.
- R(v) Rounding and range action is performed on the value v. See Figure 20-5 on page 20-10. The result is canonical.
- R(b) The value b is converted to the exact floating-point number v, and then action R(v) is performed. The result is canonical.
- T(x) The canonical result x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
- XiC IEEE-invalid-operation-exception control, bit 0 of the M4 field.

Figure 20-24. Results: Some Single-Operand Instructions

<table>

<td>Extended DFP</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M3 field:

<table>
<thead>
<tr>
<th>M3</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>1</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>2</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>3</td>
<td>Round to prepare for shorter precision</td>
</tr>
<tr>
<td>4</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>5</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>6</td>
<td>Round toward +∞</td>
</tr>
</tbody>
</table>

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception con-
trol is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the \( M_2 \) modifier field is 1-7, it is unpredictable which rounding method is performed.

In the absence of an interruption, if the second operand is an infinity, the result is the canonical infinity; if the second operand is a QNaN, the result is the canonicalized source QNaN that has the same sign and payload as the source; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

Bit 1 of the \( M_4 \) field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored.

When the result differs in value from the second operand, if XxC is zero, an IEEE-inexact exception is recognized. If XxC one, then no IEEE-inexact exception is recognized.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the delivered value is exact, the preferred quantum is the larger value of one and the quantum of the second operand; when the delivered value is inexact, the preferred quantum is one. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-25 on page 20-42 for a detailed description of the results of FIDTR and FIXTR.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the second operand and if XqC is zero, then a quantum exception is recognized.

For FIXTR, the R fields must designate valid floating-point-register fields; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (FIXTR only)
- Transaction constraint

</tbody>
</table>

Explanations:

The results do not depend on this condition or mask bit.

*The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.

This condition is true by virtue of the state of some condition to the left of this column.

XnC is defined only if the floating-point extension facility is installed.

The value derived when the source value, b, is rounded to an integer using the effective rounding method.

Fn Finite nonzero number (includes both subnormal and normal).

PiDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-15.

PiDq(04) Program interruption for data exception, quantum-exception condition q, with DXC of 04 in hex. It is defined only if the floating-point extension facility is installed.

Q Quantum of the second operand.

SF i IEEE invalid-operation flag, FPC 1.0.

SFq Quantum exception flag, FPC 1.5. The flag is defined only if the floating-point extension facility is installed.

SFx IEEE inexact flag, FPC 1.4.

T(x) The canonical result x is placed at the target operand location. The result, when it is a finite number, is always represented with the preferred quantum.

Figure 20-25. Results: LOAD FP INTEGER
converted to the same value with a quantum of one.

**LOAD LENGTHENED**

<table>
<thead>
<tr>

</tr>
<tr>
<td>LXDTR</td>
<td>'B3DC'</td>
<td>Long DFP source, extended DFP result</td>
</tr>
</tbody>
</table>

The second operand is converted to a longer format, and the result is placed at the first-operand location.

Bit 0 of the \( M_4 \) field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). Bits 1-3 are ignored. When XiC is zero, recognition of IEEE-invalid-operation exception is not suppressed; when XiC is one, recognition of the exception is suppressed.

When the second operand is a finite number, the value of the second operand is placed in the target format.

When the second operand is an infinity, if XiC is zero, the result is the canonical infinity for the target format; if XiC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being extended by appending zeros on the left, and all decimals in the encoded trailing-significand field being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload extended by appending zeros on the left.

When the second operand is an SNaN, if XiC is zero, an invalid-operation exception is recognized and the nontrap result is the corresponding QNaN with the payload extended by appending zeros on the left; if XiC is one, no invalid-operation exception is recognized, and the result is the canonicalized source SNaN with the payload extended by appending zeros on the left.

The sign of the result is the same as the sign of the second operand.

The delivered value is always exact and the preferred quantum is the quantum of the second operand.

When XiC is zero, the result placed at the first-operand location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-24 on page 20-41 for a detailed description of the results of this instruction.

For LXDTR, the \( R_1 \) field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LXDTR only)
- Transaction constraint

**Programming Notes:**

1. Unassigned bits in the \( M_4 \) field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

2. The equivalent operations of LOAD LENGTHENED (short to long) in the Power architecture do not recognize the invalid-operation exception for both BFP and DFP. The equivalent operations of LOAD LENGTHENED in z/Architecture do recognize the exception for BFP. The IEEE-invalid-operation exception control (XiC) is provided for compatibility.

3. Infinities produced as DFP results have the reserved field set to zero and have canonical decimals in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.
LOAD ROUNDED

</tbody>
</table>

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

The second operand, if it is a finite number, is rounded as specified by the modifier in the M3 field:

<table>
<thead>
<tr>
<th>M3</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>1</td>

</tr>
<tr>
<td>4</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>5</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>6</td>
<td>Round toward $+\infty$</td>
</tr>
<tr>
<td>7</td>
<td>Round toward $-\infty$</td>
</tr>
<tr>
<td>8</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>9</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>10</td>
<td>Round toward $+\infty$</td>
</tr>
<tr>
<td>11</td>
<td>Round toward $-\infty$</td>
</tr>
<tr>
<td>12</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>13</td>
<td>Round to nearest with ties toward 0</td>
</tr>
<tr>
<td>14</td>
<td>Round away from 0</td>
</tr>
<tr>
<td>15</td>
<td>Round to prepare for shorter precision</td>
</tr>
</tbody>
</table>

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M3 modifier field is 1-7, it is unpredictable which rounding method is performed.

Bit 0 of the M4 field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XIC). When XIC is zero, recognition of IEEE-invalid-operation exception is not suppressed; when XIC is one, recognition of IEEE-invalid-operation exception is suppressed.

When the floating-point extension facility is installed, bit 1 of the M4 field is the IEEE-inexact-exception control (XxC), and bits 2-3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact-exception is suppressed.

In the absence of a trap overflow or trap underflow, the result is in the format and length of the target. However, when a trap overflow or trap underflow occurs, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. In this case, the result is selected from a subset of the cohort for the delivered value in the source format. This subset consists of members that have the number of DFP significand digits equal to or less than the precision of the target format. For LEDTR, the result has at most seven DFP significant digits; for LDXTR, the result has at most 16 DFP significant digits.

When the floating-point extension facility is not installed, and if the M4 field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the second operand is an infinity, if XIC is zero, the result is the canonical infinity for the target format; if XIC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being shortened by removing leftmost digits, and declets corresponding to the shortened trailing significand being canonicalized.
When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload shortened by removing leftmost digits.

When the second operand is an SNaN, if XiC is zero, an invalid-operation exception is recognized and the nontrap result is the corresponding QNaN with the payload shortened by removing leftmost digits; if XiC is one, no invalid-operation exception is recognized, and the result is the canonicalized source SNaN with the payload shortened by removing leftmost digits.

The sign of the result is the same as the sign of the second operand.

When the delivered value is exact, the preferred quantum is the quantum of the second operand; when the delivered value is inexact, the preferred quantum is the smallest quantum.

When XiC is zero, the result placed at the first-operation location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-24 on page 20-41 for a detailed description of the results of this instruction.

For LDXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LDXTR only)
- Transaction constraint

**Programming Notes:**

1. LOAD ROUNDED and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with the precision of a shorter format and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable rounding method is used by the subsequent LOAD ROUNDED instruction.

2. Unassigned bits in the M₄ field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

3. The equivalent operation of LOAD ROUNDED (long to short) in the Power architecture does not recognize the invalid-operation exception. IEEE-invalid-operation-exception control (XiC) is provided for compatibility.

4. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

5. In case of a trap overflow or a trap underflow, the number of DFP significand digits of the delivered result is limited to the precision of the target format. For example, when the source operand is $75958100 \times 10^{369}$ and is represented with the quantum of $10^{369}$, execution of LEDTR using the round-away-from-0 rounding method produces a value of $7595810 \times 10^{178}$ with the delivered quantum of $10^{178}$ as the trap overflow result.
The product of the second operand (the multiplicand) and the third operand (the multiplier) is placed at the first-operand location.

If both source operands are finite numbers, they are multiplied to form an intermediate product. The intermediate product is rounded to the target format and the rounded value is then placed at the first-operand location.

When the floating-point extension facility is installed, the intermediate product is rounded by rounding as specified by the modifier in the $M_4$ field:

$$
\begin{align*}
M_4 & \quad \text{Effective Rounding Method} \\
0 & \quad \text{According to the current DFP rounding mode} \\
1 & \quad \text{Round to nearest with ties away from 0} \\
2 & \quad \text{According to the current DFP rounding mode} \\
3 & \quad \text{Round to prepare for shorter precision} \\
4 & \quad \text{Round to nearest with ties to even} \\
5 & \quad \text{Round toward 0} \\
6 & \quad \text{Round toward } +\infty \\
7 & \quad \text{Round toward } -\infty \\
8 & \quad \text{Round to nearest with ties to even} \\
9 & \quad \text{Round toward 0} \\
10 & \quad \text{Round toward } +\infty \\
11 & \quad \text{Round toward } -\infty \\
12 & \quad \text{Round to nearest with ties away from 0} \\
13 & \quad \text{Round to nearest with ties toward 0} \\
14 & \quad \text{Round away from 0} \\
15 & \quad \text{Round to prepare for shorter precision}
\end{align*}
$$

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate product is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

When the delivered value is exact, the preferred quantum is the product of the quanta of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-26 on page 20-48 for a detailed description of the results of this instruction.

If one source operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

For MXTR and MXTRA, the $R$ fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:
- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (MXTR and MXTRA only)
- Transaction constraint

Programming Notes:
1. Interchanging the two operands in a DFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the canonical QNaN derived from the second operand; or when both operands are SNaNs and the IEEE invalid-operation
When both the second and third operands are finite numbers, if the quantum of the third operand is equal to or larger than the requested quantum, the value of the third operand with the requested quantum is placed at the first-operand location. If the quantum of the third operand is smaller than the requested quantum, the third operand is rounded to the requested quantum by rounding as specified by the modifier in the M₄ field, and the result with the requested quantum is placed at the first-operand location.

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC.
register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

The preferred quantum is the requested quantum. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-27 on page 20-50 for a detailed description of the results of this instruction.

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested quantum. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

An IEEE inexact exception is recognized when the result differs in value from the third operand.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the third operand and if XqC is zero, then a quantum exception is recognized.

For QAXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (QAXTR only)
- Transaction constraint
Programming Notes:

1. When the third operand is larger than \((10^p - 1) \times 10^{Q_b}\) in magnitude, an invalid-operation exception is recognized, where \(p\) is the format precision and \(10^{Q_b}\) is the requested quantum.

   The expression, \((10^p - 1) \times 10^{Q_b}\), specifies the largest magnitude that can be represented with the requested quantum in the format. A value larger than \((10^p - 1) \times 10^{Q_b}\) in magnitude will have more than \(p\) digits when the value is represented with the requested quantum.

2. When both source operands are finite numbers, an invalid-operation exception can occur only if the requested quantum is smaller than the quantum of the third operand; and an inexact exception can occur only if the requested quantum is larger than the quantum of the third operand.

### Table 20-27: Results: QUANTIZE

| Relation | Is \(|V_c| > (10^p - 1) \times 10^{Q_b}\)? | Result for Q(b:c) |
|----------|----------------------------------------|-------------------|
| \(10^{Q_b} < 10^{Q_c}\) | Yes | Xi: T(dNaN) |
| \(10^{Q_b} = 10^{Q_c}\) | | T(c) |
| \(10^{Q_b} > 10^{Q_c}\) | | Rq(c) |

### Explanation:

1. The quantum of the second operand and the third operand is \(10^{Q_b}\) and \(10^{Q_c}\), respectively.

- **dNaN**: Default NaN.
- **E(0)**: The value zero with the quantum of operand b is placed at the target operand location.
- **Fn**: Finite nonzero number (includes both subnormal and normal).
- **Q(b:c)**: See Figure 20-28.
- **T(x)**: The canonical result x is placed at the target operand location.
- **Xi**: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

### Figure 20-28. Results: Q(b:c)
### REROUND

**Mnemonic** \( R_1, R_2, R_3, M_4 \) \([RRF-b]\)

<table>
<thead>
<tr>
<th>Op Code</th>
<th>( R_3 )</th>
<th>( M_4 )</th>
<th>( R_1 )</th>
<th>( R_2 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>24</td>
<td>28</td>
<td>31</td>
</tr>
</tbody>
</table>

**Op Code** | **Operands**
--- | ---
RRDTR | "B3F7" Long DFP
RRXTR | "B3FF" Extended DFP

The third operand is rounded to the requested significance, and the result is placed at the first-operand location.

The requested significance, which specifies a number of DFP significant digits, is an unsigned binary integer and is in bit positions 58-63 of general register \( R_2 \). The contents of bit positions 0-57 of general register \( R_2 \) are ignored.

When the third operand is a finite number, if the requested significance is zero, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is greater than the requested significance, then the third operand is rounded to the requested significance, and the result with the requested significance is placed at the first-operand location.

The third operand is rounded to the requested significance by rounding as specified by the modifier in the \( M_4 \) field:

<table>
<thead>
<tr>
<th>( M_4 )</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>1</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>2</td>
<td>According to the current DFP rounding mode</td>
</tr>
<tr>
<td>3</td>
<td>Round to prepare for shorter precision</td>
</tr>
<tr>
<td>4</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>5</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>6</td>
<td>Round toward (+\infty)</td>
</tr>
</tbody>
</table>

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the \( M_4 \) modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

When the delivered value is exact, if the requested significance is zero, or if the requested significance is nonzero and the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the preferred quantum is the quantum of the third operand. When the delivered value is exact, if the requested significance is nonzero and the number of DFP significant digits of the third operand is greater than the requested significance, then the preferred quantum is the quantum that corresponds to the requested significance.
When the delivered value is inexact, the preferred quantum is the quantum that corresponds to the requested significance.

If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-29 for a detailed description of the results of this instruction.

<td>--</td>
</tr>
</tbody>
</table>

Explanation:

-- Not applicable.

* The SNaN is converted to the corresponding QNaN and placed at the target operand location.

dNaN Default NaN.

Fn Nonzero finite numbers (includes both subnormal and normal).

k The requested significance.

m Number of DFP significant digits in the third operand (c).

Qmax Maximum right-units-view exponent.

Rp(c) The third operand (c) is rounded to the requested significance. The result is canonical and is represented with the preferred quantum.

Explanation:

\( T(x) \) The canonical result x is placed at the target operand location. The result is canonical and, when it is a finite number, is represented with the preferred quantum.

Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-29. Results: REROUND

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested significance. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

When an invalid-operation exception is recognized, the IEEE inexact exception is not recognized.

In the absence of an invalid-operation exception, if the result differs in value from the third operand, an IEEE inexact exception is recognized.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the third operand and if XqC is zero, then a quantum exception is recognized.

For RRXTR, the \( R_1 \) and \( R_3 \) fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (RRXTR only)
- Transaction constraint

Programming Notes:

1. REROUND and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with a precision other than any supported format precision and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable round-
ing method is used by the subsequent REROUND instruction.

2. When the rounded intermediate value is larger than \((10^k - 1) \times 10^{Q_{\text{max}}}\) in magnitude, an invalid-operation exception is recognized, where \(k\) is the requested significance and \(10^{Q_{\text{max}}}\) is the largest quantum for the format.

The expression, \((10^k - 1) \times 10^{Q_{\text{max}}}\), specifies the largest magnitude that can be represented with the requested significance in the format. A value larger than \((10^p - 1) \times 10^{Q_{\text{b}}}\) in magnitude will have a quantum larger than \(10^{Q_{\text{max}}}\) when the value is represented with the requested significance.

The significand of the third operand is shifted left the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNaN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

\[\text{SHIFT SIGNIFICAND RIGHT}\]

<table>
<thead>

</tbody>
</table>

The significand of the third operand is shifted right the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SLXT, the \(R_1\) and \(R_3\) fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SLXT only)
- Transaction constraint

**Programming Note:** Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.
Digits shifted out of the rightmost digit are lost. Zeros are supplied to the vacated positions on the left. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNaN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical. When the result is an infinity, if all digits in the trailing significand are zero, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SRXT, the R₃ and R₅ fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SRXT only)
- Transaction constraint

**Programming Note:** Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

### SUBTRACT

<table>

</tr>
</tbody>
</table>

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the third operand, if numeric, participates in the operation with its sign bit inverted. When the third operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 20-11 on page 20-20 for the detailed results of ADD.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

For SXTR and SXTRA, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

**IEEE Exceptions:**
- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (SXTR and SXTRA only)
- Transaction constraint

**Programming Note:** See the programming notes for ADD.

**TEST DATA CLASS**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>R1,D2(X2,B2)</th>
<th>OpCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>TDCET</td>
<td>'ED50' Short DFP</td>
<td></td>
</tr>
<tr>
<td>TDCDT</td>
<td>'ED54' Long DFP</td>
<td></td>
</tr>
<tr>
<td>TDCXT</td>
<td>'ED58' Extended DFP</td>
<td></td>
</tr>
</tbody>
</table>

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 20-30, DFP operands are divided into six classes: zero, subnormal, normal, infinity, quiet NaN, and signaling NaN:

<table>
<thead>
<tr>
<th>DFP data class</th>
<th>Bit used when sign is +</th>
<th>Bit used when sign is -</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero</td>
<td>52</td>
<td>53</td>

<tr>
<td>Infinity</td>
<td>58</td>
<td>59</td>
</tr>
<tr>
<td>Quiet NaN</td>
<td>60</td>
<td>61</td>
</tr>
<tr>
<td>Signaling NaN</td>
<td>62</td>
<td>63</td>
</tr>
</tbody>
</table>

**Figure 20-30. Second-Operand-Address Bits for TEST DATA CLASS**

corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDCXT, the R1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

**IEEE Exceptions:** None.

**Program Exceptions:**
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDCXT only)
- Transaction constraint

**Programming Notes:**

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.

2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, BFP TEST DATA CLASS uses bits 54 and 55 for normal number, and bits 56 and 57 for subnormal number.
The group and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data group and sign. Bits 0-51 of the second-operand address are ignored.

TEST DATA GROUP is used to determine whether a finite number is safe. A finite number is safe if the exponent is neither maximum nor minimum, and the leftmost significand digit is zero.

Figure 20-31 on page 20-57 shows the data groups and the bit assignment. There are six data groups: safe zero, zero with extreme exponent, nonzero with extreme exponent, safe nonzero, nonzero leftmost significand digit with nonextreme exponent, and special. The special group is defined for infinity and NaN. Depending on the model, subnormal with nonextreme exponent may be placed in the nonzero-with-extreme-exponent group or the safe-nonzero group.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the group and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDGXT, the $R_1$ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

### Test Data Group

<table>
<thead>

<th>OpCode</th>
<th>Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>R_1, X_2, X_4, B_2</td>
<td></td>
</tr>
</tbody>
</table>

### Resulting Condition Code:

- 0: Selected bit is 0 (no match)
- 1: Selected bit is 1 (match)
- 2: --
- 3: --

### IEEE Exceptions:

None.

### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDGXT only)
- Transaction constraint

### Programming Notes:

1. TEST DATA GROUP provides a way to test an operand without risk of an exception or setting the IEEE flags.
2. TEST DATA GROUP can be issued after an operation that produces a DFP result to quickly determine if the result is safe. For DFP results that are finite numbers, the result is safe if using a wider data format by the operation would have produced the same value and quantum. A safe result has two important characteristics: (1) the exponent is neither the maximum exponent nor the minimum exponent, and (2) the leftmost significand digit is zero.
3. TEST DATA GROUP may be used to test whether a nonzero finite number is safe by setting bits 58 and 59 of the second-operand address to ones.
4. TEST DATA GROUP may be used to test whether a nonzero finite number has reached the limit of the format precision but not the limit of the format range by setting bits 60 and 61 of the second-operand address to ones.
5. Subnormal with nonextreme exponent may be grouped with either the nonzero-with-extreme exponent group or the safe-nonzero group. The
program shouldn’t depend on which group sub-normal with nonextreme exponent is in.

### Densely Packed Decimal (DPD)

#### Decimal-to-DPD Mapping

The mapping of a 3-digit decimal number (000 - 999) to a 10-bit value, called a declet is shown in Figure 20-32 on page 20-58. The DPD entries are shown in hexadecimal. The first two digits of the decimal number are shown in the leftmost column and the third digit along the top row. The table is split into two halves, with the right half being a continuation of the left half.

#### DPD-to-Decimal Mapping

The mapping of the 10-bit declet to a 3-digit decimal number is shown in Figure 20-33 on page 20-59. The 10-bit declet value is split into a 6-bit index shown in the left column and a 4-bit index shown along the top row, both represented in hexadecimal. The values marked with an asterisk are results mapped from noncanonical declets and are explained further in the following section.

<table>
<thead>

* Result mapped from a noncanonical decit.
Overview

The vector facility provided in the z/Architecture architectural mode provides fixed-sized vectors ranging from one to sixteen elements. For most instructions, all of the data contained in a vector is operated on by the instructions defined in this facility. Some instructions only operate on a subset of the elements within a vector. If a vector is made up of multiple elements, each element is processed in parallel with the others. Instruction completion does not occur until processing of all elements is complete.

Vector Registers and Controls

Vector Enablement Control

The vector instructions should only be used if both the vector enablement control (bit 46) and the AFP-register-control (bit 45) in control register zero are set to one. If the vector facility for z/Architecture is installed and a vector instruction is executed without the vector enablement control set, a data exception with DXC FE hex is recognized. If bit 45 of control register zero is not also set to one, it is unpredictable if a data exception is recognized. If the vector facility
for z/Architecture is not installed, an operation exception is recognized.

**Programming Note:** When a control program initially enables the vector facility for z/Architecture for a task, which may occur in response to a data exception with DXC FE, it should ensure that newly enabled full vector registers as well as the rightmost portions of vector registers that overlap with any enabled floating-point registers are zeroed.

**Vector Storage Accesses**

All vector data appears in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also “Storage Addressing” on page 3-2.)

**Saturating Arithmetic**

Some vector operations perform saturating operations. Saturation for signed binary integers means that if there is an overflow, the result is set to the largest positive number; if there is an underflow, the result is set to the largest negative number. Saturation for unsigned binary integers means that if there is an overflow, the result is set to the largest representable number; if there is an underflow, the result is set to zero.

Figure 21-2. Summary of Vector Support Instructions

**Instructions**

All vector instructions, defined in chapters 21-24, have a field in bits 36-39 of the instruction labeled as RXB. This field contains the most significant bit for each of the vector register designated operands. Bits for register designations not specified by the instruction are reserved and should be set to zero; otherwise the program may not operate compatibly in the future.

The bits are defined as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>MSB of Vector Register in Instruction Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>36</td>
<td>8-11</td>
</tr>
<tr>
<td>37</td>
<td>12-15</td>
</tr>
<tr>
<td>38</td>
<td>16-19</td>
</tr>
<tr>
<td>39</td>
<td>32-35</td>
</tr>
</tbody>
</table>

**Programming Note:** It is assumed that the assembler will set these bits whenever a vector register designation greater than 15 is specified.

Unless otherwise specified, all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Each instruction has an extended-mnemonic section which describes recommended extended mnemonics and their corresponding machine assembler syntax.

</table>

**Explanation:**

- G^7: Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
- G^9: Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
- A: Access exceptions for logical addresses.
- B_2: B_2 field designates an access register in the access-register mode.
- C*: Condition code optionally set.
- Dv: Vector-instruction data exception
- SP: Specification exception.
- ST: PER storage-alteration event.
- VF: Vector facility for z/Architecture
- VR: VRI instruction format
- VR: VRR instruction format
- VR: VRS instruction format
- VR: VX instruction format
- VR: VR instruction format

*Figure 21-2: Summary of Vector Support Instructions*
VECTOR GATHER ELEMENT

VGEF  \[E7\] \(V_1, D_2(V_2, B_2), M_3\)  [VRV]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 36 & 40 & 47 \\
\end{array}
\]

The element-sized second operand replaces the specified element of the first operand indexed by the \(M_3\) field. The remaining elements are left unchanged. If the \(M_3\) field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VGEF the elements in all operands are 4-bytes in size; for VGEG the elements in all operands are 8-bytes in size.

The second-operand address is generated by adding the unsigned binary integer value from the element in vector-register \(V_2\) indexed by the \(M_3\) field with the address in the \(B_2\) register along with the \(D_2\) value.

The displacement for VECTOR GATHER ELEMENT is treated as a 12-bit unsigned integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Extended Mnemonics:**
- Extended Mnemonic  Base Mnemonic
  - VZERO \(V_1\)  VGBM \(V_1,0\)
  - VONE \(V_1\)  VGBM \(V_1,X'FFFF'\)

**Programming Note:** VECTOR GENERATE BYTE MASK is the preferred method for setting a vector register to all zeroes or ones.

VECTOR GENERATE BYTE MASK

VGGM  \[E7\] \(V_1, I_2\)  [VRI-a]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 32 & 36 & 40 & 47 \\
\end{array}
\]

For each bit in the second operand, if the bit is one, all bit positions in the corresponding byte element of the first operand are set to ones. If the bit is zero, all bit positions in the corresponding byte element of the first operand are set to zeros.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Extended Mnemonics:**

**Programming Note:** VECTOR GENERATE BYTE MASK is the preferred method for setting a vector register to all zeroes or ones.

VECTOR GENERATE MASK

VGM  \[E7\] \(V_1, I_2, I_3, M_4\)  [VRI-b]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 24 & 32 & 36 & 40 & 47 \\
\end{array}
\]

For each element in the first operand a bit mask is generated. The mask consists of bits set to one starting at the bit position specified by the unsigned integer value in \(I_2\) and ending with the bit position specified by the unsigned integer value in \(I_3\). All other bit positions are set to zero. Only the number of bits needed to represent all of the bit positions for the
specified element size are used from the I\(_2\) and I\(_3\) fields, other bits are ignored. If the bit position in the I\(_2\) field is greater than the bit position in the I\(_3\) field, the range of bits wraps at the maximum bit position for the specified element size.

The M\(_4\) field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<td>Doubleword</td>
</tr>
<tr>
<td>4-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2 for VL)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Programming Note:** For VL, performance may be reduced if the second operand is not on a quadword boundary.

<tbody>
<tr>
<td>'E7' V(_1),V(_2)</td>
<td>[VRR-a]</td>
</tr>
</tbody>
</table>

The 128-bit second operand is placed unchanged in the first-operand location.

The displacement for VL is treated as a 12-bit unsigned integer.
VECTORN LOAD ELEMENT

### Extended Mnemonic
- VLEB \( V_1, D_2(X_2, B_2), M_3 \) [VRX]
- VLEH \( V_1, D_2(X_2, B_2), M_3 \) [VRX]
- VLEF \( V_1, D_2(X_2, B_2), M_3 \) [VRX]
- VLEG \( V_1, D_2(X_2, B_2), M_3 \) [VRX]

### Base Mnemonic
- VLREF \( V_1, D_2(X_2, B_2), M_3 \)
- VLREG \( V_1, D_2(X_2, B_2), M_3 \)

#### Programming Note:
For VLEB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

### Vector Load Element Immediate

#### VLEIB
- Extended Mnemonic: \( 'E7' V_1 X_2 B_2 D_2 M_3 \)
- Immediate: \( '00' \)

#### VLEIH
- Extended Mnemonic: \( 'E7' V_1 X_2 B_2 D_2 M_3 \)
- Immediate: \( '01' \)

#### VLEIF
- Extended Mnemonic: \( 'E7' V_1 X_2 B_2 D_2 M_3 \)
- Immediate: \( '02' \)

#### VLEG
- Extended Mnemonic: \( 'E7' V_1 X_2 B_2 D_2 M_3 \)
- Immediate: \( '03' \)

The element-sized second operand replaces the specified element of the first operand indexed by the \( M_3 \) field. The remaining elements are left unchanged. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR LOAD ELEMENT is treated as a 12-bit unsigned integer.

For VLEB the elements are byte sized. For VLEH the elements are halfword sized. For VLEF the elements are word sized. For VLEG the elements are doubleword sized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

### Vector Load Element Immediate

#### VLEIB
- Extended Mnemonic: \( 'E7' V_1 I_2 M_3 \)
- Immediate: \( '00' \)

#### VLEIH
- Extended Mnemonic: \( 'E7' V_1 I_2 M_3 \)
- Immediate: \( '01' \)

#### VLEIF
- Extended Mnemonic: \( 'E7' V_1 I_2 M_3 \)
- Immediate: \( '02' \)

#### VLEG
- Extended Mnemonic: \( 'E7' V_1 I_2 M_3 \)
- Immediate: \( '03' \)

The signed binary integer second operand is sign extended, if necessary, and replaces the specified element of the first operand. The remaining elements are left unchanged. The \( M_3 \) field specifies the element index of the first operand to replace. For VLEIB, only bits 8-15 of the second operand are placed into the byte element; bits 0-7 are ignored. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VLEIB the elements are byte sized. For VLEIH the elements are word sized. For VLEIF the elements are halfword sized. For VLEG the elements are doubleword sized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
**Programming Note:** For VLEIB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

**VECTOR LOAD GR FROM VR ELEMENT**

VLGV $R_1$, $V_3$, $B_2$, $D_2$, $M_4$ [VRS-c]

The element of the third operand indexed by the second-operand address is placed in the first-operand location. The third operand is a vector register. The first operand is a general register. If the index specified by the second-operand address is greater than the highest numbered element in the third operand, of the specified element size, the result in the first operand is unpredictable.

If the vector register element is smaller than a doubleword, the element is right aligned in the 64-bit general register and zeros fill the remaining bits.

The second-operand address is not used to address data; instead the rightmost 12 bits of the address are used to specify the index of an element within the third operand.

The $M_4$ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>
<thead>
<tr>
<th>$M_4$</th>
<th>Element Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Byte</td>
</tr>
<tr>
<td>1</td>
<td>Halfword</td>
</tr>
<tr>
<td>2</td>
<td>Word</td>
</tr>
<tr>
<td>3</td>
<td>Doubleword</td>
</tr>
<tr>
<td>4-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

**Extended Mnemonic** | **Base Mnemonic**
--- | ---
VLGVB $R_1$, $V_3$, $D_2(B_2)$ | VLGV $R_1$, $V_3$, $D_2(B_2)$,0
VLGVH $R_1$, $V_3$, $D_2(B_2)$ | VLGV $R_1$, $V_3$, $D_2(B_2)$,1
VLGVF $R_1$, $V_3$, $D_2(B_2)$ | VLGV $R_1$, $V_3$, $D_2(B_2)$,2
VLGVG $R_1$, $V_3$, $D_2(B_2)$ | VLGV $R_1$, $V_3$, $D_2(B_2)$,3

**VECTOR LOAD LOGICAL ELEMENT AND ZERO**

VLLEZ $V_1$, $X_2$, $B_2$, $D_2$, $M_3$ [VRX]

The unsigned element-sized second operand is placed in the rightmost sub-element or element of the leftmost doubleword element of the vector-register specified first operand. The bit positions of all other elements are set to zero. The element size is determined by the ES value in the $M_3$ field.

The displacement for VLLEZ is treated as a 12-bit unsigned binary integer.

The $M_3$ field specifies the element size control (ES). The ES control specifies the size of the element in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>
<thead>
<tr>
<th>$M_3$</th>
<th>Element Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Byte</td>
</tr>
<tr>
<td>1</td>
<td>Halfword</td>
</tr>
<tr>
<td>2</td>
<td>Word</td>
</tr>
<tr>
<td>3</td>
<td>Doubleword</td>
</tr>
<tr>
<td>4-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
**Vector Load Multiple**

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>
<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLLEZB V_i D_j(X_k B_2)</td>
<td>VLLEZ V_i D_j(X_k B_2),0</td>
</tr>
<tr>
<td>VLLEZH V_i D_j(X_k B_2)</td>
<td>VLLEZ V_i D_j(X_k B_2),1</td>
</tr>
<tr>
<td>VLLEZF V_i D_j(X_k B_2)</td>
<td>VLLEZ V_i D_j(X_k B_2),2</td>
</tr>
<tr>
<td>VLLEZG V_i D_j(X_k B_2)</td>
<td>VLLEZ V_i D_j(X_k B_2),3</td>
</tr>
</tbody>
</table>

**Programming Note:** This instruction can be used for loading scalar values into vector registers.

The set of vector registers starting with the first operand vector register designation and ending with the third operand vector register designation are loaded from storage beginning at the location specified by the second operand address and continuing through as many locations as needed.

The vector registers are loaded in ascending order of their register numbers starting with the first operand vector register designation and continuing up to and including the third operand vector register designation. If the third operand vector register designation is less than the first operand vector register designation, a specification exception is recognized. The number of registers to be loaded is at most sixteen. If a range of more than sixteen registers is specified, a specification exception is recognized.

The displacement for VLM is treated as a 12-bit unsigned binary number.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

---

**Vector Load To Block Boundary**

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>
<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLLEZB V_1 D_2(X_k B_2),M_3</td>
<td>VLLEZ V_1 D_2(X_k B_2),0</td>
</tr>
<tr>
<td>VLLEZH V_1 D_2(X_k B_2),M_3</td>
<td>VLLEZ V_1 D_2(X_k B_2),1</td>
</tr>
<tr>
<td>VLLEZF V_1 D_2(X_k B_2),M_3</td>
<td>VLLEZ V_1 D_2(X_k B_2),2</td>
</tr>
<tr>
<td>VLLEZG V_1 D_2(X_k B_2),M_3</td>
<td>VLLEZ V_1 D_2(X_k B_2),3</td>
</tr>
</tbody>
</table>

**Programming Notes:**

1. On some models, performance may be improved if the second operand is on a doubleword boundary.
2. If the first operand vector register designation and the third operand vector register designation specify the same vector register only 16-bytes are loaded.

The single vector-register first operand is loaded starting at the zero indexed byte element with bytes from the second operand. If a boundary condition is encountered, the rest of the first operand is unpredictable. Access exceptions are not recognized for second-operand locations beyond the specified boundary. If no boundary is encountered, all byte elements of the first operand are loaded with data from storage.

The displacement for VLBB is treated as a 12-bit unsigned integer.

The M_3 field specifies a code indicating the boundary at which the second operand ends. If a reserved value is specified, a specification exception is recognized.

**Code Boundary**

<table>
<thead>
<tr>
<th>Code</th>
<th>Boundary</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>64-Byte</td>
</tr>
<tr>
<td>1</td>
<td>128-Byte</td>
</tr>
<tr>
<td>2</td>
<td>256-Byte</td>
</tr>
<tr>
<td>3</td>
<td>512-Byte</td>
</tr>
<tr>
<td>4</td>
<td>1K-Byte</td>
</tr>
<tr>
<td>5</td>
<td>2K-Byte</td>
</tr>
<tr>
<td>6</td>
<td>4K-Byte</td>
</tr>
<tr>
<td>7-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2)
Programming Notes:

1. In certain circumstances, data may be loaded past the block boundary. However, this will only occur if there are no access exceptions on that data. The program should not depend on the unpredictable data being loaded by a particular model.

2. This instruction can be used for loading null-terminated character data without crossing a page, segment, or region boundary unnecessarily.

3. If a block size code equal to the cache line size of the processor is specified, performance may be improved due to the fact that subsequent accesses will be aligned.

4. The LOAD COUNT TO BLOCK BOUNDARY instruction may be used with the same specified boundary to obtain a count of the number of bytes loaded.

**VECTOR LOAD VR ELEMENT FROM GR**

\[ \text{VLVG} \quad V_1, R_3, D_2(B_2), M_4 \]  
\[ \text{[VRS-b]} \]

The third operand of size specified by the ES value in the \( M_4 \) field is placed into the element of the first operand indexed by the second-operand address. The third operand is a general register. The first operand is a vector register. If the index, specified by the second-operand address, is greater than the highest numbered element in the first operand, of the specified element size, it is unpredictable. Which element, if any, is replaced.

For element sizes less than doubleword the rightmost bits of the third operand are used.

The second operand is not used to address data; instead the rightmost 12 bits of the address are used to specify the index of an element within the first operand.

**VECTOR LOAD VR FROM GRS DISJOINT**

\[ \text{VLVGP} \quad V_1, R_2, R_3 \]  
\[ \text{[VRR-f]} \]

The general register specified second operand placed unchanged into bit positions 0-63 of the first operand. The general register specified third operand is placed unchanged into bit positions 64-127 of the first operand.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint
**VECTOR LOAD WITH LENGTH**

\[
\text{VLL} \quad \text{V}_1, \text{R}_3, \text{D}_2(\text{B}_2) \quad [\text{VRS-b}]
\]

```
<table>
<thead>
<tr>
<th></th>
<th>E7</th>
<th>V1</th>
<th>R3</th>
<th>B2</th>
<th>D2</th>
<th></th>
<th>RXB</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>36</td>
<td>40</td>
<td>47</td>
</tr>
</tbody>
</table>
```

Proceeding from left to right, bytes of the first operand are loaded from the second-operand location. The general-register \( R_3 \) contains a 32-bit unsigned integer that represents the highest indexed byte to load. If the third operand contains a value greater than or equal to the highest byte index of the vector, all bytes of the first operand are loaded. Zeros are placed in any bytes that are not loaded.

Access exceptions are only recognized for the bytes of the second operand that are loaded from storage.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Extended Mnemonics:**

\[
\text{VMRHB} \quad \text{V}_1, \text{V}_2, \text{V}_3 \quad \text{VMRH} \quad \text{V}_1, \text{V}_2, \text{V}_3, 0
\]

\[
\text{VMRHH} \quad \text{V}_1, \text{V}_2, \text{V}_3 \quad \text{VMRH} \quad \text{V}_1, \text{V}_2, \text{V}_3, 1
\]

\[
\text{VMRFH} \quad \text{V}_1, \text{V}_2, \text{V}_3 \quad \text{VMRH} \quad \text{V}_1, \text{V}_2, \text{V}_3, 2
\]

\[
\text{VMRFG} \quad \text{V}_1, \text{V}_2, \text{V}_3 \quad \text{VMRH} \quad \text{V}_1, \text{V}_2, \text{V}_3, 3
\]

**VECTOR MERGE HIGH**

\[
\text{VMRH} \quad \text{V}_1, \text{V}_2, \text{V}_3, \text{M}_4 \quad [\text{VRR-c}]
\]

```

</table>

A source vector is created from the concatenation of the second operand followed by the third operand. In a left to right fashion each signed element in the source vector is reduced in size by half and placed in the corresponding element of the first operand. If the element in the source vector is outside of the allowable range of the target element, the target element is set to the maximum value in the target format in the direction of the overflow.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in
the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

\[ \text{VECTOR PACK LOGICAL SATURATE} \]

The \( M_5 \) field has the following format:

\[
\begin{array}{c|c|c|c}
\hline
\text{Reserved} & \text{Condition Code Set (CS)} & \text{Other Bits} \\
\hline
\text{Reserved} & \text{Reserved} & \text{Reserved} \\
\hline
\end{array}
\]

The bits of the \( M_5 \) field are defined as follows:

- **Reserved**: Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- **Condition Code Set (CS)**: If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

**Resulting Condition Code**: When bit 3 of the \( M_5 \) field is one, the condition code is set as follows:

<table>
<thead>
<tr>
<th>Condition Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No saturation</td>
</tr>
<tr>
<td>1</td>
<td>At least one but not all elements saturated</td>
</tr>
<tr>
<td>2</td>
<td>--</td>
</tr>
<tr>
<td>3</td>
<td>Saturation on all elements</td>
</tr>
</tbody>
</table>

When bit 3 of the \( M_5 \) field is zero, the code remains unchanged.

**Program Exceptions**:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics**:

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>
<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPKSH ( V_1, V_2, V_3 )</td>
<td>VPKS ( V_1, V_2, V_3, 1,0 )</td>
</tr>
<tr>
<td>VPKSF ( V_1, V_2, V_3 )</td>
<td>VPKS ( V_1, V_2, V_3, 2,0 )</td>
</tr>
</tbody>
</table>

A source vector is created from the concatenation of the second operand followed by the third operand. In a left to right fashion, each unsigned integer element in the source vector is reduced in size by half and placed in the corresponding element in the first operand. If the magnitude of the element in the source vector is greater than the largest magnitude representable in the target element, the target element is set to the largest representable magnitude value.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

The \( M_4 \) field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

<table>
<thead>
<tr>
<th>( M_4 ) Element Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reserved</td>
</tr>
<tr>
<td>1</td>
<td>Halfword</td>
</tr>
<tr>
<td>2</td>
<td>Word</td>
</tr>
<tr>
<td>3</td>
<td>Doubleword</td>
</tr>
<tr>
<td>4-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The \( M_5 \) field has the following format:

\[
\begin{array}{c|c|c|c}
\hline
\text{Reserved} & \text{Reserved} & \text{Reserved} \\
\hline
\text{Reserved} & \text{Reserved} & \text{Reserved} \\
\hline
\end{array}
\]

The bits of the \( M_5 \) field are defined as follows:
Reserved: Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Condition Code Set (CS): If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When bit 3 of the M₅ field is one, the condition code is set as follows:

0  No saturation
1  At least one but not all elements saturated
2  --
3  Saturation on all elements

When bit 3 of the M₅ field is zero, the code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic | Base Mnemonic
--- | ---
VPKLSH V₁,V₂,V₃ | VPKLS V₁,V₂,V₃,1,0
VPKLSF V₁,V₂,V₃ | VPKLS V₁,V₂,V₃,2,0
VPKLSG V₁,V₂,V₃ | VPKLS V₁,V₂,V₃,3,0
VPKLSHS V₁,V₂,V₃ | VPKLS V₁,V₂,V₃,1,1
VPKLSFS V₁,V₂,V₃ | VPKLS V₁,V₂,V₃,2,1
VPKLSGS V₁,V₂,V₃ | VPKLS V₁,V₂,V₃,3,1

VECTOR PERMUTE

A source vector is created from the concatenation of the second operand followed by the third operand. The byte element of the source vector indexed by the five least significant bits of each byte element of the fourth operand is placed into the byte element of the first operand corresponding to the byte element in the fourth operand.

If the same register is used to designate the first operand as either the second, third, or fourth operands the original source value is used throughout the operation with no intermediate updates.

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR PERMUTE DOUBLEWORD IMMEDIATE

<table>
<thead>
<tr>
<th>VPDI</th>
<th>V₁,V₂,V₃,M₄</th>
<th>[VRR-c]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
</tr>
</tbody>
</table>

The first, second and third operands consist of double word elements. Bit 1 of the M₄ field is the index which selects which doubleword of the second operand is placed into the zero indexed doubleword of the first operand. Bit 3 of the M₄ field is the index which selects which doubleword of the third operand is placed in the doubleword element with index one of the first operand.

The M₄ field has the following format:

<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
</table>

The bits of the M₄ field are defined as follows:

- Reserved: Bits 0 and 2 are reserved and should be zeros; otherwise, the program may not operate compatibly in the future.

- Second Operand Index (I₂): Bit 1 provides the index of the doubleword in the second operand to be placed in the first operand.

- Third operand index (I₃): Bit 3 provides the index of the doubleword in the third operand to be placed in the first operand.

If the same register is used to designate the first operand as either the second or third operands, the
VECTOR REPLICATE

The element of the third operand indexed by the unsigned integer in I2 is replicated across all elements of the first operand. If the value of the unsigned integer in I2 is greater than the highest element number in the third operand, of the specified element size, a specification exception is recognized.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M4 Element Size
0 Byte
1 Halfword
2 Word
3 Doubleword
4-15 Reserved

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Extended Mnemonics:

<table>
<thead>

<td>VREPIG V1,I2</td>
<td>VREPI V1,I2,3</td>
</tr>
</tbody>
</table>
**VECTOR SCATTER ELEMENT**

VSCEF \( V_x, D_y(V_2, B_2), M_3 \) [VRV]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 36 & 40 & 47 \\
\hline
\text{‘E7’} & V_1 & V_2 & B_2 & D_2 & M_3 & RXB & \text{‘1B’} \\
\end{array}
\]

VSCEG \( V_x, D_y(V_2, B_2), M_3 \) [VRV]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 36 & 40 & 47 \\
\hline
\text{‘E7’} & V_1 & V_2 & B_2 & D_2 & M_3 & RXB & \text{‘1A’} \\
\end{array}
\]

The element of the first operand designated by the \( M_3 \) field is placed unchanged into the second-operand location. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VSCEF the elements are 4-bytes in size; for VSCEG the elements are 8-bytes in size.

The second-operand address is generated by adding the unsigned binary integer value from the element in vector-register \( V_2 \) indexed by the \( M_3 \) field with the address in the \( B_2 \) register along with the \( D_2 \) value.

The displacement for VECTOR SCATTER ELEMENT is treated as a 12-bit unsigned integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Programming Notes:**

1. The VECTOR SCATTER ELEMENT instruction can be used to perform a store when doing scalar computation in vector registers and the address resides in a vector register. However, depending on the model, performance may be better if address computations are done in general registers.

2. For VGEF care must be taken to ensure that the values in the second operand elements are unsigned. Otherwise, when running in 64-bit addressing mode program behavior might not be as expected.

**VECTOR SELECT**

VSEL \( V_x, V_y, V_z, V_4 \) [VRR-e]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 20 & 32 & 40 & 47 \\
\hline
\text{‘E7’} & V_1 & V_2 & V_3 & V_4 & RXB & \text{‘8D’} \\
\end{array}
\]

For each bit in the fourth operand that contains a zero, the corresponding bit from the third operand is placed in the corresponding bit of the first operand. For each bit in the fourth operand that contains a one, the corresponding bit from the second operand is placed in the corresponding bit of the first operand.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**VECTOR SIGN EXTEND TO DOUBLEWORD**

VSEG \( V_x, M_3 \) [VRR-a]

\[
\begin{array}{cccccccc}
0 & 8 & 12 & 16 & 32 & 40 & 47 \\
\hline
\text{‘E7’} & V_1 & V_2 & V_3 & M_3 & RXB & \text{‘5F’} \\
\end{array}
\]

The leftmost bit of the rightmost element-sized sub-element of each doubleword of the second operand is replicated across all bit positions of all other elements in the doubleword. The result is placed in the corresponding doubleword of the first operand.

The \( M_3 \) field specifies the element size control (ES). The ES control specifies the size of the element in each doubleword of the second operand. If a reserved value is specified, a specification exception is recognized.

**M3 Element Size**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Byte</td>
</tr>
<tr>
<td>1</td>
<td>Halfword</td>
</tr>
<tr>
<td>2</td>
<td>Word</td>
</tr>
<tr>
<td>3-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
**VECTOR STORE**

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

**Extended Mnemonic** | **Base Mnemonic**
--- | ---
VSEGB | VSEG | V1,V2,0
VSEGH | VSEG | V1,V2,1
VSEGF | VSEG | V1,V2,2

**Programming Notes:**

1. This instruction allows for a value to be sign extended after being loaded with VECTOR LOAD LOGICAL ELEMENT AND ZERO.
2. To sign extend to smaller element sizes the VECTOR UNPACK instructions can be used.

**VECTOR STORE**

VST | V1,D2(X2,B2) | [VRX]

**Extended Mnemonic Base Mnemonic**

\[ \text{E7} \quad \text{V1} \quad \text{X2} \quad \text{B2} \quad \text{D2} \quad \text{M3} \quad \text{RXB} \quad \text{0E} \]

The 128-bit value in the first operand is stored to the storage location specified by the second operand.

The displacement for VST is treated as a 12-bit unsigned integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Programming Note:** Performance may be reduced if the second operand is not on a quadword boundary.

**VECTOR STORE ELEMENT**

VSTEB | V1,D2(X2,B2),M3 | [VRX]

**Extended Mnemonic Base Mnemonic**

\[ \text{E7} \quad \text{V1} \quad \text{X2} \quad \text{B2} \quad \text{D2} \quad \text{M3} \quad \text{RXB} \quad \text{08} \]

The element of the first operand designated by the third operand is placed unchanged into the second operand location. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized. For VSTEB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

The displacement for VECTOR STORE ELEMENT is treated as a 12-bit unsigned integer.

For VSTEB the elements are byte sized. For VSTEH the elements are halfword sized. For VSTEF the elements are word sized. For VSTEG the elements are doubleword sized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
VECTOR STORE MULTIPLE

\[\text{VSTM} \quad V_1, V_2, D_2(B_2) \quad [\text{VRS-a}]\]

The set of vector registers starting with the first operand vector register designation and ending with the third operand vector register designation are placed in the storage area beginning at the location specified by the second-operand address and continuing through as many locations as needed.

The contents of bit positions 0-127 of the vector registers are stored in successive 16-byte fields beginning at the second-operand address.

The vector registers are stored in the ascending order of their register numbers, starting with the first operand vector register designation and continuing up to and including the third operand vector register designation. If the third operand vector register designation is less than the first operand vector register designation, a specification exception is recognized.

The number of registers to be stored is at most sixteen. If a range of more than sixteen registers is specified, a specification exception is recognized.

The displacement for VSTM is treated as a 12-bit unsigned binary number.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Programming Notes:**
1. On some models performance may be improved if the second operand is on a doubleword boundary.
2. If the first operand vector register designation and the third operand vector register designation specify the same vector register only 16-bytes are stored.

VECTOR STORE WITH LENGTH

\[\text{VSTL} \quad V_1, R_3, D_2(B_2) \quad [\text{VRS-b}]\]

Proceeding from left to right, bytes from the first operand are stored at the second-operand location. The general register specified third operand contains a 32-bit unsigned integer containing a value that represents the highest indexed byte to store. If the third operand contains a value greater than or equal to the highest byte index of the vector, all bytes of the first operand are stored.

Access exceptions are only recognized on bytes stored.

The displacement for VECTOR STORE WITH LENGTH is treated as a 12-bit unsigned integer.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR UNPACK HIGH

\[\text{VUPH} \quad V_1, V_2, M_3 \quad [\text{VRR-a}]\]

The elements of the left-most half of the vector-register second operand are sign extended and placed into double-sized elements in the first operand. The right-most half of the second operand are ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The \(M_3\) field specifies the element size control (ES). The ES control specifies the size of the elements in the second operand. The first operand contains elements twice the size of those specified by the ES.
control. If a reserved value is specified, a specification exception is recognized.

### M₃ Element Size

<table>
<thead>
<tr>
<th>0</th>

<td>VUPL ( V_1V_2,2 )</td>
</tr>
</tbody>
</table>

**VECTOR UNPACK LOGICAL LOW**

\[
\text{VUPLL} \quad V_1V_2M_3 \quad [\text{VRR-a}]
\]

The elements of the right-most half of the second operand are zero extended and placed into double-sized elements in the first operand. The left-most half of the second operand is ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The \( \text{M}_3 \) field specifies the element size control (ES). The ES control specifies the size of the elements in the second operand. The first operand contains elements double the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

\[ \text{M}_3 \quad \text{Element Size} \]
0  Byte
1  Halfword
2  Word
3-15  Reserved

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

### Instructions

Many instructions have an extended mnemonic section which describe recommended extended mnemonics and their corresponding machine assembler syntax.
Unless otherwise specified all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

*Figure 22-1. Summary of Vector Integer Instructions*
VECTORS ADD

VA \ V_1 V_2 V_3 M_4 [VRR-c]

\textquote{0 \ 8 \ 12 \ 16 \ 20 \ 32 \ 36 \ 40 \ 47}

The contents of each element of the second operand are added to the contents of each corresponding element of the third operand and the resulting sum or sums are placed in the first operand. Each element is treated as a signed binary integer of size specified by the element size control in the M_4 field.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position.

No fixed point overflow exceptions are recognized.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

\begin{align*}
M_4 & \text{ Element Size} \\
0 & \text{Byte} \\
1 & \text{Halfword} \\
2 & \text{Word} \\
3 & \text{Doubleword} \\
4 & \text{Quadword} \\
5-15 & \text{Reserved}
\end{align*}

\textbf{Condition Code:} The code remains unchanged.

\textbf{Program Exceptions:}

- Data with DXC FE, Vector Instruction
VECTOR ADD COMPUTE CARRY

\[
\text{VACC} \quad V_1, V_2, V_3, M_4 \quad \text{[VRR-c]}
\]

The contents of each element of the second operand are added to the contents of each corresponding element of the third operand. If the addition of two elements results in a carry out of bit zero, a value of one is placed in the corresponding element of the first operand. If there is no carry out of bit zero, a value of zero is placed in the corresponding element of the first operand. Each element is treated as an unsigned binary integer of size specified by the element size in the \(M_4\) field.

The \(M_4\) field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

\[
\begin{array}{c|c}
\text{M}_4 & \text{Element Size} \\
0 & \text{Byte} \\
1 & \text{Halfword} \\
2 & \text{Word} \\
3 & \text{Doubleword} \\
4 & \text{Quadword} \\
5-15 & \text{Reserved}
\end{array}
\]

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

- **VACCB** \(V_1, V_2, V_3\)
- **VACCH** \(V_1, V_2, V_3, 1\)
- **VACCF** \(V_1, V_2, V_3, 2\)
- **VACCG** \(V_1, V_2, V_3, 3\)
- **VACCQ** \(V_1, V_2, V_3, 4\)

VECTOR ADD WITH CARRY

\[
\text{VAC} \quad V_1, V_2, V_3, V_4, M_5 \quad \text{[VRR-d]}
\]

The contents of the second operand are added to the third operand to form an intermediate quadword sum. Subsequently, the rightmost bit of the fourth operand concatenated with 127 bits of zero on its left are added to the intermediate sum and the resulting sum is placed in the first operand. All bits except for the rightmost bit position of the fourth operand are ignored. Each operand is treated as a 128-bit unsigned binary integer.

When there is an overflow, the result is obtained by allowing any carry into the leftmost-bit position and ignoring any carry out of the leftmost-bit position.

No fixed point overflow exceptions are recognized.

The \(M_5\) field must contain a value of 4; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
**VECTOR AVERAGE**

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>
<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>VACQ V&lt;sub&gt;1&lt;/sub&gt;,V&lt;sub&gt;2&lt;/sub&gt;,V&lt;sub&gt;3&lt;/sub&gt;,V&lt;sub&gt;4&lt;/sub&gt;</td>
<td>VAC V&lt;sub&gt;1&lt;/sub&gt;,V&lt;sub&gt;2&lt;/sub&gt;,V&lt;sub&gt;3&lt;/sub&gt;,V&lt;sub&gt;4&lt;/sub&gt;,4</td>
</tr>
</tbody>
</table>

**VECTOR ADD WITH CARRY COMPUTE CARRY**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VACCC V&lt;sub&gt;1&lt;/sub&gt;,V&lt;sub&gt;2&lt;/sub&gt;,V&lt;sub&gt;3&lt;/sub&gt;,V&lt;sub&gt;4&lt;/sub&gt;,M&lt;sub&gt;5&lt;/sub&gt;</td>
<td>[VRR-d]</td>
</tr>
</tbody>
</table>

The contents of the second operand are added to the third operand to form an intermediate quadword sum. Subsequently, the rightmost bit of the fourth operand concatenated with 127 bits of zero on its left are added to the intermediate sum. All bits except for the rightmost bit position of the fourth operand are ignored. If the addition results in a carry out of the leftmost bit, a value of one is placed in the first operand. If there is no carry out of the leftmost bit, a value of zero is placed in the first operand. Each operand is treated as a 128-bit unsigned binary integer.

The M<sub>5</sub> field must contain a value of 4; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**VECTOR AND**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VN V&lt;sub&gt;1&lt;/sub&gt;,V&lt;sub&gt;2&lt;/sub&gt;,V&lt;sub&gt;3&lt;/sub&gt;</td>
<td>[VRR-c]</td>
</tr>
</tbody>
</table>

The AND of the second and third operands is placed in the first operand.

**VECTOR AND WITH COMPLEMENT**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VNC V&lt;sub&gt;1&lt;/sub&gt;,V&lt;sub&gt;2&lt;/sub&gt;,V&lt;sub&gt;3&lt;/sub&gt;</td>
<td>[VRR-c]</td>
</tr>
</tbody>
</table>

The AND of the second operand and the bit-wise complement of the third operand is placed in the first operand.

**VECTOR AVERAGE**

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VAVG V&lt;sub&gt;1&lt;/sub&gt;,V&lt;sub&gt;2&lt;/sub&gt;,V&lt;sub&gt;3&lt;/sub&gt;,M&lt;sub&gt;4&lt;/sub&gt;</td>
<td>[VRR-c]</td>
</tr>
</tbody>
</table>

The connective AND is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both operands contain ones; otherwise, the result bit is set to zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Programming Note:** This instruction is useful for zeroing out bits under a mask.
VECTOR AVERAGE LOGICAL

VAVGL V1, V2, V3, M4 [VRR-c]

<table>
<thead>
<tr>
<th>'E7'</th>
<th>V1</th>
<th>V2</th>
<th>V3</th>
<th>M4</th>
<th>RXB</th>
<th>'F0'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>36</td>
</tr>
</tbody>
</table>

The average of the corresponding elements of the second and third operands is placed in the corresponding element of the first operand.

For VECTOR AVERAGE, each element of the second operand and the corresponding element of the third operand are sign extended by one bit. The elements are then added together along with an additional value of one. The sum is then shifted right by one bit to produce an element sized result in the corresponding element of the first operand.

For VECTOR AVERAGE LOGICAL, each element of the second operand and the corresponding element of the third operand are extended by one bit by appending a zero on the left. The elements are then added together along with an additional value of one. The sum is then shifted right by one bit to produce an element sized result in the corresponding element of the first operand.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M4 | Element Size
---|----------------
0  | Byte
1  | Halfword
2  | Word
3  | Doubleword
4-15 | Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR CHECKSUM

VCKSM V1, V2, V3 [VRR-c]

<table>
<thead>
<tr>
<th>'E7'</th>
<th>V1</th>
<th>V2</th>
<th>V3</th>
<th>RXB</th>
<th>'66'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>36</td>
</tr>
</tbody>
</table>

The word-sized elements from the second operand are added together one-by-one along with the element in word one of the third operand. The sum is placed in word one of the first operand. Zeros are placed in word elements 0, and 2-3 of the first operand. The word-sized elements are all treated as 32-bit unsigned binary integers. After each addition of an element, a carry out of bit position 0 of the sum is added to bit position 31 of the result in word element one of the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. The contents of the third operand should contain zero at the start of a checksum computation algorithm.

2. A16-bit checksum is used in, for example, the TCP/IP application. The following program can be executed after a 32-bit checksum has been computed:

VERLLF V2, V1, 16(0)
VAF V2, V1, V2
The halfword in element 2 will contain the 16-bit checksum.

**VECTOR ELEMENT COMPARE**

**VEC** \( V_1, V_2, M_3 \) \[VRR-a\]

<table>
<thead>
<tr>
<th>Element</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>0</td>
</tr>
<tr>
<td>Halfword</td>
<td>1</td>
</tr>
<tr>
<td>Word</td>
<td>2</td>
</tr>
<tr>
<td>Doubleword</td>
<td>3</td>
</tr>
</tbody>
</table>

**VECTOR ELEMENT COMPARE LOGICAL**

**VECL** \( V_1, V_2, M_3 \) \[VRR-a\]

The single element of specified size of the first and second operands are compared and the result is indicated in the condition code.

The elements compared are treated as signed binary integers for VEC and unsigned binary integers for VECL.

The index of the element that is being compared is dependent on the size of the element being compared. Figure 22-2 specifies what element is compared for each element size.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

Extended Mnemonic | Base Mnemonic
--- | ---
VECB \( V_1, V_2 \) | VEC \( V_1, V_2, 0 \)
VECH \( V_1, V_2 \) | VEC \( V_1, V_2, 1 \)
VECF \( V_1, V_2 \) | VEC \( V_1, V_2, 2 \)
VECG \( V_1, V_2 \) | VEC \( V_1, V_2, 3 \)
VECLB \( V_1, V_2 \) | VECL \( V_1, V_2, 0 \)
VECLH \( V_1, V_2 \) | VECL \( V_1, V_2, 1 \)
VECLF \( V_1, V_2 \) | VECL \( V_1, V_2, 2 \)
VECLG \( V_1, V_2 \) | VECL \( V_1, V_2, 3 \)

**VECTOR COMPARE EQUAL**

**VCEQ** \( V_1, V_2, V_3, M_4, M_5 \) \[VRR-b\]

The unsigned binary integer elements of the second operand are compared with the corresponding unsigned binary integer elements of the third operand. If the element in the second operand is equal to the element in the third operand, all of the bit positions of the corresponding element in the first operand are set to ones; otherwise they are all set to zeros.

The \( M_4 \) field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

**Resulting Condition Code:**
0 Operand elements equal
1 First operand element low
2 First operand element high
3 --
The M₅ field has the following format:

```
0 1 2 3
```

The bits of the M₅ field are defined as follows:

- **Reserved**: Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- **Condition Code Set (CS)**: If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

**Resulting Condition Code:**

When bit 3 of the M₅ field is one, the condition code is set as follows:

- 0: All elements equal
- 1: At least one, but not all elements equal
- 2: None
- 3: No element equal

When bit 3 of the M₅ field is zero, the code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

<table>

<td></td>
</tr>
</tbody>
</table>

**Programming Note**: Depending on the model, setting the condition code may result in reduced performance.

**VECTOR COMPARE HIGH**

```
VCH V₁,V₂,V₃,M₄,M₅ [VRR-b]
```

The signed elements of the second operand are compared to the corresponding signed elements of the third operand. If the element in the second operand is greater than the element in the third operand, all of the bit positions of the corresponding element in the first operand are set to ones; otherwise, they are all set to zeros.

The M₄ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>
<thead>
<tr>
<th>M₄ Element Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: Byte</td>
</tr>
<tr>
<td>1: Halfword</td>
</tr>
<tr>
<td>2: Word</td>
</tr>
<tr>
<td>3: Doubleword</td>
</tr>
<tr>
<td>4-15: Reserved</td>
</tr>
</tbody>
</table>

The M₅ field has the following format:

```
0 1 2 3
```

The bits of the M₅ field are defined as follows:

- **Reserved**: Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- **Condition Code Set (CS)**: If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

**Resulting Condition Code:**

When bit 3 of the M₅ field is one, the condition code is set as follows:

- 0: All elements high
- 1: Some elements high
- 2: --
- 3: No element high
When bit 3 of the M₅ field is zero, the code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>

**Programming Notes:**

1. Depending on the model, setting the condition code may result in reduced performance.
2. To do a COMPARE NOT HIGH LOGICAL, reverse the second and third operands.

**VEVECTOR COUNT LEADING ZEROS**

VCLZ V₁,V₂,M₃

For each element in the second operand, the number of leftmost zeros are counted and placed in the corresponding element of the first operand.

The bits of each element in the second operand are scanned left to right for the leftmost one bit. A binary integer designating the bit position of the leftmost one bit, or the number of bits in the element if there is no one bit, is placed in the corresponding element of the first operand.

The M₃ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>

</tr>
<tr>
<td>4-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
VECTOR EXCLUSIVE OR

VX V1,V2,V3 [VRR-c]

The EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR GALOIS FIELD MULTIPLY SUM

VGFM V1,V2,V3,M4 [VRR-c]

Each element of the second operand is multiplied in a Galois field with the corresponding element of the third operand. The Galois field has an order of two. This multiplication is similar to standard binary multiplication, but instead of adding the shifted multiplicand it is exclusive ORed. The resulting even-odd pairs of double element-sized products are exclusive ORed with each other and placed in the corresponding double-wide element of the first operand.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M4  Element Size
0  Byte
1  Halfword
2  Word
3  Doubleword
4-15  Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic Base Mnemonic
VCTZB V1,V2 VCTZ V1,V2,0
VCTZH V1,V2 VCTZ V1,V2,1
VCTZF V1,V2 VCTZ V1,V2,2
VCTZG V1,V2 VCTZ V1,V2,3

VECTOR GALOIS FIELD MULTIPLY SUM AND ACCUMULATE

VGFM V1,V2,V3,V4,M5 [VRR-d]

Each element of the second operand is multiplied in a Galois field with the corresponding element of the third operand. The Galois field has an order of two. This multiplication is similar to standard binary multiplication, but instead of adding the shifted multiplicand it is exclusive ORed. The resulting even-odd pairs of double element-sized products are exclusive ORed with each other and placed in the corresponding double-wide element of the first operand.

The M5 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M5  Element Size
0  Byte
1  Halfword
2  Word
3  Doubleword
4-15  Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic Base Mnemonic

### VECTOR MAXIMUM

VMX V1, V2, V3, M4 [VRR-c]

```
0 8 12 16 20 32 36 40 47
'E7' V1 V2 V3 / / / / / / / / M4 RXB 'FF'
```

Each element of the second operand is compared to the corresponding element of the third operand. The greater of the two values is placed into the corresponding element of the first operand. If the operands are equal the value of both elements is placed in the corresponding element of the first operand.

For VECTOR MAXIMUM the operands are treated as signed integer elements. For VECTOR MAXIMUM LOGICAL the operands are treated as unsigned integer elements.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

### Condition Code:
The code remains unchanged.

### Program Exceptions:

```
0 8 12 16 20 32 36 40 47
'E7' V1 V2 V3 / / / / / / / / M4 RXB 'FE'
```

### VECTOR MINIMUM LOGICAL

VMNL V1, V2, V3, M4 [VRR-c]

```
0 8 12 16 20 32 36 40 47
'E7' V1 V2 V3 / / / / / / / / M4 RXB 'FC'
```
Each element of the second operand is compared to the corresponding element of the third operand. The smaller of the two values is placed into the corresponding element of the first operand. If the operands are equal the value of both elements is placed in the corresponding element of the first operand.

For VECTOR MINIMUM the operands contain signed integer elements, for VECTOR MINIMUM LOGICAL the operands contain unsigned integer elements.

The M₄ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)

</tr>
</tbody>
</table>

**VECTOR MULTIPLY LOW**

VML | V<sub>1</sub>,V<sub>2</sub>,V<sub>3</sub>,M<sub>4</sub> | [VRR-c] |

The integer elements of the second operand are multiplied by the corresponding integer elements of the third operand producing a double element-sized intermediate product. The least-significant half of the resulting product is placed into the corresponding element of the first operand. Any overflow or carry from the final addition is ignored.

**Programming Notes:**

1. The results from VML are the same if the elements are treated as unsigned binary integers or signed binary integers.
2. VECTOR MULTIPLY LOW is analogous to MULTIPLY SINGLE in chapter 7.
3. The extended mnemonic VMLHW is not VMLH because that would conflict with VECTOR MULTIPLY LOW.

**VECTOR MULTIPLY EVEN**

VME | V<sub>1</sub>,V<sub>2</sub>,V<sub>3</sub>,M<sub>4</sub> | [VRR-c] |
VECTOR MULTIPLY LOGICAL EVEN

VMLE V1,V2,V3,M4 [VRR-c]

The even indexed elements of the second operand are multiplied with the corresponding even indexed elements of the third operand and the resulting double element width product is placed into the corresponding even and odd indexed element pair of the first operand. The odd elements of the second and third operands are ignored.

For VECTOR MULTIPLY EVEN the elements are treated as signed binary integers. For VECTOR MULTIPLY LOGICAL EVEN the elements are treated as unsigned binary integers.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M4 Element Size
0 Byte
1 Halfword
2 Word
3-15 Reserved

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic | Base Mnemonic
-----------------|------------------
VMEB V1,V2,V3 | VME V1,V2,V3,0
VMEH V1,V2,V3 | VME V1,V2,V3,1
VMEF V1,V2,V3 | VME V1,V2,V3,2
VMLEB V1,V2,V3 | VMLE V1,V2,V3,0
VMLEH V1,V2,V3 | VMLE V1,V2,V3,1

VECTOR MULTIPLY ODD

VMO V1,V2,V3,M4 [VRR-c]

The odd indexed elements of the second operand are multiplied with the corresponding odd indexed elements of the third operand and the resulting double element width product is placed into the corresponding even and odd indexed element pair of the first operand. The even elements of the second and third operands are ignored.

For VECTOR MULTIPLY ODD the elements are treated as signed binary integers. For VECTOR MULTIPLY LOGICAL ODD the elements are treated as unsigned binary integers.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M4 Element Size
0 Byte
1 Halfword
2 Word
3-15 Reserved

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
**Extended Mnemonics:**

**VECTOR NOR**

VNO V1,V2,V3 [VRR-c]

The NOR of the second and third operands is placed at the first-operand location.

The connective NOR is applied to the operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit in both operands contains a zero; otherwise, the result bit is set to zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Programming Note:** VNO can be used to provide the functionality of a bit-wise NOT operation by specifying the same vector-register for V2 and V3.

**Extended Mnemonics:**

**VECTOR OR**

VO V1,V2,V3 [VRR-c]

The OR of the second and third operands is placed at the first-operand location.

The connective OR is applied to the operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit in one or both operands contains a one; otherwise, the result bit is set to zero.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

**Programming Note:** VNO can be used to provide the functionality of a bit-wise NOT operation by specifying the same vector-register for V2 and V3.

**VECTOR POPULATION COUNT**

VPOPCT V1,V2,M3 [VRR-a]

For each byte element of the second operand the count of the number of bits that are one is stored in the corresponding byte element of the first operand. Each byte element in the result contains an 8-bit binary integer in the range of 0-8.

The M3 field is reserved and must contain zeros, otherwise a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Programming Note:** To count all of the ones in various element sizes a combination of VECTOR SUM ACROSS instructions may be used.
For VERLLV, each element in the second operand is rotated left by the number of bits specified in the corresponding element of the third operand modulo the element size in bits. For VERLL, each element in the third operand is rotated left by the number of bits specified by the second-operand address, modulo the number of bits in the specified element size. Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The result is placed in the corresponding element the first operand.

For VERLL, The displacement is treated as a 12-bit unsigned integer.

For VERLL, The second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be rotated. The remainder of the address is ignored.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>

</tr>
<tr>
<td>2</td>
<td>Word</td>
</tr>
<tr>
<td>3</td>
<td>Doubleword</td>
</tr>
<tr>
<td>4-15</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Programming Note:** Although the rotate amount is defined to be an unsigned integer of the number of bits necessary to specify a full rotate left amount for an element, a negative value may be encoded which effectively specifies a rotate-right amount.

For VERLLVB, VERLLVH, VERLLVF, and VERLLVG, the number of bits is specified by the fourth operand. Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The result is placed in the corresponding element the first operand.

Each element of the second operand is rotated left by the number of bits specified by the fourth operand. Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The third operand contains a mask in each element. For each bit in the third operand that is one, the corresponding bit of the rotated elements in the second operand replaces the corresponding bit in the first operand. For each bit in the third operand that is zero, the corresponding bit of the first operand remains unchanged. Except for the case when the first operand is the same as either the second or third operand, the second and third operands remain unchanged.

The fourth operand is an unsigned binary integer specifying the number of bits to rotate each element in the second operand by. If the value is larger than the number of bits in the specified element size, the value is reduced modulo the number of bits in the element.

The M5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<td>VERIM V₁,V₂,V₃,I₄,2</td>
</tr>
<tr>
<td>VERIMG V₁,V₂,V₃,I₄</td>
<td>VERIM V₁,V₂,V₃,I₄,3</td>
</tr>
</tbody>
</table>

**Programming Notes:**
1. A combination of VERIM and VGM may be used to accomplish the full functionality of ROTATE AND INSERT SELECTED BITS in Chapter 7.
2. Although the bits of the I₄ field are defined to contain an unsigned binary integer specifying the number of bits to rotate each element left, a negative value may be coded which effectively specifies a rotate-right amount.

**VECTOR ELEMENT SHIFT LEFT**

VESLV V₁,V₂,V₃,M₄ [VRR-c]

<table>
<thead>
<tr>
<th>‘E7’</th>
<th>V₁</th>
<th>V₂</th>
<th>V₃</th>
<th>I₄</th>
<th>M₄</th>
<th>RXB</th>
<th>‘70’</th>
</tr>
</thead>
<tbody>

<td>0</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
<td>32</td>
<td>36</td>
<td>40</td>
</tr>
</tbody>
</table>

For VESLV, each element in the second operand is shifted left by the number of bits specified in the corresponding element in the third operand modulo the number of bits in an element. For VESL, each element in the third operand is shifted left by the number of bits specified by the second-operand address modulo the number of bits in the specified element size. Bits shifted out of bit 0 of each element are lost and zeros are supplied to the vacated bit positions to the right of each element. The result is placed in the first operand.

For VESL, the displacement is treated as a 12-bit unsigned integer.

For VESL, the second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be shifted. The leftmost bits of the address are ignored.

The M₄ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

VECTOR ELEMENT SHIFT RIGHT ARITHMETIC

VESRAV V1, V2, V3, M4 [VRR-c]

VESRA V1, V3, D2(B2), M4 [VRS-a]

For VESRAV, each element in the second operand is shifted right by the number of bits specified in the corresponding element of the third operand modulo the number of bits in the specified element size. For VESRA, each element in the third operand is shifted right by the number of bits specified in the second-operand address modulo the number of bits in the specified element size. The result is placed in the corresponding element of the first operand with the vacated bits replaced with the original high order bit of each element.

For VESRA, the displacement is treated as a 12-bit unsigned integer.

For VESRA, the second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be shifted. The leftmost bits of the address are ignored.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

</tbody>
</table>

A double-wide source vector of byte elements is created by concatenating the second operand followed by the third operand. The result is placed in the first operand.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
VECTOR SHIFT RIGHT ARITHMETIC

VSRA V1, V2, V3 [VRR-c]

The second operand is shifted right by the number of bits specified by an unsigned binary integer in bits 5-7 of each byte of the third operand. Bits 5-7 of the bytes in the third operand should all contain the same value, otherwise the result is unpredictable. Bits shifted out of bit 127 are lost and bits equal to bit zero are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT ARITHMETIC BY BYTE

VSRAB V1, V2, V3 [VRR-c]

The second operand is shifted right by the number of bytes specified by the unsigned integer in bits 1-4 of byte seven of the third operand. Bits shifted out of bit 127 are lost and zeros are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT LOGICAL

VSRL V1, V2, V3 [VRR-c]

The second operand is shifted right by the number of bits specified by an unsigned binary integer in bits 5-7 of each byte of the third operand. Bits 5-7 of the bytes in the third operand should all contain the same value, otherwise the result is unpredictable. Bits shifted out of bit 127 are lost and zeros are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT LOGICAL BY BYTE

VSRLB V1, V2, V3 [VRR-c]

The second operand is shifted right by the number of bytes specified by the unsigned integer in bits 1-4 of byte element seven of the third operand. Bits shifted out of bit 127 are lost and zeros are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint
VECTOR SUBTRACT

\[ \text{VS} \quad V_1, V_2, V_3, M_4 \quad [\text{VRR-c}] \]

The contents of each element of the third operand are subtracted from the contents of each corresponding element of the second operand and the resulting difference is placed in the corresponding element of the first operand. Each element is treated as a signed binary integer specified by the element size control in the \( M_4 \) field.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position.

The \( M_4 \) field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

\[
\begin{array}{cccccccc}
\text{M}_4 & \text{ES} & 0 & 1 & 2 & 3 & 4 & 5-15 \\
\text{Element Size} & & \text{Byte} & \text{Halfword} & \text{Word} & \text{Doubleword} & \text{Quadword} & \text{Reserved} \\
\end{array}
\]

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Programming Note:** The same results are obtained if the contents of each element contain unsigned binary integers.

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>
<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSB ( V_1, V_2, V_3 )</td>
<td>VS ( V_1, V_2, V_3, 0 )</td>
</tr>
<tr>
<td>VSH ( V_1, V_2, V_3 )</td>
<td>VS ( V_1, V_2, V_3, 1 )</td>
</tr>
</tbody>
</table>

VECTOR SUBTRACT COMPUTE BORROW INDICATION

\[ \text{VSCBI} \quad V_1, V_2, V_3, M_4 \quad [\text{VRR-c}] \]

The contents of each element of the third operand are subtracted from the contents of each corresponding element of the second operand. An indication of borrow is placed in the corresponding element of the first operand.

If the resulting subtraction results in a carry out of bit zero, a value of one is placed in the corresponding element of the first operand; otherwise, a value of zero is placed in the corresponding element of the first operand. The operands are treated as unsigned binary integers of size specified by the element size control in the \( M_4 \) field.

The \( M_4 \) field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

\[
\begin{array}{cccccccc}
\text{M}_4 & \text{ES} & 0 & 1 & 2 & 3 & 4 & 5-15 \\
\text{Element Size} & & \text{Byte} & \text{Halfword} & \text{Word} & \text{Doubleword} & \text{Quadword} & \text{Reserved} \\
\end{array}
\]

**Condition Code:** The code remains unchanged.

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

<td>VSCBIQ V1,V2,V3</td>
<td>VSCBI V1,V2,V3,4</td>
</tr>
</tbody>
</table>

A subtraction is performed by adding the contents of the second operand with the bitwise complement of the third operand along with a borrow indication from the rightmost bit position of the fourth operand and the result is placed in the first operand. All bit positions to the left of the rightmost bit position of the fourth operand are ignored. Each operand is treated as an unsigned binary integer.

When there is an overflow, the result is obtained by allowing any carry into the leftmost-bit position and ignoring any carry out of the leftmost-bit position.

No fixed point overflow exceptions are recognized.

The M5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION in conjunction with VECTOR SUBTRACT WITH BORROW INDICATION can be used to perform subtractions on values with a precision greater than a quadword.
VECTOR SUM ACROSS DOUBLEWORD

VSUMG V₁,V₂,V₃, M₄ [VRR-c]

The four halfword or two word sub-elements in each of the doubleword elements of the second operand are summed and then added to the corresponding righthmost sub-element of the corresponding doubleword of the third operand. The full-precision intermediate-sum is extended on the left with zeros to a doubleword and the results are placed in the corresponding doubleword of the first operand.

The M₄ field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M₄ Element Size
0 Reserved
1 Halfword
2 Word
3-15 Reserved

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

VECTOR SUM ACROSS WORD

VSUM V₁,V₂,V₃, M₄ [VRR-c]

The two halfword elements or four byte elements of each word element of the second operand are added together along with the corresponding rightmost sub-element of each word in the third operand. The full-precision intermediate-sum is extended on the left with zeros to a word and the result is placed in the corresponding word element of the first operand.

The M₄ field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M₄ Element Size
0-1 Reserved
2 Word
3 Doubleword
4-15 Reserved

Condition Code: The code remains unchanged.

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:
The second operand contains a mask. The bits in the mask correspond one for one with the bits of the first operand. A mask bit of one indicates that the first-operand bit is to be tested. When a mask bit is zero, the first operand bit is ignored. When all first-operand bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are all ones, condition code 3 is set; otherwise, condition code 1 is set.

**Resulting Condition Code:**

| 0 | Selected bits all zeros; or all mask bits zero |
| 1 | Selected bits a mix of zeros and ones          |
| 2 | --                                             |
| 3 | Selected bits all ones                        |

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint
Chapter 23. Vector String Instructions

Vector String Facility

The vector string facility provides instructions to accelerate the processing of strings of character data.

Instructions

All of the instructions except for VECTOR ISOLATE STRING have the ability to produce an index to a character element within a vector. This index is always placed in the rightmost bits of the leftmost doubleword of the vector. This index will often be used in scalar computation for address generation and will need to be transferred to a general register. If an element index is needed the index will have to be shifted right by the appropriate number of bits.

Unless otherwise specified, all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Each instruction has an Extended Mnemonic section which describe recommended extended mnemonics and their corresponding machine assembler syntax.

Programming Note: For all instructions that optionally set the condition code, performance may be degraded if the condition code is set.

<td></td>
</tr>
</tbody>
</table>

Proceeding from left to right, each element of the second operand is compared for equality with every
If the invert-result (IN) flag in the M5 field is one, then each indication in the first intermediate result is inverted.

If the zero-search (ZS) flag in the M5 field is one, each element in the second operand is also compared with zeros and a second intermediate result is created with an indication for each element if that element is equal to zero. If the ZS flag is zero, the second intermediate result contains all false indications.

If the result-type (RT) flag is zero, for each of the two intermediate results, the index of the lowest indexed true result is obtained. The index is then converted to a byte index by multiplying by the number of bytes in an element. The minimum of the indices obtained from the two intermediate results is then computed. If no true result is found in either intermediate result, a final index equal to the number of bytes in the vector is produced. The index is placed into byte seven of the first operand; all other bytes of the first operand are set to zero.

If the RT flag in the M5 field is one, for each element in the second operand, if the indication in the first intermediate result is true, the bit positions of the corresponding element in first operand are set to ones. If the first intermediate result element contains a false indication the bit positions of the corresponding element in the first operand are set to zero. No indication of true results in the second intermediate value are indicated in the first operand.

The ES field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>

<td>Reserved</td>
</tr>
</tbody>
</table>

The bits of the M5 field are defined as follows:

- **Invert Result (IN):** If bit 0 is zero, the operation proceeds using the comparison indication values in the first intermediate result. If one, the operation proceeds with the comparison indication values in the first intermediate result inverted.

- **Result Type (RT):** If bit 1 is zero, a byte index is stored into byte seven of the first operand and zeros are stored in all other elements. If bit 1 is one, each resulting element is a bit-vector.

- **Zero Search (ZS):** If bit 2 is one, each element of the second operand is also compared for equality with zero.

- **Condition Code Set (CS):** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the resulting condition code section below.

**Resulting Condition Code:**

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, there are no true indications in a lower indexed element in the first intermediate result than a true indication in the second intermediate result. That is, there were no matching elements before an element containing zero in the second operand.

1 At least one indication in the first intermediate result is true. All indications in the second intermediate result are false. That is, there was at least one match in the second operand and, if the ZS-bit is one, no zero matches.

2 If the ZS-bit is one and at least one indication in the first intermediate result is true with a lower index than a true indication in the second intermediate result.

3 All indications in the first intermediate and second intermediate results are false.
**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

<td>VFAE V1, V2, V3, 0, (M5</td>
</tr>
</tbody>
</table>

**Programming Notes:**

1. If the RT flag is zero, a byte index is always stored into the first operand for any element size. For example, if the specified element size is halfword and the 2nd indexed halfword compared equal, a byte index of 4 would be stored.

2. If the CS bit is one, conditions codes 0 and 2 can only be set if the ZS-bit is one.

**VECTOR FIND ELEMENT EQUAL**

![VECTOR FIND ELEMENT EQUAL](image)

Proceeding from left to right, the elements of the second operand are compared with the corresponding elements of the third operand and optionally with zero.

If two elements are equal, the byte index of the first byte of the left-most equal element is placed in byte seven of the first operand. Zeros are stored in the remaining bytes of the first operand. If no bytes are found to be equal, or are equal to zero if the zero search (ZS) bit is one, an index equal to the number of bytes in the vector is stored in byte seven of the first operand. Zeros are stored in the remaining bytes.

If the ZS bit is one in the M5 field, each element in the second operand is also compared for equality with zero. If a zero element is found in the second operand before any other elements of the second and third operands are found to be equal, the byte index of the first byte of the element found to be zero is stored in byte seven the first operand and zeros are stored in all other byte locations. If the condition code-set (CS) flag is one, the condition code is set to zero.

The M4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>
<thead>
<tr>

<td>Reserved</td>
</tr>
</tbody>
</table>

The M5 field has the following format:

```
0 1 2 3
ZE/CS
```

The bits of the M5 field are defined as follows:

- **Reserved:** Bits 0-1 are reserved and must be zero. Otherwise, a specification exception is recognized.
- **Zero Search (ZS):** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- **Condition Code Set (CS):** If bit 3 is zero, the condition code remains unchanged. If one, the condition code is set as specified in the following section.

**Resulting Condition Code:**

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:
0 If the ZS-bit is one, in the second operand there were no equal comparisons in an element with an index less than an element whose contents are zero.

1 Comparison detected a match between the second and third operands in some element. If the ZS-bit is one, there were no zero comparisons in the second operand.

2 If the ZS-bit is one, there was a match between the second and third operands with a lower index than a match with zero in the second operand.

3 No elements compared equal. Additionally, if the ZS-bit is one, no elements contain zero.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VFEEZFS V$1$,V$2$,V$3$+3

VFENE V$1$,V$2$,V$3$,M$4$,M$5$] [VRR-b]

Proceeding from left to right, the elements of the second operand are compared with the corresponding elements of the third operand and optionally with zeros. The elements of the second and third operands are treated as unsigned binary integers.

If two elements are not equal, the byte index of the leftmost not-equal element is placed in byte seven of the first operand and zeros are stored to all other bytes. If the condition code set (CS) bit in the M$5$ field is one, the condition code is set to indicate which operand was greater. If all elements were equal, a byte index equal to the vector size is placed in byte seven of the first operand and zeros are placed in all other byte locations and if the CS bit is one, condition code 3 is set.

If the zero search (ZS) bit is one in the M$5$ field, each element in the second operand is also compared for equality with zero. If a zero element is found in the second operand with a lower index than any other element of the second operand found to be unequal, the byte index of the first byte of the element found to be zero is stored in byte seven of the first operand. Zeros are stored in all other bytes and condition code 0 is set.

The M$4$ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

<table>

</tr>
</tbody>
</table>

Proceeding from left to right, the elements of the second operand are compared to ranges specified by values in even-odd element pairs of the third and fourth operands and, optionally, against an element containing zero. The element in the second and third operand are treated as unsigned binary integers.

The elements of the third and fourth operands form range comparisons to which are applied to elements of the second operand. The even-odd pairs of elements in the third operand define values for the limits of the ranges. The corresponding even-odd pair of elements in the fourth operand contain control information to specify the comparison to be done with each value in the third operand. A range comparison is said to be true if the comparisons on both elements in the even-odd pair are true.

Each element in the second operand is compared against every range specified by the even-odd element pairs in the third and fourth operands. A first intermediate result is created from this comparison with an indication for each element in the second operand if the element was contained in any of the specified ranges.

If the invert-result (IN) flag in the M6 field is one, then each indication in the first intermediate result is inverted.

If the zero-search (ZS) flag in the M6 field is one, each element in the second operand is also compared with zeros and a second intermediate result is created with an indication for each element if that element is equal to zero. If the ZS flag is zero the second intermediate result contains all false indications.

If the result-type (RT) flag is zero, for each of the two intermediate results, the index of the lowest indexed true result is obtained. The index is then converted to a byte index by multiplying by the number of bytes in an element. The minimum of the indices obtained from the two intermediate results is then computed. If no true result is found in either intermediate result, a final index equal to the number of bytes in the vector is produced. The index is placed into byte seven of the first operand; all other bytes of the first operand are set to zero.

If the RT flag in the M6 field is one, for each element in the second operand, if the indication in the first intermediate result is true, the bit positions of the corresponding element in first operand are set to ones. If the first intermediate result element contains a false indication the bit positions of the corresponding element in the first operand are set to zero. No indication of true results in the second intermediate value are indicated in the first operand.

The fourth operand elements have the following format:

If ES equals 0:

<table>
<thead>
<tr>
<th>ELH</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>7</td>
<td></td>
</tr>
</tbody>
</table>

If ES equals 1:

<table>
<thead>
<tr>
<th>ELH</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>15</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
If ES equals 2:

- **Equal (E):** When one, a comparison for equality is made.
- **Low (L):** When one, a less than comparison is performed.
- **High (H):** When one, a greater than comparison is performed.
- All other bits are reserved and should be zero to ensure future compatibility.

The control bits may be used in any combination. If none of the bits are set, the comparison will always produce a false result. If all of the bits are set, the comparison will always produce a true result.

The M5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

The M6 field has the following format:

- **Element Size**
  - 0: Byte
  - 1: Halfword
  - 2: Word
  - 3-15: Reserved

The M6 field has the following format:

- **Invert Result (IN):** If bit 0 is zero, the operation proceeds using the comparison indication values in the first intermediate result. If one, the operation proceeds with the comparison indication values in the first intermediate result inverted.
- **Result Type (RT):** If bit 1 is zero, a byte index is stored into byte seven of the first operand and zeros are stored in all other elements. If bit 1 is one, each resulting element is a bit-vector.
- **Zero Search (ZS):** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- **Condition Code Set (CS):** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the following section.

**Resulting Condition Code:**

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

1. **0** If the ZS-bit is one, there are no true indications in a lower indexed element in the first intermediate result than a true indication in the second intermediate result. That is, there were no matching elements before an element containing zero in the second operand.
2. **1** At least one indication in the first intermediate result is true. All indications in the second intermediate result are false. That is, there was at least one match in the second operand and, if the ZS-bit is one, no zero matches.
3. **2** If the ZS-bit is one and at least one indication in the first intermediate result is true with a lower index than a true indication in the second intermediate result.
4. **3** All indications in the first intermediate and second intermediate results are false.

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

</tbody>
</table>

**Programming Notes:**

1. To create a comparison that is a range with only one bound, either place that comparison in both the even and odd elements of the pair in the third and fourth operands or place the operand in a single element of the pair with the comparison needed in the corresponding element of the fourth operand, and set the other element in the fourth operand to have all three control bits set.

2. To create a comparison for equality place the same value in the even-odd pair in the third operand. The corresponding even-odd element pair in the fourth operand should contain elements with only a one in the EQ bit.

3. If all available ranges are not needed, the control bits in the fourth operand should all be zero for the elements in the unneeded range. The corresponding elements in the third operand are ignored.
### IEEE Exception Handling

When a vector instruction is executed and a trapping IEEE exception condition is encountered, instruction execution is suppressed for all elements, except that the floating-point-control register is updated with the VXC.

If trapping vector-processing exception conditions exist for multiple elements, the exception of the lowest-indexed element is recognized.

When either a trapping IEEE overflow or IEEE underflow exception occur concurrently on the same element with a trapping IEEE inexact exception, only the IEEE overflow or IEEE underflow exception is recognized.

### Result Figures

Concise descriptions of the results produced by many of the vector floating point instructions are made by means of figures which contain columns and rows representing all possible combinations of data class for the source operand elements of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand element data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results for an element is

**Notes:**

The vector facility for z/Architecture provides support for long-format binary-floating-point (BFP) operations, with the exception of VECTOR LOAD LENGTHENED which operates on short-format BFP numbers and VECTOR LOAD ROUNDED which produces a short-format BFP result. Numerically, the results in each element are the same as would occur as if an instruction in Chapter 19 was used to compute the result. Some instructions have different result figures noting changes due to different exception handling described below.

When a vector instruction is executed, no trapping IEEE exceptions are encountered on any elements, and a non-trapping IEEE exception condition is encountered on an element, the flag bit for that exception is set in the floating-point-control (FPC) register and the IEEE defined default value is placed in the corresponding element of the target operand. If multiple elements have non-trapping IEEE exception conditions then each element sets the flag bit in the FPC register and the defined default values are placed in the corresponding elements of the target operand.
a program interruption. In the case of a program interruption on any element, the operation is suppressed.

Figure 24-1, “IEEE Exception and Flag Abbreviations” on page 24-2 shows IEEE exceptions and flag abbreviations that are used in the result figures.

</tbody>
</table>

Explanations:

1 The symbol “Xi” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, if the element is the leftmost element upon which an exception is recognized the vector interrupt code (VIC) in the vector exception code (VXC) is set to 1 hex, the VIX is set to the index of the element recognizing the exception, and a program interruption for a vector-processing exception occurs.

2 The symbol “Xz” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed if the element is the leftmost element upon which an exception is recognized the vector interrupt code (VIC) in the vector exception code (VXC) is set to 2 hex, the VIX is set to the index of the element recognizing the exception, and a program interruption for a data exception occurs.

Instructions

Each instruction has an Extended Mnemonic section which describes recommended extended mnemonics and their corresponding machine assembler syntax. Not all assemblers may provide these mnemonics.

Most vector floating-point instructions have a single element control bit. If this bit is set to one, indicating only one element is to be executed, performance may be improved on some models. When the single element control bit is set the bit positions of all other elements besides the zero indexed element are unpredictable. A mnemonic with the initial V replaced with a W indicates the instruction will only operate on a single element.

VECTOR FP ADD

VFA \( V_1, V_2, V_3, M_4, M_5 \) [VRR-c]

\[
\begin{array}{cccccccccc}
\text{E7} & V_1 & V_2 & V_3 & / / / / / / & M_6 & M_4 & R_{XB} & \text{E3}'
\end{array}
\]

0 8 12 16 20 28 32 36 40 47

The floating-point element or elements of the third operand are added to the corresponding floating-point element or elements of the second operand. The results are placed in the corresponding elements of the first operand. All operand elements contain long-format BFP numbers.

If the corresponding elements of both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operand elements with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward \(-\infty\), in which method the sign is minus.
- The sign of the sum \( x + x \) is the sign of \( x \), even when \( x \) is zero.

**Explanation:**

- \( \sigma^7 \) Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
- \( \sigma^9 \) Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
- \( C \) Condition code set.
- \( C^* \) Condition code optionally set.
- \( Dv \) Vector-instruction data exception.
- \( SP \) Specification exception.
- \( VF \) Vector facility for z/Architecture.
- \( VRI \) VRI instruction format.
- \( VRR \) VRR instruction format.
- \( Xi \) IEEE invalid-operation exception.
- \( Xo \) IEEE overflow exception.
- \( Xu \) IEEE underflow exception.
- \( Xx \) IEEE inexact exception.
- \( Xz \) IEEE division-by-zero exception.
If one operand element is an infinity and the other is a finite number, the result is that infinity. If both operand elements are infinities of the same sign, the result is the same infinity. If the two operand elements are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 24-3 on page 24-5 for detailed information on the results for each element.

The M₄ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₅ field has the following format:

```
0 1 3
```

The bits of the M₅ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **Reserved:** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid Operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

</tr>
<tr>
<td>SNaN</td>
<td>Xi: T(a*)</td>
</tr>
</tbody>
</table>

**Explanation:**

* The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.

dNaN Default NaN.

Dn Subnormal number.

Nn Normal number.

R(v) Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.

Rezd Exact zero-difference result. See Figure 24-4 on page 24-6.

T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.

Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

<td>Overflow</td>
<td>+∞1</td>
<td>+Nmax</td>
<td>+∞1</td>
<td>+Nmax</td>
</tr>
</tbody>
</table>

**Explanation:**

– This situation cannot occur.
* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.
1 The nontrap result r is considered to have been incremented.
2 The exact-zero-difference case applies only to VECTOR FP ADD, VECTOR FP SUBTRACT, VECTOR FP MULTIP Y AND ADD, and VECTOR FP MULTIPLY AND SUBTRACT. For all other vector BFP operations, a zero result is detected by inspection of the source operand elements without use of the R(v) function.

**Legend:**

- **d**: The denormalized value. The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.
- **g**: The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
- **v**: Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For VECTOR LOAD ROUNDED, v is the source value (a).
- **Dmin**: Smallest (in magnitude) representable subnormal number in the target format.
- **Nmax**: Largest (in magnitude) representable finite number in the target format.
- **Nmin**: Smallest (in magnitude) representable normal number in the target format.

---

Figure 24-4. Action for R(v): Rounding and Range Function (Part 1 of 2)
The zero-indexed element of the first operand is compared with the zero-indexed element of the second operand, and the condition code is set to indicate the result.

If both operand elements are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operand elements remain unchanged. If the difference is exactly zero with either sign, the operand elements are equal; this includes zero operand elements (so +0 equals -0). If a nonzero difference is positive or negative, the first operand element is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operand elements of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operand elements as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operand elements are QNaNs and neither operand element is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operand elements are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a vector-processing exception with a VXC indicating an IEEE invalid-operation occurs. If
the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-14, “Results: COMPARE” on page 19-18 for a detailed description of the results of this instruction substituting the first operand element for (a) and the second operand element for (b).

The M₃ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₄ field must be zero otherwise a specification exception is recognized.

**Resulting Condition Code:**

0  Operand elements equal
1  First operand element low
2  First operand element high
3  Operand elements unordered

**IEEE Exceptions:**

- Invalid operation

**Program Exceptions:**

- Data with DXC FE, Vector instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

<table>

<td>WFK V1,V2,3,0</td>
</tr>
</tbody>
</table>

**Programming Notes:**

1. **VECTOR FP COMPARE AND SIGNAL SCALAR** may be used to set a condition code to be used by a subsequent branch for program control flow.

2. **VECTOR FP COMPARE AND SIGNAL SCALAR** may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to recognize an exception when the result is unordered due to a QNaN.

**VECTOR FP COMPARE EQUAL**

\[ VFCE V_1, V_2, M_4, M_5, M_6 \] [VRR-c]

The floating-point element or elements of the second operand are compared for equality with the corresponding element or elements of the third operand. If equal, the bits of the corresponding element in the first operand are set to all ones, otherwise the bits are set to all zeros. The second and third operand elements contain long-format BFP numbers.

If any of the elements in the second or third operands are SNaNs, an IEEE invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-5 on page 24-10 for a detailed description of the results for each element.

The \( M_4 \) field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The bits of the \( M_5 \) field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **Reserved:** Bits 1, 2, and 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

The bits of the \( M_6 \) field are defined as follows:

- **Reserved:** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.

- **Condition Code Set (CS):** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

**Resulting Condition Code:** When Bit 3 of the \( M_6 \) field is one, the code is set as follows:

0 All elements equal (All T results in Figure 24-5)
1 Mix of equal, and unequal or unordered elements (A mix of T and F results in Figure 24-5)
2 --
3 All elements not equal or unordered (All F results in Figure 24-5)

Otherwise, the code remains unchanged.

**IEEE Exceptions:**

- Invalid Operation
**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

</table>

**Explanation:**
- T: Corresponding element in operand one is set to all ones
- F: Corresponding element in operand one is set to all zeros
- C(a=b): Basic compare result. T if a=b and F if a≠b.
- Fn: Finite nonzero number (includes both subnormal and normal).
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

*Figure 24-5. Results: VECTOR FP COMPARE EQUAL*

**VECTOR FP COMPARE HIGH**

VFCH V₁, V₂, V₃, M₄, M₅, M₆ [VRR-c]

The floating-point element or elements of the second operand are compared with each corresponding floating-point element or elements of the third operand. If the element in the second operand is greater than the element in the third operand, the bit positions of the corresponding element in the first operand are set to one. Otherwise, the bit positions in the corresponding element of the first operand are set to zeros. The second and third operand elements contain long-format BFP numbers.

If any of the elements in the second and third operands are SNaNs, an IEEE invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption with a VXC indicating and IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-6 on page 24-12 for a detailed description of the results for each element.

The M₄ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.
The M₅ field has the following format:

```
0 1 2 3
```

The bits of the M₅ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **Reserved:** Bits 1, 2, and 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M₆ field has the following format:

```
0 2 3
```

The bits of the M₆ field are defined as follows:

- **Reserved:** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.

- **Condition Code Set (CS):** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

**Resulting Condition Code:** When Bit 3 of the M₆ field is one, the code is set as follows:

0. All elements greater than (All T results in Figure 24-6)
1. Mix of greater than, and non-greater than or unordered elements (A mix of T and F results in Figure 24-6)
2. All elements not greater than, or unordered (All F results in Figure 24-6)

Otherwise, the code remains unchanged.

**IEEE Exceptions:**

- Invalid operation

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

</tbody>
</table>

**Programming Note:** Condition Code 1 will never be presented if the S-bit is set to one.
VECTOR FP COMPARE HIGH OR EQUAL

The floating-point element or elements of the second operand are compared with each corresponding floating-point element or elements of the third operand. If the element in the second operand is greater than or equal to the element in the third operand, the bit positions of the corresponding element in the first operand are set to one. Otherwise the bit positions in the corresponding element of the first operand are set to zeros. The second and third operand elements contain long-format BFP numbers.

If any of the floating-point elements in the second or third operand are SNaNs, an IEEE invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-7 on page 24-13 for a detailed description of the results for each element.

The M₄ field must contain a value of three, all other values are reserved. If a reserved value is specified a specification exception is recognized.

The M₅ field has the following format:

<table>
<thead>
<tr>
<th>S</th>

</tbody>
</table>
VECTOR FP CONVERT FROM FIXED 64-BIT

The signed binary integer doubleword element or elements of the second operand are converted to a long-format binary floating-point number. The results are placed in the corresponding element or elements of the first-operand location.

The M₃ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₄ field has the following format:

```
S X C
0 1 2 3
```

The bits of the M₄ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **IEEE-inexact-exception control (XxC):** Bit 1 of the M₄ field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

- **Reserved:** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

The converted result is rounded by the rounding method as specified by the modifier in the M₅ field:

<table>
<thead>
<tr>
<th>M₅</th>
<th>Effective Rounding Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>According to current BFP rounding mode</td>
</tr>
<tr>
<td>1</td>
<td>Round to nearest with ties away from 0</td>
</tr>
<tr>
<td>3</td>
<td>Round to prepare for shorter precision</td>
</tr>
<tr>
<td>4</td>
<td>Round to nearest with ties to even</td>
</tr>
<tr>
<td>5</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>6</td>
<td>Round toward +∞</td>
</tr>
<tr>
<td>7</td>
<td>Round toward −∞</td>
</tr>
</tbody>
</table>

An M₅ modifier other than 0, 1, or 3-7 is invalid. The M₅ field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M₅ modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-15 for a detailed description of the results for each element.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Inexact

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>

</thead>
<tbody>
<tr>
<td>VCDGB V₁,V₂,M₄,M₅</td>
<td>VCDG V₁,V₂,3,M₄,M₅</td>
</tr>
<tr>
<td>WCDGB V₁,V₂,M₃,M₅</td>
<td>VCDG V₁,V₂,3,(8</td>
</tr>
</tbody>
</table>
The unsigned binary integer doubleword element or elements in the second operand are converted to long-format binary floating-point number. The results are placed in the corresponding element or elements of the first-operand location.

The M₃ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₄ field has the following format:

The bits of the M₄ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **IEEE-inexact-exception control (XxC):** Bit 1 of the M₄ field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
**Reserved:** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

The converted result is rounded by the rounding method as specified by the modifier in the M₅ field:

M₅ Effective Rounding Method
0  According to current BFP rounding mode
1  Round to nearest with ties away from 0
3  Round to prepare for shorter precision
4  Round to nearest with ties to even
5  Round toward 0
6  Round toward +∞
7  Round toward -∞

An M₅ modifier other than 0, 1, or 3-7 is invalid. The M₅ field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M₅ modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-15 for a detailed description of the results for each element.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

</tr>
<tr>
<td></td>
<td>M₃, M₄</td>
<td>'C2'</td>
</tr>
</tbody>
</table>

The BFP long-format floating-point element or elements of the second operand are rounded to an integer value and then converted to the fixed-point format. The doubleword signed binary integer result is placed in the corresponding element of the first-operand location.

If the second operand element is a finite number, it is rounded to an integer value by the rounding method as specified by the modifier in the M₅ field:

M₅ Effective Rounding Method
0  According to current BFP rounding mode
1  Round to nearest with ties away from 0
3  Round to prepare for shorter precision
4  Round to nearest with ties to even
5  Round toward 0
6  Round toward +∞
7  Round toward -∞

An M₅ modifier other than 0, 1, or 3-7 is invalid. The M₅ field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M₅ modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The sign of the result is the sign of the second operand element, except that a zero result has a plus sign.

See Figure 24-9 on page 24-17 for a detailed description of the results for each element.

The M₃ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.
The $M_4$ field has the following format:

$$
\begin{array}{c|c|c|c}
X & S & x & C \\
0 & 1 & 2 & 3 \\
\end{array}
$$

The bits of the $M_4$ field are defined as follows:

- **Single-Element-Control ($S$):** If bit 0 of the $M_4$ field is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **IEEE-inexact-exception control ($XxC$):** Bit 1 of the $M_4$ field is the $XxC$ bit. If $XxC$ is zero, recognition of IEEE-inexact exception is not suppressed; if $XxC$ is one, recognition of IEEE-inexact exception is suppressed.

- **Reserved:** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact
- Invalid operation

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Explanation:

– The results do not depend on this condition or mask bit.
1 This condition is true by virtue of the state of some condition to the left of this column.
f The value n converted to a fixed-point result.
n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
MN Maximum negative number representable in the target fixed-point format.
MP Maximum positive number representable in the target fixed-point format.
PIV(h) Program interruption for vector-processing exception with VXC containing the element index and a VIC of h in hex.
SFi IEEE invalid-operation flag, FPC 1.0.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.

Figure 24-9. Results: VECTOR FP CONVERT TO FIXED 64 (Continued)

VECTOR FP CONVERT TO LOGICAL 64-BIT

The BFP long-format floating-point element or elements of the second operand are rounded to an integer value and then converted to the fixed-point format. The doubleword unsigned binary integer result is placed in the corresponding element of the first-operand location.

If the second operand element is a finite number, it is rounded to an integer value by the rounding method as specified by the modifier in the M5 field:

M5 Effective Rounding Method

0 According to current BFP rounding mode
1 Round to nearest with ties away from 0
3 Round to prepare for shorter precision
4 Round to nearest with ties to even
5 Round toward 0
6 Round toward +∞
7 Round toward -∞

An M5 modifier other than 0, 1, or 3-7 is invalid. The M5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The sign of the result is the sign of the second operand element, except that a zero result has a plus sign.

See Figure 24-10 on page 24-20 for a detailed description of the results for each element.

The M5 field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.
The M₄ field has the following format:

```
X
S x x C
0 1 2 3
```

The bits of the M₄ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **IEEE-inexact-exception control (XxC):** Bit 1 of the M₄ field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

- **Reserved:** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Inexact
- Invalid operation

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

</table>

**Explanations:**

- The results do not depend on this condition or mask bit.
- This condition is true by virtue of the state of some condition to the left of this column.
- The value n converted to a fixed-point result.
- The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
- Maximum unsigned number representable in the target fixed-point format.
- Program interruption for vector-processing exception with VXC containing the element index and a VIC of h in hex.
- IEEE invalid-operation flag, FPC 1.0.
- IEEE inexact flag, FPC 1.4.
- The value x is placed at the target operand element location if no trapping exceptions on other elements.

</tbody>
</table>

The element or elements of the second operand (the dividend) are divided by the corresponding element or elements in the third operand (the divisor), and the quotient or quotients are placed at the corresponding elements in first-operand location. No remainder is preserved.
If the divisor is nonzero and both the dividend and divisor are finite numbers, the second operand element is divided by the third operand element to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the corresponding operand element signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 24-11 on page 24-22 for a detailed description of the results of each element.

The M₄ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₅ field has the following format:

```
S / / / 0 1 3
```

The bits of the M₅ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **Reserved:** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

<td>X: T(dNaN)</td>
</tr>
<tr>
<td>QNaN</td>
<td>T(a)</td>
</tr>
<tr>
<td>SNaN</td>
<td>X: T(a')</td>
</tr>
</tbody>
</table>

**Explanation:**

* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
* F\( n \) Finite nonzero number (includes both subnormal and normal).
* R(v) Rounding and range action is performed on the value \( v \). See Figure 24-4 on page 24-6.
* T(x) The value \( x \) is placed at the target operand element location if no trapping exceptions on other elements.
* Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
* Xz: IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

**Figure 24-11. Results: DIVIDE**

When the M5 modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

In the absence of an interruption, if the second operand element is an infinity or a QNaN, the result is that operand element; if the second operand element is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand element, even when the result is zero.

The M3 field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M4 field has the following format:

```
0 1 2 3
```

The bits of the M4 field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-
indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **IEEE-inexact-exception control (XxC):** Bit 1 of the M₄ field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

- **Reserved:** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

See Figure 24-12 on page 24-24 for a detailed description of the results for each element.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Inexact

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Programming Notes:**

1. VECTOR LOAD FP INTEGER rounds BFP numbers to an integer values. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.

2. If the BFP operand element is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.

</tr>
<tr>
<td>SNaN</td>
<td>No</td>
<td>1</td>
<td>–</td>
<td>–</td>
<td>PIV(1)</td>
</tr>
</tbody>
</table>

**Explanation:**
- The results do not depend on this condition or mask bit.
- * The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.
- 1 This condition is true by virtue of the state of some condition to the left of this column.
- n The value derived when the source value, a, is rounded to a floating-point integer using the effective rounding mode.
- Fn Finite nonzero number (includes both subnormal and normal).
- PIV(h) Program interruption for vector-processing exception, with a VXC containing the element index and a VIC of h in hex.
- SFi IEEE invalid-operation flag, FPC 1.0.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.

---

**VECTOR FP LOAD LENGTHENED**

When the second operand element is a finite number, the value of the second operand element is placed in the target format. The exponent of the second operand element is converted to the corresponding exponent in the result format, and the fraction is extended by appending zeros on the right.

If the second operand element is an infinity, the result is an infinity of the same sign. If the second operand element is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

---

The leftmost word-sized sub-element of each doubleword element or elements of the second operand containing short-format BFP numbers are converted to long-format BFP numbers, and the results are placed at the corresponding doubleword elements in the first-operand.
The sign of the result is the same as the sign of the source.

See Figure 24-8 on page 24-15 for a detailed description of the results for each element.

The M₃ field must contain a value of two, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₄ field has the following format:

```
  S  | 0 | 1 | 2 | 3
```

The bits of the M₄ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **Reserved:** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- **Invalid operation**

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Extended Mnemonics:**

<table>
<thead>
<tr>
<th>Extended Mnemonic</th>
<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLDEB V₁,V₂</td>
<td>VLDE V₁,V₂,2,0</td>
</tr>
<tr>
<td>WLDEB V₁,V₂</td>
<td>VLDE V₁,V₂,2,8</td>
</tr>
</tbody>
</table>

**VECTOR FP LOAD ROUNDED**

The elements of the second operand, are rounded to the precision of the next smallest element size, and the result is placed at the corresponding even elements in the first-operand location. The data in the odd elements of the first operand is unpredictable. Elements of the second operand are long-format BFP numbers.

The sign of the resulting element or elements is the same as the corresponding element of the second operand.

The second operand element, if a finite number, is rounded by the rounding method as specified by the modifier in the M₅ field:

- **M₅ Effective Rounding Method**
  - 0 According to current BFP rounding mode
  - 1 Round to nearest with ties away from 0
  - 3 Round to prepare for shorter precision
  - 4 Round to nearest with ties to even
  - 5 Round toward 0
  - 6 Round toward +∞
  - 7 Round toward −∞

An M₅ modifier other than 0, 1, or 3-7 is invalid. The M₅ field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M₅ modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-15 for a detailed description of the results for each element.

The M₃ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.
VECTOR FP MULTIPLY

The M4 field has the following format:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **IEEE-inexact-exception control (XxC):** Bit 1 of the M4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

- **Reserved:** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**
- Invalid operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

**Programming Note:** The sign of the rounded result is the same as the sign of the operand element, even when the result is zero.

**Extended Mnemonics:**

<table>
<thead>

<th>Base Mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>WLEDB V1,V2,M4,M5</td>
<td>VLED V1,V2,3,(8</td>
</tr>
</tbody>
</table>

The product of the element or elements of the second operand (the multiplier) and the corresponding element or elements of the third operand (the multiplicand) are placed in the corresponding element or elements of the first operand. The second and third operand elements contain long-format BFP numbers.

The two corresponding operand elements, if finite numbers, are multiplied, forming an intermediate product. The result is rounded to the operand format according to the current BFP rounding mode.

The sign of the product, if the product is numeric, is the exclusive OR of the operand element signs. This includes the sign of a zero or infinite product.

If one operand element is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 24-13 on page 24-27 for a detailed description of the results for each element.

The M5 field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M5 field has the following format:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.
Reserved: Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:
- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification

Extended Mnemonics:

Extended Mnemonic Base Mnemonic
VFMB V1,V2,V3 VFM V1,V2,V3,3,0
WFMB V1,V2,V3 VFM V1,V2,V3,3,8

Programming Note: Interchanging the two operand elements in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operand elements are QNaNs, in which case the result is the second operand element; or when both operand elements are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the second operand element.

Explanation:
* The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.

dNaN Default NaN.
Fn Finite nonzero number (includes both subnormal and normal).
R(v) Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 24-13. Results: VECTOR FP MULTIPLY

VECTOR FP MULTIPLY AND ADD

VFMA V1,V2,V3,V4,M5,M6 [VRR-e]

VECTOR FP MULTIPLY AND SUBTRACT

VFMS V1,V2,V3,V4,M5,M6 [VRR-e]

The element or elements of the third operand are multiplied by the corresponding element or elements.
of the second operand, and then the corresponding
element or elements of the fourth operand are added
to or subtracted from the products. The sum or differ-
ences are placed at the corresponding first-operand
element locations. All operand elements contain
long-format BFP numbers. The VECTOR FP MULTI-
PLY AND ADD and VECTOR FP MULTIPLY AND
SUBTRACT operations may be summarized as fol-

gows, where “(i)” represents the “i”th indexed element
of the operand:

\[
\text{op}_1(i) = \text{op}_2(i) \cdot \text{op}_3(i) \pm \text{op}_4(i)
\]

When all of the corresponding operand elements are
finite numbers, the third and second BFP operand
elements are multiplied, forming an intermediate
product, and the corresponding first operand element
is then added (or subtracted) algebraically to (or
from) the intermediate product, forming an interme-
diate sum. The intermediate sum, if nonzero, is
rounded to the operand format according to the cur-
cent BFP rounding mode and then placed at the cor-
responding element of the first-operand location. The
exponent and fraction of the intermediate product are
maintained exactly; rounding and range checking
occur only on the intermediate sum.

See Figure 24-14 for a detailed description of the
results for each element of VECTOR FP MULTIPLY
AND ADD. The results for each element of VECTOR
FP MULTIPLY AND SUBTRACT are the same,
except that the fourth operand element, if numeric,
participates in the operation with its sign bit inverted.
When the fourth operand element is a NaN, it partici-
pates in the operation with its sign bit unchanged.

The \( M_6 \) field must contain a value of three, all other
values are reserved. If a reserved value is specified,
a specification exception is recognized.

The \( M_5 \) field has the following format:

\[
\begin{array}{c}
\text{S} \\
0 \ 1 \ 3
\end{array}
\]

The bits of the \( M_5 \) field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to
  one, the operation takes place only on the zero-
  indexed element in the vector. In the absence of
  a trapping exception condition, the bit positions
  of all other elements in the first operand vector are
  unpredictable. If bit 0 is set to zero, the
  operation occurs on all elements in the vector.

- **Reserved:** Bits 1 to 3 are reserved and must be
  zero. Otherwise, a specification exception is rec-
  ognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture
  is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception
  and element index

**Extended Mnemonics:**

<table>

</tr>
</tbody>
</table>

**Programming Note:** VECTOR FP MULTIPLY AND
ADD and VECTOR FP MULTIPLY AND SUBTRACT
produce a precise intermediate value, and a single
rounding operation is performed after the addition or
subtraction. This definition is consistent with the
Power architecture, and, in certain applications, can
be used to great advantage, especially in algorithms
used in math libraries.
The sign of the element or elements of the second operand are modified in a manner specified by the value of the M5 field. The modified sign bit and the rest of the unchanged second operand element are placed into the corresponding element in the first operand. All operand elements contain long-format BFP numbers.

The sign operation is performed even if the element contains zero. If the element contains a QNaN or SNaN, the sign is still set without causing an IEEE exception.

The M5 field indicates the operation to perform on the sign bit.

<tr>
<td>2</td>
<td>The sign bit is set to zero (positive)</td>
</tr>
</tbody>
</table>
If any other $M_3$ values are specified, a specification exception is recognized.

The $M_3$ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The $M_4$ field has the following format:

```
S 1 3
```

The bits of the $M_4$ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. The bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- **Reserved:** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None

**Program Exceptions:**
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

**Extended Mnemonics:**

<table>

**VECTOR FP SQUARE ROOT**

```
<table>
<thead>
<tr>
<th>VFSQ</th>
<th>$V_1,V_2,M_3,M_4$</th>
</tr>
</thead>
<tbody>
<tr>
<td>VRR-a</td>
<td></td>
</tr>
</tbody>
</table>
```

The square roots of each element of the second operand are placed at the corresponding elements of the first-operand location. All operand elements contain long-format BFP numbers.

The result rounded according to the current BFP rounding mode is placed at the first operand element location.

If the second operand element is a positive finite number, the result is the square root of that number with a plus sign. If the operand element is a zero of either sign, the result is a zero of the same sign. If the operand element is $+\infty$, the result is $+\infty$.

If the second operand element is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 24-8 on page 24-15 for a detailed description of the results for each element.

The $M_3$ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The $M_4$ field has the following format:

```
S 1 3
```

The bits of the $M_4$ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- **Reserved:** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.
IEEE Exceptions:
- Invalid operation
- Inexact

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

<table>
<thead>

</tr>
</tbody>
</table>

VECTOR FP SUBTRACT

VFS V1,V2,V3,M4,M5 [VRR-c]

The floating-point element or elements in the third operand are subtracted from the floating-point element or elements of the second operand, and the difference is placed in the floating-point element or elements at the first-operand location. All operand elements contain long-format BFP numbers.

The execution of VECTOR FP SUBTRACT is identical to that of VECTOR FP ADD, except that the third operand element, if numeric, participates in the operation with its sign bit inverted. When the third operand contains an element that is a NaN, it participates in the operation with its sign bit unchanged. See Figure 24-3 on page 24-5 for the detailed results for each element of VECTOR FP ADD.

The M4 field must contain a value of three, all other values are reserved. If a reserved value is specified a specification exception is recognized.

The M5 field has the following format:

<table>
<thead>
<tr>
<th>S</th>
<th>S</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

The bits of the M5 field are defined as follows:

- Single-Element-Control (S): If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- Reserved: Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:
- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

</tr>
</tbody>
</table>

VECTOR FP TEST DATA CLASS IMMEDIATE

VFTCI V1,V2,I3,M5 [VRRI-e]

The class and sign of the floating-point element or elements of the second operand are examined to select one bit from the third-operand. If the selected bit is set, all bit positions of the corresponding element in the first operand are set to ones, otherwise...
they are set to zero. All operand elements contain long-format BFP numbers.

The 12 bits of the third operand, bits 16-27 of the instruction text, are used to specify 12 combinations of BFP data class and sign.

As shown in Figure 24-15, BFP operand elements are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

One or more of the third-operand bits may be set to one.

Operand elements, including SNaNs and QNaNs, are examined without causing an IEEE exception.

The M₄ field must contain a value of three, all other values are reserved. If a reserved value is specified, a specification exception is recognized.

The M₅ field has the following format:

![Table of BFP Element Class and Bit Used](image)

The bits of the M₅ field are defined as follows:

- **Single-Element-Control (S):** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. The bit positions of all other elements in the first operand vector are unpredictable. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- **Reserved:** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0: Selected bit is 1 for all elements (match)
- 1: Selected bit is 1 for at least one but not all elements (when S-bit is zero)
- 2-3: Selected bit is 0 for all elements (no match)

### IEEE Exceptions:

- None.

### Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

### Extended Mnemonics:

- **Extended Mnemonic** | **Base Mnemonic**
  - VFTCIDB $V_1,V_2,I_3$
  - WFTCIDB $V_1,V_2,I_3$

### Programming Notes:

1. VECTOR TEST DATA CLASS provides a way to test operand elements without risk of an exception or setting the IEEE flags.
2. When the S bit is set it is impossible to get a Condition Code of 1.
3. Use VECTOR FP COMPARE EQUAL if you want behavior similar to LOAD AND TEST in Chapter 19.

Number Representation

Binary Integers

Signed Binary Integers
Signed binary integers are most commonly represented as halfwords (16 bits) or words (32 bits). In both lengths, the leftmost bit (bit 0) is the sign of the number. The remaining bits (bits 1-15 for halfwords and 1-31 for words) are used to specify the magnitude of the number. Binary integers are also referred to as fixed-point numbers, because the radix point (binary point) is considered to be fixed at the right, and any scaling is done by the programmer.

Positive binary integers are in true binary notation with a zero sign bit. Negative binary integers are in two's-complement notation with a one bit in the sign position. In all cases, the bits between the sign bit and the leftmost significant bit of the integer are the same as the sign bit (that is, all zeros for positive numbers, all ones for negative numbers).

Negative binary integers are formed in two's-complement notation by inverting each bit of the positive binary integer and adding one. As an example using the halfword format, the binary number with the decimal value +26 is made negative (-26) in the following manner:

\[
\begin{align*}
+26 & \quad 00000000\ 00011010 \\
\text{Invert} & \quad 11111111\ 11100101 \\
\text{Add} & \quad 00000000\ 00000001 \\
\hline
-26 & \quad 11111111\ 11100110 \quad \text{(Two's complement form)}
\end{align*}
\]

(S is the sign bit.)

This is equivalent to subtracting the number:

\[
\begin{align*}
00000000\ 00011010 \\
\text{from} & \quad 10000000\ 00000000
\end{align*}
\]

Negative binary integers are changed to positive in the same manner.

The following addition examples illustrate two's-complement arithmetic and overflow conditions. Only eight bit positions are used.
The presence or absence of an overflow condition may be recognized from the carries:

- There is no overflow:
  1. If there is no carry into the leftmost bit position and no carry out (examples 1 and 3).
  2. If there is a carry into the leftmost position and also a carry out (examples 2 and 4).

- There is an overflow:
  1. If there is a carry into the leftmost position but no carry out (example 5).
  2. If there is no carry into the leftmost position but there is a carry out (example 6).

The following are 16-bit signed binary integers. The first is the maximum positive 16-bit binary integer. The last is the maximum negative 16-bit binary integer (the negative 16-bit binary integer with the greatest absolute value).

\[
\begin{align*}
2^{15} - 1 &= 32,767 = 0111 \ 1111 \ 1111 \ 1111 \\
2^{16} &= 65,536 = 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \\
2^8 &= 1 \ 000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \\
0 &= 0 \ 000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \\
-2^0 &= -1 = 1 \ 111 \ 1111 \ 1111 \ 1111 \ 1111 \ 1111 \ 1111 \\
-2^1 &= -2 = 1 \ 111 \ 1111 \ 1111 \ 1111 \ 1111 \ 1111 \ 1110 \\
-2^{16} &= -65,536 = 1 \ 111 \ 1111 \ 1111 \ 1111 \ 0000 \ 0000 \ 0000 \\
-2^{31} + 1 &= -2 \ 147 \ 483 \ 647 = 0 \ 000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0001 \\
-2^{31} &= -2 \ 147 \ 483 \ 648 = 1 \ 000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \\
\end{align*}
\]

Figure A-1 illustrates several 32-bit signed binary integers arranged in descending order. The first is the maximum positive binary integer that can be represented by 32 bits, and the last is the maximum negative binary integer that can be represented by 32 bits.

\[Figure \ A-1. \ 32-\text{Bit Signed Binary Integers}\]
signed binary integers, except that the leftmost bit is interpreted as another numeric bit rather than a sign bit. There is no complement notation because all unsigned binary integers are considered positive.

The following examples illustrate the addition of unsigned binary integers. Only eight bit positions are used. The examples are numbered the same as the corresponding examples for signed binary integers.

1. \[ \begin{align*} 57 &= 0011\ 1001 \\ 35 &= 0010\ 0011 \end{align*} \]

\[ 92 = 0101\ 1100 \]

2. \[ \begin{align*} 57 &= 0011\ 1001 \\ 221 &= 1101\ 1101 \end{align*} \]

\[ 278 = \star 0001\ 0110 \quad \text{*Carry out of leftmost position} \]

3. \[ \begin{align*} 35 &= 0010\ 0011 \\ 199 &= 1100\ 0111 \end{align*} \]

\[ 234 = 1110\ 1010 \]

4. \[ \begin{align*} 199 &= 1100\ 0111 \\ 221 &= 1101\ 1101 \end{align*} \]

\[ 420 = \star 1010\ 0100 \quad \text{*Carry out of leftmost position} \]

5. \[ \begin{align*} 57 &= 0011\ 1001 \\ 92 &= 0101\ 1100 \end{align*} \]

\[ 149 = 1001\ 0101 \]

6. \[ \begin{align*} 199 &= 1100\ 0111 \\ 164 &= 1010\ 0100 \end{align*} \]

\[ 363 = \star 0110\ 1011 \quad \text{*Carry out of leftmost position} \]

A carry out of the leftmost bit position may or may not imply an overflow, depending on the application.

Figure A-2 illustrates several 32-bit unsigned binary integers arranged in descending order.

### Decimal Integers

Decimal integers consist of one or more decimal digits and a sign. Each digit and the sign are represented by a 4-bit code. The decimal digits are in binary-coded decimal (BCD) form, with the values 0-9 encoded as 0000-1001. The sign is usually represented as 1100 (C hex) for plus and 1101 (D hex) for minus. These are the preferred sign codes, which are generated by the machine for the results of decimal-arithmetic operations. There are also several alternate sign codes (1010, 1110, and 1111 for plus; 1011 for minus). The alternate sign codes are accepted by the machine as valid in source operands but are not generated for results.

Decimal integers may have different lengths, from one to 16 bytes. Of the many decimal formats, only two will be considered here: signed-packed-decimal and zoned. In the signed-packed-decimal format, each byte contains two decimal digits, except for the rightmost byte, which contains the sign code in the right half. For decimal arithmetic, the number of decimal digits in the signed-packed-decimal format can vary from one to 31. Because decimal integers must consist of whole bytes and there must be a sign code on the right, the number of decimal digits in this format is always odd. If an even number of significant digits is desired, a leading zero must be inserted on the left.

In the zoned format, each byte consists of a decimal digit on the right and the zone code 1111 (F hex) on the left, except for the rightmost byte where the sign code replaces the zone code. Thus, a decimal integer in the zoned format can have from one to 16 digits. The zoned format may be used directly for input
and output in the extended binary-coded-decimal interchange code (EBCDIC), except that the sign must be separated from the rightmost digit and handled as a separate character. For positive (unsigned) numbers, however, the sign can simply be represented by the zone code of the rightmost digit because the zone code is one of the acceptable alternate codes for plus.

In either format, negative decimal integers are represented in true notation with a separate sign. As for binary integers, the radix point (decimal point) of decimal integers is considered to be fixed at the right, and any scaling is done by the programmer.

The following are some examples of decimal integers shown in hexadecimal notation:

<table>
<thead>
<tr>
<th>Decimal Value</th>
<th>Signed Packed Format</th>
<th>Zoned Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>+123</td>
<td>12 3C or 12 3F</td>
<td>F1 F2 C3</td>
</tr>
<tr>
<td>-4321</td>
<td>04 32 1D</td>
<td>F4 F3 F2 D1</td>
</tr>
<tr>
<td>+000050</td>
<td>00 00 05 0C or 00 00 05 0F</td>
<td>F0 F0 F0 F0 F5 C0 or F0 F0 F0 F0 F5 F0</td>
</tr>
<tr>
<td>-7</td>
<td>00 00 0C or 00 00 0F</td>
<td>D7</td>
</tr>
<tr>
<td>00000</td>
<td>00 00 0C or 00 00 0F</td>
<td>00 00 0C or 00 00 0F</td>
</tr>
</tbody>
</table>

Under some circumstances, a zero with a minus sign (negative zero) is produced. For example, the multiplicand:

00 12 3D (-123)

times the multiplier:

0C (+0)

generates the product:

00 00 0D (-0)

because the product sign follows the algebraic rule of signs even when the value is zero. A negative zero, however, is equivalent to a positive zero in that they compare equal in a decimal comparison.

**Hexadecimal-Floating-Point Numbers**

A hexadecimal-floating-point (HFP) number is expressed as a hexadecimal fraction multiplied by a separate power of 16. The term floating point indicates that the placement, of the radix (hexadecimal) point, or scaling, is automatically maintained by the machine.

The part of an HFP number which represents the significant digits of the number is called the fraction. A second part specifies the power (exponent) to which 16 is raised and indicates the location of the radix point of the number. The fraction and exponent may be represented by 32 bits (short format), 64 bits (long format), or 128 bits (extended format).

**Short HFP Number**

```
S Characteristic | 6-Digit Fraction
0 1 8 31
```

**Long HFP Number**

```
Word
S Characteristic | 14-Digit Fraction
0 1 8 31
1 14-Digit Fraction (continued)
32 63
```

**Extended HFP Number**

```
Word
S Characteristic | Leftmost 14 Digits of 28-Digit Fraction
0 1 8 31
1 Leftmost 14 Digits of 28-Digit Fraction (continued)
32 63
2 Low-Order S Characteristic | Rightmost 14 Digits of 28-Digit Fraction
64 72 95
3 Rightmost 14 Digits of 28-Digit Fraction (continued)
96 127
```
An HFP number has two signs: one for the fraction and one for the exponent. The fraction sign, which is also the sign of the entire number, is the leftmost bit of each format (0 for plus, 1 for minus). The numeric part of the fraction is in true notation regardless of the sign. The numeric part is contained in bits 8-31 for the short format, in bits 8-63 for the long format, and in bits 8-63 followed by bits 72-127 for the extended format.

The exponent sign is obtained by expressing the exponent in excess-64 notation; that is, the exponent is added as a signed number to 64. The resulting number is called the characteristic. It is located in bits 1-7 for all formats. The characteristic can vary from 0 to 127, permitting the exponent to vary from -64 through 0 to +63. This provides a scale multiplier in the range of $16^{-64}$ to $16^{63}$. A nonzero fraction, if normalized, has a value less than one and greater than or equal to 1/16, so that the range covered by the magnitude $M$ of a normalized floating-point number is:

\[
16^{-65} \leq M < 16^{63}
\]

In decimal terms:

- $16^{-65}$ is approximately $5.4 \times 10^{-79}$
- $16^{63}$ is approximately $7.2 \times 10^{75}$

More precisely,

In the short format:

\[
16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63}
\]

In the long format:

\[
16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63}
\]

In the extended format:

\[
16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63}
\]

Within a given fraction length (6, 14, or 28 digits), an HFP operation will provide the greatest precision if the fraction is normalized. A fraction is normalized when the leftmost digit (bit positions 8, 9, 10, and 11) is nonzero. It is unnormalized if the leftmost digit contains all zeros.

If normalization of the operand is desired, the HFP instructions that provide automatic normalization are used. This automatic normalization is accomplished by left-shifting the fraction (four bits per shift) until a nonzero digit occupies the leftmost digit position. The characteristic is reduced by one for each digit shifted.

Figure A-3 illustrates sample normalized short HFP numbers. The last two numbers represent the smallest and the largest positive normalized numbers.

### Conversion Example

Convert the decimal number 59.25 to a short HFP number. (In another appendix are tables for the conversion of hexadecimal and decimal integers and fractions.)

1. The number is separated into a decimal integer and a decimal fraction.

\[
59.25 = 59 + 0.25
\]

2. The decimal integer is converted to its hexadecimal representation.

\[
59_{10} = 3B_{16}
\]

3. The decimal fraction is converted to its hexadecimal representation.

\[
0.25_{10} = 0.4_{16}
\]

4. The integral and fractional parts are combined and expressed as a fraction times a power of 16 (exponent).
3B.4_{16} = 0.3B4_{16} \times 16^2

5. The characteristic is developed from the exponent and converted to binary.

\[
\text{base + exponent} = \text{characteristic} \\
64 + 2 = 66 = 1000010
\]

6. The fraction is converted to binary and grouped hexadecimally.

\[.3B4_{16} = .0011\ 1011\ 0100\]

7. The characteristic and the fraction are stored in the short format. The sign position contains the sign of the fraction.

\[
\begin{array}{cc}
\text{S Char} & \text{Fraction} \\
0 & 1000010 \ 0011\ 1011\ 0100\ 0000\ 0000\ 0000
\end{array}
\]

Examples of instruction sequences that may be used to convert between signed binary integers and HFP numbers are shown in “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

**Instruction-Use Examples**

The following examples illustrate the use of many of the unprivileged instructions. Before studying one of these examples, the reader should consult the instruction description.

The instruction-use examples are written principally for assembler-language programmers, to be used in conjunction with the appropriate assembler-language publications.

Most examples present one particular instruction, both as it is written in an assembler-language statement and as it appears when assembled in storage (machine format).

**Machine Format**

All machine-format values are given in hexadecimal notation unless otherwise specified. Storage addresses are also given in hexadecimal. Hexadecimal operands are shown converted into binary, decimal, or both if such conversion helps to clarify the example for the reader.

**Assembler-Language Format**

In assembler-language statements, registers and lengths are presented in decimal. Displacements, immediate operands, and masks may be shown in decimal, hexadecimal, or binary notation; for example, 12, X'C', and B'1100' represent the same value. Whenever the value in a register or storage location is referred to as “not significant,” this value is replaced during the execution of the instruction.

When SS-format instructions are written in the assembler language, lengths are given as the total number of bytes in the field. This differs from the machine definition, in which the length field specifies the number of bytes to be added to the field address to obtain the address of the last byte of the field. Thus, the machine length is one less than the assembler-language length. The assembler program automatically subtracts one from the length specified when the instruction is assembled.

In some of the examples, symbolic addresses are used in order to simplify the examples. In assembler-language statements, a symbolic address is represented as a mnemonic term written in all capitals, such as FLAGS, which may denote the address of a storage location containing data or program-control information. When symbolic addresses are used, the assembler supplies actual base and displacement values according to the programmer’s specifications. Therefore, the actual values for base and displacement are not shown in the assembler-language format or in the machine-language format. For assembler-language formats, in the labels that designate instruction fields, the letter “S” is used to indicate the combination of base and displacement fields for an operand address. (For example, S2 represents the combination of B2 and D2.) In the machine-language format, the base and displacement address components are shown as asterisks (****).

**Addressing Mode in Examples**

Except where otherwise specified, the examples assume the 24-bit addressing mode.

**General Instructions**

(See Chapter 7, “General Instructions” for a complete description of the general instructions.)
ADD HALFWORD (AH)

The ADD HALFWORD instruction algebraically adds the contents of a two-byte field in storage to the contents of a register. The storage operand is expanded to 32 bits after it is fetched and before it is used in the add operation. The expansion consists in propagating the leftmost (sign) bit 16 positions to the left. For example, assume that the contents of storage locations 2000-2001 are to be added to register 5. Initially:

- Register 5 contains 00 00 00 19 = 2510.
- Storage locations 2000-2001 contain FF FE = \(-2^{10}\).
- Register 12 contains 00 00 18 00.
- Register 13 contains 00 00 01 50.

The format of the required instruction is:

<table>
<thead>
<tr>
<th>Machine Format</th>
<th>Assembler Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code  R1,D2(X2,B2)</td>
<td>AH 5,X'6B0'(13,12)</td>
</tr>
</tbody>
</table>

After the instruction is executed, register 5 contains 00 00 00 17 = 2310. Condition code 2 is set to indicate a result greater than zero.

AND (N, NC, NI, NR)

When the Boolean operator AND is applied to two bits, the result is one when both bits are one; otherwise, the result is zero. When two bytes are ANDed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ANDing two bytes:

- First-operand byte: 0011 01012
- Second-operand byte: 0101 11002
- Result byte: 0001 01002

NI Example

A frequent use of the AND instruction is to set a particular bit to zero. For example, assume that storage location 4891 contains 0100 00112. To set the rightmost bit of this byte to zero without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

<table>
<thead>
<tr>
<th>Machine Format</th>
<th>Assembler Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code  D1(B1),I2</td>
<td>NI 1(8),X'FE'</td>
</tr>
</tbody>
</table>

When this instruction is executed, the byte in storage is ANDed with the immediate byte (the I2 field of the instruction):

- Location 4891: 0100 00112
- Immediate byte: 1111 11102
- Result: 0100 00102

The resulting byte, with bit 7 set to zero, is stored back in location 4891. Condition code 1 is set.

Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)

Four unprivileged instructions (BRANCH AND LINK, BRANCH AND SAVE, BRANCH AND SAVE AND SET MODE, and BRANCH AND SET MODE) are available, together with the unconditional branch (BRANCH ON CONDITION with a mask of 15), to provide linkage between subroutines. BRANCH AND LINK (BAL or BALR) is provided primarily for compatibility with programs written for System/370; BRANCH AND SAVE (BAS or BASR) is recommended instead for programs which are to be executed using ESA/370. The instructions BRANCH AND SAVE AND SET MODE (BASSM) and BRANCH AND SET MODE (BSM) provide subroutine linkage together with switching between the 24-bit and the 31-bit addressing modes. The use of these instructions is discussed in a programming note at the end of “Subroutine Linkage without the Linkage Stack.” (See also the semiprivileged instruction BRANCH AND STACK.)
The following example compares the operation of these instructions and of the unconditional-branch instruction BRANCH ON CONDITION (BC or BCR with a mask of 15). Assume that each instruction in turn is located at the current instruction address, ready to be executed next. For the first set of examples, the addressing-mode bit, PSW bit 32, is initially zero (24-bit addressing in effect). For the second set, PSW bit 32 is initially one (31-bit addressing). Assume also that general register 5 is to receive the linkage information, and that general register 6 contains the branch address.

The format of the BALR instruction is:

<table>
<thead>
<tr>
<th>Machine Format</th>
<th>Assembler Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code R1 R2</td>
<td>Op Code R1 R2</td>
</tr>
<tr>
<td>05 5 6</td>
<td>BALR 5,6</td>
</tr>
</tbody>
</table>

The other linkage instructions in the RR format have the same format but different op codes:

- BASR 0D
- BASSM 0C
- BSM 0B

For comparison with the RR-format instructions, the results of two RX-format instructions are also shown.

The format of the BAL instruction is:

<table>
<thead>
<tr>
<th>Machine Format</th>
<th>Assembler Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code R1 X2 B2 D2</td>
<td>Op Code R1 D2(X2,B2)</td>
</tr>
<tr>
<td>45 5 0 6 000</td>
<td>BAL 5,0(0,6)</td>
</tr>
</tbody>
</table>

The BAS instruction has the same format, but the op code is 4D.

The BCR instruction specifies only one register:

<table>
<thead>
<tr>
<th>Machine Format</th>
<th>Assembler Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code M1 R2</td>
<td>Op Code M1 R2</td>
</tr>
<tr>
<td>07 5 6</td>
<td>BCR 15,6</td>
</tr>
</tbody>
</table>

Assume that:

- Register 5 contains BB BB BB BB.
- Register 6 contains 82 46 8A CE.
- PSW bits 32-63 contain
  - 00 00 10 D6 (for 24-bit addressing).
  - 80 00 10 D6 (for 31-bit addressing).
- Condition code is 012.
- Program mask is 11002.

The effect of executing each instruction in turn is as follows:

**24-Bit Mode Initially**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Register 5</th>
<th>PSW (32-63)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before</td>
<td>BB BB BB BB 00 00 10 D6</td>
<td></td>
</tr>
<tr>
<td>BCR 15,6</td>
<td>BB BB BB BB 00 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BAL 5,0(0,6)</td>
<td>9C 00 10 DA 00 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BAS 5,0(0,6)</td>
<td>00 00 10 DA 00 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BALR 5,6</td>
<td>9C 00 10 DA 00 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BASR 5,6</td>
<td>00 00 10 DB 00 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BASSM 5,6</td>
<td>00 00 10 DB 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BSM 5,6</td>
<td>3B BB BB BB 82 46 8A CE</td>
<td></td>
</tr>
</tbody>
</table>

**31-Bit Mode Initially**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Register 5</th>
<th>PSW (32-63)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before</td>
<td>BB BB BB BB 80 00 10 D6</td>
<td></td>
</tr>
<tr>
<td>BCR 15,6</td>
<td>BB BB BB BB 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BAL 5,0(0,6)</td>
<td>80 00 10 DA 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BAS 5,0(0,6)</td>
<td>80 00 10 DA 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BALR 5,6</td>
<td>80 00 10 DA 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BASR 5,6</td>
<td>80 00 10 DB 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BASSM 5,6</td>
<td>80 00 10 DB 82 46 8A CE</td>
<td></td>
</tr>
<tr>
<td>BSM 5,6</td>
<td>82 BB BB BB 82 46 8A CE</td>
<td></td>
</tr>
</tbody>
</table>

Note that a value of zero in the R2 field of any of the RR-format instructions indicates that the branching function is not to be performed; it does not refer to register 0. Likewise, a value of zero in the R1 field of the BSM instruction indicates that the old value of
PSW bit 32 is not to be saved and that register 0 is to be left unchanged. Register 0 can be designated by the R1 field of instructions BAL, BALR, BAS, BASR, and BASSM, however. In the RX-format branch instructions, branching occurs independent of whether there is a value of zero in the B2 field or X2 field of the instruction. However, when the field is zero, instead of using the contents of general register 0, a value of zero is used for that component of address generation.

**Programming Note:** It should be noted that execution of BAL in the 24-bit addressing mode results in bit 0 of register 5 being set to one. This is because the ILC for an RX-format instruction is 10. This is the only case in which bit zero of the return register does not correctly reflect the addressing mode of the caller. Thus, BSM may be used to return for BALR, BAS, BASR, and BASSM in both the 24-bit and the 31-bit addressing modes, but it cannot be used to return if the program was called by using BAL in the 24-bit addressing mode.

**Other BALR and BASR Examples**
The BALR or BASR instruction with the R2 field set to zero may be used to load a register for use as a base register. For example, in the assembler language, the two statements:

```
BALR    15,0
USING   *,15
```

or

```
BASR    15,0
USING   *,15
```

indicate that the address of the next sequential instruction following the BALR or BASR instruction will be placed in register 15, and that the assembler may use register 15 as a base register until otherwise instructed. (The USING statement is an "assembler instruction" and is thus not a part of the object program.)

**BRANCH AND STACK (BAKR)**
The semiprivileged BRANCH AND STACK instruction facilitates linkage between subroutines by saving status in a linkage-stack state entry (sometimes called a branch state entry to distinguish it from a program-call state entry). When BRANCH AND STACK has been used, the return from the called program is made by means of the PROGRAM RETURN instruction. PROGRAM RETURN restores access registers 2-14, general registers 2-14, and the PSW with values saved in the state entry, except that it leaves the PER mask unchanged and sets the condition code to an unpredictable value. The use of BRANCH AND STACK is discussed in “Branching Using the Linkage Stack” on page 5-74.

**BRANCH AND STACK**

BRANCH AND STACK can be used to perform a calling linkage, or it can be used at or near the entry point of the called program, depending on whether the R1 field of the instruction is zero or nonzero, respectively. If the R1 field is zero, bits 32-63 of the PSW saved in the state entry indicate the current addressing mode (24-bit or 31-bit) and the address of the next sequential instruction after the BRANCH AND STACK instruction or an EXECUTE instruction. If the R1 field is nonzero, bits 32-63 of the PSW saved in the state entry are set with a value generated from the contents of general register R1; bit 32 of the PSW is set equal to bit 0 of the register, and bits 1-31 of the PSW are set with an address generated from bits 1-31 of the register under the control of bit 0 of the register. Bits 32-63 of the PSW saved in the state entry are referred to in the following examples as the return value.

The branch address for the instruction is generated from the contents of general register R2 under the control of the current addressing mode. Bit 0 of general register R2 does not affect the operation. If the R2 field of the instruction is zero, the operation is performed without branching.

In addition to saving a complete PSW (except with an unpredictable PER mask) in the state entry, BRANCH AND STACK saves the new value of bits 32-63 of the current PSW in the state entry. Bits 32-63 are referred to in the following examples as the branch value.

The following examples contain cases in which bit 32 of the current PSW is either zero or one (24-bit or 31-bit addressing) before BRANCH AND STACK is executed and in which bit 0 of the general register designated by a nonzero R1 or R2 field is either zero or one.

**BAKR Example 1**
This example shows BAKR used in a calling program. BAKR performs a branch, and the return is to be the next sequential instruction.
The format of the BAKR instruction is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁</th>
<th>R₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>B240</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

**Assembler Format**

Op Code R₁,R₂

BAKR 0,6

Assume four cases of initial values, as follows:

<table>
<thead>
<tr>
<th>PSW (32-63)</th>
<th>Register 6</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. 00 00 10 D6</td>
<td>02 46 8A CE</td>
</tr>
<tr>
<td>2. 00 00 10 D6</td>
<td>82 46 8A CE</td>
</tr>
<tr>
<td>3. 80 00 10 D6</td>
<td>02 46 8A CE</td>
</tr>
<tr>
<td>4. 80 00 10 D6</td>
<td>82 46 8A CE</td>
</tr>
</tbody>
</table>

The results in the four cases are as follows:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Branch Value and PSW (32-63)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. 00 00 10 DA</td>
<td>00 46 8A CE</td>
</tr>
<tr>
<td>2. 00 00 10 DA</td>
<td>82 46 8A CE</td>
</tr>
<tr>
<td>3. 80 00 10 DA</td>
<td>02 46 8A CE</td>
</tr>
<tr>
<td>4. 80 00 10 DA</td>
<td>82 46 8A CE</td>
</tr>
</tbody>
</table>

**BAKR Example 2**

This example shows BAKR used in a called program. BAKR does not perform a branch, and the return is to be as specified in general register R₁.

The format of the BAKR instruction is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁</th>
<th>R₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>B240</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

**Assembler Format**

Op Code R₁,R₂

BAKR 5,6

Assume eight cases of initial values, as follows:

<table>
<thead>
<tr>
<th>Register 5</th>
<th>Register 6</th>
<th>PSW (32-63)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. 04 00 10 D6</td>
<td>06 99 99 00</td>
<td>00 46 8A CE</td>
</tr>
<tr>
<td>2. 04 00 10 D6</td>
<td>86 99 99 00</td>
<td>82 46 8A CE</td>
</tr>
<tr>
<td>3. 04 00 10 D6</td>
<td>06 99 99 00</td>
<td>00 46 8A CE</td>
</tr>
<tr>
<td>4. 04 00 10 D6</td>
<td>86 99 99 00</td>
<td>82 46 8A CE</td>
</tr>
<tr>
<td>5. 84 00 10 D6</td>
<td>06 99 99 00</td>
<td>00 46 8A CE</td>
</tr>
<tr>
<td>6. 84 00 10 D6</td>
<td>86 99 99 00</td>
<td>82 46 8A CE</td>
</tr>
<tr>
<td>7. 84 00 10 D6</td>
<td>06 99 99 00</td>
<td>00 46 8A CE</td>
</tr>
<tr>
<td>8. 84 00 10 D6</td>
<td>86 99 99 00</td>
<td>82 46 8A CE</td>
</tr>
</tbody>
</table>

The results in the eight cases are as follows:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Branch Value and PSW (32-63)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. 00 00 10 D6</td>
<td>00 99 99 00</td>
</tr>
<tr>
<td>2. 00 00 10 D6</td>
<td>86 99 99 00</td>
</tr>
<tr>
<td>3. 00 00 10 D6</td>
<td>00 99 99 00</td>
</tr>
<tr>
<td>4. 00 00 10 D6</td>
<td>86 99 99 00</td>
</tr>
<tr>
<td>5. 84 00 10 D6</td>
<td>00 99 99 00</td>
</tr>
<tr>
<td>6. 84 00 10 D6</td>
<td>86 99 99 00</td>
</tr>
<tr>
<td>7. 84 00 10 D6</td>
<td>00 99 99 00</td>
</tr>
<tr>
<td>8. 84 00 10 D6</td>
<td>86 99 99 00</td>
</tr>
</tbody>
</table>
BRANCH ON CONDITION (BC, BCR)

The BRANCH ON CONDITION instruction tests the condition code to see whether a branch should or should not occur. The branch occurs only if the current condition code corresponds to a one bit in a mask specified by the instruction.

For example, assume that an ADD (A or AR) operation has been performed and that a branch to address 6050 is desired if the sum is zero or less (condition code is 0 or 1). Also assume:

Register 10 contains 00 00 50 00.
Register 11 contains 00 00 10 00.

The RX form of the instruction performs the required test (and branch if necessary) when written as:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>M1</th>
<th>X2</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 7 CBA 0 5 0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Assembler Format

Op Code M1, D2(X2, B2)

BRANCH ON INDEX HIGH (BXH)

BXH Example 1

The BRANCH ON INDEX HIGH instruction is an index-incrementing and loop-controlling instruction that causes a branch whenever the sum of an index value and an increment value is greater than some compare value. For example, assume that:

Register 4 contains 00 00 00 8A = 13810 = the index.
Register 6 contains 00 00 00 02 = 210 = the increment.
Register 7 contains 00 00 00 AA = 17010 = the compare value.

<table>
<thead>
<tr>
<th>Condition Code</th>
<th>Instruction (Mask) Bit</th>
<th>Mask Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>10</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>11</td>
<td>1</td>
</tr>
</tbody>
</table>

(See also “Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)” on page A-8 for an example of the BCR instruction.)

BRANCH ON COUNT (BCT, BCTR)

The BRANCH ON COUNT instruction is often used to execute a program loop for a specified number of times. For example, assume that the following represents some lines of coding in an assembler-language program:

```
LUPE AR 8,1
BACK BCT 6,LUPE
```

where register 6 contains 00 00 00 03 and the address of LUPE is 6826. Assume that, in order to address this location, register 10 is used as a base register and contains 00 00 68 00.

The format of the BCT instruction is:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>X2</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>46 6 0 A 026</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

</tbody>
</table>

When the instruction is executed, first the contents of register 6 are added to register 4, second the sum is compared with the contents of register 7, and third the decision whether to branch is made. After execution:

Register 4 contains 00 00 00 8C = 14010.

Registers 6 and 7 are unchanged.

Since the new value in register 4 is not yet greater than the value in register 7, the branch to address 7130 is not taken. Repeated use of the instruction will eventually cause the branch to be taken when the value in register 4 reaches 17210.

**BXH Example 2**

When the register used to contain the increment is odd, that register also becomes the compare-value register. The following assembler-language subroutine illustrates how this may be used to search a table.

<table>
<thead>
<tr>
<th>Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 Bytes</td>
</tr>
<tr>
<td>ARG1</td>
</tr>
<tr>
<td>ARG2</td>
</tr>
<tr>
<td>ARG3</td>
</tr>
<tr>
<td>ARG4</td>
</tr>
<tr>
<td>ARG5</td>
</tr>
<tr>
<td>ARG6</td>
</tr>
</tbody>
</table>

Assume that:

Register 8 contains the search argument.

Register 9 contains the width of the table in bytes (00 00 00 04).

Register 10 contains the length of the table in bytes (00 00 00 18).

Register 11 contains the starting address of the table.

Register 14 contains the return address to the main program.

As the following subroutine is executed, the argument in register 8 is successively compared with the arguments in the table, starting with argument 6 and working backward to argument 1. If an equality is found, the corresponding function replaces the argument in register 8. If an equality is not found, zero replaces the argument in register 8.

```
SEARCH LNR 9,9
NOTEQUAL BXH 10, 9, LOOP
NOTFOUND SR 8, 8
BCR 15, 14
LOOP CH 8, 0(10, 11)
BC 7, NOTEQUAL
LH 8, 8(10, 11)
BCR 15, 14
```

The first instruction (LNR) causes the value in register 9 to be made negative. After execution of this instruction, register 9 contains FF FF FF FC = -410. Considering the case when no equality is found, the BXH instruction will be executed seven times. Each time BXH is executed, a value of -4 is added to register 10, thus reducing the value in register 10 by 4. The new value in register 10 is compared with the -4 value in register 9. The branch is taken each time until the value in register 10 is -4. Then the branch is not taken, and the SR instruction sets register 8 to zero.

**BRANCH ON INDEX LOW OR EQUAL (BXLE)**

The BRANCH ON INDEX LOW OR EQUAL instruction performs the same operation as BRANCH ON INDEX HIGH, except that branching occurs when the sum is lower than or equal to (instead of higher than) the compare value. As the instruction which increments and tests an index value in a program loop, BXLE is useful at the end of the loop and BXH at the beginning. The following assembler-language routines illustrate loops with BXLE.
BXLE Example 1
Assume that a group of ten 32-bit signed binary integers are stored at consecutive locations, starting at location GROUP. The integers are to be added together, and the sum is to be stored at location SUM.

```
SR  5,5   Set sum to zero
LA  6,GROUP Load first address
SR  7,7   Set index to zero
LA  8,4   Load increment 4
LA  9,39  Load compare value
LOOP A  5,0(7,6) Add integer to sum
BXLE 7,8,LOOP Test end of loop
ST 5,SUM Store sum
```

The two-instruction loop contains an ADD (A) instruction which adds each integer to the contents of general register 5. The ADD instruction uses the contents of general register 7 as an index value to modify the starting address obtained from register 6. Next, BXLE increments the index value by 4, the increment previously loaded into register 8, and compares it with the compare value in register 9, the odd register of this even-odd pair. The compare value was previously set to 39, which is one less than the number of bytes in the data area; this is also the address, relative to the starting address, of the rightmost byte of the last integer to be added. When the last integer has been added, BXLE increments the index value to the next relative address (40), which is found to be greater than the compare value (39) so that no branching takes place.

BXLE Example 2
The technique illustrated in Example 1 is restricted to loops containing instructions in the RX instruction format. That format allows both a base register and an index register to be specified (double indexing).

For instructions in other formats, where an index register cannot be specified, the previous technique may be modified by having the address itself serve as the index value in a BXLE instruction and by using as the compare value the address of the last byte to be added. When the last integer has been added, BXLE increments the index value to the next relative address (40), which is found to be greater than the compare value (39) so that no branching takes place.

The technique shown in Example 2 does not work, however, on an ESA/370 system when it is in the 31-bit addressing mode and the data is located at the rightmost end of a 31-bit address space. In this case, the compare value would be set to $2^{31}-1$, which is the largest possible 32-bit signed binary value. The reason the technique does not work is that the BXLE and BXH instructions treat their operands as 32-bit signed binary integers. When the address in general register 6 reaches the value $2^{31}-4$, BXLE increments it to a value that is interpreted as $-2^{31}$, rather than $2^{31}$, and the comparison remains low, which causes looping to continue indefinitely.

This situation can be avoided by not allowing data areas to extend to the rightmost location in a 31-bit address space or by using other techniques; these may include double indexing when possible, as in Example 1, or starting at the end and stepping downward through the data area with a negative increment.

COMPARE AND FORM CODEWORD (CFC)
See “Sorting Instructions” on page A-53.

COMPARE HALFWORD (CH)
The COMPARE HALFWORD instruction compares a 16-bit signed binary integer in storage with the contents of a register. For example, assume that:

- Register 4 contains FF FF 00 00 = -32,768_{10}.
- Register 13 contains 00 01 60 50.
- Storage locations 16080-16081 contain 8000 = -32,768_{10}.

When the instruction:
is executed, the contents of locations 16080-16081 are fetched, expanded to 32 bits (the sign bit is propagated to the left), and compared with the contents of register 4. Because the two numbers are equal, condition code 0 is set.

**COMPARE LOGICAL (CL, CLC, CLI, CLR)**

The COMPARE LOGICAL instruction differs from the signed-binary comparison instructions (C, CH, CR) in that all quantities are handled as unsigned binary integers or as unstructured data.

**CLC Example**
The COMPARE LOGICAL (CLC) instruction can be used to perform the byte-by-byte comparison of storage fields up to 256 bytes in length. For example, assume that the following two fields of data are in storage:

Field 1

1886 1891
D1 D6 C8 D5 E2 D6 D5 6B C1 4B C2 4B

Field 2

1900 1908
D1 D6 C8 D5 E2 D6 D5 6B C1 4B C3 4B

Also assume:

Register 9 contains 00 00 18 80.

Register 7 contains 00 00 19 00.

Execution of the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>I2</th>
<th>B1</th>
<th>D1</th>
</tr>
</thead>
<tbody>
<tr>
<td>95</td>
<td>AF</td>
<td>A</td>
<td>003</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code  D1(B1), I2

| CLI     | 3(10), X'AF' |

sets condition code 1, indicating that the contents of field 1 are lower in value than the contents of field 2.

Because the collating sequence of the EBCDIC code is determined simply by a logical comparison of the bits in the code, the CLC instruction can be used to collate EBCDIC-coded fields. For example, in EBCDIC, the above two data fields are:

Field 1: JOHNSON,A.B.
Field 2: JOHNSON,A.C.

Condition code 1 indicates that JOHNSON,A.B. should precede JOHNSON,A.C. for the fields to be in alphabetic sequence.

**CLI Example**
The COMPARE LOGICAL (CLI) instruction compares a byte from the instruction stream with a byte from storage. For example, assume that:

Register 10 contains 00 00 17 00.

Storage location 1703 contains 7E.

Execution of the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>I2</th>
<th>B1</th>
<th>D1</th>
</tr>
</thead>
<tbody>
<tr>
<td>95</td>
<td>AF</td>
<td>A</td>
<td>003</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code  D1(B1),I2

| CLI     | 3(10), X'AF' |

sets condition code 1, indicating that the first operand (the quantity in main storage) is lower than the second (immediate) operand.

**CLR Example**
Assume that:
Register 4 contains 00 00 00 01 = 1.

Register 7 contains FF FF FF FF = 2^32 - 1.

Execution of the instruction:

Machine Format
Op Code  R1, R2
15 4 7

Assembler Format
Op Code  R1, R2
CLR 4, 7

sets condition code 1. Condition code 1 indicates that the first operand is lower than the second.

If, instead, the signed-binary comparison instruction COMPARE (CR) had been executed, the contents of register 4 would have been interpreted as +1 and the contents of register 7 as -1. Thus, the first operand would have been higher, so that condition code 2 would have been set.

**COMPARE LOGICAL CHARACTERS UNDER MASK (CLM)**

The COMPARE LOGICAL CHARACTERS UNDER MASK (CLM) instruction provides a means of comparing bytes selected from a general register to a contiguous field of bytes in storage. The M3 field of the CLM instruction is a four-bit mask that selects zero to four bytes from a general register, each mask bit corresponding, left to right, to a register byte. In the comparison, the register bytes corresponding to ones in the mask are treated as a contiguous field. The operation proceeds left to right. For example, assume that:

Storage locations 10200-10202 contain F0 BC 7B.

Register 12 contains 00 01 00 00.

Register 6 contains F0 BC 5C 7B.

Execution of the instruction:

Machine Format
Op Code  R1, M3, B2, D2

Assembler Format
Op Code  R1, M3, D2(B2)

causes the following comparison:

Register 6:  F0 BC 5C 7B
Mask M3:   1 1 0 1
-- --        --

Because the selected bytes are equal, condition code 0 is set.

**COMPARE LOGICAL LONG (CLCL)**

The COMPARE LOGICAL LONG instruction is used to compare two operands in storage, byte by byte. Each operand can be of any length. Two even-odd pairs of general registers (four registers in all) are used to locate the operands and to control the execution of the CLCL instruction, as illustrated in the following diagram. The first register of each pair must be an even register, and it contains the storage address of an operand. The odd register of each pair contains the length of the operand it covers, and the leftmost byte of the second-operand odd register contains a padding byte which is used to extend the shorter operand, if any, to the same length as the longer operand.

The following illustrates the assignment of registers in the 24-bit addressing mode:

R1 (even) // First-Operand Address

R1+1 (odd) // First-Operand Length
In the 31-bit addressing mode, the operand addresses would be in bit positions 1-31 of the even registers shown above.

Since the CLCL instruction may be interrupted during execution, the interrupting program must preserve the contents of the four registers for use when the instruction is resumed.

The following instructions set up two register pairs to control a text-string comparison. For example, assume:

<table>
<thead>
<tr>
<th>Operand 1</th>
<th>Address: 20800_{16}</th>
<th>Length: 100_{10}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand 2</td>
<td>Address: 20A00_{16}</td>
<td>Length: 132_{10}</td>
</tr>
</tbody>
</table>

Padding Byte
| Address: 20003_{16} | Length: 1 | Value: 40_{16} |

Register 12 contains 00 02 00 00.

The setup instructions are:

<table>
<thead>
<tr>
<th>OP</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>LA</td>
<td>4, X’800’(12)</td>
<td>Set register 4 to start of first operand</td>
</tr>
<tr>
<td>LA</td>
<td>5, 100</td>
<td>Set register 5 to length of first operand</td>
</tr>
<tr>
<td>LA</td>
<td>8, X’A00’(12)</td>
<td>Set register 8 to start of second operand</td>
</tr>
<tr>
<td>LA</td>
<td>9, 132</td>
<td>Set register 9 to length of second operand</td>
</tr>
<tr>
<td>ICM</td>
<td>9, B’1000’(3)</td>
<td>Insert padding byte in leftmost byte position of register 9</td>
</tr>
</tbody>
</table>

Register pair 4,5 defines the first operand. Bits 8-31 of register 4 contain the storage address of the start of an EBCDIC text string, and bits 8-31 of register 5 contain the length of the string, in this case 100 bytes.

Register pair 8,9 defines the second operand, with bits 8-31 of register 8 containing the starting location of the second operand and bits 8-31 of register 9 containing the length of the second operand, in this case 132 bytes. Bits 0-7 of register 9 contain an EBCDIC blank character (X’40’) to pad the shorter operand. In this example, the padding byte is used in the first operand, after the 100th byte, to compare with the remaining bytes in the second operand.

With the register pairs thus set up, the format of the CLCL instruction is:

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLCL</td>
<td>4, 8</td>
<td></td>
</tr>
</tbody>
</table>

When this instruction is executed, the comparison starts at the left end of each operand and proceeds to the right. The operation ends as soon as an inequality is detected or the end of the longer operand is reached.

If this CLCL instruction is interrupted after 60 bytes have compared equal, the operand lengths in registers 5 and 9 will have been decremented to 40 and 72, respectively. The operand addresses in registers 4 and 8 will have been incremented to X’2083C’ and X’20A3C’; the leftmost byte of registers 4 and 8 will have been set to zero. The padding byte X’40’ remains in register 9. When the CLCL instruction is reexecuted with these register contents, the comparison resumes at the point of interruption.

Now, assume that the instruction is interrupted after 110 bytes. That is, the first 100 bytes of the second operand have compared equal to the first operand, and the next 10 bytes of the second operand have compared equal to the padding byte (blank). The residual operand lengths in registers 5 and 9 are 0 and 22, respectively, and the operand addresses in registers 4 and 8 are X’20864’ (the value when the first operand was exhausted) and X’20A6E’ (the current value for the second operand).

When the comparison ends, the condition code is set to 0, 1, or 2, depending on whether the first operand...
is equal to, less than, or greater than the second operand, respectively.

When the operands are unequal, the addresses in registers 4 and 8 indicate the bytes that caused the mismatch.

**COMPARE LOGICAL STRING (CLST)**

The COMPARE LOGICAL STRING instruction is used to compare a first operand designated by general register $R_1$ and a second operand designated by general register $R_2$. The comparison is made left to right, byte by byte, until unequal bytes are compared, an ending character specified in general register 0 is encountered in either operand, or a CPU-determined number of bytes have been compared. The condition code is set to 0 if the two operands are equal, to 1 if the first operand is low, to 2 if the second operand is low, or to 3 if a CPU-determined number of bytes have been compared. If the ending character is found in both operands simultaneously, the operands are equal. If it is found in only one operand, that operand is low.

When condition code 1 or 2 is set, the addresses of the last bytes processed in the first and second operands are placed in general registers $R_1$ and $R_2$, respectively. These are the addresses of unequal bytes in the two operands, or they are the address of an ending character in one operand and of the byte in the corresponding byte position in the other operand. When condition code 3 is set, the addresses of the next bytes to be processed are placed in the registers. When condition code 0 is set, the contents of the registers remain unchanged.

Following are examples of first and second operands beginning at decimal locations 1000 and 2000, respectively. The addresses in general registers $R_1$ and $R_2$ are 1000 and 2000, respectively. The ending character in general register 0 is 00 hex (as in the C programming language). The values of the operand bytes are shown in hex, and the resulting condition code and final contents of general registers $R_1$ and $R_2$ are shown.

**Example 1**

1000 2000
C1 C2 C3 00  C1 C2 C3 00
CC: 0; (R1): 1000; (R2): 2000

**Example 2**

1000 2000
40 40 40 C1  40 40 40 C2
CC: 1; (R1): 1003; (R2): 2003

**Example 3**

1000 2000
40 40 40 C2  40 40 40 C1
CC: 2; (R1): 1003; (R2): 2003

**Example 4**

1000 2000
C1 C2 C3 00  C1 C2 C3 C4
CC: 1; (R1): 1003; (R2): 2003

**Example 5**

1000 2000
C1 C2 C3 C4  C1 C2 C3 00
CC: 2; (R1): 1003; (R2): 2003

**Example 6**

Assuming that the CPU-determined number of bytes compared is 256:

1000 1256 2000 2256
40 .. 40 00  40 .. 40 00
CC: 3; (R1): 1256; (R2): 2256

**Example 7**

1000 2000
00 40 40 40  40 40 40 40
CC: 1; (R1): 1000; (R2): 2000

**Example 8**

1000 2000
40 40 40 40  00 40 40 40
CC: 2; (R1): 1000; (R2): 2000

**Example 9**

1000 2000
00 40 40 40  00 40 40 40
CC: 0; (R1): 1000; (R2): 2000

**CONVERT TO BINARY (CVB)**

The CONVERT TO BINARY instruction converts an eight-byte, signed-packed-decimal number into a signed binary integer and loads the result into a gen-
eral register. After the conversion operation is completed, the number is in the proper form for use as an operand in signed binary arithmetic. For example, assume:

Storage locations 7608-760F contain a decimal number in the signed-packed-decimal format: 00 00 00 00 25 59 4C (+25,594).

The contents of register 7 are not significant.

Register 13 contains 00 00 76 00.

The format of the conversion instruction is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁</th>
<th>X₂</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>4F</td>
<td>7</td>
<td>0</td>
<td>0</td>
<td>008</td>
</tr>
</tbody>
</table>

**Assembler Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁, D₂(X₂, B₂)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVB</td>
<td>7,8(0,13)</td>
</tr>
</tbody>
</table>

After the instruction is executed, register 7 contains 00 00 63 FA.

**CONVERT TO DECIMAL (CVD)**

The CONVERT TO DECIMAL instruction is the opposite of the CONVERT TO BINARY instruction. CVD converts a signed binary integer in a register to signed-packed-decimal number and stores the eight-byte result. For example, assume:

Register 1 contains the signed binary integer: 00 00 0F 0F.

Register 13 contains 00 00 76 00.

The format of the instruction is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁</th>
<th>X₂</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>4E</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>008</td>
</tr>
</tbody>
</table>

**Assembler Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁, D₂(X₂, B₂)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVD</td>
<td>1,8(0,13)</td>
</tr>
</tbody>
</table>

After the instruction is executed, storage locations 7608-760F contain 00 00 00 00 03 85 5C (+3855).

The plus sign generated is the preferred plus sign, 1100₂.

**DIVIDE (D, DR)**

The DIVIDE instruction divides the dividend in an even-odd register pair by the divisor in a register or in storage. Since the instruction assumes the dividend to be 64 bits long, it is important first to extend a 32-bit dividend on the left with bits equal to the sign bit. For example, assume that:

Storage locations 3550-3553 contain 00 00 08 DE = 2270₁₀ (the dividend).

Storage locations 3554-3557 contain 00 00 00 32 = 50₁₀ (the divisor).

The initial contents of registers 6 and 7 are not significant.

Register 8 contains 00 00 35 50.

The following assembler-language statements load the registers properly and perform the divide operation:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>L 6,0(0,8)</td>
<td>Places 00 00 08 DE into register 6.</td>
</tr>
<tr>
<td>SRDA 6,32(0)</td>
<td>Shifts 00 00 08 DE into register 7.</td>
</tr>
<tr>
<td>D 6,4(0,8)</td>
<td>Register 6 is filled with zeros (sign bits).</td>
</tr>
</tbody>
</table>

The plus sign generated is the preferred plus sign, 1100₂.

The machine format of the above DIVIDE instruction is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁</th>
<th>X₂</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>5D</td>
<td>6</td>
<td>0</td>
<td>8</td>
<td>004</td>
</tr>
</tbody>
</table>

After the instructions listed above are executed:

Register 6 contains 00 00 00 14 = 20₁₀ = the remainder.

Register 7 contains 00 00 00 2D = 45₁₀ = the quotient.
Note that if the dividend had not been first placed in register 6 and shifted into register 7, register 6 might not have been filled with the proper dividend-sign bits (zeros in this example), and the DIVIDE instruction might not have given the expected results.

**EXCLUSIVE OR (X, XC, XI, XR)**

When the Boolean operator EXCLUSIVE OR is applied to two bits, the result is one when either, but not both, of the two bits is one; otherwise, the result is zero. When two bytes are EXCLUSIVE ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of the EXCLUSIVE OR of two bytes:

First-operand byte: 0011 0101
Second-operand byte: 0101 1100
Result byte: 0110 1001

**XC Example**

The EXCLUSIVE OR (XC) instruction can be used to exchange the contents of two areas in storage without the use of an intermediate storage area. For example, assume two three-byte fields in storage:

Field 1: 00000000 00010111 10010000
Field 2: 00000000 00010100 00000001

Execution of the instruction (assume that register 7 contains 00 00 03 58):

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L</th>
<th>B₁</th>
<th>D₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>D7 02</td>
<td>7</td>
<td>008</td>
<td>7</td>
<td>001</td>
<td></td>
</tr>
</tbody>
</table>

Assembler Format

Op Code D₁(L, B₁), D₂(B₂)

| XC 1(3,7), 8(7) |

produces the following result:

Field 1: 00000000 00000001 10010001 = 00 03 91₁₆
Field 2: 00000000 00010100 00000001 = 00 14 0₁₆
Result: 00000000 00010111 10010000 = 00 17 90₁₆

The result of this operation replaces the former contents of field 2. Field 2 now contains the original value of field 1. Condition code 1 is set to indicate a nonzero result.

Lastly, execution of the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L</th>
<th>B₁</th>
<th>D₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>D7 02</td>
<td>7</td>
<td>001</td>
<td>7</td>
<td>008</td>
<td></td>
</tr>
</tbody>
</table>

Assembler Format

Op Code D₁(L, B₁), D₂(B₂)

| XC 1(3,7), 8(7) |

produces the following result:

Field 1: 00000000 00000001 10010001 = 00 03 91₁₆
Field 2: 00000000 00010100 00000001 = 00 14 0₁₆
Result: 00000000 00010111 10010000 = 00 17 90₁₆

The result of this operation replaces the former contents of field 1. Field 1 now contains the original value of field 2. Condition code 1 is set to indicate a nonzero result.
XI Example
A frequent use of the EXCLUSIVE OR (XI) instruction is to invert a bit (change a zero bit to a one or a one bit to a zero). For example, assume that storage location 8082 contains 0110 1001₂. To invert the leftmost and rightmost bits without affecting any of the other bits, the following instruction can be used (assume that register 9 contains 00 00 80 80):

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>I₂</th>
<th>B₁</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>97</td>
<td>81</td>
<td>9</td>
<td>002</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code D₁(B₁),I₂

XI 2(9),X'81'

When the instruction is executed, the byte in storage is EXCLUSIVE ORed with the immediate byte (the I₂ field of the instruction):

Location 8082: 0110 1001₂
Immediate byte: 1000 0001₂

Result: 1110 1000₂

The resulting byte is stored back in location 8082. Condition code 1 is set to indicate a nonzero result.

Notes:

1. With the XC instruction, fields up to 256 bytes in length can be exchanged.
2. With the XR instruction, the contents of two registers can be exchanged.
3. Because the X instruction operates storage to register only, an exchange cannot be made solely by the use of X.
4. A field EXCLUSIVE ORed with itself is cleared to zeros.
5. For additional examples of the use of EXCLUSIVE OR, see “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

EXECUTE (EX)

The EXECUTE instruction causes one target instruction in main storage to be executed out of sequence without actually branching to the target instruction. Unless the R₁ field of the EXECUTE instruction is zero, bits 8-15 of the target instruction are ORed with bits 56-63 of the R₁ register before the target instruction is executed. Thus, EXECUTE may be used to supply the length field for an SS instruction without modifying the SS instruction in storage. For example, assume that a MOVE (MVC) instruction is the target that is located at address 3820, with a format as follows:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L</th>
<th>B₁</th>
<th>D₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Assembler Format

Op Code D₁(L,B₁),D₂(B₂)

MVC 3(1,12),0(13)

where register 12 contains 00 00 89 13 and register 13 contains 00 00 90 A0.

Further assume that at storage address 5000, the following EXECUTE instruction is located:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R₁</th>
<th>X₂</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
<td>1</td>
<td>0</td>
<td>A</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code R₁,X₂(B₂,B₂)

EX 1,0(0,10)

where register 10 contains 00 00 38 20 and register 1 contains 00 0F F0 03.

When the instruction at 5000 is executed, the rightmost byte of register 1 is ORed with the second byte of the target instruction:

Instruction byte: 0000 0000₂ = 00
Register byte: 0000 0011₂ = 03

Result: 0000 0011₂ = 03

causing the instruction at 3820 to be executed as if it originally were:
Machine Format

Op Code  L   B₁   D₁   B₂   D₂
        02   03   C    003  D    000

Assembler Format

Op Code  D₁(L₁,B₁),D₂(B₂)
        MVC  3(4,12),0(13)

However, after execution:

Register 1 is unchanged.
The instruction at 3820 is unchanged.
The contents of the four bytes starting at location 90A0 have been moved to the four bytes starting at location 8916.
The CPU next executes the instruction at address 5004 (PSW bits 104-127 contain 00 50 04).

FIND LEFTMOST ONE (FLOGR)

FIND LEFTMOST ONE may be used to locate free objects, the availability of which is tracked in a hierarchical bit map.

In the following example, the hierarchical bit map consists of multiple levels of bits, each level having 64 times the number of bits as the next lower-numbered level. This example shows four levels, mapping a total of 16M objects, however additional levels may be added to manage larger numbers of objects.

The highest-numbered bit map level (L3 in this illustration) represents the availability of individual objects, for example, records or pages. A one bit indicates that the object is available, and a zero bit means that the object is not available.

In lower-numbered bit map levels (L0, L1, and L2 in this illustration), a bit position corresponds to a doubleword in the next higher-numbered level. When a bit in a lower-numbered bit map level is one, at least one bit of the corresponding doubleword in the higher-level is one. When a bit in a lower-numbered bit map level is zero, no bits in the corresponding higher-level doubleword are one.

An example of using FIND LEFTMOST ONES to quickly locate the next available lowest-numbered object, as mapped by such a hierarchical bit map, is shown below. Upon completion, at the label "FOUND", general register 15 contains the number of the located object. If no objects are available, the code branches to the label "NOTFND".

```
LA 15,0 Zero accumulator
LA 9,OFFSET Point to table
LA 10,4 Load increment
LA 11,ENOFF-1 Load compare value
FIND LGR 7,15 Copy accum. to R7
ALGF 7,0(,9) Add # DWs to bits
SLLG 7,7,3 Get byte offset
LG 1,BITS(7) Get DW to test
FLOGR 0,1 Find leftmost one
BZ NOTFND No one bits found
SLLG 15,15,6 Times # bits in DW
AGR 15,0 Add bit just found
BXLEG 9,10,FIND Do for each level
FOUND STG 1,BITS(7) Update changed bit
...
NOTFND [Any instruction]
```

OFFSET DC A((L0-BITS)/8) Offset to level 0
DC A((L1-BITS)/8) Offset to level 1
DC A((L2-BITS)/8) Offset to level 2
DC A((L3-BITS)/8) Offset to level 3
ENDOFF EQU * End of table

BITS DS 0D Start of bit map
L0 DS FD -L0 (64 objects)
L1 DS 64FD -L1 (4K objects)
L2 DS (64+64)FD -L2 (256K objects)
L3 DS (64+64+64)FD -L3 (16M objects)

This code sequence shows the zeroing of the found bit with the STORE (STG) instruction at the label "FOUND". Proper maintenance of such a hierarchical bit map requires that when all bits of a doubleword become zeros, the corresponding bit in the next lower-numbered level is set to zeros. Similarly, when adding a free object to the highest level, the corresponding bits in lower-numbered levels must be set to one. These maintenance functions are not shown.

Note, in a multiprocessing environment, access to the bit map is assumed to be serialized for the duration of the update process.
INSERT CHARACTERS UNDER MASK (ICM)

The INSERT CHARACTERS UNDER MASK (ICM) instruction may be used to replace all or selected bytes in a general register with bytes from storage and to set the condition code to indicate the value of the inserted field.

For example, if it is desired to insert a three-byte address from FIELD A into register 5 and leave the leftmost byte of the register unchanged, assume:

Machine Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, M_3, S_2 \\
\text{BF} \quad 5, 7, * * * *
\end{array}
\]

Assembler Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, M_3, S_2 \\
\text{ICM} \quad 5, B'0111', \text{FIELD A}
\end{array}
\]

FIELD A: FE DC BA
Register 5 (before): 12 34 56 78
Register 5 (after): 12 FE DC BA
Condition code (after): 1 (leftmost bit of inserted field is one)

As another example:

Machine Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, M_3, S_2 \\
\text{BF} \quad 6, 9, * * * *
\end{array}
\]

Assembler Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, M_3, S_2 \\
\text{ICM} \quad 6, B'1001', \text{FIELD B}
\end{array}
\]

FIELD B: 12 34
Register 6 (before): 00 00 00 00
Register 6 (after): 12 00 00 34
Condition code (after): 2 (inserted field is nonzero with leftmost zero bit)

When the mask field contains 1111, the ICM instruction produces the same result as LOAD (L) (provided that the indexing capability of the RX format is not needed), except that ICM also sets the condition code. The condition-code setting is useful when an all-zero field (condition code 0) or a leftmost one bit (condition code 1) is used as a flag.

LOAD (L, LR)

The LOAD instruction takes four bytes from storage or from a general register and place them unchanged into a general register. For example, assume that the four bytes starting with location 21003 are to be loaded into register 10. Initially:

Register 5 contains 00 02 00 00.
Register 6 contains 00 00 10 03.
The contents of register 10 are not significant.
Storage locations 21003-21006 contain 00 00 AB CD.

To load register 10, the RX form of the instruction can be used:

Machine Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, D_2(X_2, B_2) \\
L \quad 10, 0(5, 6)
\end{array}
\]

Assembler Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, D_2(X_2, B_2) \\
L \quad 10, 0(5, 6)
\end{array}
\]

After the instruction is executed, register 10 contains 00 00 AB CD.

LOAD ADDRESS (LA)

The LOAD ADDRESS instruction provides a convenient way to place a nonnegative binary integer up to $4095_{10}$ in a register without first defining a constant and then using it as an operand. For example, the following instruction places the number $2048_{10}$ in register 1:

Machine Format

\[
\begin{array}{c}
\text{Op Code} \quad R_1, X_2, B_2, D_2 \\
41 \quad 1 \quad 0 \quad 0 \quad 800
\end{array}
\]
The LOAD ADDRESS instruction can also be used to increment a register by an amount up to 409510 specified in the \(D_2\) field. Depending on the addressing mode, only the rightmost 24 or 31 bits of the sum are retained, however. The leftmost bits of the 32-bit result are set to zeros. For example, assume that register 5 contains 00 12 34 56.

The instruction:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>(R_1)</th>
<th>(X_2)</th>
<th>(B_2)</th>
<th>(D_2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>5</td>
<td>0</td>
<td>5</td>
<td>00A</td>
</tr>
</tbody>
</table>

**Assembler Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>(R_1),(D_2)((X_2),(B_2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>LA</td>
<td>5,10(0,5)</td>
</tr>
</tbody>
</table>

adds 10 (decimal) to the contents of register 5 as follows:

Register 5 (old): 00 12 34 56  
\(D_2\) field: 00 00 00 0A  
Register 5 (new): 00 12 34 60

The register may be specified as either \(B_2\) or \(X_2\). Thus, the instruction LA 5,10(5,0) produces the same result.

As the most general example, the instruction LA 6,10(5,4) forms the sum of three values: the contents of register 4, the contents of register 5, and a displacement of 10 and places the 24-bit or 31-bit sum with zeros appended on the left in register 6.

**LOAD HALFWORD (LH)**

The LOAD HALFWORD instruction places unchanged a halfword from storage into the right half of a register. The left half of the register is loaded with zeros or ones according to the sign (leftmost bit) of the halfword.

For example, assume that the two bytes in storage locations 1803-1804 are to be loaded into register 6. Also assume:

- The contents of register 6 are not significant.
- Register 14 contains 00 00 18 03.
- Locations 1803-1804 contain 00 20.

The instruction required to load the register is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>(R_1)</th>
<th>(X_2)</th>
<th>(B_2)</th>
<th>(D_2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>48</td>
<td>6</td>
<td>0</td>
<td>E</td>
<td>000</td>
</tr>
</tbody>
</table>

**Assembler Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>(R_1),(D_2)((X_2),(B_2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>LH</td>
<td>6,0(0,14)</td>
</tr>
</tbody>
</table>

After the instruction is executed, register 6 contains 00 00 00 20. If locations 1803-1804 had contained a negative number, for example, A7 B6, a minus sign would have been propagated to the left, giving FF FF A7 B6 as the final result in register 6.

**MOVE (MVC, MVI)**

**MVC Example**

The MOVE (MVC) instruction can be used to move data from one storage location to another. For example, assume that the following two fields are in storage:

Field 2048:

<table>
<thead>
<tr>
<th>2052</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>C1 C2 C3 C4 C5 C6 C7 C8 CA CB</td>
</tr>
</tbody>
</table>

Field 3840:

<table>
<thead>
<tr>
<th>3848</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
<tr>
<td>F1 F2 F3 F4 F5 F6 F7 F8 F9</td>
</tr>
</tbody>
</table>

Also assume:

- Register 1 contains 00 00 20 48.
- Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:
Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L</th>
<th>B₁</th>
<th>D₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>D2</td>
<td>07</td>
<td>1</td>
<td>000</td>
<td>2</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>D₁(L,B₁),D₂(B₂)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVC</td>
<td>0(8,1),0(2)</td>
</tr>
</tbody>
</table>

After the instruction is executed, field 1 becomes:

Field 2 is unchanged.

MVC can also be used to propagate a byte through a field by starting the first-operand field one byte location to the right of the second-operand field. For example, suppose that an area in storage starting with address 358 contains the following data:

<table>
<thead>
<tr>
<th>Location</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>358</td>
<td>00</td>
</tr>
<tr>
<td>359</td>
<td>F1</td>
</tr>
<tr>
<td>360</td>
<td>F2</td>
</tr>
</tbody>
</table>

With the following MVC instruction, the zeros in location 358 can be propagated throughout the entire field (assume that register 11 contains 00 00 03 58):

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L</th>
<th>B₁</th>
<th>D₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>D2</td>
<td>07</td>
<td>1</td>
<td>000</td>
<td>2</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>D₁(L,B₁),D₂(B₂)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVC</td>
<td>1(8,11),0(11)</td>
</tr>
</tbody>
</table>

Because MVC is executed as if one byte were processed at a time, the above instruction, in effect, takes the byte at address 358 and stores it at 359 (359 now contains 00), takes the byte at 359 and stores it at 35A, and so on, until the entire field is filled with zeros. Note that an MVI instruction could have been used originally to place the byte of zeros in location 358.

Notes:

1. Although the field occupying locations 358-360 contains nine bytes, the length coded in the assembler format is equal to the number of moves (one less than the field length).

2. The order of operands is important even though only one field is involved.

**MVI Example**

The MOVE (MVI) instruction places one byte of information from the instruction stream into storage. For example, the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>I₂</th>
<th>B₁</th>
<th>D₁</th>
</tr>
</thead>
<tbody>
<tr>
<td>92</td>
<td>5B</td>
<td>1</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>D₁(B₁),I₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVC</td>
<td>0(1),C'$'$</td>
</tr>
</tbody>
</table>

may be used, in conjunction with the instruction EDIT AND MARK, to insert the EBCDIC code for a dollar symbol at the storage address contained in general register 1 (see also the example for EDIT AND MARK).

**MOVE INVERSE (MVCIN)**

The MOVE INVERSE (MVCIN) instruction can be used to move data from one storage location to another while reversing the order of the bytes within the field. For example, assume that the following two fields are in storage:

<table>
<thead>
<tr>
<th>Field 1</th>
<th>2048</th>
<th>2052</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>C1</td>
<td>C2</td>
</tr>
<tr>
<td></td>
<td>C3</td>
<td>C4</td>
</tr>
<tr>
<td></td>
<td>C5</td>
<td>C6</td>
</tr>
<tr>
<td></td>
<td>C7</td>
<td>C8</td>
</tr>
<tr>
<td></td>
<td>C9</td>
<td>CA</td>
</tr>
<tr>
<td></td>
<td>CB</td>
<td></td>
</tr>
</tbody>
</table>

Also assume:

- Register 1 contains 00 00 20 48.
- Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:
After the instruction is executed, field 1 becomes:

<table>
<thead>
<tr>
<th>Field</th>
<th>2048</th>
<th>2052</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>F8 F7 F6 F5 F4 F3 F2 F1 C9 CA CB</td>
<td></td>
</tr>
</tbody>
</table>

Field 2 is unchanged.

**Note:** This example uses the same general registers, storage locations, and original values as the first example for MVC. For MVCIN, the second-operand address must designate the rightmost byte of the field to be moved, in this case location 3847. This is accomplished by means of the 7 in the D2 field of the instruction.

### MOVE LONG (MVCL)

The MOVE LONG (MVCL) instruction can be used for moving data in storage as in the first example of the MVC instruction, provided that the two operands do not overlap. MVCL differs from MVC in that the address and length of each operand are specified in an even-odd pair of general registers. Consequently, MVCL can be used to move more than 256 bytes of data with one instruction. As an example, assume:

Register 2 contains 00 0A 00 00.
Register 3 contains 00 00 08 00.
Register 8 contains 00 06 00 00.
Register 9 contains 00 00 08 00.

Execution of the instruction:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>E8</td>
<td>07</td>
<td>1</td>
</tr>
</tbody>
</table>

**Assembler Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>D1(L,B1),D2(B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVCIN</td>
<td>0(8,1),7(2)</td>
</tr>
</tbody>
</table>

If register 3 had contained F0 00 04 00, only the 1,024 bytes from locations A0000-A03FF would have been moved to locations 60000-603FF. The remaining locations 60400-607FF of the first operand would have been filled with 1,024 copies of the padding byte X’F0’, as specified by the leftmost byte of register 3. Bits 8-31 of register 2 would have been incremented by 40016, bits 8-31 of register 8 would have been incremented by 80016, and bits 0-7 of registers 2 and 8 would have been set to zeros. Bits 8-31 of registers 3 and 9 would still have been decremented to zero. Condition code 2 would have been set to indicate that the first operand is longer than the second.

Instead, MVCL may be used to clear a storage area to zeros as follows. Assume register 8 and 9 are set up as before. Register 3 contains only zeros, specifying zero length for the second operand and a zero padding byte. Register 2 is not used to access storage, and its contents are not significant. Executing the instruction MVCL 8,2 causes locations 60000-607FF to be filled with zeros. Bits 8-31 of register 8 are incremented by 80016, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of register 9 are decremented to zero, and condition code 2 is set to indicate that the first operand is longer than the second.

### MOVE NUMERICS (MVN)

Two related instructions, MOVE NUMERICS and MOVE ZONES, may be used with decimal data in the zoned format to operate separately on the rightmost
four bits (the numeric bits) and the leftmost four bits (the zone bits) of each byte. Both are similar to MOVE (MVC), except that MOVE NUMERIC moves only the numeric bits and MOVE ZONES moves only the zone bits.

To illustrate the operation of the MOVE NUMERIC instruction, assume that the following two fields are in storage:

Field A

<table>
<thead>
<tr>
<th>7090</th>
<th>7093</th>
</tr>
</thead>
<tbody>
<tr>
<td>C6</td>
<td>C7</td>
</tr>
<tr>
<td>C8</td>
<td>C9</td>
</tr>
</tbody>
</table>

Field B

<table>
<thead>
<tr>
<th>7041</th>
<th>7046</th>
</tr>
</thead>
<tbody>
<tr>
<td>F0</td>
<td>F1</td>
</tr>
<tr>
<td>F2</td>
<td>F3</td>
</tr>
<tr>
<td>F4</td>
<td>F5</td>
</tr>
</tbody>
</table>

Also assume:

Register 14 contains 00 00 70 90.
Register 15 contains 00 00 70 40.

After the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L</th>
<th>B1</th>
<th>D1</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>D1</td>
<td>03</td>
<td>F</td>
<td>001</td>
<td>E</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code: D1(B1),D2(B2)

MVN 1(4,15),0(14)

is executed, field B becomes:

<table>
<thead>
<tr>
<th>7041</th>
<th>7046</th>
</tr>
</thead>
<tbody>
<tr>
<td>F6</td>
<td>F7</td>
</tr>
<tr>
<td>F8</td>
<td>F9</td>
</tr>
<tr>
<td>F4</td>
<td>F5</td>
</tr>
</tbody>
</table>

The numeric bits of the bytes at locations 7090-7093 have been stored in the numeric bits of the bytes at locations 7041-7044. The contents of locations 7090-7093 and 7045-7046 are unchanged.

### MOVE STRING (MVST)

The MOVE STRING instruction is used to move a second operand designated by general register R2 to a first-operand location designated by general register R1. The movement is made left to right until an ending character specified in general register 0 has been moved or a CPU-determined number of bytes have been moved. The condition code is set to 1 if the ending character was moved or to 3 if a CPU-determined number of bytes were moved.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R1, and the contents of general register R2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R1 and R2, respectively.

Following is an example program that sets string A equal to the concatenation of string B followed by string C, where the length of each of strings B and C is unknown, and the end of each of strings B and C is indicated by an ending character of 00 hex (as in the C programming language). The program is not written for execution in the access-register mode.

MOVE WITH OFFSET (MVO)

MOVE WITH OFFSET may be used to shift a signed-packed-decimal number an odd number of digit positions or to concatenate a sign to an unsigned-packed-decimal number.

Assume that the three-byte unsigned-packed-decimal number in storage locations 4500-4502 is to be moved to locations 5600-5603 and given the sign of the signed-packed-decimal number ending at location 5603. Also assume:

Register 12 contains 00 00 56 00.
Register 15 contains 00 00 45 00.

Storage locations 5600-5603 contain 77 88 99 0C.
Storage locations 4500-4502 contain 12 34 56.

After the instruction:
MVO is executed, the storage locations 5600-5603 contain 01 23 45 6C. Note that the second operand is extended on the left with one zero to fill out the first-operand field.

MOVE ZONES (MVZ)

The MOVE ZONES instruction can operate on overlapping or nonoverlapping fields, as can the instructions MOVE (MVC) and MOVE NUMERICS. When operating on nonoverlapping fields, MOVE ZONES works like the MOVE NUMERICS instruction (see its example), except that MOVE ZONES moves only the zone bits of each byte. To illustrate the use of MOVE ZONES with overlapping fields, assume that the following data field is in storage:

Also assume that register 15 contains 00 00 08 00. The instruction:

After the instruction is executed, the product is in the register pair 4 and 5:

Register 4 contains 00 00 00 00.
Register 5 contains 00 00 4E CE = 20,17410.
Storage locations 3750-3753 are unchanged.

The RR format of the instruction can be used to square the number in a register. Assume that register 7 contains 00 01 00 05. The contents of register 6 are not significant. The instruction:

After the instruction is executed, the product is in the register pair 4 and 5:

Also assume that register 15 contains 00 00 08 00. The instruction:

The instruction required for performing the multiplication is:

The contents of register 4 are not significant.
Register 5 contains 00 00 00 9A = 15410 = the multiplicand.
Register 11 contains 00 00 06 00.
Register 12 contains 00 00 30 00.
Storage locations 3750-3753 contain 00 00 00 83 = 13110 = the multiplier.

The instruction required for performing the multiplication is:
multiplies the number in register 7 by itself and places the result in the pair of registers 6 and 7:

Register 6 contains 00 00 00 01.
Register 7 contains 00 0A 00 19.

MULTIPLY HALFWORD (MH)

The MULTIPLY HALFWORD instruction is used to multiply the contents of a register by a two-byte field in storage. For example, assume that:

Register 11 contains 00 00 00 15 =21_{10} = the multiplicand.
Register 14 contains 00 00 01 00.
Register 15 contains 00 00 20 00.
Storage locations 2102-2103 contain FF D9 = -39_{10} = the multiplier.

The instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, D2(X2, B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MH</td>
<td>11,2(14,15)</td>
</tr>
</tbody>
</table>

multiplies the two numbers. The product, FF FF FC CD = -819_{10}, replaces the original contents of register 11.

Only the rightmost 32 bits of a product are stored in a register; any significant bits on the left are lost. No program interruption occurs on overflow.

OR (O, OC, OI, OR)

When the Boolean operator OR is applied to two bits, the result is one when either bit is one; otherwise, the result is zero. When two bytes are ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ORing two bytes:

First-operand byte: 0011 0101_2
Second-operand byte: 0101 1100_2
Result byte: 0111 1101_2

OI Example

A frequent use of the OR instruction is to set a particular bit to one. For example, assume that storage location 4891 contains 0100 0010_2. To set the rightmost bit of this byte to one without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>I2, B1, D1</th>
</tr>
</thead>
<tbody>
<tr>
<td>OI</td>
<td>1(8), X'01'</td>
</tr>
</tbody>
</table>

When this instruction is executed, the byte in storage is ORed with the immediate byte (the I2 field of the instruction):

Location 4891: 0100 0010_2
Immediate byte: 0000 0001_2
Result: 0100 0011_2

The resulting byte with bit 7 set to one is stored back in location 4891. Condition code 1 is set.

PACK (PACK)

Assume that storage locations 1000-1003 contain the following zoned-decimal number that is to be converted to a signed-packed-decimal number and left in the same location:

```
Zoned number: F1 F2 F3 CA
```

Also assume that register 12 contains 00 00 10 00. After the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L1, L2, B1, D1, B2, D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>F2</td>
<td>3 3 C 000 C 000</td>
</tr>
</tbody>
</table>

A-29
Assembler Format
Op Code   \(D_1(L_1,B_1),D_2(L_2,B_2)\)

PACK   \(0(4,12),0(4,12)\)

is executed, the result in locations 1000-1003 is in
the signed-packed-decimal format:

Signed-packed number  \[0001234C\]

Notes:
1. This example illustrates the operation of PACK
   when the first- and second-operand fields overlap
   completely.
2. During the operation, the second operand was
   extended on the left with zeros.

ROTATE THEN EXCLUSIVE OR
SELECTED BITS

The following example illustrates the use of ROTATE
THEN EXCLUSIVE OR SELECTED BITS to deter-
mine if the access-control bits of a page’s storage-
protection key match the key in the PSW. In this
example, only the condition code is set; the result
is not placed in the first-operand register.

LAY 9,BLOCK Point to storage block.
IVSK 14,9 Insert key into bits 56-63.
EPSW 4,0 Extract PSW key (bits 40-43).
RXSBG 4,14,128+40,43,16 Compare keys.

On completion, the condition code will be set to zero
if the PSW key matches the access-control bits in the
storage key of page addressed by general register 9.
Condition code 1 will be set if the keys do not match.

ROTATE THEN INSERT SELECTED
BITS

1. The following example illustrates the use of ROTATE
   THEN INSERT SELECTED BITS to extract the various DAT-table indices of a virtual
   address contained in general register 8. This
   example shows the use of the zero-remaining-
   bits control to set the remaining bits of the result
   registers to zero.

The virtual address in general register 8 is
assumed to be 123456789ABCDEF0 hex.

RISBG 1,8,53,128+63,11 Get reg. 1st index.
RISBG 2,8,53,128+63,22 Get reg. 2nd index.
RISBG 3,8,53,128+63,33 Get reg. 3rd index.
RISBG 4,8,53,128+63,44 Get segment index.
RISBG 5,8,56,128+63,52 Get page index.
RISBG 6,8,52,128+63,0 Get byte index.

The condition code following each RISBG is 2.
On completion, general registers 1-6 contain the
region-first index, region-second index, region-
third index, segment index, page index, and byte
index, respectively, as follows:

GR1: 0000000000000091 (RFX)
GR2: 00000000000000515 (RSX)
GR3: 0000000000000004F1 (RTX)
GR4: 000000000000001AB (SX)
GR5: 0000000000000000CD (PX)
GR6: 0000000000000000EF0 (BX)

2. The following example illustrates shifting a 64-bit
   value to the left by \(L\) bits:

RISBG R,0,0,X’80’+63,-\(L\)

3. The following example illustrates shifting a 32-bit
   value to the right by \(R\) bits and setting the left-
   most 32 bits to zero:

RISBG R,32+R,0,X’80’+63,-\(R\)

4. The following example illustrates zeroing bits \(S\)
   through \(E\) of general register 3.

RISBG 3,mod64(E+1),128+mod64(S-1),0

\(Mod64\) represents a modulo function which
effectively ANDs the value in parentheses with
3F hex.

ROTATE THEN OR SELECTED BITS

The following example illustrates the use of ROTATE
THEN OR SELECTED BITS to rotate and combine
selected bits of general registers 6 and 8.

LG 6,=X’004C487040CF4600’
LG 8,=X’C07FAF37FC968280’
ROSBG 6,8,54,32
On completion, condition code 1 is set, and general register 6 is as follows:

GR6: 00DECAF0C0FFEE00

Note that only bits 8-54 of the registers are ORed; bits 0-7 and 55-63 of general register 6 are not modified.

**SEARCH STRING (SRST)**

The SEARCH STRING instruction is used to search a second operand designated by general register R₂ for a character specified in general register 0. The length of the second operand is known — the address of the first byte after the second operand is in general register R₁.

When the specified character is found, condition code 1 is set, the address of the character is placed in general register R₁, and the contents of general register R₂ remain unchanged. When the address of the next second-operand byte to be examined equals the address in general register R₁, condition code 2 is set, and the contents of general register R₁ and R₂ remain unchanged. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R₂, and the contents of general register R₁ remain unchanged.

**SRST Example 1**

Following is an example program that determines the end of string A, as indicated by an ending character equal to 00 hex (as in the C programming language), and then determines the address of the first character equal to C1 hex in the string. The program is not written for execution in the access-register mode.

```assembly
L 5,STRAADR
SR 0,0
LOOPO SRST 0,5
BC 1,LOOPO
L 5,STRAADR
LR 4,0
LA 0,X'C1'
```

**SRST Example 2**

Following is an example program that determines the address of the first character equal to C1 hex in the string A whose length is known. The program is not written for execution in the access-register mode.

```assembly
L 5,STRAADR
L 4,STRALEN
AR 4,5
LA 0,X'C1'
LOOPO SRST 4,5
BC 1,LOOPO
BC 2,NOTFND
FOUND [Any instruction]
...
NOTFND [Any instruction]
```

In this example, the value in STRALEN may be a length that either does or does not include an ending character at the end of the string, provided that the ending character is not the character for which the search is made.

**SHIFT LEFT DOUBLE (SLDA)**

The SHIFT LEFT DOUBLE instruction shifts the 63 numeric bits of an even-odd register pair to the left, leaving the sign bit unchanged. Thus, the instruction performs an algebraic left shift of a 64-bit signed binary integer.

For example, if the contents of registers 2 and 3 are:

```
00 7F 0A 72   FE DC BA 98 =
00000000 01111111 00001010 01110010
11111110 11011100 10111010 100110002
```

The instruction:

```
```

<table>
<thead>
<tr>
<th>Machine Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Op Code R₂ B₂ D₂</td>
</tr>
<tr>
<td>8F 2 ///// 0 01F</td>
</tr>
</tbody>
</table>

A-31
results in registers 2 and 3 both being left-shifted 31 bit positions, so that their new contents are:

```
7F 6E 5D 4C 00 00 00 00 = 01111111 01101110 01011101 01001100
00000000 00000000 00000000 00000000
```

Because significant bits are shifted out of bit position 1 of register 2, overflow is indicated by setting condition code 3, and, if the fixed-point-overflow mask bit in the PSW is one, a fixed-point-overflow program interruption occurs.

**SHIFT LEFT SINGLE (SLA)**

The SHIFT LEFT SINGLE instruction is similar to SHIFT LEFT DOUBLE, except that it shifts only the 31 numeric bits of a single register. Therefore, this instruction performs an algebraic left shift of a 32-bit signed binary integer.

For example, if the contents of register 2 are:

```
00 7F 0A 72 = 00000000 01111111 00001010 01110010
```

The instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, B2, D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>BE</td>
<td>8, 7</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, D2(B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SLA</td>
<td>2, 8(0)</td>
</tr>
</tbody>
</table>

results in register 2 being shifted left eight bit positions so that its new contents are:

```
7F 0A 72 00 = 01111111 00001010 01110010 00000000
```

Condition code 2 is set to indicate that the result is greater than zero.

If a left shift of nine places had been specified, a significant bit would have been shifted out of bit position 1. Condition code 3 would have been set to indicate this overflow and, if the fixed-point-overflow mask bit in the PSW were one, a fixed-point overflow interruption would have occurred.

**STORE CHARACTERS UNDER MASK (STCM)**

STORE CHARACTERS UNDER MASK (STCM) may be used to place selected bytes from a register into storage. For example, if it is desired to store a three-byte address from general register 8 into location FIELD3, assume:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, M3, S2</th>
</tr>
</thead>
<tbody>
<tr>
<td>STCM</td>
<td>8, B'0111', FIELD3</td>
</tr>
</tbody>
</table>

Register Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, M3, S2</th>
</tr>
</thead>
<tbody>
<tr>
<td>STCM</td>
<td>8, B'0111', FIELD3</td>
</tr>
</tbody>
</table>

Register 8: 12 34 56 78
FIELD3 (before): not significant
FIELD3 (after): 34 56 78

As another example:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, M3, S2</th>
</tr>
</thead>
<tbody>
<tr>
<td>STCM</td>
<td>9, B'0101', FIELD2</td>
</tr>
</tbody>
</table>

Register Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, M3, S2</th>
</tr>
</thead>
<tbody>
<tr>
<td>STCM</td>
<td>9, B'0101', FIELD2</td>
</tr>
</tbody>
</table>

Register 9: 01 23 45 67
FIELD2 (before): not significant
FIELD2 (after): 23 67

**STORE MULTIPLE (STM)**

Assume that the contents of general registers 14, 15, 0, and 1 are to be stored in consecutive four-byte fields starting with location 4050 and that:

```
Register 14 contains 00 00 25 63.
```
Register 15 contains 00 01 27 36.
Register 0 contains 12 43 00 62.
Register 1 contains 73 26 12 57.
Register 6 contains 00 00 40 00.
The initial contents of locations 4050-405F are not significant.

The STORE MULTIPLE instruction allows the use of just one instruction to store the contents of the four registers:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>R3</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>90</td>
<td>E</td>
<td>1</td>
<td>6</td>
<td>050</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, R3, D2(B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STM</td>
<td>14, 1, X'50'(6)</td>
</tr>
</tbody>
</table>

After the instruction is executed:

- Locations 4050-4053 contain 00 00 25 63.
- Locations 4054-4057 contain 00 01 27 36.
- Locations 4058-405B contain 12 43 00 62.
- Locations 405C-405F contain 73 26 12 57.

TEST UNDER MASK (TM)

The TEST UNDER MASK instruction examines selected bits of a byte and sets the condition code accordingly. For example, assume that:

- Storage location 9999 contains FB.
- Register 7 contains 00 00 99 90.

Assume the instruction to be:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>I2</th>
<th>B1</th>
<th>D1</th>
</tr>
</thead>
<tbody>
<tr>
<td>91</td>
<td>C3</td>
<td>7</td>
<td>009</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>D1(B1), I2</th>
</tr>
</thead>
<tbody>
<tr>
<td>TM</td>
<td>9(7), B'11000011'</td>
</tr>
</tbody>
</table>

The instruction tests only those bits of the byte in storage for which the mask bits are ones:

- FB = 1111 10112
- Mask = 1100 00112
- Test = 11xx xx112

Condition code 3 is set: all selected bits in the test result are ones. (The bits marked “x” are ignored.)

If location 9999 had contained B9, the test would have been:

- B9 = 1011 10012
- Mask = 1100 00112
- Test = 10xx xx012

Condition code 1 is set: the selected bits are both zeros and ones.

If location 9999 had contained 3C, the test would have been:

- 3C = 0011 11002
- Mask = 1100 00112
- Test = 00xx xx002

Condition code 0 is set: all selected bits are zeros.

Note: Storage location 9999 remains unchanged.

TRANSLATE (TR)

The TRANSLATE instruction can be used to translate data from any character code to any other desired code, provided that each character code consists of eight bits or fewer. An appropriate translation table is required in storage.

In the following example, EBCDIC code is translated to ASCII code. The first step is to create a 256-byte table in storage locations 1000-10FF. This table contains the characters of the ASCII code in the sequence of the binary representation of the EBCDIC code; that is, the ASCII representation of a
character is placed in storage at the starting address of the table plus the binary value of the EBCDIC representation of the same character.

For simplicity, the example shows only the part of the table containing the decimal digits:

```
<table>
<thead>
<tr>
<th>DC</th>
<th>L</th>
<th>B1</th>
<th>D1</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>03</td>
<td>C</td>
<td>000</td>
<td>F</td>
<td>000</td>
<td></td>
</tr>
</tbody>
</table>
```

Assume that the four-byte field at storage location 2100 contains the EBCDIC code for the digits 1984:

Locations 2100-2103 contain F1 F9 F8 F4.

Register 12 contains 00 00 21 00.

Register 15 contains 00 00 10 00.

As the instruction:

```
Machine Format
Op Code  D1(L,B1),D2(B2)
```

```
Assembler Format
Op Code  D1(L,B1),D2(B2)
```

is executed, the binary value of each EBCDIC byte is added to the starting address of the table, and the resulting address is used to fetch an ASCII byte:

Table starting address: 1000
First EBCDIC byte: F1
Address of ASCII byte: 10F1

After execution of the instruction:

Locations 2100-2103 contain 31 39 38 34.

Thus, the ASCII code for the digits 1984 has replaced the EBCDIC code in the four-byte field at storage location 2100.

**TRANSLATE AND TEST (TRT)**

The TRANSLATE AND TEST instruction can be used to scan a data field for characters with a special meaning. To indicate which characters have a special meaning, a table similar to the one used for the TRANSLATE instruction is set up, except that zeros in the table indicate characters without any special meaning and nonzero values indicate characters with a special meaning.

Figure A-4 on page A-34 has been set up to distinguish alphabetic characters (A to Z and 0 to 9) from blanks, certain special symbols, and all other characters which are considered invalid. EBCDIC coding is assumed. The 256-byte table is assumed stored at locations 2000-20FF.

Note: If the character codes in the statement being translated occupy a range smaller than 00 through FF₁₆, a table of fewer than 256 bytes can be used.

**Figure A-4. Translate and Test Table**

The table entries for the alphabetic characters in EBCDIC are 00; thus, the letter A (code C1) corresponds to byte location 20C1, which contains 00.

The 15 special symbols have nonzero entries from 0₄₁₆ to 3C₁₆ in increments of 4. Thus, the blank (code 40) has the entry 0₄₁₆, the period (code 4B) has the entry 0₈₁₆, and so on.

All other table positions have the entry 40₁₆ to indicate an invalid character.

The table entries are chosen so that they may be used to select one of a list of 16 words containing

```
<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>

</tbody>
</table>
addresses of different routines to be entered for each special symbol or invalid character encountered during the scan.

Assume that this list of 16 branch addresses is stored at locations 3004-3043.

Starting at storage location CA80, there is the following sequence of 21,10 EBCDIC characters, where “b” stands for a blank.

Locations CA80-CA94:
UNPKbPROUT(9),WORD(5)

Also assume:
Register 1 contains 00 00 CA 7F.
Register 2 contains 00 00 30 00.
Register 15 contains 00 00 20 00.

As the instruction:
Machine Format
Op Code  D1(L,B1),D2(B2)
Assembler Format
Op Code  D1(L,B1),D2(B2)

is executed, the value of the first source byte, the EBCDIC code for the letter U, is added to the starting address of the table to produce the address of the table entry to be examined:

Table starting address      2000
Source byte (U)         E4
—————————————————–
Address of table entry      20E4

Because zeros were placed in storage location 20E4, no special action occurs. The operation continues with the second and subsequent source bytes until it reaches the blank in location CA84. When this symbol is reached, its value is added to the starting address of the table, as usual:

UNPACK (UNPK)

Assume that storage locations 2501-2502 contain a signed-packed-decimal number that is to be unpacked and placed in storage locations 1000-1004. Also assume:
Register 12 contains 00 00 10 00.
Register 13 contains 00 00 25 00.
Storage locations 2501-2502 contain 12 3D.
The initial contents of storage locations 1000-1004 are not significant.

After the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L1</th>
<th>L2</th>
<th>B1</th>
<th>D1</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>F3</td>
<td>4</td>
<td>1</td>
<td>C</td>
<td>000</td>
<td>D</td>
<td>001</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code \( D_1(L_1,B_1),D_2(L_2,B_2) \)

UNPK \( 0(5,12),1(2,13) \)

is executed, the storage locations 1000-1004 contain F0 F0 F1 F2 D3.

**UPDATE TREE (UPT)**

See “Sorting Instructions” on page A-53.

---

**Decimal Instructions**

(See Chapter 8, “Decimal Instructions” for a complete description of the decimal instructions.)

**ADD DECIMAL (AP)**

Assume that the signed-packed-decimal number at storage locations 500-503 is to be added to the signed-packed-decimal number at locations 2000-2002. Also assume:

Register 12 contains 00 00 06 00.
Register 13 contains 00 00 03 00.
Storage locations 700-703 contain 17 25 35 6D.
Storage locations 500-502 contain 72 14 2D.

After the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L1</th>
<th>L2</th>
<th>B1</th>
<th>D1</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>FA</td>
<td>2</td>
<td>3</td>
<td>C</td>
<td>000</td>
<td>0</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code \( D_1(L_1,B_1),D_2(L_2,B_2) \)

\( AP \ 0(3,12),0(4,13) \)

is executed, the storage locations 2000-2002 contain 73 88 5C; condition code 2 is set to indicate that the result is greater than zero. Note that:

1. Because the two numbers had different signs, they were in effect subtracted.
2. Although the second operand is longer than the first operand, no overflow interruption occurs because the result can be entirely contained within the first operand.

**COMPARE DECIMAL (CP)**

Assume that the signed-packed-decimal contents of storage locations 700-703 are to be algebraically compared with the signed-packed-decimal contents of locations 500-502. Also assume:

Register 12 contains 00 00 06 00.
Register 13 contains 00 00 03 00.
Storage locations 700-703 contain 17 25 35 6D.
Storage locations 500-502 contain 72 14 2D.

After the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L1</th>
<th>L2</th>
<th>B1</th>
<th>D1</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>F9</td>
<td>3</td>
<td>2</td>
<td>C</td>
<td>100</td>
<td>D</td>
<td>200</td>
</tr>
</tbody>
</table>

Assembler Format

Op Code \( D_1(L_1,B_1),D_2(L_2,B_2) \)

\( CP \ X'100' (4,12),X'200' (3,13) \)

is executed, condition code 1 is set, indicating that the first operand (the contents of locations 700-703) is less than the second.
DIVIDE DECIMAL (DP)

Assume that the signed-packed-decimal number at storage locations 2000-2004 (the dividend) is to be divided by the signed-packed-decimal number at locations 3000-3001 (the divisor). Also assume:

Register 12 contains 00 00 20 00.
Register 13 contains 00 00 30 00.
Storage locations 2000-2004 contain 01 23 45 67 8C.
Storage locations 3000-3001 contain 32 1D.

After the instruction:

Machine Format

Assembler Format

Op Code  D1(L1,B1),D2(L2,B2)

DP    0(5,12),0(2,13)

is executed, the dividend is entirely replaced by the signed quotient and remainder, as follows:

Notes:

1. Because the dividend and divisor have different signs, the quotient receives a negative sign.
2. The remainder receives the sign of the dividend and the length of the divisor.
3. If an attempt were made to divide the dividend by the one-byte field at location 3001, the quotient would be too long to fit within the four bytes allotted to it. A decimal-divide exception would exist, causing a program interruption.

EDIT (ED)

Before data in the signed-packed-decimal or unsigned-packed-decimal format can be used in a printed report, digits and signs must be converted to printable characters. Moreover, punctuation marks, such as commas and decimal points, may have to be inserted in appropriate places. The highly flexible EDIT instruction performs these functions in a single instruction execution.

This example shows step-by-step one way that the EDIT instruction can be used. The field to be edited (the source) is four bytes long; it is edited against a pattern 13 bytes long. The following symbols are used:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Blank character</td>
</tr>
<tr>
<td>d(21)</td>
<td>Significance starter</td>
</tr>
<tr>
<td>d(20)</td>
<td>Digit selector</td>
</tr>
</tbody>
</table>

Assume that register 12 contains:

00 00 10 00

and that the source and pattern fields are:

Source

1200 1203

Pattern

1000 100C

Execution of the instruction:

Machine Format

Assembler Format

Op Code  D1(L1,B1),D2(L2,B2)

ED    0(13,12),X’200'(12)

alters the pattern field as follows:
Thus, after the instruction is executed, the pattern field contains the result as follows:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Digit</th>
<th>Significance Indicator (Before/After)</th>
<th>Rule</th>
<th>Location 1000-100C</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>0</td>
<td>off/off</td>
<td>leave(1)</td>
<td>bdd,d(d.ddbCR</td>
</tr>
<tr>
<td>d</td>
<td>0</td>
<td>off/off</td>
<td>fill</td>
<td>bbd,d(d.ddbCR</td>
</tr>
<tr>
<td>d</td>
<td>2</td>
<td>off/on(2)</td>
<td>digit</td>
<td>bb2,d(d.ddbCR</td>
</tr>
<tr>
<td>,</td>
<td>5</td>
<td>on/on</td>
<td>same</td>
<td>bb2,5(d.ddbCR</td>
</tr>
<tr>
<td>(</td>
<td>7</td>
<td>on/on</td>
<td>digit</td>
<td>bb2,57d.ddbCR</td>
</tr>
<tr>
<td>)</td>
<td>4</td>
<td>on/on</td>
<td>digit</td>
<td>bb2,574.ddbCR</td>
</tr>
<tr>
<td>.</td>
<td>2</td>
<td>on/on</td>
<td>digit</td>
<td>bb2,574.2dbCR</td>
</tr>
<tr>
<td>d</td>
<td>6+</td>
<td>on/off(3)</td>
<td>digit</td>
<td>bb2,574.26dbCR</td>
</tr>
<tr>
<td>b</td>
<td>0</td>
<td>off/off</td>
<td>fill</td>
<td>bb2,574.26bbR</td>
</tr>
<tr>
<td>C</td>
<td>0</td>
<td>off/off</td>
<td>fill</td>
<td>bb2,574.26bbR</td>
</tr>
<tr>
<td>R</td>
<td>0</td>
<td>off/off</td>
<td>fill</td>
<td>bb2,574.26bbR</td>
</tr>
</tbody>
</table>

Notes:
1. This character is the fill byte.
2. First nonzero decimal source digit turns on significance indicator.
3. Plus sign in the four rightmost bits of the byte turns off significance indicator.

Thus, after the instruction is executed, the pattern field contains the result as follows:

**Pattern**

<table>
<thead>
<tr>
<th>1000</th>
<th>100C</th>
</tr>
</thead>
<tbody>
<tr>
<td>40 40</td>
<td>F2 6B F5 F7 F4 4F F2 F6 40 40</td>
</tr>
<tr>
<td>b b 2</td>
<td>5 7 4</td>
</tr>
</tbody>
</table>

This pattern field prints as:

2,574.26

The source field remains unchanged. Condition code 2 is set because the number was greater than zero.

If the number in the source field is changed to the negative number 00 00 02 6D and the original pattern is used, the edited result this time is:

**Pattern**

<table>
<thead>
<tr>
<th>1000</th>
<th>100C</th>
</tr>
</thead>
<tbody>
<tr>
<td>40 40</td>
<td>40 40 40 40 40 40 40 40</td>
</tr>
<tr>
<td>b b b b</td>
<td>b b 0</td>
</tr>
</tbody>
</table>

This pattern field prints as:

$2,574.26

Condition code 2 is set to indicate that the number edited was greater than zero.

The significance starter forces the significance indicator to the on state and hence causes a leading zero and the decimal point to be preserved. Because the minus-sign code has no effect on the significance indicator, the characters CR are printed to show a negative (credit) amount.

Condition code 1 is set (number less than zero).

**EDIT AND MARK (EDMK)**

The EDIT AND MARK instruction may be used, in addition to the functions of EDIT, to insert a currency symbol, such as a dollar sign, at the appropriate position in the edited result. Assume the same source in storage locations 1200-1203, the same pattern in locations 1000-100C, and the same contents of general register 12 as for the EDIT instruction above. The previous contents of general register 1 (GR1) are not significant; a LOAD ADDRESS instruction is used to set up the first digit position that is forced to print if no significant digits occur to the left.

The instructions:

- **LA 1,6(0,12)** Load address of forced significant digit into GR1
- **EDMK 0(13,12),X’200'(12)** Leave address of first significant digit in GR1
- **BCTR 1,0** Subtract 1 from address in GR1
- **MVI 0(1),C ‘$’** Store dollar sign at address in GR1

produce the following results for the two examples under EDIT:

**Pattern**

<table>
<thead>
<tr>
<th>1000</th>
<th>100C</th>
</tr>
</thead>
<tbody>
<tr>
<td>40 5B</td>
<td>F2 6B F5 F7 F4 4F F2 F6 40 40 40</td>
</tr>
<tr>
<td>b b b</td>
<td>b b 0</td>
</tr>
</tbody>
</table>

This pattern field prints as:

$2,574.26

Condition code 2 is set to indicate that the number edited was greater than zero.
Pattern

This pattern field prints as:

$0.26 \text{ CR}$

Condition code 1 is set because the number is less than zero.

MULTIPLY DECIMAL (MP)

Assume that the signed-packed-decimal number in storage locations 1202-1204 (the multiplicand) is to be multiplied by the signed-packed-decimal number in locations 500-501 (the multiplier).

The multiplicand must first be extended to have at least two bytes of leftmost zeros, corresponding to the multiplier length, so as to avoid a data exception during the multiplication. ZERO AND ADD can be used to move the multiplicand into a longer field.

Assume:

Register 4 contains 00 00 12 00.
Register 6 contains 00 00 05 00.

Then execution of the instruction:

ZAP X'100'(5,4),2(3,4)

sets up a new multiplicand in storage locations 1300-1304:

Now, after the instruction:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>1202</th>
<th>1204</th>
</tr>
</thead>
<tbody>
<tr>
<td>38</td>
<td>46</td>
<td>00</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>500</th>
<th>501</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>10</td>
</tr>
</tbody>
</table>

The multiplicand must first be extended to have at least two bytes of leftmost zeros, corresponding to the multiplier length, so as to avoid a data exception during the multiplication. ZERO AND ADD can be used to move the multiplicand into a longer field.

decimal right shift

In this example, the contents of storage location FIELD1 are shifted three places to the left, effectively multiplying the contents of FIELD1 by 1000. FIELD1 is six bytes long. The following instruction performs the operation:

Machine Format

| Op Code L1 L2 B1 D1 B2 D2 |
|--------------------------|---|---|---|---|---|---|
| FC 4 1 4 100 6 000 |

Assembler Format

| Op Code D1(L1,B1),D2(L2,B2) |
|-----------------------------|---|---|
| MP X'100'(5,4),0(2,6) |

is executed, storage locations 1300-1304 contain the product: 01 23 45 66 0C.

SHIFT AND ROUND DECIMAL (SRP)

The SHIFT AND ROUND DECIMAL (SRP) instruction can be used for shifting decimal numbers in storage to the left or right. When a number is shifted right, rounding can also be done.

Decimal Left Shift

In this example, the contents of storage location FIELD2 are shifted one place to the right, effectively multiplying the contents of FIELD1 by 1000. FIELD1 is six bytes long. The following instruction performs the operation:

Machine Format

| Op Code L1 I3 S1 B2 D2 |
|------------------------|---|---|---|---|---|
| F0 5 0 * * * 0 003 |

Assembler Format

| Op Code S1(L1),S2,I3 |
|---------------------|---|---|
| SRP FIELD1(6),3,0 |

FIELD1 (before): 00 01 23 45 67 8C
FIELD1 (after): 12 34 56 78 00 0C

The second-operand address in this instruction specifies the shift amount (three places). The rounding digit, I3, is not used in a left shift, but it must be a valid decimal digit. After execution, condition code 2 is set to show that the result is greater than zero.

Decimal Right Shift

In this example, the contents of storage location FIELD2 are shifted one place to the right, effectively
dividing the contents of FIELD2 by 10 and discarding the remainder. FIELD2 is five bytes in length. The following instruction performs this operation:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L₁</th>
<th>I₃</th>
<th>S₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>F0</td>
<td>4</td>
<td>0</td>
<td>***</td>
<td>0</td>
<td>03F</td>
</tr>
</tbody>
</table>

Assembler Format

SRP FIELD2(5),64-1,0

FIELD 2 (before): 01 23 45 67 8C
FIELD 2 (after): 00 12 34 56 7C

In the SRP instruction, shifts to the right are specified in the second-operand address by negative shift values, which are represented as a six-bit value in two’s complement form.

The six-bit two’s complement of a number, n, can be specified as 64 - n. In this example, a right shift of one is represented as 64 - 1.

Condition code 2 is set.

Decimal Right Shift and Round

In this example, the contents of storage location FIELD3 are shifted three places to the right and rounded, in effect dividing by 1000 and rounding up. FIELD3 is four bytes in length.

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L₁</th>
<th>I₃</th>
<th>S₁</th>
<th>B₂</th>
<th>D₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>F0</td>
<td>3</td>
<td>5</td>
<td>***</td>
<td>0</td>
<td>03D</td>
</tr>
</tbody>
</table>

Assembler Format

SRP FIELD3(4),64-3,5

FIELD 3 (before): 12 39 60 0D
FIELD 3 (after): 00 01 24 0D

The shift amount (three places) is specified in the D₂ field. The I₃ field specifies a rounding digit of 5. The rounding digit is added to the last digit shifted out (which is a 6), and the carry is propagated to the left. The sign is ignored during the addition.

Condition code 1 is set because the result is less than zero.

Multiplying by a Variable Power of 10

Since the shift value specified by the SRP instruction specifies both the direction and amount of the shift, the operation is equivalent to multiplying the decimal first operand by 10 raised to the power specified by the shift value.

If the shift value is to be variable, it may be specified by the B₂ field instead of the displacement D₂ of the SRP instruction. The general register designated by B₂ should contain the shift value (power of 10) as a signed binary integer.

A fixed scale factor modifying the variable power of 10 may be specified by using both the B₂ field (variable part in a general register) and the D₂ field (fixed part in the displacement).

The SRP instruction uses only the rightmost six bits of the effective address D₂(B₂) and interprets them as a six-bit signed binary integer to control the left or right shift as in the preceding shift examples.
**ZERO AND ADD (ZAP)**

Assume that the signed-packed-decimal number at storage locations 4500-4502 is to be moved to locations 4000-4004 with four leading zeros in the result field. Also assume:

- Register 9 contains 00 00 40 00.
- Storage locations 4000-4004 contain 12 34 56 78 90.
- Storage locations 4500-4502 contain 38 46 0D.

After the instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>L1</th>
<th>L2</th>
<th>B1</th>
<th>D1</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8</td>
<td>4</td>
<td>2</td>
<td>9</td>
<td>000</td>
<td>9</td>
<td>500</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>D1(L1,B1),D2(L2,B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZAP</td>
<td>0(5,9),X'500'(3,9)</td>
</tr>
</tbody>
</table>

is executed, the storage locations 4000-4004 contain 00 00 38 46 0D; condition code 1 is set to indicate a negative result without overflow.

Note that, because the first operand is not checked for valid sign and digit codes, it may contain any combination of hexadecimal digits before the operation.

**Hexadecimal-Floating-Point Instructions**

(See Chapter 9, “Floating-Point Overview and Support Instructions” for a complete description of the hexadecimal-floating-point instructions.)

In this section, the abbreviations FPR0, FPR2, FPR4, and FPR6 stand for floating-point registers 0, 2, 4, and 6 respectively.

**ADD NORMALIZED (AD, ADR, AE, AER, AXR)**

The ADD NORMALIZED instruction performs the addition of two HFP numbers and places the normalized result in a floating-point register. Neither of the two numbers to be added must necessarily be in normalized form before addition occurs. For example, assume that:

- FPR6 contains the unnormalized number C3 08 21 00 00 00 00 00 = -82.116 = -130.0610 approximately.
- Storage locations 2000-2007 contain the normalized number 41 12 34 56 00 00 00 00 = +1.23456 16 = +1.1410 approximately.
- Register 13 contains 00 00 20 00.

The instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>X2</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>7A</td>
<td>6</td>
<td>0</td>
<td>0</td>
<td>000</td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1,X2(B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>AE</td>
<td>6,0(0,13)</td>
</tr>
</tbody>
</table>

performs the short-precision addition of the two operands, as follows.

The characteristics of the two numbers (43 and 41) are compared. Since the number in storage has a characteristic that is smaller by 2, it is right-shifted two hexadecimal digit positions. One guard digit is retained on the right. The fractions of the two numbers are then added algebraically:

<table>
<thead>
<tr>
<th>Fraction GD1</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPR6</td>
</tr>
<tr>
<td>Shifting from storage</td>
</tr>
<tr>
<td>Intermediate sum</td>
</tr>
<tr>
<td>Left-shifted sum</td>
</tr>
<tr>
<td>Guard digit</td>
</tr>
</tbody>
</table>

Because the intermediate sum is unnormalized, it is left-shifted to form the normalized HFP number -80.ECBB16 = -128.9210 approximately. Combining the sign with the characteristic, the result is C2 80 EC BB, which replaces the left half of FPR6. The right half of FPR6 and the contents of storage locations 2000-2007 are unchanged. Condition code 1 is set to indicate a result less than zero.
If the long-precision instruction AD were used, the result in FPR6 would be C2 80 EC BA 00 00 00. Note that use of the long-precision instruction would avoid a loss of precision in this example.

**ADD UNNORMALIZED (AU, AUR, AW, AWR)**

The ADD UNNORMALIZED instruction operates the same as the ADD NORMALIZED instruction, except that the final result is not normalized. For example, using the same operands as in the example for ADD NORMALIZED, when the short-precision instruction:

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>X2</th>
<th>B2</th>
<th>D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>7E 6 0 D 000</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, D2(X2, B2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>AU 6,0(0,13)</td>
<td></td>
</tr>
</tbody>
</table>

is executed, the two numbers are added as follows:

\[
\begin{align*}
\text{FPR6} & \quad \text{Fraction GD}^1 \\
& \quad -43 08 21 00 \\
\text{Shifted number from storage} & \quad +43 00 12 34 5 \\
\text{Intermediate sum} & \quad -43 08 0E CB B
\end{align*}
\]

\(^1\) Guard digit

The guard digit participates in the addition but is discarded. The unnormalized sum replaces the left half of FPR6. Condition code 1 is set because the result is less than zero.

The truncated result in FPR6 (C3 08 0E CB 00 00 00 00) shows a loss of a significant digit when compared to the result of short-precision normalized addition.

**COMPARE (CD, CDR, CE, CER)**

Assume that FPR4 contains 43 00 00 00 00 00 00 00 (zero), and FPR6 contains 35 12 34 56 78 9A BC DE (a positive number). The contents of the two registers are to be compared using a long-precision COMPARE instruction.

Machine Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>29 4 6</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Assembler Format

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1, R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDR 4,6</td>
<td></td>
</tr>
</tbody>
</table>

The number with the smaller characteristic, which is in register FPR6, is right-shifted 43 - 35 hex (67 - 53 decimal) or 14 digit positions, so that the two characteristics agree. The shifted number is 43 00 00 00 00 00 00 00, with a guard digit of one. Therefore, when the two numbers are compared, condition code 1 is set, indicating that operand 1 in FPR4 is less than operand 2 in FPR6.

If the example is changed to a second operand with a characteristic of 34 instead of 35, so that FPR6 contains 34 12 34 56 78 9A BC DE, the operand is right-shifted 15 positions, leaving all fraction digits and the guard digit as zeros. Condition code 0 is set, indicating equality. This example shows that two HFP numbers with different characteristics or fractions may compare equal if the numbers are unnormalized or zero.

As another example of comparing unnormalized HFP numbers, 41 00 12 34 56 78 9A BC compares equal to all numbers of the form 3F 12 34 56 78 9A BC 0X (X represents any hexadecimal digit). When the COMPARE instruction is executed, the two rightmost digits are shifted right two places, the 0 becomes the guard digit, and the X does not participate in the comparison.

However, when two normalized HFP numbers are compared, the relationship between numbers that compare equal is unique: each digit in one number must be the same as the corresponding digit in the other number.

**DIVIDE (DD, DDR, DE, DER)**

Assume that the first operand (the dividend) is in FPR2 and the second operand (the divisor) in FPR0. If the operands are in the short-precision divisor format, the resulting quotient is returned to FPR2 by the instruction:
Several examples of short-precision HFP division, with the dividend in FPR2 and the divisor in FPR0, are shown below. For case A, the result, which replaces the dividend, is obtained in the following steps.

**HALVE (HDR, HER)**

HALVE produces the same result as HFP DIVIDE with a divisor of 2.0. Assume FPR2 contains the long-precision number +48 30 00 00 00 00 00 0F. The following HALVE instruction produces the result +48 18 00 00 00 00 00 07 in FPR2:

**MULTIPLY (MD, MDR, MDE, MDER, MXD, MXDR, MXR)**

For this example, the following long-precision operands are in FPR0 and FPR2:

- FPR0: -33 606060 60606060
- FPR2: -5A 200000 20000020

A long-precision product is generated by the instruction:

If the operands were not already normalized, the instruction would first normalize them. It then generates an intermediate result consisting of the full 28-digit hexadecimal product fraction obtained by multiplying the 14-digit hexadecimal operand fractions, together with the appropriate sign and a characteristic that is the sum of the operand characteristics less 64 (40 hex):

</tbody>
</table>

Case C shows a number being divided by 4.0. Case D divides the same number by 2.0, and case E divides the result of case D again by 2.0. The results of cases C and E differ in the rightmost hexadecimal digit position, which illustrates an effect of result truncation.
The fraction multiplication is performed as follows:

\[
\begin{align*}
\frac{.606060606060}{.2000020000020} & = \frac{C0C0C0C0C0C0C0}{C0C0C0C0C0C0} \\
& = .0C0C0C181818241818180C0C0C00
\end{align*}
\]

Attaching the sign and characteristic to the fraction gives:

\[+4D0C0C0C181818241818180C0C0C00\]

Because this intermediate product has a leading zero, it is then normalized. The truncated final result placed in FPR0 is:

\[+4C C0C0C181818241\]

**Hexadecimal-Floating-Point-Number Conversion**

The following examples illustrate one method of converting between binary fixed-point numbers (32-bit signed binary integers) and normalized HFP numbers. Conversion must provide for the different representations used with negative numbers: the two's-complement form for signed binary integers, and the signed-absolute-value form for the fractions of HFP numbers.

**Fixed Point to Hexadecimal Floating Point**

The method used here inverts the leftmost bit of the 32-bit signed binary integer, which is equivalent to adding \(2^{31}\) to the number and considering the result to be positive. This changes the number from a signed integer in the range \(2^{31} - 1\) through \(-2^{31}\) to an unsigned integer in the range \(2^{32} - 1\) through 0. After conversion to the long HFP format, the value \(2^{31}\) is subtracted again.

Assume that general register 9 (GR9) contains the integer -59 in two's-complement form:

\[GR9: \quad FF \quad FF \quad FF \quad C5\]

Further, assume two eight-byte fields in storage: TEMP, for use as temporary storage, and TWO31, which contains the floating-point constant \(2^{31}\) in the following format:

\[\text{TWO31:} \quad 4E \quad 00 \quad 00 \quad 00 \quad 80 \quad 00 \quad 00 \quad 00\]

This is an unnormalized long HFP number with the characteristic 4E, which corresponds to a radix point (hexadecimal point) to the right of the number.

The following instruction sequence performs the conversion:

\[
X \quad 9, \text{TWO31} + 4 \\
\text{ST} \quad 9, \text{TEMP} + 4 \\
\text{MVC} \quad \text{TEMP}(4), \text{TWO31} \\
\text{LD} \quad 2, \text{TEMP} \\
\text{SD} \quad 2, \text{TWO31}
\]

The EXCLUSIVE OR (X) instruction inverts the leftmost bit in general register 9, using the right half of the constant as the source for a leftmost one bit. The next two instructions assemble the modified number in an unnormalized long HFP format, using the left half of the constant as the plus sign, the characteristic, and the leading zeros of the fraction. LOAD (LD) places the number unchanged in floating-point register 2. The SUBTRACT NORMALIZED (SD) instruction performs the final two steps by subtracting \(2^{31}\) in HFP form and normalizing the result.

**Hexadecimal Floating Point to Fixed Point**

The procedure described here consists basically in reversing the steps of the previous procedure. Two additional considerations must be taken into account. First: the HFP number may not be an exact integer. Truncating the excess hexadecimal digits on the right requires shifting the number one digit position farther to the right than desired for the final result, so that the units digit occupies the position of the guard digit. Second: the HFP number may have to be tested as to whether it is outside the range of numbers representable as a 32-bit signed binary integer.

Assume that floating-point register 6 contains the number 59.2510 = 3B.416 in normalized form:

\[\text{FPR6:} \quad 42 \quad 3B \quad 40 \quad 00 \quad 00 \quad 00 \quad 00 \quad 00\]
Further, assume three eight-byte fields in storage: TEMP, for use as temporary storage, and the constants $2^{32}$ (TWO32) and $2^{31}$ (TWO31R) in the following formats:

\[
\begin{align*}
\text{TWO32:} & \quad 4E 00 00 01 00 00 00 00 \\
\text{TWO31R:} & \quad 4F 00 00 00 08 00 00 00
\end{align*}
\]

The constant TWO31R is shifted right one more position than the constant TWO31 of the previous example, so as to force the units digit into the guard-digit position.

The following instruction sequence performs the integer truncation, range tests, and conversion to a signed binary integer in general register 8 (GR8):

\[
\begin{align*}
\text{SD} & \quad 6, \text{TWO31R} & \text{Result} & \text{FPR6:} \\
& \quad & C87F \text{ FFFF C500 0000} \\
\text{BC} & \quad 11, \text{OVERFLOW} & \text{Branch to overflow routine if result is greater than or equal to zero} \\
\text{AW} & \quad 6, \text{TWO32} & \text{FPR6:} & 4E00 0000 8000 003B \\
\text{BC} & \quad 4, \text{OVERFLOW} & \text{Branch to overflow routine if result is less than zero} \\
\text{STD} & \quad 6, \text{TEMP} & \text{TEMP:} & 4E00 0000 8000 003B \\
\text{XI} & \quad \text{TEMP+4,X’80’} & \text{TEMP:} & 4E00 0000 0000 003B \\
\text{L} & \quad 8, \text{TEMP+4} & \text{GR8:} & 0000 003B
\end{align*}
\]

The SUBTRACT NORMALIZED (SD) instruction shifts the fraction of the number to the right until it lines up with TWO31R, which causes the fraction digit 4 to fall to the right of the guard digit and be lost; the result of subtracting $2^{31}$ from the remaining digits is renormalized. The result should be less than zero; if not, the original number was too large in the positive direction. The first BRANCH ON CONDITION (BC) performs this test.

The ADD UNNORMALIZED (AW) instruction adds $2^{32}$, $2^{31}$ to correct for the previous subtraction and another $2^{31}$ to change to an all-positive range. The second BC tests for a result less than zero, showing that the original number was too large in the negative direction. The unnormalized result is placed in temporary storage by the STORE (STD) instruction. There the leftmost bit of the binary integer is inverted by the EXCLUSIVE OR (XI) instruction to subtract $2^{31}$ and thus convert the unsigned number to the signed format. The final result is loaded into GR8.

### Multiprogramming and Multiprocessing Examples

When two or more programs sharing common storage locations are being executed concurrently in a multiprogramming or multiprocessing environment, one program may, for example, set a flag bit in the common-storage area for testing by another program. It should be noted that the instructions AND (NI, NIY, or NC), EXCLUSIVE OR (XI, XIY, or XC), and OR (OI, OIY, or OC) could be used to set flag bits in a multiprogramming environment; but when the interlocked-access facility 2 is not installed, the same instructions may cause program logic errors in a multiprocessing configuration where two or more CPUs can fetch, modify, and store data in the same storage locations simultaneously.

### Example of a Program Failure Using OR Immediate

The following example assumes that the interlocked-access facility 2 is not installed.

Assume that two independent programs try to set different bits to one in a common byte in storage. The following example shows how the use of the instruction OR immediate (OI) can fail to accomplish this, if the programs are executed simultaneously on two different CPUs. One of the possible error situations is depicted.

<table>
<thead>
<tr>
<th>Execution of instruction</th>
<th>Flags</th>
<th>Execution of instruction</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>OI FLAGS,X’01’ on CPU A</td>
<td></td>
<td>OI FLAGS,X’80’ on CPU B</td>
<td></td>
</tr>
<tr>
<td>Fetch FLAGS X’00’</td>
<td>X’00’</td>
<td>Fetch FLAGS X’00’</td>
<td></td>
</tr>
<tr>
<td>OR X’01’ into X’00’</td>
<td>X’00’</td>
<td>OR X’80’ into X’00’</td>
<td></td>
</tr>
<tr>
<td>Store X’01’ into FLAGS</td>
<td></td>
<td>Store X’80’ into FLAGS</td>
<td></td>
</tr>
<tr>
<td>X’80’ into FLAGS</td>
<td></td>
<td>Flags should have value of X’81’ following both updates.</td>
<td></td>
</tr>
</tbody>
</table>

The problem shown here is that the value stored by the OI instruction executed on CPU A overlays the value that was stored by CPU B. The X’80’ flag bit
was erroneously turned off, and the data is now invalid.

The COMPARE AND SWAP instruction has been provided to overcome this and similar problems.

When the interlocked-access facility 2 is installed, the update performed by OR (OI) instruction is an interlocked-update reference, and the problem illustrated here does not occur.

**Conditional Swapping Instructions (CS, CDS)**

The COMPARE AND SWAP (CS) and COMPARE DOUBLE AND SWAP (CDS) instructions can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas.

The following examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions illustrate the applications for which the instructions are intended. It is important to note that these are examples of functions that can be performed by programs while the CPU is enabled for interruption (multiprogramming) or by programs that are being executed in a multiprocessor configuration. That is, the routine allows a program to modify the contents of a storage location while the CPU is enabled, even though the routine may be interrupted by another program on the same CPU that will update the location, and even though the possibility exists that another CPU may simultaneously update the same location.

The COMPARE AND SWAP instruction first checks the value of a storage location and then modifies it only if the value is what the program expects; normally this would be a previously fetched value. If the value in storage is not what the program expects, then the location is not modified; instead, the current value of the location is loaded into a general register, in preparation for the program to loop back and try again. During the execution of COMPARE AND SWAP, no other CPU can perform a store access or interlocked-update access at the specified location.

To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference. See the programming notes of COMPARE AND SWAP for an example of how COMPARE AND SWAP can be unsuccessful due to an OR IMMEDIATE instruction executed by another CPU.

**Setting a Single Bit**

The following instruction sequence shows how the COMPARE AND SWAP instruction can be used to set a single bit in storage to one. Assume that the first byte of a word in storage called “WORD” contains eight flag bits.

```
LA 6,X’80’  Put bit to be ORed into GR6
SLL 6,24    Shift left 24 places to align the byte to be ORed with the location of the flag bits within WORD
L 7,WORD    Fetch current flag values
RETRY LR 8,7 Load flags into GR8
OR 8,6      Set bit to one
CS 7,8,WORD Store new flags if current flags unchanged, or re-fetch current flag values if changed
BC 4,RETRY  If new flags are not stored, try again
```

The format of the COMPARE AND SWAP instruction is:

**Machine Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1</th>
<th>R2</th>
<th>S2</th>
</tr>
</thead>
<tbody>
<tr>
<td>BA</td>
<td>7</td>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

**Assembler Format**

<table>
<thead>
<tr>
<th>Op Code</th>
<th>R1,R2,S2</th>
</tr>
</thead>
<tbody>
<tr>
<td>CS</td>
<td>7,8,WORD</td>
</tr>
</tbody>
</table>

The COMPARE AND SWAP instruction compares the first operand (general register 7 containing the current flag values) to the second operand in storage (WORD) while no CPU other than the one executing the COMPARE AND SWAP instruction is permitted to perform a store access or interlocked-update access at the specified storage location.

If the comparison is successful, indicating that the flag bits have not been changed since they were fetched, the modified copy in general register 8 is stored into WORD. If the flags have been changed, the compare will not be successful, and their new values are loaded into general register 7.
The conditional branch (BC) instruction tests the condition code and reexecutes the flag-modifying instructions if the COMPARE AND SWAP instruction indicated an unsuccessful comparison (condition code 1). When the COMPARE AND SWAP instruction is successful (condition code 0), the flags contain valid data, and the program exits from the loop.

The branch to RETRY will be taken only if some other program modifies the contents of WORD. This type of a loop differs from the typical “bit-spin” loop. In a bit-spin loop, the program continues to loop until the bit changes. In this example, the program continues to loop only if the value does change during each iteration. If a number of CPUs simultaneously attempt to modify a single location by using the sample instruction sequence, one CPU will fall through on the first try, another will loop once, and so on until all CPUs have succeeded.

**Updating Counters**

In this example, a 32-bit counter is updated by a program using the COMPARE AND SWAP instruction to ensure that the counter will be correctly updated. The original value of the counter is obtained by loading the word containing the counter into general register 7. This value is moved into general register 8 to provide a modifiable copy, and general register 6 (containing an increment to the counter) is added to the modifiable copy to provide the updated counter value. The COMPARE AND SWAP instruction is used to ensure valid storing of the counter.

The program updating the counter checks the result by examining the condition code. The condition code 0 indicates a successful update, and the program can proceed. If the counter had been changed between the time that the program loaded its original value and the time that it executed the COMPARE AND SWAP instruction, the execution would have loaded the new counter value into general register 7 and set the condition code to 1, indicating an unsuccessful update. The program must then repeat the update sequence until the execution of the COMPARE AND SWAP instruction results in a successful update.

The following instruction sequence performs the above procedure:

```asm
LA  6,1 Put increment (1) into GR6
L  7,CNTR Put original counter value into GR7
```

The following shows two CPUs, A and B, executing this instruction sequence simultaneously: both CPUs attempt to add one to CNTR.

<table>
<thead>
<tr>
<th>CPU A</th>
<th>CPU B</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>GR7</td>

</tr>
</tbody>
</table>

**Bypassing Post and Wait**

See the MVS Programming: Authorized Assembler Services Guide (SA22-7608) for details on bypassing the z/OS WAIT and POST routines.

**Lock/Unlock**

When a common storage area larger than a double-word is to be updated, it is usually necessary to provide special interlocks to ensure that a single program at a time updates the common area. Such an area is called a serially reusable resource (SRR).

In general, updating a list, or even scanning a list, cannot be safely accomplished without first “freezing” the list. However, the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions can be used in certain restricted situations to perform queuing and list manipulation. Of prime importance is the capability to perform the lock/unlock functions and to provide sufficient queuing to resolve contentions, either in a LIFO or FIFO manner. The lock/unlock
functions can then be used as the interlock mechanism for updating an SRR of any complexity.

The lock/unlock functions are based on the use of a "header" associated with the SRR. The header is the common starting point for determining the states of the SRR, either free or in use, and also is used for queuing requests when contentions occur. Contentions are resolved using WAIT and POST. The general programming technique requires that the program that encounters a "locked" SRR must "leave a mark on the wall" indicating the address of an ECB on which it will WAIT. The "unlocking" program sees the mark and posts the ECB, thus permitting the waiting program to continue. In the two examples given, all programs using a particular SRR must use either the LIFO queuing scheme or the FIFO scheme; the two cannot be mixed. When more complex queuing is required, it is suggested that the queue for the SRR be locked using one of the two methods shown.

**Lock/Unlock with LIFO Queuing for Contentions**

The header consists of a word, that is, a four-byte field aligned on a word boundary. The word can contain zero, a positive value, or a negative value.

- A zero value indicates that the serially reusable resource (SRR) is free.
- A negative value indicates that the SRR is in use but no additional programs are waiting for the SRR.
- A positive value indicates that the SRR is in use and that one or more additional programs are waiting for the SRR. Each waiting program is identified by an element in a chained list. The positive value in the header is the address of the element most recently added to the list.

Each element consists of two words. The first word is used as an ECB; the second word is used as a pointer to the next element in the list. A negative value in a pointer indicates that the element is the last element in the list. The element is required only if the program finds the SRR locked and desires to be placed in the list.

The following chart describes the action taken for LIFO LOCK and LIFO UNLOCK routines. The routines following the chart allow enabled code to perform the actions described in the chart.

<table>
<thead>
<tr>
<th>Function</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LIFO LOCK</strong></td>
<td><strong>Header Contains Zero</strong></td>
</tr>
<tr>
<td>(the incoming element is at location A)</td>
<td>SRR is free. Set the header to a negative value. Use the SRR.</td>
</tr>
<tr>
<td><strong>LIFO UNLOCK</strong></td>
<td>Error</td>
</tr>
</tbody>
</table>

**LIFO LOCK Routine:**

**Initial Conditions:**

- GR1 contains the address of the incoming element.
- GR2 contains the address of the header.

```assembly
LLOCK SR 3,3 GR3 = 0
ST 3,0(1) Initialize the ECB
LNR 0,1 GR0 = a negative value
TRYAGN CS 3,0,0(2) Set the header to a negative value if the header contains zeros
BC 8,USE Did the header contain zeros?
ST 3,4(1) No, store the value of the header into the pointer in the incoming element
CS 3,1,0(2) Store the address of the incoming element into the header
LA 3,0(0) GR3 = 0
BC 7,TRYAGN Did the header get updated?
WAIT ECB=(1) Yes, wait for the resource; the ECB is in the incoming element
USE [Any instruction]
```
**LIFO UNLOCK Routine:**

Initial Conditions:

- GR2 contains the address of the header.

LUNLK L 1,0(2) GR1 = the contents of the header

A LTR 1,1 Does the header contain a negative value?

BC 4,B No, load the pointer

L 0,4(1) CS 1,0,0(2) from the 'last in' element and store it in the header

BC 7,A Did the header get updated?

POST (1) Yes, post the 'last in' element

BC 15,EXIT Continue

B SR 0,0 The header contains a negative value; free

CS 1,0,0(2) BC 7,A the header and continue

EXIT [Any instruction]

Note that the LOAD instruction L 1,0(2) at location LUNLK would have to be CS 1,1,0(2) if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD instruction to fetch a four-byte operand aligned on a word boundary such that, if another CPU changes the word being fetched by an operation which is also at least word-consistent, either the entire new or the entire old value of the word is obtained, and not a combination of the two. (See “Storage-Operand Consistency” on page 5-123.)

**Lock/Unlock with FIFO Queuing for Contentions**

The header always contains the address of the most recently entered element. The header is originally initialized to contain the address of a posted ECB. Each program using the serially reusable resource (SRR) must provide an element regardless of whether contention occurs. Each program then enters the address of the element which it has provided into the header, while simultaneously it removes the address previously contained in the header. Thus, associated with any particular program attempting to use the SRR are two elements, called the “entered element” and the “removed element.” The “entered element” of one program becomes the “removed element” for the immediately following program. Each program then waits on the removed element, uses the SRR, and then posts the entered element.

When no contention occurs, that is, when the second program does not attempt to use the SRR until after the first program is finished, then the POST of the first program occurs before the WAIT of the second program. In this case, the bypass-post and bypass-wait routines described in the preceding section are applicable. For simplicity, these two routines are shown only by name rather than as individual instructions.

In the example, the element need be only a single word, that is, an ECB. However, in actual practice, the element could be made larger to include a pointer to the previous element, along with a program identification. Such information would be useful in an error situation to permit starting with the header and chaining through the list of elements to find the program currently holding the SRR.

It should be noted that the element provided by the program remains pointed to by the header until the next program attempts to lock. Thus, in general, the entered element cannot be reused by the program. However, the removed element is available, so each program gives up one element and gains a new one. It is expected that the element removed by a particular program during one use of the SRR would then be used by that program as the entry element for the next request to the SRR.

It should be noted that, since the elements are exchanged from one program to the next, the elements cannot be allocated from storage that would be freed and reused when the program ends. It is expected that a program would obtain its first element and release its last element by means of the routines described in “Free-Pool Manipulation.”

The following chart describes the action taken for FIFO LOCK and FIFO UNLOCK.

<table>
<thead>
<tr>
<th>Function</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIFO LOCK</td>
<td>Store address A into the header.</td>
</tr>
<tr>
<td>(the incoming element is at location A)</td>
<td>WAIT; the ECB is at the location addressed by the old contents of the header.</td>
</tr>
<tr>
<td>FIFO UNLOCK</td>
<td>POST; the ECB is at location A.</td>
</tr>
</tbody>
</table>

The following routines allow enabled code to perform the actions described in the previous chart.

**FIFO Lock Routine:**

Initial conditions:
- GR3 contains the address of the header.
- GR4 contains the address, A, of the element currently owned by this program. This element becomes the entered element.

FLOCK LR 2,4 GR2 now contains address of element to be entered
SR 1,1 GR1 = 0
ST 1,0(2) Initialize the ECB
L 1,0(3) GR1 = contents of the header
TRYAGN CS 1,2,0(3) Enter address A into header while remembering old contents of header into GR1; GR1 now contains address of removed element
LR 4,1 Removed element becomes new currently owned element
HSWAIT Perform bypass-wait routine; if ECB already posted, continue; if not, wait; GR1 contains the address of the ECB

USE [Any instruction]

**FIFO Unlock Routine:**

Initial conditions:
- GR2 contains the address of the removed element, obtained during the FLOCK routine.
- GR5 contains 40 00 00 00₁₆

FUNLK LR 1,2 Place address of entered element in GR1; GR1 = address of ECB to be posted
SR 0,0 GR0 = 0; GR0 has a post code of zero
OR 0,5 Set bit 1 of GR0 to one
HSPOST Perform bypass-post routine; if ECB has not been waited on, then mark posted and continue; if it has been waited on, then post
CONTINUE [Any instruction]

**Free-Pool Manipulation**

It is anticipated that a program will need to add and delete items from a free list without using the lock/unlock routines. This is especially likely since the lock/unlock routines require storage elements for queuing and may require working storage. The lock/unlock routines discussed previously allow simultaneous lock routines but permit only one unlock routine at a time. In such a situation, multiple additions and a single deletion to the list may all occur simultaneously, but multiple deletions cannot occur at the same time. In the case of a chain of pointers containing free storage buffers, multiple deletions along with additions can occur simultaneously. In this case, the removal cannot be done using the COMPARE AND SWAP instruction without a certain degree of exposure.

Consider a chained list of the type used in the example in section “Lock/Unlock with LIFO Queuing for Contentions” on page A-48. Assume that the first two elements are at locations A and B, respectively. If one program attempted to remove the first element and was interrupted between the fourth and fifth instructions of the LUNLK routine, the list could be changed so that elements A and C are the first two elements when the interrupted program resumes execution. The COMPARE AND SWAP instruction would then succeed in storing the value B into the header, thereby destroying the list.

The probability of the occurrence of such list destruction can be reduced to near zero by appending to the header a counter that indicates the number of times elements have been added to the list. The use of a 32-bit counter guarantees that the list will not be destroyed unless the following events occur, in the exact sequence:

1. An unlock routine is interrupted between the fetch of the pointer from the first element and the update of the header.
2. The list is manipulated, including the deletion of the element referenced in 1, and exactly $2^{32}$ (or an integer multiple of $2^{32}$) additions to the list are performed. Note that this takes on the order of days to perform in any practical situation.
3. The element referenced in 1 is added to the list.
4. The unlock routine interrupted in 1 resumes execution.
The following routines use such a counter in order to allow multiple, simultaneous additions and removals at the head of a chain of pointers.

The list consists of a doubleword header and a chain of elements. The first word of the header contains a pointer to the first element in the list. The second word of the header contains a 32-bit counter indicating the number of additions that have been made to the list. Each element contains a pointer to the next element in the list. A zero value indicates the end of the list.

The following chart describes the free-pool-list manipulation.

<table>
<thead>
<tr>
<th>Function</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD TO LIST (the incoming element is at location A)</td>
<td>Store the first word of the header into location A. Store the address A into the first word of the header. Decrement the second word of the header by one.</td>
</tr>
<tr>
<td>DELETE FROM LIST</td>
<td>The list is empty. Set the first word of the header to the value of the contents of location A. Use element A.</td>
</tr>
</tbody>
</table>

The following routines allow enabled code to perform the free-pool-list manipulation described in the above chart.

**ADD TO FREE LIST Routine:**

Initial Conditions:

- GR2 contains the address of the element to be added.
- GR4 contains the address of the header.

ADDQ LM 0,1,0(4) GR0,GR1 = contents of the header
TRYAGN ST 0,4(2) Point the new element to the top of the list
LR 3,1 Move the count to GR3
AHI 3,1 Increment the count
CDS 0,2,0(4) Update the header
BC 7,TRYAGN

**DELETE FROM FREE LIST Routine:**

Initial conditions:

- GR4 contains the address of the header.

DELETQ LM 2,3,0(4) GR2,GR3 = contents of the header
TRYAGN LTR 2,2 Is the list empty?
BC 8,EMPTY Yes, get help
L 0,4(2) No, GR0 = the pointer from the first element
LR 1,3 Move the count to GR1
CDS 2,0,0(4) Update the header
BC 7,TRYAGN
USE [Any instruction] The address of the removed element is in GR2

**Notes:**

1. The LM (LOAD MULTIPLE) instructions at locations ADDQ and DELETQ would have to be CDS (COMPARE DOUBLE AND SWAP) instructions if it were not for the rule concerning storage-oper- and consistency. This rule requires the LOAD MULTIPLE instructions to fetch an eight-byte operand aligned on a doubleword boundary such that, if another CPU changes the doubleword being fetched by an operation which is also at least doubleword-consistent, either the entire new or the entire old value of the doubleword is obtained, and not a combination of the two. (See “Storage-Operand Consistency” on page 5-123.)

2. The add-to-free-list and delete-from-free-list examples shown above assume that the pointer to the next element in the list is in the second word of the element, as described “Lock/Unlock with LIFO Queuing for Contentions” on page A-48.

**PERFORM LOCKED OPERATION (PLO)**

The PERFORM LOCKED OPERATION instruction can be used in a multiprogramming or multiprocess- ing environment to perform compare, load, compare-and-swap, and store operations on two or more dis- contiguous locations that can be words or double- words. The operations are performed as an atomic set of operations under the control of a lock that is held only for the duration of the execution of a single PERFORM LOCKED OPERATION instruction, as opposed to across the execution of multiple instruc- tions. Since lock contention is resolved by the CPU and is very brief, the program need not include a method for dealing with the case when the lock to be
used is held by a program being executed by another CPU. Also, there need be no concern that the program may be interrupted while it holds a lock, since PERFORM LOCKED OPERATION will complete its operation and release its lock before an interruption can occur.

PERFORM LOCKED OPERATION can be thought of as performing concurrent interlocked updates of multiple operands. However, the instruction does not actually perform any interlocked update, and a serially reusable resource cannot be updated predictably through the use of both PERFORM LOCKED OPERATION and conditional-swapping instructions (CS and CDS).

Following is an example of how PERFORM LOCKED OPERATION can be used to add an element at the beginning of a queue.

Assume the following variables associated with the queue: S, which is a sequence number that is incremented anytime the queue is changed; H (for head), which is the address of the first element on the queue; and C, which is a count of the number of elements on the queue. Assume a queue element contains a variable, F (for forward), which is the address of the next element on the queue. If a new element, N, is to be enqueued at the head of the queue, that can be done by setting F in N to H and then performing the following atomic set of operations:

\[
\begin{align*}
S+1 & \rightarrow S \\
A(N) & \rightarrow H \\
C+1 & \rightarrow C
\end{align*}
\]

where A(N) is the address of N.

The enqueueing of N can be done by means of the following steps:

1. Obtain consistent values of S, H, and C, meaning obtain S and obtain the H and C that are consistent with that value of S.
2. Store H in N.F.
3. By means of PLO.csdst (PERFORM LOCKED OPERATION performing compare and swap and double store), with S as the swap variable and H and C as the store variables, add one to S, set H to A(N), and add one to C, provided that S still has the value obtained in step 1. If S has already been changed, go back to step 1.

Consistent values of S, H, and C cannot necessarily be obtained simply by using three LOAD instructions because a PERFORM LOCKED OPERATION instruction being executed by another CPU may have completed an update of S but not yet of H or C. In this case, the three LOAD instructions will obtain the new S but the old H or C. However, as will be described, it may be possible to use three LOAD instructions.

If S is obtained while holding the lock, meaning by means of PERFORM LOCKED OPERATION, then H and C can be obtained by LOAD instructions since no other CPU can subsequently change H or C without changing S, as observed when the lock is held.

The parameter list used by the PLO.csdst is as follows, assuming the access-register mode is not used:

<table>
<thead>
<tr>
<th>Address</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>40</td>
<td></td>
</tr>
<tr>
<td>48</td>
<td>A(N)</td>
</tr>
<tr>
<td>56</td>
<td></td>
</tr>
<tr>
<td>64</td>
<td>A(H)</td>
</tr>
<tr>
<td>72</td>
<td></td>
</tr>
<tr>
<td>80</td>
<td>C+1</td>
</tr>
<tr>
<td>88</td>
<td></td>
</tr>
<tr>
<td>96</td>
<td></td>
</tr>
<tr>
<td>104</td>
<td>A(C)</td>
</tr>
</tbody>
</table>

The program is as follows:

```
LA RT,H Initialize addresses in PL (T = temp)  
ST RT,PL+76 Op4 address (address of H)  
LA RT,C  
ST RT,PL+108 Op6 address (address of C)  
LA RN,N Address of N  
ST RN,PL+60 Initialize op3 in PL (address of N)  
LA R1,S PLT address = address of S  
SR RS,RS Dummy S. CC1 will probably be set  
SR R0,R0 Function code 0 (compare and load)
```
PLO   RS,S,RS,S Obtain S while holding lock
------------------------------------------
LA   R0,16     Function code 16 (csdst)
LOOP L  RT,H    Consistent H
ST  RT,OFSTF(RN) OFSTF = offset of F in N
   RT,C    Consistent C
LA  RT,1(RT) C+1
ST  RT,PL+92 Initialize op5 in PL
       (C+1)
LA  RSP,1(RS) RS/RSP = even-odd pair.
       S+1 in RSP
PLO   RS,S,0,PL
BNZ LOOP   Br if S changed (if CC not 0)

Note the following about the first PERFORM LOCKED OPERATION instruction (PLO.cl). If S is not zero (which is probably true), S (the second operand, op2) is loaded into RS (the first-operand comparison value, op1c). If S is zero, S (the fourth operand, op4) is loaded into RS (the third operand, op3). Either of these loads occurs while the lock is held. It is unnecessary to test the condition code to determine which load occurred.

The above program may be a simplification. If the queue has associated with it a variable, T (for tail), that is the address of the last element on the queue, and the queue is currently empty. T also must be set when N is added to the queue. This would require a different program using a compare-and-swap-and-triple-store operation.

If the queue is added to, deleted from, and rearranged by means of PERFORM LOCKED OPERATION instructions in which the sequence number, S, is always the second operand, then, since the definition of PERFORM LOCKED OPERATION specifies that the second operand is always stored last, the first PERFORM LOCKED OPERATION instruction in the above program can be replaced by a LOAD instruction. The three instructions within the dashed lines would be replaced by L RS,S.

---

**Sorting Instructions**

**Tree Format**

Two instructions, COMPARE AND FORM CODE-WORD and UPDATE TREE, refer to a tree — a data structure with a specific format. A tree consists of some number (always odd) of consecutively numbered nodes. Node 1 is the root of the tree. Every node except the root has one parent node in the same tree. Every parent node has two son nodes. Every even-numbered node is the leftson of its parent node, and every odd-numbered node (except node 1) is the rightson of its parent node. Division by two (ignoring remainder) of the node number gives the parent node number. Nodes with sons are also called internal nodes, and nodes without sons are called terminal nodes. Figure A-5 on page A-54 illustrates schematically a 21-node tree with arrows drawn from each parent node to each son node.

A tree is used for merging several sorted sequences of records into a single merged sequence of records. At each step in the merging process, there exists the initial part of the merged sequence and the remaining parts of each of the sorted sequences that are being merged. Each step consists in selecting the lowest record (the record with the lowest key when sorting in ascending sequence) from all of the as yet unmerged parts of the sorted sequences and adding it to the merged sequence. Each terminal node in the tree represents one of the sorted sequences. The number of internal nodes in the tree is one less than the number of sorted sequences. Each internal node conceptually contains one record from each of the sorted sequences but one; these are the lowest records, from all but one of the sorted sequences, that have not yet been added to the merged sequence. In addition, there is the lowest record from the one remaining sorted sequence. This additional record is compared and interchanged with nodes of the tree to select the record to be added next to the merged sequence. This processing begins with the parent of the terminal node that represents the one remaining sorted sequence, and it continues from that node along the path to the root of the tree. The selected record emerges from the root of the tree.

The tree may perhaps be most easily explained by considering each node to represent a comparison operation in an “elimination tournament” to find the lowest record. After the tournament has been com-
pleted, each node has an associated "loser" record which had a higher key in the comparison represented by that node. Besides a loser record at each node, there is one record (the "winner") which is not associated with any node since it never compared high. The next step would be to introduce a new record from the same sorted sequence from which the winner record originated and replay the tournament with the new record in place of the former winner. It can be seen that it is unnecessary to do all the comparisons represented by all the nodes in the tree — most of them are unaffected by the new record replacing the former winner. In fact, it is sufficient to redo only those node comparisons in which the former winner record participated. Each new record is inserted into the tree at the terminal node that represents the sorted sequence containing the record. The use of the tree assumes that programming provides a method of remembering at which terminal node each winning record originated. The instruction UPDATE TREE allows for a new record to be inserted at a terminal node and the tree to be updated so that a new winner record is left in the general registers.

Rather than comparing the actual keys of records, much of the merge logic can be performed using "codewords" to represent a record key rather than referring to actual keys. The value of a codeword at a node in the tree depends not only on the record's key but also on the key of the winning record in the last comparison at that node. The codeword consists of two parts:

1. Bits 16-31 contain the one’s complement of the first halfword in which the record key differs from that of the node’s winning record.

2. Bits 0-15 specify the byte offset of the halfword in this record’s key just beyond the halfword value (complemented) in bit positions 16-31.

When comparing records in the path of the last winner record, if the new record is also represented by a codeword resulting from a comparison with the last winner, all codewords in the update path are with respect to the same winner. When comparing such codewords, a high codeword represents a low key and vice versa. Thus, when codewords are unequal, a node entry with a high codeword (representing a low actual key) should move up the tree.

In the case of a tie value of codewords, it is necessary to refer to the actual keys. This is done by the instruction COMPARE AND FORM CODEWORD, which resolves the ambiguity and computes a new codeword for the high-key (loser) record.

The eight bytes at each node of a tree consist of (1) a codeword for this record, computed with respect to the last record which compared low against this record and (2) a parameter usable to locate this record, for example, a direct or indirect address.

The instruction UPDATE TREE is so defined that tree updating stops after equal codewords are detected and the tie-breaking instruction COMPARE AND FORM CODEWORD can be used, after which UPDATE TREE can resume tree updating at the point where equal codewords were previously found.

COMPARE AND FORM CODEWORD may alternatively be used for merging in descending sequence. In that case, bits 16-31 of the codeword at a node contain the true value of the first halfword in which the record key differs from that of the node’s winning record. When the descending option of COMPARE AND FORM CODEWORD is used, the higher of two codewords represents the higher key.

![Schematic Diagram of Merge Control Tree with 21 Nodes](image-url)
Example of Use of Sort Instructions

An example illustrates how the instructions UPDATE TREE and COMPARE AND FORM CODEWORD may be used in the merge operation within a sort program. A five-way merge requires a tree data structure with four internal nodes and five terminal-node positions. The schematic diagram shown later in this section illustrates such a tree, containing four internal nodes (not counting the dummy node) and five input sequences for a merge, one sequence at each terminal-node position. Each record in an input sequence in the diagram is indicated by its address. The actual record contents are shown in Figure A-7 on page A-58. Each record contains 16 bytes, consisting of the following fields:

<table>
<thead>
<tr>
<th>Byte Offset (hexadecimal)</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-5</td>
<td>Six-byte record key.</td>
</tr>
<tr>
<td>6-7</td>
<td>Halfword node index specifying the input sequence of the next record of this input sequence.</td>
</tr>
<tr>
<td>8-B</td>
<td>Address of the next record in the same input sequence.</td>
</tr>
<tr>
<td>C-F</td>
<td>This chaining field is initially zero. At the completion of the merge, this field is to contain the address of the next record in the merged sequence.</td>
</tr>
</tbody>
</table>

The merge process forms a single sorted sequence from five input sequences, each of which is in sorted order. This process can be subdivided into three steps:

1. A priming step takes the first record from each of the five input sequences and places them in the tree data structure. For each record to be introduced into the tree, first its codeword value is computed with respect to the lowest possible key value of all zeros. This codeword, with a second word which contains the address of the record represented by that node value, forms a doubleword node value that can be placed at the appropriate node. After priming, the node values, one each from each of the five input sequences, will have been placed in the tree so that each of the four internal nodes contains one node value and the node value for a winner record has emerged from the root of the tree.

2. After each winner emerges from the tree, the main merge process is performed repeatedly. Each iteration introduces the node value for one new record into the tree and produces a node value for a new winner record. The tree plus the winner must at all times contain precisely one node value from each input sequence being merged. Therefore, the new node value that is introduced into the tree on each iteration must come from the same input sequence from which the winner node value in the preceding iteration originated.

3. When the node value for the last record of an input sequence emerges as a winner, there is no successor record from that input sequence to be introduced into the tree on the next iteration. Hence, the order of the merge must be reduced by one for each such occurrence. This runout process will consist of one or more iterations for each of a four-way, three-way, two-way, and one-way merge. The onset of runout occurs in the example when it is found that the next input record from a sequence is lower than its predecessor (a sequence break).

The priming process is discussed next, and the state of the tree is shown after priming is complete. Then, a short program that uses the instructions UPDATE TREE and COMPARE AND FORM CODEWORD to perform the main merge is described. An abbreviated trace is then presented to show the status of the tree and certain general registers for 16 iterations of the main merge. The runout process is not discussed in this example.

Priming begins by forming the node value for the first record of each input sequence. The first word of the node value is the codeword formed by executing COMPARE AND FORM CODEWORD on a record key containing all binary zeros. The second word of the node value is the address of the record represented by that node value. The node values for the first record of each input sequence are:

<table>
<thead>
<tr>
<th>Sequence Index</th>
<th>Node Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>0006 FFFC 0000 1030</td>
</tr>
<tr>
<td>30</td>
<td>0006 FFFB 0000 1040</td>
</tr>
<tr>
<td>38</td>
<td>0006 FFFA 0000 1050</td>
</tr>
<tr>
<td>40</td>
<td>0004 FFTE 0000 1080</td>
</tr>
<tr>
<td>48</td>
<td>0006 FFF9 0000 1069</td>
</tr>
</tbody>
</table>

In the example, the tree data structure is assumed to have base address X’1000’, which is kept in general register 4 (to match the expected use in UPDATE TREE). Similarly, internal-node index values and

A-55
input-sequence index values are always used from general register 5.

Although the tree-priming program is not part of this example, the UPDATE TREE instruction is used in creating it as follows. First, the codeword position for each internal node of the tree is initialized to all ones (X’FFFFFFF’). This artifice fills the tree with dummy low records. Then, for each record in the table, (1) the sequence index is loaded into general register 5, (2) the node value is loaded into general registers 0 and 1, and (3) UPDATE TREE is executed. At the completion of this priming process, the tree-node contents in the example are as shown on line 0 of Figure A-9 on page A-60. The contents of the general registers are as shown on the first line of Figure A-8 on page A-59.

The figure illustrating the program for the main merge is divided into three groups of columns, containing the absolute program, the general-register trace, and the symbolic program. The first part of the program extends from symbolic locations L1 through L2; it introduces a new record into the tree and executes an UPDATE TREE instruction. If no tied codewords are encountered in UPDATE TREE, then the BRANCH ON CONDITION instruction following UPDATE TREE loops back to L1 to introduce the next record into the tree. This BRANCH ON CONDITION instruction is suitable for use when UPDATE TREE operates in accordance with either its method 1 (setting condition code 1) or its method 2 (setting condition code 3). (The preceding sentence applies to 370-XA. In ESA/370 and ESA/390, UPDATE TREE operates in accordance with only method 2, which is not to say that it cannot set condition code 1. Method 2, but not method 1, tests for the condition that sets condition code 3.)

If UPDATE TREE encounters tied codewords, then the UPDATE TREE instruction is completed, the subsequent BRANCH ON CONDITION instruction does not branch, and control falls through to the second part of the program, which handles entries with tied codewords. This part then branches back to UPDATE TREE at L2, which resumes the tree updating. It is possible for tied codewords to be encountered at any level in the tree (or indeed at all levels), so that the tied-codeword part of the program may be entered up to three times for each record introduced.

The general-register trace for the first part of the main merge shows the contents of the first seven general registers after each instruction is executed during the first iteration. Note that the merged-chain field (at 1140) serves as the anchor for the merged-chain address chain through the records. The trace shows only the lower half of certain general registers, whose upper half is always zero.

Figure A-9 on page A-60 gives an abbreviated trace of the entire main merge of 16 records. For each record introduced into the tree, there are one or more lines (always an odd number) given in the figure to show the tree updating, which results finally in a winner in GR0 and GR1. The first line for each record shows the values of GR5, GR2, and GR3 before the first or only execution of UPDATE TREE. For the even-numbered lines, the storage updating by UPDATE TREE of tree nodes is shown (read left to right to follow the order of swapping). For example, consider line 10 and the corresponding UPDATE TREE: since GR5 contains 28, the first storage node examined is 1010 (refer to the schematic diagram). Since the codeword in GR0 is 0004 FFFE (same as for GR2), which is less than that of the word at 1010 (0006 FFF0), the doubleword at 1010 is swapped with that in GR0 and GR1. A second comparison at 1008 in the same execution of UPDATE TREE causes another register-storage doubleword swap, which leaves the winner (record 1040) in GR1 at the completion of UPDATE TREE (see the column at the far right of Figure A-9 on page A-60).

When a codeword comparison is made which does not result in a tie or a swap (that is, when the storage-codeword value is low), an asterisk appears in the trace for that storage entry.

When equal codewords are found, the execution of UPDATE TREE is completed. The following line in each such case shows the result of the tied-codeword routine, which always stores a new codeword and may also store a new record address before branching back to L2 to execute UPDATE TREE again. In this line, the notation “loses” or “wins” means that the node loses or wins, respectively.

The tie-break trace part of Figure A-8 on page A-59 shows the treatment of the third record (that is, the first record for which UPDATE TREE encounters a tied codeword). This corresponds to line 31 in Figure A-9 on page A-60.

The following is a summary of the steps that are needed to use this example for verification purposes:

1. Initialize storage as follows:
a. 1008 through 102F from line 0 of Figure A-9 on page A-60

b. 1030 through 114F from Figure A-7 on page A-58

c. 1150 through 1189 from Figure A-8 on page A-59

2. Initialize GRs per first line in Figure A-8 and trace first record per Figure A-8.

3. Trace to completion of each UPT or BC 15,L2 (once for each line of Figure A-9). A detailed trace of the GRs for the tied-codeword part of line 31 of Figure A-9 is given in the lower part of Figure A-8.

4. Verify that addresses in the chain beginning at 103C and continuing through 114C are as shown in the right-hand column of Figure A-7.

Note: Each node and input sequence is identified by a number which is the hexadecimal node index. Each input sequence is given as a list of record addresses (also in hexadecimal).

</table>

**Explanation:**

1 Line 0 shows the values in the tree after it is primed.
2 Means no swap.
3 ** Means no swap if UPDATE TREE method 1 is used or no examination if UPDATE TREE method 2 is used. Only method 2 is included in ESA/370 and ESA/390.
4 CC = 0 UPDATE TREE finds a tie and sets condition code 0.
5 Loses The tied-codeword routine finds that the node loses.
6 Wins The tied-codeword routine finds that the node wins.
7 Equal The tied-codeword routine finds that the keys are equal.
8 Branch Branches to terminate at 118A on sequence break.
9 No comp No compare.

*Figure A-9. Abbreviated Trace of Main Merge Processing*
Appendix B. Lists of Instructions

The following figures list instructions by name, mnemonic, and operation code. Some models may offer instructions that do not appear in the figures, such as those provided for assists or as part of special or custom features.

The operation code for the interpretive execution facility is not included in this appendix. See the publication IBM System/370 Extended Architecture Interpretive Execution, SA22-7095, for the operation code associated with that facility.

The operation code 00 hex with a two-byte instruction format is allocated for use by the program when an indication of an invalid operation is required. Operation code 00 hex will never be assigned to an instruction implemented in the CPU.

Explanation of Symbols in “Characteristics” and “Page” Columns:

$ Causes serialization.
¢ Causes serialization and checkpoint synchronization.
¢1 Causes serialization and checkpoint synchronization when the M1 and R2 fields contain 1111 binary and 0000 binary, respectively. Causes only serialization when the fast-BCR-serialization facility is installed, and the M1 and R2 fields contain 1110 binary and 0000 binary, respectively.
¢2 Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.
¢3 Causes serialization and checkpoint synchronization when the set-key control is one.
£ Causes specific-operand serialization.
£1 Causes specific-operand serialization when the interlocked-access facility 1 is installed and the storage operand is aligned on an integral boundary corresponding to its size.
£2 Causes specific-operand serialization when the interlocked-access facility 2 is installed.
σ1 Restricted from transactional execution.
σ2 Restricted from transactional execution when R2 nonzero and branch tracing is enabled.
σ3 Restricted from transactional execution when mode tracing is enabled.
σ4Restricted from transactional execution when a monitor-event condition occurs.
σ5 Model dependent whether the instruction is restricted from transactional execution.
σ6 Restricted from transactional execution when the effective allow-AR-modification control is zero.
σ7 Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
σ8 May be restricted from transactional execution depending on machine conditions.
σ9 Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized. For PFD and PFDRL, the instruction is restricted only when the code in the M1 field is 6 or 7; for STCMH, the instruction is restricted only when the M3 field is zero and the code in the R1 field is 6 or 7.
σ10 Restricted to forward branches in the constrained transactional-execution mode.
σ11 PFD and PFDRL restricted from transactional execution when the code in the M1 field is 6 or 7; STCMH restricted when the M3 field is zero, and the code in the R1 field is 6 or 7.
A* Access exceptions for logical addresses. The optional asterisk indicates that a PER ZAD event is not recognized.
A1* Access exceptions; not all access exceptions may occur; see instruction description for details. The optional asterisk indicates that a PER ZAD event is not recognized.
A1 Access exceptions for instruction address.
B PER branch event.
B1 B1 field designates an access register in the access-register mode.
B2 B2 field designates an access register in the access-register mode.
B4 B4 field designates an access register in the access-register mode.
B† B1 field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.
| B‡ | B§ field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary. |
| BP | B§ field designates an access register when PSW bits 16 and 17 have the value 01. |
| C  | Condition code is set. |
| C* | Condition code is optionally set. |
| C¹ | Condition code is set when the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one. |
| CT | Configuration-topology facility. |
| CX | Constrained transactional-execution facility. |
| C2 | DAT-enhancement facility 2. |
| Da | AFP-register data exception. |
| Db | BFP-instruction data exception. |
| Dc | Compare-and-trap data exception. |
| DE | DAT-enhancement facility. |
| DF | Decimal-overflow exception. |
| Dg | General-operand data exception. |
| DK | Decimal-divide exception. |
| DM | Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code. |
| DO | Distinct-operands facility. |
| Dt | DFP-instruction data exception. |
| Dv | Vector-instruction data exception. |
| E  | E instruction format. |
| E2 | Extended-translation facility 2. |
| E3 | Extended-translation facility 3. |
| ED1 | Enhanced-DAT facility 1. |
| ED2 | Enhanced-DAT facility 2. |
| EH | Execution-hint facility. |
| EI | Extended-immediate facility. |
| EO | HFP-exponent-overflow exception. |
| ES | Expanded-storage facility. |
| ET | Extract-CPU-time facility. |
| EU | HFP-exponent-underflow exception. |
| EX | Execute exception. |
| F  | Floating-point-extension facility. |
| FC | Designation of access registers depends on the function code of the instruction. |
| FG | FPR-GR-transfer facility. |
| FK | HFP-floating-point-divide exception. |
| FL | Store-facility-list-extended facility. |
| FS | Floating-point-support-sign-handling facility. |
| G0 | Instruction execution includes the implied use of general register 0. |
| G1 | Instruction execution includes the implied use of general register 1. |
| G2 | Instruction execution includes the implied use of general register 2. |
| G4 | Instruction execution includes the implied use of general register 4. |
| GE | General-instructions-extension facility. |
| GM | Instruction execution includes the implied use of multiple general registers. |
| GS | Instruction execution includes the implied use of general register 1 as the subsystem-identification word. |
| HM | HFP-multiply-add/subtract facility. |
| HW | High-word facility. |
| I  | I instruction format. |
| IE | IE instruction format. |
| I1 | Access register 1 is implicitly designated in the access-register mode. |
| I4 | Access register 4 is implicitly designated in the access-register mode. |
| IC | Condition code alternative to interruptible instruction. |
| IF | Fixed-point-overflow exception. |
| IA | Interlocked-access facility. |
| I1 | Interruptible instruction. |
| IK | Fixed-point-divide exception. |
| LS | HFP-significance exception. |
| L  | New condition code is loaded. |
| LD | Long-displacement facility. |
| LT | Load-and-trap facility. |
| LZ | Load-and-zero-rightmost-byte facility. |
| L1 | Load/store-on-condition facility 1. |
| L2 | Load/store-on-condition facility 2. |
| MD | Designation of access registers in the access-register mode is model-dependent. |
| ME | Monitor event. |
| MI | Miscellaneous-instruction-extensions facility. |
| MII | MII instruction format. |
| MO | Move-with-optional-specifications facility. |
| MS | Message-security assist. |
| M3 | Message-security assist extension 3. |
| M4 | Message-security assist extension 4. |
| M5 | Message-security assist extension 5. |
| N  | Instruction is new in z/Architecture as compared to ESA/390. |
N3  Instruction is new in z/Architecture and has been added to ESA/390.
OP  Operand exception.
P   Privileged-operation exception; also, restricted from transactional execution.
PA  Processor-assist facility.
PC  DFP packed-conversion facility.
PK  Population-count facility.
PE  Parsing-enhancement facility.
PF  PFPO facility.
Q   Privileged-operation exception for semiprileged instructions; also, restricted from transactional execution.
R1  R1 field designates an access register in the access-register mode.
R2  R2 field designates an access register in the access-register mode.
R3  R3 field designates an access register in the access-register mode.
RA  Reusable-ASN-and-LX facility.
RB  Reset-reference-bits-multiple facility.
RI  RI instruction format.
RIE RIE instruction format.
RIL RIL instruction format.
RIS RIS instruction format.
RM  R1 field designates an access register in the access-register mode.
RR  RR instruction format.
RRD RRD instruction format.
RRE RRE instruction format.
RRF RRF instruction format.
RRS RRS instruction format.
RS  RS instruction format.
RSI RSI instruction format.
RSL RSL instruction format.
RSY RSY instruction format.
RX  RX instruction format.
RXE RXE instruction format.
RXF RXF instruction format.
RXY RXY instruction format.
S   S instruction format.
SC  Store-clock-fast facility.
SE  Special operation, stack-empty, stack-specification, and stack-type exceptions.
SF  Special-operation, stack-full, and stack-specification exceptions.
SI  SI instruction format.
SIL SIL instruction format.
SIY SIY instruction format.
SMI SMI instruction format.
SO  Special-operation exception.
SP  Specification exception.
SQ  HFP-square-root exception.
SS  SS instruction format.
SSE SSE instruction format.
SSF SSSF instruction format.
ST  PER storage-alteration event.
SU  PER store-using-real-address event.
SW  Special-operation exception and space-switch event.
T   Trace exceptions (which include trace table, addressing, and low-address protection).
TF  Decimal-floating-point facility.
TR  Decimal-floating-point-rounding facility.
TS  TOD-clock-steering facility.
TX  Transactional-execution facility.
U   Condition code is unpredictable.
U1  R1 field designates an access register unconditionally.
U2  R2 field designates an access register unconditionally.
UB  R1 and R3 fields designate access registers unconditionally, and B2 field designates an access register in the access-register mode.
UE  HFP unnormalized-extensions facility.
VF  Vector facility for z/Architecture.
VRI VRI instruction format.
VRR VRR instruction format.
VRS VRS instruction format.
VRX VRX instruction format.
VRF VRF instruction format.
WE  Space-switch event.
XF  IEEE-exception-simulation facility.
Xg  Simulated IEEE exception.
Xi  IEEE invalid-operation exception.
Xo  IEEE overflow exception.
Xq  Quantum exception (if the floating-point extension facility is installed).
Xu  IEEE underflow exception.
XX  Execute-extension facility.
Xx  IEEE inexact exception.
Xz  IEEE division-by-zero exception.
ZF  Decimal-floating-point-zoned-conversion facility.
Z\(^1\)  Additional exceptions and events for PROGRAM CALL (which include ASX-translation, EX-translation, LX-translation, PC-translation-specification, special-operation, stack-full, and stack-specification exceptions and space-switch event).
Z\(^2\)  Additional exceptions and events for PROGRAM TRANSFER (which include AFX-translation, ASX-translation, primary-authority, and special-operation exceptions and space-switch event).
Z\(^3\)  Additional exceptions for SET SECONDARY ASN (which include AFX translation, ASX translation, secondary authority, and special operation).
Z\(^4\)  Additional exceptions and events for PROGRAM RETURN (which include AFX-translation, ASX-translation, secondary-authority, special-operation, stack-empty, stack-operation, stack-specification, and stack-type exceptions and space-switch event).
Z\(^5\)  Additional exceptions for BRANCH AND STACK (which include special operation, stack full, and stack specification).
Z\(^6\)  Additional exceptions and events for PROGRAM TRANSFER WITH INSTANCE (which include AFX-translation, ASTE-instance, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).
Z\(^7\)  Additional exceptions for SET SECONDARY ASN WITH INSTANCE (which include AFX translation, ASTE instance, ASX translation, secondary authority, special operation, and subspace replacement).

Figure B-3. Instructions Arranged by Operation Code (Part 22 of 22)
Appendix C. Condition-Code Settings

This appendix lists the condition-code setting for instructions in z/Architecture which set the condition code. In addition to those instructions listed which set the condition code, the condition code may be changed by DIAGNOSE and the target of EXECUTE. The condition code is loaded by LOAD PSW, LOAD PSW EXTENDED, PROGRAM RETURN, RESUME PROGRAM, and SET PROGRAM MASK and by an interruption. The condition code is set to zero by initial CPU reset and is loaded by the successful conclusion of the initial-program-loading sequence.

Some models may offer instructions which set the condition code and do not appear in this document, such as those provided for assists or as part of special or custom features.

Figure C-1. Summary of Condition-Code Settings (Part 6 of 7)
### Explanation and Notes:

1. Code is not set by the instruction.
2. For DIAGNOSE, the resulting condition code is model-dependent.
3. For LOAD REAL ADDRESS, condition code 3 is set if address-space-control element not available, region-table entry outside table or invalid, segment-table entry outside table, or, for LRA in 24- or 31-bit mode when bits 0-32 of entry address not all zeros, segment- or page-table entry invalid.
4. For LOAD PSW, LOAD PSW EXTENDED, and RESUME PROGRAM, the condition code is loaded from the condition-code field of the second operand.
5. For SET PROGRAM MASK, the condition code is loaded from bit positions 2 and 3 of the first operand.
6. For various vector-facility instructions, the condition code is optionally set based on the CS control in the M₃ field of the instruction.

**Figure G-1. Powers of 2**
Appendix H. Hexadecimal Tables

The following tables aid in converting hexadecimal values to decimal values, or the reverse.

**Direct Conversion Table**

This table provides direct conversion of decimal and hexadecimal numbers in these ranges:

<table>
<thead>
<tr>
<th>Hexadecimal</th>
<th>Decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>000 to FFF</td>
<td>0000 to 4095</td>
</tr>
</tbody>
</table>

To convert numbers outside these ranges, and to convert fractions, use the hexadecimal and decimal conversion tables that follow the direct conversion table in this appendix.
### Conversion Table: Hexadecimal and Decimal Integers

#### POWERS OF 16 TABLE

<table>
<thead>
<tr>
<th>Hex</th>
<th>Decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>256</td>
</tr>
<tr>
<td>3</td>
<td>4096</td>
</tr>
<tr>
<td>4</td>
<td>65536</td>
</tr>
<tr>
<td>5</td>
<td>1048576</td>
</tr>
</tbody>
</table>

#### EXAMPLE

**Conversion of Hexadecimal Value D34**

1. D  = 3328
2. 3  = 48
3. 4  = 4
4. Decimal  = 3380

#### EXAMPLE

**Conversion of Decimal Value 3380**

1. D  = -3328
2. 3  = -48
3. 4  = -4
4. Hexadecimal  = D34

#### TO CONVERT HEXADECIMAL TO DECIMAL

1. Locate the column of the decimal numbers corresponding to the leftmost digit or letter of the hexadecimal; select from this column and record the number that corresponds to the position of the hexadecimal digit or letter.
2. Repeat step 1 for the next (second from the left) position.
3. Repeat step 1 for the units (third from the left) position.
4. Add the numbers selected from the table to form the decimal number.

**HEXADECIMAL TO DECIMAL**

Successive cumulative multiplication from left to right, adding units position.

**Example:**

\[D34_{16} = 3380_{10}\]

\[D = 13\]
\[3 = + 3\]
\[4 = + 4\]
\[3380\]

#### TO CONVERT DECIMAL TO HEXADECIMAL

1. (a) Select from the table the highest decimal number that is equal to or less than the number to be converted.
   (b) Record the hexadecimal of the column containing the selected number.
   (c) Subtract the selected decimal from the number to be converted.
2. Using the remainder from step 1(c), repeat all of step 1 to develop the second position of the hexadecimal (and a remainder)
3. Using the remainder from step 2, repeat all of step 1 to develop the units position of the hexadecimal.
4. Combine the terms to form the hexadecimal number.

**DECIMAL TO HEXADECIMAL**

Divide and collect the remainder in reverse order.

**Example:**

\[3380_{10} = X_{16}\]

\[16\mid 3380 \rightarrow 4\]
\[16\mid 211 \rightarrow 3\]
\[16\mid 13 \rightarrow D\]
\[3380_{10} = D34_{16}\]

### TO CONVERT .ABC HEXADECIMAL TO DECIMAL

1. Find .A in position 1 = .6250
2. Find .0B in position 2 = .0429 6825
3. Find .00C in position 3 = .0029 2968 7500
4. .ABC is equal to .6708 9843 7500

### TO CONVERT .13 DECIMAL TO HEXADECIMAL

1. Find .1250 next lowest to .1300 subtract = .1250 = .2 Hex
2. Find .0039 0625 next lowest to .0050 0000 subtract = .0039 0625 = .01
3. Find .0009 7656 2500 subtract = .0009 7656 2500 = .004
4. Find .0001 0681 5234 375 subtract = .0001 0681 523 4375 = .0007
5. .13 Decimal is approximately equal to .2147 Hex

---

To convert fractions beyond the capacity of the table, use techniques below:

### HEXADECIMAL TO FRACTION DECIMAL

Convert the hexadecimal fraction to its decimal equivalent using the same technique as for integer numbers. Divide the results by 16^n (n is the number of fraction positions).

**Example:**

\[
.8A7_{16} = \frac{.540771}{16^3} = 0.00000002215_{10}
\]

### DECIMAL FRACTION TO HEXADECIMAL

Collect integer parts of product in the order of calculation.

**Example:**

\[
.5408_{10} = .8A7_{16}
\]
**Hexadecimal Addition and Subtraction Table**

Example: $6 + 2 = 8$, $8 - 2 = 6$, and $8 - 6 = 2$

authority table (AT) 5-30
designation 3-29, 5-59
length 3-29, 5-59
origin 3-29, 5-59
authorization
ASN 3-32
index (AX) 3-32, 5-30
key mask (AKM) 5-38
mechanisms 5-28
summary of 5-32
testing of 5-75
authorization check 16-52
indicator for (in ERW) 16-52
automatic reconfiguration 1-28
auxiliary storage 3-2, 3-35
availability (characteristic of a system) 1-32
AW (ADD UNNORMALIZED) HFP instruction 18-9
AWR (ADD UNNORMALIZED) HFP instruction 18-9
AX (authorization index) 3-32, 5-30
AXBR (ADD) BFP instruction 19-15
AXR (ADD NORMALIZED) HFP instruction 18-8
AY (ADD) binary instruction 7-25

B
B field of instruction 5-11
backed-up bit (machine-check condition) 11-17
backup
processing (synchronous machine-check condition) 11-17
backward stack-entry address 5-81
backward stack-entry validity bit 5-81
BAKR (BRANCH AND STACK) instruction 10-10
examples A-10
BAL (BRANCH AND LINK) instruction 7-34
examples A-8
BALR (BRANCH AND LINK) instruction 7-34
examples A-8
BAS (BRANCH AND SAVE) instruction 7-35
example A-8
base address 5-11
register for 2-4
base-AST-entry origin (BASTEO) 5-68
base-authority state 10-7
base space 5-17
base-space bit 5-69
basic addressing mode
bit in entry-table entry 5-38
basic I/O functions 15-1
basic PROGRAM CALL 5-73, 10-89
BASR (BRANCH AND SAVE) instruction 7-35
example A-8
BASSM (BRANCH AND SAVE AND SET MODE) instruction 7-36
example A-8
BASTEO (base-AST-entry origin) 5-68
BC (BRANCH ON CONDITION) instruction 7-37
example A-12
BCR (BRANCH ON CONDITION) instruction 7-37
BCT (BRANCH ON COUNT) instruction 7-38
example A-12
BCTG (BRANCH ON COUNT) instruction 7-38
BCTGR (BRANCH ON COUNT) instruction 7-38
BCTR (BRANCH ON COUNT) instruction 7-38
example A-12
BFP
data class
testing of 19-41
BFP (binary floating point) 9-4
BFP data 19-2
conversion of 9-27
BFP facility 19-1
BFP-instruction data exception 6-24
bias for exponent 9-2, 19-2, 20-3
function of view 9-2
summary for BFP 19-2, 19-3
summary for DFP 20-3, 20-6
biased exponent 9-2, 19-2, 20-3
big endian 7-243, 7-337
bimodal addressing

VLEH (VECTOR LOAD ELEMENT) vector instruction 21-6
VLEIB (VECTOR LOAD ELEMENT IMMEDIATE) vector instruction 21-6
VLEIF (VECTOR LOAD ELEMENT IMMEDIATE) vector instruction 21-6
VLEIG (VECTOR LOAD ELEMENT IMMEDIATE) vector instruction 21-6
VLEIH (VECTOR LOAD ELEMENT IMMEDIATE) vector instruction 21-6
VLGV (VECTOR LOAD GR FROM VR ELEMENT) vector instruction 21-7
VLL (VECTOR LOAD WITH LENGTH) vector instruction 21-10
VLLEZ (VECTOR LOAD LOGICAL ELEMENT AND ZERO) vector instruction 21-7
VLM (VECTOR LOAD MULTIPLE) vector instruction 21-8
VLP (VECTOR LOAD POSITIVE) vector instruction 22-12
VLR (VECTOR LOAD) vector instruction 21-5
VLEREP (VECTOR LOAD AND REPLICATE) vector instruction 21-5
VLVG (VECTOR LOAD VR ELEMENT FROM GR) vector instruction 21-9
VLVGP (VECTOR LOAD VR FROM GRS DISJOINT) vector instruction 21-9
VM-gdata-space facility 1-28
VMAE (VECTOR MULTIPLY AND ADD EVEN) vector instruction 22-15
VMAH (VECTOR MULTIPLY AND ADD HIGH) vector instruction 22-14
VMAL (VECTOR MULTIPLY AND ADD LOW) vector instruction 22-14
VMALE (VECTOR MULTIPLY AND ADD LOGICAL EVEN) vector instruction 22-15
VMALH (VECTOR MULTIPLY AND ADD LOGICAL HIGH) vector instruction 22-15
VMALO (VECTOR MULTIPLY AND ADD LOGICAL ODD) vector instruction 22-16
VMAO (VECTOR MULTIPLY AND ADD ODD) vector instruction 22-16
VME (VECTOR MULTIPLY EVEN) vector instruction 22-17
VMH (VECTOR MULTIPLY HIGH) vector instruction 22-16
VML (VECTOR MULTIPLY LOW) vector instruction 22-17
VMLE (VECTOR MULTIPLY LOGICAL EVEN) vector instruction 22-18
VMLH (VECTOR MULTIPLY LOGICAL HIGH) vector instruction 22-16
VMLO (VECTOR MULTIPLY LOGICAL ODD) vector instruction 22-18
VMN (VECTOR MINIMUM) vector instruction 22-13
VMNL (VECTOR MINIMUM LOGICAL) vector instruction 22-13
VMO (VECTOR MULTIPLY ODD) vector instruction 22-18
VMRH (VECTOR MERGE HIGH) vector instruction 21-10
VMRL (VECTOR MERGE LOW) vector instruction 21-10
VMX (VECTOR MAXIMUM) vector instruction 22-13
VMXL (VECTOR MAXIMUM LOGICAL) vector instruction 22-13
VN (VECTOR AND) vector instruction 22-5
VNC (VECTOR AND WITH COMPLEMENT) vector instruction 22-5
VNO (VECTOR NOR) vector instruction 22-19
VO (VECTOR OR) vector instruction 22-19
volatile storage 3-2
effect of power-on reset on 4-61
voting digit 9-13
VPDI (VECTOR PERMUTE DOUBLEWORD IMMEDIATE) vector instruction 21-13
VPERM (VECTOR PERMUTE) vector instruction 21-13
VPK (VECTOR PACK) vector instruction 21-11
VPKLS (VECTOR PACK LOGICAL SATURATE) vector instruction 21-12
VPKS (VECTOR PACK SATURATE) vector instruction 21-11
VPOPCT (VECTOR POPULATION COUNT) vector instruction 22-19
VREP (VECTOR REPLICATE) vector instruction 22-19
VREPI (VECTOR REPLICATE IMMEDIATE) vector instruction 21-14
VS (VECTOR SUBTRACT) vector instruction 22-25
VSBCBI (VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION) vector instruction 22-26
VSBI (VECTOR SUBTRACT WITH BORROW INDICATION) vector instruction 22-26
VSCBI (VECTOR SUBTRACT COMPUTE BORROW INDICATION) vector instruction 22-25
VSCEF (VECTOR SCATTER ELEMENT) vector instruction 21-15
VSCEG (VECTOR SCATTER ELEMENT) vector instruction 21-15
VSEG (VECTOR SIGN EXTEND TO DOUBLEWORD) vector instruction 21-15
VSEL (VECTOR SELECT) vector instruction 21-15
VSL (VECTOR SHIFT LEFT) vector instruction 22-23
VSLB (VECTOR SHIFT LEFT BY BYTE) vector instruction 22-23
VSLDB (VECTOR SHIFT LEFT DOUBLE BY BYTE) vector instruction 22-24
VSRA (VECTOR SHIFT RIGHT ARITHMETIC) vector instruction 22-23
VSRAB (VECTOR SHIFT RIGHT ARITHMETIC BY BYTE) vector instruction 22-24
VSRL (VECTOR SHIFT RIGHT LOGICAL) vector instruction 22-24
VSRLB (VECTOR SHIFT RIGHT LOGICAL) vector instruction 22-24
VST (VECTOR STORE) vector instruction 21-16
VSTEB (VECTOR STORE ELEMENT) vector instruction 21-16
VSTEF (VECTOR STORE ELEMENT) vector instruction 21-16
VSTEG (VECTOR STORE ELEMENT) vector instruction 21-16
VSTEH (VECTOR STORE ELEMENT) vector instruction 21-16
VSTL (VECTOR STORE WITH LENGTH) vector instruction 21-17
VSTM (VECTOR STORE MULTIPLE) vector instruction 21-17
VSTRC (VECTOR STRING RANGE COMPARE) vector instruction 23-6
VSUM (VECTOR SUM ACROSS WORD) vector instruction 22-27
VSUMG (VECTOR SUM ACROSS DOUBLEWORD) vector instruction 22-27
VSUMQ (VECTOR SUM ACROSS QUADWORD) vector instruction 22-27
VTAM use of symbol translation 7-160
VTM (VECTOR TEST UNDER MASK) vector instruction 22-28
VUPH (VECTOR UNPACK HIGH) vector instruction 21-17
VUPL (VECTOR UNPACK LOW) vector instruction 21-18
VUPLH (VECTOR UNPACK LOGICAL) vector instruction 21-18
VUPLL (VECTOR UNPACK LOGICAL LOW) vector instruction 21-19
VX (VECTOR EXCLUSIVE OR) vector instruction 22-11
VXC (vector-exception code) 6-19

W
wait indicator 12-6
wait-state bit
in the PSW 4-5
warning (machine-check condition) 11-16
subclass-mask bit for 11-25
warning-track-interruption facility 1-23
WFC (VECTOR FP COMPARE SCALAR) vector instruction 24-7
WFK (VECTOR FP COMPARE AND SIGNAL SCALAR) vector instruction 24-8
word 3-3
word-concurrent storage references 5-124
working allegiance (I/O) 15-12
wraparound
of instruction addresses 5-10
of PER addresses 4-32
of register numbers
for LOAD MULTIPLE instruction 7-238
for STORE MULTIPLE instruction 7-335
of storage addresses 3-7
controlled by addressing mode 3-7
for MOVE INVERSE instruction 7-245
for MOVE LONG EXTENDED instruction 7-250
for MOVE LONG instruction 7-246
for MOVE LONG UNICODE instruction 7-254
for MOVE WITH OPTIONAL SPECIFICATIONS instruction 10-67
of TOD clock 4-41

X
X (EXCLUSIVE OR) instruction 7-212
X field of instruction 5-11
XA (extended architecture)
See 370-XA architecture
XC (EXCLUSIVE OR) instruction 7-213
examples A-20
XG (EXCLUSIVE OR) instruction 7-212
XGR (EXCLUSIVE OR) instruction 7-212
XI (EXCLUSIVE OR) instruction 7-213
example A-21
XIHF (EXCLUSIVE OR IMMEDIATE) instruction 7-214
XILF (EXCLUSIVE OR IMMEDIATE) instruction 7-214
XIY (EXCLUSIVE OR) instruction 7-213
XR (EXCLUSIVE OR) instruction 7-212
XRK (EXCLUSIVE OR) binary instruction 7-212
XSCH (CANCEL SUBCHANNEL) instruction 14-3  
XY (EXCLUSIVE OR) instruction 7-212

Z
Z bit (zero condition-code bit) 16-12  
as cause of intermediate interruption condition 16-18
z/Architecture architecture  
additions to 1-2, 1-7  
original highlights of 1-2
ZAP (ZERO AND ADD) instruction 8-14  
example A-41
zero  
instruction-length code 6-7  
negative

See negative zero  
normal meaning for byte value xxvii  
setting floating-point register to 9-35  
true (HFP number) 18-1  
zero-address-detection PER event mask for 4-24
ZERO AND ADD instruction 8-14  
example A-41
zero condition code (Z bit in SCSW) 16-12  
zero-padding control 7-155
zone bits 8-1  
moving of 7-259
zoned decimal numbers 8-1  
zoned-decimal numbers  
examples A-4
Communicating Your Comments to IBM

Title: IBM z/Architecture Principles of Operation

Publication No: SA22-7832-10

If you especially like or dislike anything about this book, please use one of the methods listed below to send your comments to IBM. Whichever method you choose, make sure you send your name, address, and telephone number if you would like a reply.

Feel free to comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. However, the comments you send should pertain to only the information in this manual and the way in which the information is presented. To request additional publications, or to ask questions or make comments about the functions of IBM products or systems, you should talk to your IBM representative or to your IBM authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

If you are mailing a reader's comment form (RCF) from a country other than the United States, you can give the RCF to the local IBM branch office or IBM representative for postage-paid mailing.

- If you prefer to send comments by mail, use the RCF at the back of this book.
- If you prefer to send comments by FAX, use this number:
  - FAX: (International Access Code)+1+845+432-9405
- If you prefer to send comments electronically, use one of these network IDs:
  - Internet e-mail: mhvrdfs@us.ibm.com

Make sure to include the following in your note:

- Title and publication number of this book
- Page number or topic to which your comment applies

Optionally, if you include your telephone number, we will be able to respond to your comments by phone.
Reader's Comments — We'd Like to Hear from You

Title: IBM z/Architecture Principles of Operation
Publication No: SA22-7832-10

You may use this form to communicate your comments about this publication, its organization, or subject matter, with the understanding that IBM may use or distribute whatever information you supply in any way it believes appropriate without incurring any obligation to you. Your comments will be sent to the author's department for whatever review and action, if any, are deemed appropriate.

Note: Copies of IBM publications are not stocked at the location to which this form is addressed. Please direct any requests for copies of publications, or for assistance in using your IBM system, to your IBM representative or to the IBM branch office serving your locality.
