

DB2 10 for z/OS

SQL Reference

DB2 10 for z/OS

SQL Reference

IBM

Note

Before using this information and the product it supports, be sure to read the general information under “Notices” at the end of this information.

Sixteenth edition (October 2016)

This edition applies to DB2 10 for z/OS (product number 5605-DB2), DB2 10 for z/OS Value Unit Edition (product number 5697-P31), and to any subsequent releases until otherwise indicated in new editions. Make sure you are using the correct edition for the level of the product.

Specific changes are indicated by a vertical bar to the left of a change. A vertical bar to the left of a figure caption indicates that the figure has changed. Editorial changes that have no technical significance are not noted.

| Determining the encoding scheme and CCSID of a string | 51 |
| Expanding conversions | 54 |
| Contracting conversions | 54 |

Chapter 2. Language elements 55

| | |
|--|-----|
| Characters | 55 |
| Tokens | 56 |
| Identifiers | 57 |
| SQL identifiers | 57 |
| Host identifiers | 58 |
| Restrictions for distributed access | 59 |
| Naming conventions | 59 |
| SQL path | 65 |
| Resolution of unqualified object names | 66 |
| Qualification of unqualified object names | 67 |
| Unqualified alias, index, JAR file, sequence, table, trigger, and view names | 67 |
| Unqualified distinct type, function, procedure, and specific names | 68 |
| Aliases and synonyms | 68 |
| Authorization, privileges, permissions, masks, and object ownership | 70 |
| Authorization IDs, roles, and authorization names | 72 |
| Authorization IDs and schema names | 74 |
| Authorization IDs and statement preparation | 74 |
| Authorization IDs and dynamic SQL | 75 |
| Authorization IDs and remote execution | 78 |
| Data types | 80 |
| Nulls | 81 |
| Numbers | 81 |
| Character strings | 84 |
| Graphic strings | 94 |
| Binary strings | 95 |
| Large objects (LOBs) | 96 |
| Datetime values | 98 |
| Row ID values | 105 |
| XML values | 106 |
| Distinct types | 107 |
| Promotion of data types | 108 |
| Casting between data types | 109 |
| Implicit cast from numeric data to string data | 117 |
| Implicit cast from string data to numeric data | 118 |
| Assignment and comparison | 119 |
| Numeric assignments | 123 |
| String assignments | 127 |
| Datetime assignments | 130 |
| Row ID assignments | 131 |
| XML assignments | 131 |
| Distinct type assignments | 131 |
| Assignments to LOB locators | 133 |
| Numeric comparisons | 133 |
| String comparisons | 134 |
| Datetime comparisons | 135 |
| Row ID comparisons | 136 |
| XML comparisons | 137 |
| Conversion rules for comparisons | 137 |
| Distinct type comparisons | 141 |
| Rules for result data types | 143 |
| Numeric operands | 143 |
| Character and graphic string operands | 144 |
| Binary string operands | 145 |
| Datetime operands | 145 |
| Row ID operands | 146 |
| XML operands | 146 |

| | |
|--|-----|
| Distinct type operands | 146 |
| Constants | 147 |
| Integer constants | 147 |
| Floating-point constants | 147 |
| Decimal constants | 147 |
| Decimal floating-point constants | 148 |
| Character string constants | 149 |
| Binary string constants | 149 |
| Datetime constants | 150 |
| Graphic string constants | 153 |
| Special registers | 155 |
| General rules for special registers. | 157 |
| CURRENT APPLICATION ENCODING SCHEME | 159 |
| CURRENT CLIENT_ACCTNG | 160 |
| CURRENT CLIENT_APPLNAME | 161 |
| CURRENT CLIENT_USERID | 163 |

About this information

This book is a reference for Structured Query Language (SQL) for DB2 Universal Database™ for z/OS®. Unless otherwise stated, references to SQL in this book imply SQL for DB2® UDB for z/OS, and all objects described in this book are objects of DB2 UDB for z/OS.

The syntax and semantics of most SQL statements are essentially the same in all IBM® relational database products, and the language elements common to the products provide a base for the definition of IBM SQL. Consult IBM DB2 Universal Database SQL Reference for Cross-Platform Development if you intend to develop applications that adhere to IBM SQL.

This information assumes that your DB2 subsystem is running in DB2 10 new-function mode.

Availability of new function in DB2 10

Generally, new SQL capabilities, including changes to existing functions, statements, and limits, become available only in new-function mode, unless explicitly stated otherwise. Exceptions to this general statement include optimization and virtual storage enhancements, which are also available in conversion mode unless stated otherwise. In Version 8 and DB2 9, most utility functions were available in conversion mode. However, for DB2 10, most utility functions become available in new-function mode.

Who should read this information

This information is intended for end users, application programmers, system and database administrators, and for persons involved in error detection and diagnosis.

This information is a reference rather than a tutorial. It assumes that you are already familiar with SQL programming concepts.

When you first use this information, consider reading Chapters 1 and 2 sequentially. These chapters describe the basic concepts of relational databases and SQL, the basic syntax of SQL, and the language elements that are common to many SQL statements. The rest of the chapters and appendixes are designed for the quick location of answers to specific SQL questions. They provide you with query forms, SQL statements, SQL procedure statements, DB2 limits, SQLCA, SQLDA, catalog tables, and SQL reserved words.

DB2 Utilities Suite

Important: In this version of DB2 for z/OS, the DB2 Utilities Suite is available as an optional product. You must separately order and purchase a license to such utilities, and discussion of those utility functions in this publication is not intended to otherwise imply that you have a license to them.

The DB2 Utilities Suite can work with DB2 Sort and the DFSORT program. You are licensed to use DFSORT in support of the DB2 utilities even if you do not otherwise license DFSORT for general use. If your primary sort product is not DFSORT, consider the following informational APARs mandatory reading:

- II14047/II14213: USE OF DFSORT BY DB2 UTILITIES
- II13495: HOW DFSORT TAKES ADVANTAGE OF 64-BIT REAL ARCHITECTURE

These informational APARs are periodically updated.

DB2 utilities packaging (Utility Guide)

Terminology and citations

When referring to a DB2 product other than DB2 for z/OS, this information uses the product's full name to avoid ambiguity.

The following terms are used as indicated:

DB2 Represents either the DB2 licensed program or a particular DB2 subsystem.

Tivoli® OMEGAMON® XE

Refers to any of the following products:

- IBM Tivoli OMEGAMON XE for DB2 Performance Expert on z/OS
- IBM Tivoli OMEGAMON XE for DB2 Performance Monitor on z/OS
- IBM DB2 Performance Expert for Multiplatforms and Workgroups
- IBM DB2 Buffer Pool Analyzer for z/OS

C, C++, and C language

Represent the C or C++ programming language.

CICS® Represents CICS Transaction Server for z/OS.

IMS™ Represents the IMS Database Manager or IMS Transaction Manager.

MVS™ Represents the MVS element of the z/OS operating system, which is equivalent to the Base Control Program (BCP) component of the z/OS operating system.

RACF®

Represents the functions that are provided by the RACF component of the z/OS Security Server.

Accessibility features for DB2 10 for z/OS

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in z/OS products, including DB2 10 for z/OS. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers and screen magnifiers.
- Customization of display attributes such as color, contrast, and font size

Tip: The Information Management Software for z/OS Solutions Information Center (which includes information for DB2 10 for z/OS) and its related publications are accessibility-enabled for the IBM Home Page Reader. You can operate all features using the keyboard instead of the mouse.

Keyboard navigation

For information about navigating the DB2 10 for z/OS ISPF panels using TSO/E or ISPF, refer to the *z/OS TSO/E Primer*, the *z/OS TSO/E User's Guide*, and the *z/OS ISPF User's Guide*. These guides describe how to navigate each interface, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

Related accessibility information

IBM and accessibility

See the *IBM Accessibility Center* at <http://www.ibm.com/able> for more information about the commitment that IBM has to accessibility.

How to send your comments

Your feedback helps IBM to provide quality information. Please send any comments that you have about this book or other DB2 for z/OS documentation.

Send your comments by email to db2zinfo@us.ibm.com and include the name of the product, the version number of the product, and the number of the book. If you are commenting on specific text, please list the location of the text (for example, a chapter and section title or a help topic title).

How to read syntax diagrams

Certain conventions apply to the syntax diagrams that are used in IBM documentation.

Apply the following rules when reading the syntax diagrams that are used in DB2 for z/OS documentation:

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.

The \blacktriangleright — symbol indicates the beginning of a statement.

The — \blacktriangleright symbol indicates that the statement syntax is continued on the next line.

The \blacktriangleright — symbol indicates that a statement is continued from the previous line.

The — \blacktriangleleft symbol indicates the end of a statement.

- Required items appear on the horizontal line (the main path).

- Optional items appear below the main path.

If an optional item appears above the main path, that item has no effect on the execution of the statement and is used only for readability.

- If you can choose from two or more items, they appear vertically, in a stack. If you *must* choose one of the items, one item of the stack appears on the main path.

If choosing one of the items is optional, the entire stack appears below the main path.

If one of the items is the default, it appears above the main path and the remaining choices are shown below.

- An arrow returning to the left, above the main line, indicates an item that can be repeated.

If the repeat arrow contains a comma, you must separate repeated items with a comma.

A repeat arrow above a stack indicates that you can repeat the items in the stack.

- Sometimes a diagram must be split into fragments. The syntax fragment is shown separately from the main syntax diagram, but the contents of the fragment should be read as if they are on the main path of the diagram.

fragment-name:

- With the exception of XPath keywords, keywords appear in uppercase (for example, FROM). Keywords must be spelled exactly as shown. XPath keywords are defined as lowercase names, and must be spelled exactly as shown. Variables appear in all lowercase letters (for example, column-name). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

Conventions for describing mixed data values

When mixed data values are shown in examples, certain conventions are used to represent these values.

At sites using a double-byte character set (DBCS), character strings can include a mixture of single-byte and double-byte characters. When mixed data values are shown in the examples, the conventions shown in the following example apply:

| Convention | Representation |
|------------|--|
| $\$0$ | "shift-out" control character (X'0E'), used only for EBCDIC data |
| $\$1$ | "shift-in" control character (X'0F'), used only for EBCDIC data |
| sbc-string | SBCS string of zero or more single-byte characters |
| dbc-string | DBCS string of zero or more double-byte characters |
| ' | DBCS apostrophe |
| G | DBCS uppercase G |

Figure 1. Conventions used when mixed data values are shown in examples

Industry standards

DB2 for z/OS is developed based on specific industry standards for SQL.

- *ISO/IEC FCD 9075-1:2003, Information technology - Database languages - SQL - Part 1: Framework (SQL/Framework)*
- *ISO/IEC FCD 9075-2:2003, Information technology - Database languages - SQL - Part 2: Foundation (SQL/Foundation)*
- *ISO/IEC FCD 9075-3:2003, Information technology - Database languages - SQL - Part 3: Call-Level Interface (SQL/CLI)*
- *ISO/IEC FCD 9075-4:2003, Information technology - Database languages - SQL - Part 4: Persistent Stored Modules (SQL/PSM)*
- *ISO/IEC FCD 9075-5:2003, Information technology - Database languages - SQL- Part 5: Host Language Bindings (SQL/Bindings)*
- *ISO/IEC FCD 9075-9:2003, Information technology - Database languages - SQL - Part 9: Management of External Data (SQL/MED)*
- *ISO/IEC FCD 9075-10:2003, Information technology - Database languages - SQL - Part 10: Object Language Bindings (SQL/OLB)*
- *ISO/IEC FCD 9075-11:2003, Information technology - Database languages - SQL - Part 11: Information and Definition Schemas (SQL/Schemata)*
- *ISO/IEC FCD 9075-13:2003, Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT)*
- *ISO/IEC FCD 9075-14:2006, Information technology - Database languages - SQL - Part 14: XML-Related Specifications (SQL/XML)*
- *ANSI (American National Standards Institute) X3.135-1999, Database Language - SQL*

Chapter 1. DB2 concepts

Certain DB2 concepts are important to understand when using Structured Query Language (SQL).

The following topics provide information on these concepts:

- “SQL: The language of DB2”
- “DB2 schemas and schema qualifiers” on page 12
- “DB2 tables” on page 7
- “DB2 indexes” on page 7
- “DB2 keys” on page 8
- “Constraints” on page 24
- “Triggers” on page 30
- “Storage structures” on page 17
- “DB2 storage groups” on page 14
- “DB2 databases” on page 15
- “DB2 catalog” on page 19
- “DB2 views” on page 10
- “Sequences” on page 37
- “Routines” on page 35
- “Application processes, concurrency, and recovery” on page 31
- “Packages and application plans” on page 34
- “Distributed data” on page 38
- “Character conversion” on page 45

SQL: The language of DB2

The language that you use to access the data in DB2 tables is the *structured query language* (SQL). SQL is a standardized language for defining and manipulating data in a relational database.

The language consists of SQL statements. You can issue SQL statements to accomplish the following actions:

- Define, modify, or drop data objects, such as tables.
- Retrieve, insert, update, or delete data in tables.

You can use other SQL statements to authorize users to access specific resources, such as tables or views.

When you write an SQL statement, you specify what you want done, not how to do it. To access data, for example, you need only to name the tables and columns that contain the data. You do not need to describe how to get to the data.

In accordance with the relational model of data:

- The database is perceived as a set of tables.
- Relationships are represented by values in tables.

- Data is retrieved by using SQL to specify a *result table* that can be derived from one or more tables.

DB2 transforms each SQL statement, that is, the specification of a result table, into a sequence of operations that optimize data retrieval. This transformation occurs when the SQL statement is *prepared*. This transformation is also known as *binding*.

All executable SQL statements must be prepared before they can run. The result of preparation is the executable or *operational form* of the statement.

As the following example illustrates, SQL is generally intuitive. 

Example

Assume that you are shopping for shoes and you want to know what shoe styles are available in size 8. The SQL query that you need to write is similar to the question that you would ask a salesperson, "What shoe styles are available in size 8?" Just as the salesperson checks the shoe inventory and returns with an answer, DB2 retrieves information from a table (SHOES) and returns a result table. The query looks like this:

```
SELECT STYLE
  FROM SHOES
 WHERE SIZE = 8;
```

Assume that the answer to your question is that two shoe styles are available in a size 8: loafers and sandals. The result table looks like this:

```
STYLE
=====
LOAFERS
SANDALS
```

 (Introduction to DB2 for z/OS)

 Programming applications for performance (DB2 Performance)

Chapter 7, "Statements," on page 1145

Ways to submit SQL statements to DB2

You can use several different methods to send SQL statements to DB2 in several ways.

You can issue SQL statements from interactively from a keyboard at a terminal or through a terminal emulator.

Another way to issue SQL statements is through application programs. The programs can contain SQL statements that are statically embedded in the application. Alternatively, application programs can create their SQL statements dynamically, for example, in response to information that a user provides by filling in a form.

The method of preparing an SQL statement for execution and the persistence of its operational form distinguish static SQL from dynamic SQL.

Related concepts:

"How SQL statements are invoked" on page 1151

Related tasks:

 Overview of programming applications that access DB2 for z/OS data (DB2 Application programming and SQL)

Static SQL

The source form of a *static SQL statement* is embedded within an application program written in a host language such as COBOL. The statement is prepared before the program is executed and the operational form of the statement persists beyond the execution of the program.

 **Introductory concepts:**

Static SQL applications (Introduction to DB2 for z/OS)

Static SQL statements in a source program must be processed before the program is compiled. This processing can be accomplished through the DB2 precompiler or the DB2 coprocessor. The DB2 precompiler or the coprocessor checks the syntax of the SQL statements, turns them into host language comments, and generates host language statements to invoke DB2.

The preparation of an SQL application program includes precompilation, the preparation of its static SQL statements, and compilation of the modified source program.

Related concepts:

“How SQL statements are invoked” on page 1151

Related tasks:

 Overview of programming applications that access DB2 for z/OS data (DB2 Application programming and SQL)

Embedded dynamic SQL

Programs that contain *embedded dynamic SQL* statements must be precompiled like those that contain static SQL, but unlike static SQL, the dynamic statements are constructed and prepared at run time.

The source form of a dynamic statement is a character string that is passed to DB2 by the program using the static SQL PREPARE or EXECUTE IMMEDIATE statement. A statement that is prepared using the PREPARE statement can be referenced in a DECLARE CURSOR, DESCRIBE, or EXECUTE statement. Whether the operational form of the statement is persistent depends on whether dynamic statement caching is enabled.

SQL statements embedded in a REXX application are dynamic SQL statements. SQL statements submitted to an interactive SQL facility and to the CALL Level Interface (CLI) are also dynamic SQL.

Related concepts:

“Embedding a statement in an application program” on page 1151

“Dynamic preparation and execution” on page 1152

 Dynamic SQL applications (Introduction to DB2 for z/OS)

Related tasks:

 Including dynamic SQL in your program (DB2 Application programming and SQL)

Deferred embedded SQL

A *deferred embedded SQL* statement is neither fully static nor fully dynamic.

Like a static statement, it is embedded within an application, but like a dynamic statement, it is prepared during the execution of the application. Although prepared at run time, a deferred embedded SQL statement is processed with bind-time rules such that the authorization ID and qualifier determined at bind time for the plan or package owner are used.

Interactive SQL

Interactive SQL refers to SQL statements that you submit to DB2 by using SPUFI (SQL processor using file input), the command line processor, or by using a query tool, such as DB2 QMF™ for Workstation.

The easiest and most efficient way to run SQL is to use a query tool. DB2 Query Management Facility™ (QMF) for Workstation is a popular query tool that lets you enter and run your SQL statements easily. This topic acquaints you with using DB2 QMF for Workstation to create and run SQL statements. DB2 QMF for Workstation simplifies access to DB2 from a workstation. In fact, QMF for Workstation was built for DB2.

Although this topic focuses on DB2 QMF for Workstation, other options are available. You can use DB2 QMF for WebSphere® to enter and run SQL statements from your web browser or use DB2 QMF for TSO/CICS to enter and run SQL statements from TSO or CICS. In addition, you can enter and run SQL statements at a TSO terminal by using the SPUFI (SQL processor using file input) facility. SPUFI prepares and executes these statements dynamically. All of these tools prepare and dynamically execute the SQL statements.

The DB2 QMF family of technologies establish pervasive production and sharing of business intelligence for information-oriented tasks in the organization. DB2 QMF offers many strengths, including the following:

- Support for functionality in the DB2 database, including long names, Unicode, and SQL enhancements
- Drag-and-drop capability for building OLAP analytics, SQL queries, pivot tables, and other business analysis and reports
- Executive dashboards and data visual solutions that offer visually rich, interactive functionality and interfaces for data analysis
- Support for DB2 QMF for WebSphere, a tool that turns any web browser into a zero-maintenance, thin client for visual on demand access to enterprise DB2 data
- Re-engineered cross-platform development environment
- New security model for access control and personalization

The visual solutions previously provided by DB2 QMF Visionary are now included in the core DB2 QMF technology.

In addition to DB2 QMF for Workstation, which this topic describes, the DB2 QMF family includes the following editions:

- DB2 QMF Enterprise Edition provides the entire DB2 QMF family of technologies, enabling enterprise-wide business information across user and database operating systems. This edition consists of:
 - DB2 QMF for TSO/CICS
 - DB2 QMF High Performance Option (HPO)
 - DB2 QMF for Workstation

- DB2 QMF for WebSphere
- DataQuant for Workstation
- DataQuant for WebSphere
- DB2 QMF Classic Edition supports users who work with traditional mainframe terminals and emulators (including WebSphere Host On Demand) to access DB2 databases. This edition consists of DB2 QMF for TSO/CICS.

SQL Call Level Interface and Open Database Connectivity

The DB2 Call Level Interface (CLI) is an application programming interface in which functions are provided to application programs to process dynamic SQL statements.

DB2 CLI allows users to access SQL functions directly through a call interface. CLI programs can also be compiled using an Open Database Connectivity (ODBC) Software Developer's Kit, available from Microsoft or other vendors, enabling access to ODBC data sources. Unlike using embedded SQL, no precompilation is required. Applications developed using this interface can be executed on a variety of databases without being compiled against each of databases. Through the interface, applications use procedure calls at execution time to connect to databases, to issue SQL statements, and to get returned data and status information.

Java database connectivity and embedded SQL for Java

DB2 provides two standards-based Java™ programming APIs: Java Database Connectivity (JDBC) and embedded SQL for Java (SQL/OLB or SQLJ). Both can be used to create Java applications and applets that access DB2.

Static SQL cannot be used by JDBC. SQLJ applications use JDBC as a foundation for such tasks as connecting to databases and handling SQL errors, but can contain embedded static SQL statements in the SQLJ source files. An SQLJ file has to be translated with the SQLJ translator before the resulting Java source code can be compiled.

DB2 data structures

Data structures are elements that are required to use DB2. You can access and use these elements to organize your data. Examples of data structures include tables, table spaces, indexes, index spaces, keys, views, and databases.

The brief descriptions here show how the structures fit into an overall view of DB2. The following figure shows how some DB2 structures contain others. To some extent, the notion of “containment” provides a hierarchy of structures.

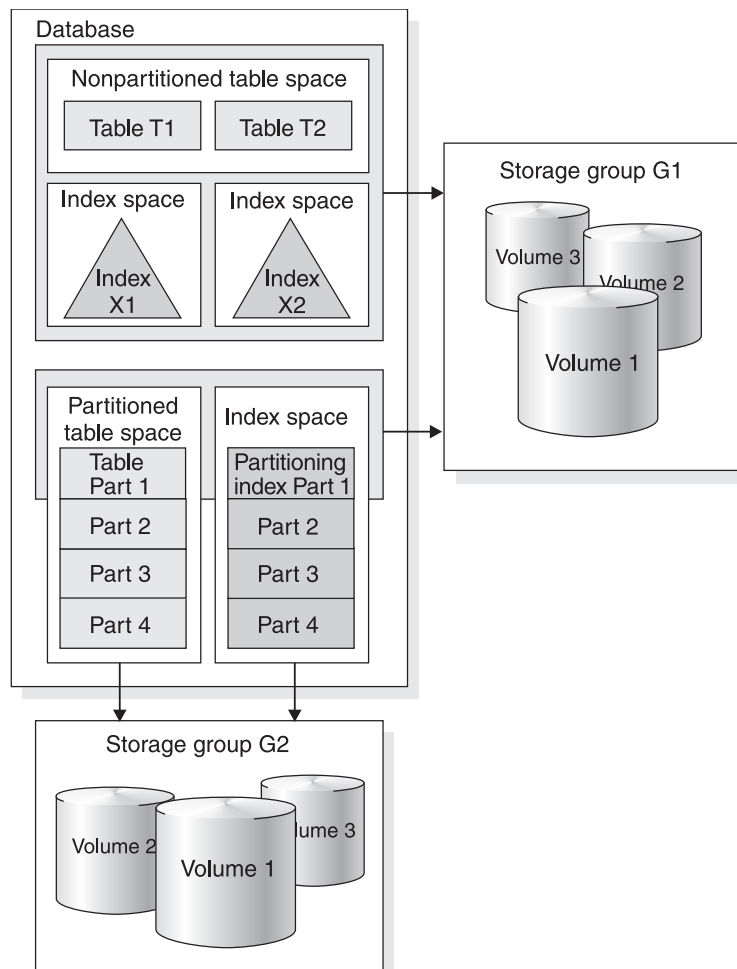

Figure 2. A hierarchy of DB2 structures

The DB2 structures from the most to the least inclusive are:

Databases

A set of DB2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside.

Storage groups

A set of volumes on disks that hold the data sets in which tables and indexes are stored.

Table spaces

A logical unit of storage in a database. A table space is a page set and can contain one or more tables.

Tables All data in a DB2 database is presented in *tables*, which are collections of rows all having the same columns. A table that holds persistent user data is a *base table*. A table that stores data temporarily is a *temporary table*.

Views A *view* is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

Indexes

An *index* is an ordered set of pointers to the data in a DB2 table. The index is stored separately from the table.

Related concepts:

“DB2 system objects” on page 19

 Implementing your database design (DB2 Administration Guide)

“Storage structures” on page 17

DB2 tables

Tables are logical structures that DB2 maintains. DB2 supports several different types of tables.

Tables are made up of columns and rows. The rows of a relational table have no fixed order. The order of the columns, however, is always the order in which you specified them when you defined the table.

At the intersection of every column and row is a specific data item, which is called a *value*. A *column* is a set of values of the same type. A *row* is a sequence of values such that the *n*th value is a value of the *n*th column of the table. Every table must have one or more columns, but the number of rows can be zero.

DB2 accesses data by referring to its content instead of to its location or organization in storage.

DB2 supports several different types of tables:

- Accelerator-only tables
- Auxiliary tables
- Base tables
- Clone tables
- Empty tables
- History tables
- Materialized query tables
- Result tables
- Temporal tables
- Temporary tables
- XML tables

 Creation of tables (Introduction to DB2 for z/OS)

 Types of tables (Introduction to DB2 for z/OS)

DB2 indexes

An *index* is an ordered set of pointers to rows of a table. DB2 can use indexes to improve performance and ensure uniqueness. Understanding the structure of DB2 indexes can help you achieve the best performance for your system.

Conceptually, you can think of an index to the rows of a DB2 table like you think of an index to the pages of a book. Each index is based on the values of data in one or more columns of a table.

The main purpose of an index is to improve performance for access to the data. In most cases, access to data is faster with an index than with a scan of the data. For example, you can create an index on the DEPTNO column of the sample DEPT table so that DB2 can easily locate a specific department and avoid reading through each row of, or *scanning*, the table.

An index is stored separately from the data in the table. Each index is physically stored in its own index space. When you define an index by using the CREATE INDEX statement, DB2 builds this structure and maintains it automatically. However, you can perform necessary maintenance such as reorganizing it or recovering the index.

Another purpose of an index is to ensure uniqueness. For example, a unique index on the employee table ensures that no two employees have the same employee number.

In most cases, the users of an index are unaware that it is being used because DB2 decides whether to use the index to access the table.

Be aware that indexes have both benefits and disadvantages. A greater number of indexes can simultaneously improve the access performance of a particular transaction and require additional processing for inserting, updating, and deleting index keys.

 [Creation of indexes \(Introduction to DB2 for z/OS\)](#)
“CREATE INDEX” on page 1585

DB2 keys

A *key* is a column or an ordered collection of columns that is identified in the description of a table, an index, or a referential constraint. Keys are crucial to the table structure in a relational database.

Keys are important in a relational database because they ensure that each record in a table is uniquely identified, they help establish and enforce referential integrity, and they establish relationships between tables. The same column can be part of more than one key.

A *composite key* is an ordered set of two or more columns of the same table. The ordering of the columns is not constrained by their actual order within the table. The term *value*, when used with respect to a composite key, denotes a composite value. For example, consider this rule: “The value of the foreign key must be equal to the value of the primary key.” This rule means that each component of the value of the foreign key must be equal to the corresponding component of the value of the primary key.

DB2 supports several types of keys.

Unique keys

A *unique constraint* is a rule that the values of a key are valid only if they are unique. A key that is constrained to have unique values is a *unique key*. DB2 uses a *unique index* to enforce the constraint during the execution of the LOAD utility and

whenever you use an INSERT, UPDATE, or MERGE statement to add or modify data. Every unique key is a key of a unique index. You can define a unique key by using the UNIQUE clause of either the CREATE TABLE or the ALTER TABLE statement. A table can have any number of unique keys.

The columns of a unique key cannot contain null values.

Primary keys

A *primary key* is a special type of unique key and cannot contain null values. For example, the DEPTNO column in the DEPT table is a primary key.

A table can have no more than one primary key. Primary keys are optional and can be defined in CREATE TABLE or ALTER TABLE statements.

The unique index on a primary key is called a *primary index*. When a primary key is defined in a CREATE TABLE statement or ALTER TABLE statement, DB2 automatically creates the primary index.

If a unique index already exists on the columns of the primary key when it is defined in the ALTER TABLE statement, this unique index is designated as the primary index when DB2 is operating in new-function mode and implicitly created the table space.

Parent keys

A *parent key* is either a primary key or a unique key in the parent table of a referential constraint. The values of a parent key determine the valid values of the foreign key in the constraint.

Foreign keys

A *foreign key* is a key that is specified in the definition of a referential constraint in a CREATE or ALTER TABLE statement. A foreign key refers to or is related to a specific parent key.

Unlike other types of keys, a foreign key does not require an index on its underlying column or columns. A table can have zero or more foreign keys. The value of a composite foreign key is null if any component of the value is null.

The following figure shows the relationship between some columns in the DEPT table and the EMP table.

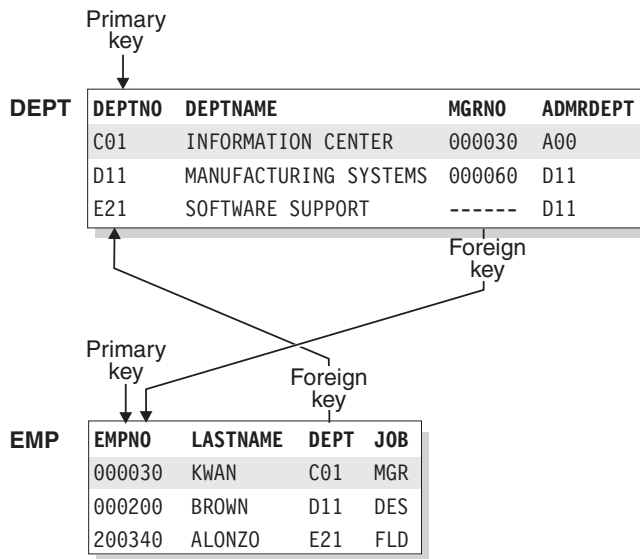

Figure 3. Relationship between DEPT and EMP tables

Figure notes: Each table has a primary key:

- DEPTNO in the DEPT table
- EMPNO in the EMP table

Each table has a foreign key that establishes a relationship between the tables:

- The values of the foreign key on the DEPT column of the EMP table match values in the DEPTNO column of the DEPT table.
- The values of the foreign key on the MGRNO column of the DEPT table match values in the EMPNO column of the EMP table when an employee is a manager.

To see a specific relationship between rows, notice how the shaded rows for department C01 and employee number 000030 share common values.

Related concepts:

“Referential constraints” on page 25

DB2 views

A *view* is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

Introductory concepts:

Creation of views (Introduction to DB2 for z/OS)

Views on the sample tables (Introduction to DB2 for z/OS)

A view is a named specification of a result table. Conceptually, creating a view is somewhat like using binoculars. You might look through binoculars to see an entire landscape or to look at a specific image within the landscape, such as a tree.

You can create a view that:

- Combines data from different base tables
- Is based on other views or on a combination of views and tables
- Omits certain data, thereby shielding some table data from users

In fact, these are common underlying reasons to use a view. Combining information from base tables and views simplifies retrieving data for a user, and limiting the data that a user can see is useful for security. You can use views for a number of different purposes. A view can:

- Control access to a table
- Make data easier to use
- Simplify authorization by granting access to a view without granting access to the table
- Show only portions of data in the table
- Show summary data for a given table
- Combine two or more tables in meaningful ways
- Show only the selected rows that are pertinent to the process that uses the view

To define a view, you use the CREATE VIEW statement and assign a name (up to 128 characters in length) to the view. Specifying the view in other SQL statements is effectively like running an SQL SELECT statement. At any time, the view consists of the rows that would result from the SELECT statement that it contains. You can think of a view as having columns and rows just like the base table on which the view is defined.

Example

GUPI

Example 1: The following figure shows a view of the EMP table that omits sensitive employee information and renames some of the columns.

Base table, **EMP**:

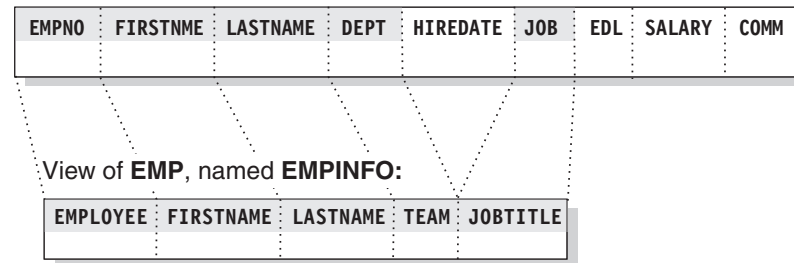

Figure 4. A view of the EMP table

Figure note: The EMPINFO view represents a table that includes columns named EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, and JOBTITLE. The data in the view comes from the columns EMPNO, FIRSTNAME, LASTNAME, DEPT, and JOB of the EMP table.

Example 2: The following CREATE VIEW statement defines the EMPINFO view that is shown in the preceding figure:

```
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
AS SELECT EMPNO, FIRSTNAME, LASTNAME, DEPT, JOB
FROM EMP;
```

When you define a view, DB2 stores the definition of the view in the DB2 catalog. However, DB2 does not store any data for the view itself, because the data exists in the base table or tables.

Example 3: You can narrow the scope of the EMPINFO view by limiting the content to a subset of rows and columns that includes departments A00 and C01 only:

```
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
AS SELECT EMPNO, FIRSTNME, LASTNAME, DEPT, JOB
WHERE DEPT = 'A00' OR DEPT = 'C01'
FROM EMP;
```

In general, a view inherits the attributes of the object from which it is derived. Columns that are added to the tables after the view is defined on those tables do not appear in the view.

Restriction: You cannot create an index for a view. In addition, you cannot create any form of a key or a constraint (referential or otherwise) on a view. Such indexes, keys, or constraints must be built on the tables that the view references.

To retrieve or access information from a view, you use views like you use base tables. You can use a SELECT statement to show the information from the view. The SELECT statement can name other views and tables, and it can use the WHERE, GROUP BY, and HAVING clauses. It cannot use the ORDER BY clause or name a host variable.

Whether a view can be used in an insert, update, or delete operation depends on its definition. For example, if a view includes a foreign key of its base table, INSERT and UPDATE operations that use the view are subject to the same referential constraint as the base table. Likewise, if the base table of a view is a parent table, DELETE operations that use the view are subject to the same rules as DELETE operations on the base table. *Read-only* views cannot be used for insert, update, and delete operations.

“CREATE VIEW” on page 1838

DB2 schemas and schema qualifiers

The objects in a relational database are organized into sets called schemas. A *schema* is a collection of named objects that provides a logical classification of objects in the database. The first part of a schema name is the qualifier.

A schema provides a logical classification of objects in the database. The objects that a schema can contain include tables, indexes, table spaces, distinct types, functions, stored procedures, and triggers. An object is assigned to a schema when it is created.

The *schema name* of the object determines the schema to which the object belongs. A user object, such as a distinct type, function, procedure, sequence, or trigger

should not be created in a *system schema*, which is any one of a set of schemas that are reserved for use by the DB2 subsystem.

When a table, index, table space, distinct type, function, stored procedure, or trigger is created, it is given a qualified two-part name. The first part is the schema name (or the qualifier), which is either implicitly or explicitly specified. The default schema is the authorization ID of the owner of the plan or package. The second part is the name of the object.

In previous versions, CREATE statements had certain restrictions when the value of CURRENT SCHEMA was different from CURRENT SQLID value. Although those restrictions no longer exist, you now must consider how to determine the qualifier and owner when CURRENT SCHEMA and CURRENT SQLID contain different values. The rules for how the owner is determined depend on the type of object being created.

CURRENT SCHEMA and CURRENT SQLID affect only dynamic SQL statements. Static CREATE statements are not affected by either CURRENT SCHEMA or CURRENT SQLID.

The following table summarizes the effect of CURRENT SCHEMA in determining the schema qualifier and owner for these objects:

- Alias
- Auxiliary table
- Created global temporary table
- Table
- View

Table 1. Schema qualifier and owner for objects

| Specification of name for new object being created | Schema qualifier of new object | Owner of new object |
|--|--------------------------------|------------------------|
| <i>name</i> (no qualifier) | value of CURRENT SCHEMA | value of CURRENT SQLID |
| <i>abc.name</i> (single qualifier) | abc | abc |
| <i>.....abc.name</i> (multiple qualifiers) | abc | abc |

The following table summarizes the effect of CURRENT SCHEMA in determining the schema qualifier and owner for these objects:

- User-defined distinct type
- User-defined function
- Procedure
- Sequence
- Trigger

Table 2. Schema qualifier and owner for additional objects

| Specification of name for new object being created | Schema qualifier of new object | Owner of new object |
|--|--------------------------------|------------------------|
| <i>name</i> (no qualifier) | value of CURRENT SCHEMA | value of CURRENT SQLID |
| <i>abc.name</i> (single qualifier) | abc | value of CURRENT SQLID |

Table 2. Schema qualifier and owner for additional objects (continued)

| Specification of name for new object being created | Schema qualifier of new object | Owner of new object |
|--|--------------------------------|------------------------|
| <i>abc.name</i> (multiple qualifiers) | abc | value of CURRENT SQLID |

“Reserved schema names” on page 2308

DB2 storage groups

DB2 *storage groups* are a set of volumes on disks that hold the data sets in which tables and indexes are stored.

The description of a storage group names the group and identifies its volumes and the VSAM (Virtual Storage Access Method) catalog that records the data sets. The default storage group, SYSDEFLT, is created when you install DB2.

Within the storage group, DB2 does the following actions:

- Allocates storage for table spaces and indexes
- Defines the necessary VSAM data sets
- Extends and deletes VSAM data sets
- Alters VSAM data sets

All volumes of a given storage group must have the same device type. However, parts of a single database can be stored in different storage groups.

DB2 can manage the auxiliary storage requirements of a database by using DB2 storage groups. Data sets in these DB2 storage groups are called *DB2-managed data sets*.

These DB2 storage groups are not the same as storage groups that are defined by the DFSMS storage management subsystem (DFSMSsms).

You have several options for managing DB2 data sets:

- Let DB2 manage the data sets. This option means less work for DB2 database administrators.

After you define a DB2 storage group, DB2 stores information about it in the DB2 catalog. (This catalog is not the same as the integrated catalog facility catalog that describes DB2 VSAM data sets). The catalog table SYSIBM.SYSSTOGROUP has a row for each storage group, and SYSIBM.SYSVOLUMES has a row for each volume. With the proper authorization, you can retrieve the catalog information about DB2 storage groups by using SQL statements.

When you create table spaces and indexes, you name the storage group from which space is to be allocated. You can also assign an entire database to a storage group. Try to assign frequently accessed objects (indexes, for example) to fast devices, and assign seldom-used tables to slower devices. This approach to choosing storage groups improves performance.

If you are authorized and do not take specific steps to manage your own storage, you can still define tables, indexes, table spaces, and databases. A default storage group, SYSDEFLT, is defined when DB2 is installed. DB2 uses SYSDEFLT to allocate the necessary auxiliary storage. Information about SYSDEFLT, as with any other storage group, is kept in the catalog tables SYSIBM.SYSSTOGROUP and SYSIBM.SYSVOLUMES.

For both user-managed and DB2-managed data sets, you need at least one integrated catalog facility (ICF) catalog; this catalog can be either a user catalog or a master catalog. These catalogs are created with the ICF. You must identify the catalog of the ICF when you create a storage group or when you create a table space that does not use storage groups.

- Let SMS manage some or all the data sets, either when you use DB2 storage groups or when you use data sets that you have defined yourself. This option offers a reduced workload for DB2 database administrators and storage administrators. You can specify SMS classes when you create or alter a storage group.
- Define and manage your own data sets using VSAM Access Method Services. This option gives you the most control over the physical storage of tables and indexes.

Recommendation: Use DB2 storage groups and whenever you can, either specifically or by default. Also use SMS managed DB2 storage groups whenever you can.

Related tasks:

 [Choosing data page sizes for LOB data \(DB2 Performance\)](#)

DB2 databases

DB2 *databases* are a set of DB2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside. You define a database by using the CREATE DATABASE statement.

Whenever a table space is created, it is explicitly or implicitly assigned to an existing database. If you create a table space and do not specify a database name, the table space is created in the default database, DSNDB04. In this case, DB2 implicitly creates a database or uses an existing implicitly created database for the table. All users who have the authority to create table spaces or tables in database DSNDB04 have authority to create tables and table spaces in an implicitly created database. If the table space is implicitly created, and you do not specify the IN clause in the CREATE TABLE statement, DB2 implicitly creates the database to which the table space is assigned.

A single database, for example, can contain all the data that is associated with one application or with a group of related applications. Collecting that data into one database allows you to start or stop access to all the data in one operation. You can also grant authorization for access to all the data as a single unit. Assuming that you are authorized to access data, you can access data that is stored in different databases.

Recommendation: Keep only a minimal number of table spaces in each database, and a minimal number of tables in each table space. Excessive numbers of table spaces and tables in a database can cause decreases in performance and manageability issues. If you reduce the number of table spaces and tables in a database, you improve performance, minimize maintenance, increase concurrency, and decrease log volume.

The following figure shows how the main DB2 data structures fit together. Two databases, A and B, are represented as squares. Database A contains a table space and two index spaces. The table space is segmented and contains tables A1 and A2. Each index space contains one index, an index on table A1 and an index on table A2. Database B contains one table space and one index space. The table space

is partitioned and contains table B1, partitions 1 through 4. The index space contains one partitioning index, parts 1 - 4.

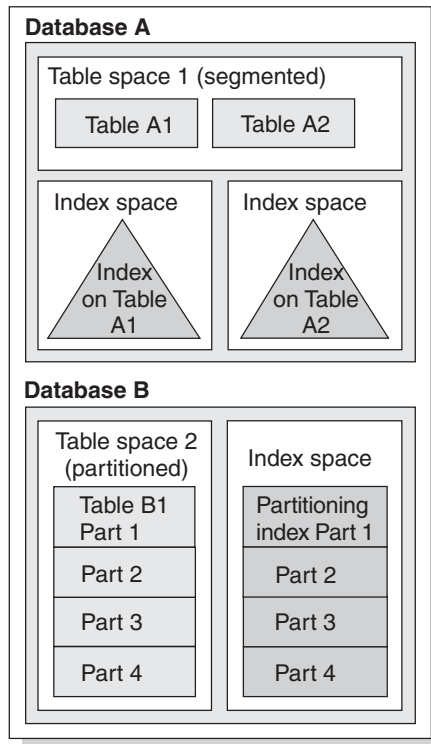

Figure 5. Data structures in a DB2 database

When you migrate to the current version, DB2 adopts the default database and default storage group that you used in the previous version. You have the same authority for the current version as you did in the previous version.

Reasons to define a database

In DB2 for z/OS, a database is a logical collection of table spaces and index spaces. Consider the following factors when deciding whether to define a new database for a new set of objects:

- You can start and stop an entire database as a unit; you can display the statuses of all its objects by using a single command that names only the database. Therefore, place a set of tables that are used together into the same database. (The same database holds all indexes on those tables.)
- Some operations lock an entire database. For example, some phases of the LOAD utility prevent some SQL statements (CREATE, ALTER, and DROP) from using the same database concurrently. Therefore, placing many unrelated tables in a single database is often inconvenient.

When one user is executing a CREATE, ALTER, or DROP statement for a table, no other user can access the database that contains that table. QMF users, especially, might do a great deal of data definition; the QMF operations SAVE DATA and ERASE *data-object* are accomplished by creating and dropping DB2 tables. For maximum concurrency, create a separate database for each QMF user.

- The internal database descriptors (DBDs) might become inconveniently large. DBDs grow as new objects are defined, but they do not immediately shrink when objects are dropped; the DBD space for a dropped object is not reclaimed

until the MODIFY RECOVERY utility is used to delete records of obsolete copies from SYSIBM.SYSCOPY. DBDs occupy storage and are the objects of occasional input and output operations. Therefore, limiting the size of DBDs is another reason to define new databases.

 [Creation of databases \(Introduction to DB2 for z/OS\)](#)

Storage structures

In DB2, a *storage structure* is a set of one or more VSAM data sets that hold DB2 tables or indexes. A storage structure is also called a *page set*.

The two primary types of storage structures in DB2 for z/OS are table spaces and index spaces.

Related concepts:

“DB2 data structures” on page 6

Related information:

 [Implementing DB2 table spaces \(DB2 Administration Guide\)](#)

 [Implementing DB2 indexes \(DB2 Administration Guide\)](#)

DB2 table spaces

A DB2 *table space* is a set of volumes on disks that hold the data sets in which tables are actually stored. Every table is stored in table space.

A table space consists of a number of VSAM linear data sets (LDSs). Table spaces are divided into equal-sized units, called *pages*. Each page is read from disk to the assigned buffer pool, or written from the buffer pool to disc, in a single operation. The page size is controlled by the buffer pool that you assign to the table space (4 KB, 8 KB, 16 KB, or 32 KB in size) for the data. The default page size is 4 KB.

Data in most table spaces can be compressed, which can allow you to store more data on each data page.

You can let DB2 create and manage the table space for you by issuing a CREATE TABLE statement that does not specify an existing table space. DB2 creates a partition-by-growth or range-partitioned universal table space and assigns the table space to the default database and the default storage group. For more information, see [Creation of table spaces \(Introduction to DB2 for z/OS\)](#).

You can also explicitly define table spaces by issuing CREATE TABLESPACE statements. You specify the database that the table space belongs to, and the storage group that it uses. When you create a table space, certain options that you specify control the type of table space that is created. In most cases, it is best to create universal table spaces. Other table space types are deprecated. That is, they are supported in DB2 10, but support might be removed in the future.

For descriptions of the various table space types, see [Types of DB2 table spaces \(Introduction to DB2 for z/OS\)](#).

Some table space types can contain more than one table. However, in the cases of the recommended universal table space types, each table space contains only a single table.

For smaller tables, multiple-table segmented table spaces can sometimes help to reduce the number of data sets that need to be managed for backup and recovery, and the number of data sets that the database system needs to open and close during DB2 operations. Nevertheless, this type is deprecated.

DB2 index spaces

An *index space* is a DB2 storage structure that contains a single index.

When you create an index by using the CREATE INDEX statement, an index space is automatically defined in the same database as the table. You can define a unique name for the index space, or DB2 can derive a unique name for you. Under certain circumstances, DB2 implicitly creates index spaces.

DB2 hash spaces

A *hash space* is a defined disk space that organizes table data for hash access.

When you enable hash access on a table, DB2 requires a defined amount of disk space to contain table data. You can specify the amount of disk space to allocate to the hash space when you create a table or alter an existing table. The hash space on a table must be large enough to contain new rows that are added to the table. If a hash space is full, new rows are relocated to the overflow index, which reduces the performance of hash access on that table. Hash spaces can contain only a single table in a universal table space, and can be partitioned by range or partitioned by growth.

DB2 system objects

Unlike the DB2 data structures that users create and access, DB2 controls and accesses system objects.

DB2 has a comprehensive infrastructure that enables it to provide data integrity, performance, and the ability to recover user data. In addition, Parallel Sysplex® data sharing uses shared system objects.

Related concepts:

“DB2 data structures” on page 6

DB2 catalog

DB2 maintains a set of tables that contain information about the data that DB2 controls. These tables are collectively known as the *catalog*.

The catalog tables contain information about DB2 objects such as tables, views, and indexes. When you create, alter, or drop an object, DB2 inserts, updates, or deletes rows of the catalog that describe the object.

The DB2 catalog consists of tables of data about everything defined to the DB2 system, including table spaces, indexes, tables, copies of table spaces and indexes, and storage groups. The system database DSNDB06 contains the DB2 catalog.

When you create, alter, or drop any structure, DB2 inserts, updates, or deletes rows of the catalog that describe the structure and tell how the structure relates to other structures. For example, SYSIBM.SYSTABLES is one catalog table that records information when a table is created. DB2 inserts a row into SYSIBM.SYSTABLES that includes the table name, its owner, its creator, and the name of its table space and its database.

To understand the role of the catalog, consider what happens when the EMP table is created. DB2 records the following data:

Table information

To record the table name and the name of its owner, its creator, its type, the name of its table space, and the name of its database, DB2 inserts a row into the catalog.

Column information

To record information about each column of the table, DB2 inserts the name of the table to which the column belongs, its length, its data type, and its sequence number by inserting a row into the catalog for each column of the table.

Authorization information

To record that the owner of the table has authorization to create the table, DB2 inserts a row into the catalog.

Tables in the catalog are like any other database tables with respect to retrieval. If you have authorization, you can use SQL statements to look at data in the catalog tables in the same way that you retrieve data from any other table in the DB2 database. DB2 ensures that the catalog contains accurate object descriptions. If you are authorized to access the specific tables or views on the catalog, you can use SELECT on the catalog. You can use INSERT, UPDATE, and DELETE statements on updatable catalog tables, but you cannot use TRUNCATE or MERGE on the catalog.

The *communications database* (CDB) is part of the DB2 catalog. The CDB consists of a set of tables that establish conversations with remote database management systems (DBMSs). The distributed data facility (DDF) uses the CDB to send and receive distributed data requests.

Tip: For best results, check the consistency of the DB2 catalog and directory regularly, even outside of the migration process. For detailed instructions, see *Verify the integrity of DB2 table spaces* and *Check for consistency between catalog tables*.

“DB2 catalog tables” on page 2388

DB2 directory

The DB2 directory contains information that DB2 uses during normal operation.

You can use SQL to retrieve data only from the directory tables that are listed in “DB2 directory tables” on page 2719. You can submit queries against the DB2 catalog for DB2 directory objects. However, in most cases, that information is not updated as a result of DB2 operations.

The directory consists of a set of DB2 tables that are stored in table spaces in system database DSNDB01. Each of the table spaces that are listed in the following table is contained in a VSAM linear data set.

Table 3. Directory table spaces

| Table space name | Description |
|------------------------------|---|
| SCT02 | Contains the internal form of SQL statements that are contained in an application. If you bound a plan with SQL statements in a prior release, DB2 created a structure in SCT02. |
| SPT01 Skeleton package | Contains the internal form of SQL statements that are contained in a package. |
| SYSSPUXA | Contains the contents of a package selection. |
| SYSSPUXB | Contains the contents of a package explain block. |
| SYSLGRNX Log range | Tracks the opening and closing of table spaces, indexes, or partitions. By tracking this information and associating it with relative byte addresses (RBAs) as contained in the DB2 log, DB2 can reduce recovery time by reducing the amount of log that must be scanned for a particular table space, index, or partition. |
| SYSUTILX System utilities | Contains a row for every utility job that is running. The row persists until the utility is finished. If the utility terminates without completing, DB2 uses the information in the row when you restart the utility. |

Table 3. Directory table spaces (continued)

| Table space name | Description |
|------------------------------------|---|
| DBD01 Database descriptor (DBD) | Contains internal information, called <i>database descriptors</i> (DBDs), about the databases that exist within the DB2 subsystem. Each database has exactly one corresponding DBD that describes the database, table spaces, tables, table check constraints, indexes, and referential relationships. A DBD also contains other information about accessing tables in the database. DB2 creates and updates DBDs whenever their corresponding databases are created or updated. |
| SYSDBDXA | Contains the contents of a DBD section. |

Tip: For best results, check the consistency of the DB2 catalog and directory regularly, even outside of the migration process. For detailed instructions, see Verify the integrity of DB2 table spaces and Check for consistency between catalog tables.

Active and archive logs

DB2 records all data changes and other significant events in a log.

If you keep these logs, DB2 can re-create those changes for you in the event of a failure or roll the changes back to a previous point in time.

DB2 writes each log record to a disk data set called the *active log*. When the active log is full, DB2 copies the contents of the active log to a disk or magnetic tape data set called the *archive log*.

You can choose either single logging or dual logging.

- A single active log contains up to 93 active log data sets.
- With dual logging, the active log has twice the capacity for active log data sets, because two identical copies of the log records are kept.

Each DB2 subsystem manages multiple active logs and archive logs. The following facts are true about each DB2 active log:

- Each log can be duplexed to ensure high availability.
- Each active log data set is a VSAM linear data set (LDS).
- DB2 supports striped active log data sets.

Related tasks:

Related information:

[Reading log records \(DB2 Administration Guide\)](#)

Bootstrap data set

The *bootstrap data set (BSDS)* is a VSAM key-sequenced data set (KSDS). This KSDS contains information that is critical to DB2, such as the names of the logs. DB2 uses information in the BSDS for system restarts and for any activity that requires reading the log.

Specifically, the BSDS contains:

- An inventory of all active and archive log data sets that are known to DB2. DB2 uses this information to track the active and archive log data sets. DB2 also uses this information to locate log records to satisfy log read requests during normal DB2 system activity and during restart and recovery processing.
- A wrap-around inventory of all recent DB2 checkpoint activity. DB2 uses this information during restart processing.
- The distributed data facility (DDF) communication record, which contains information that is necessary to use DB2 as a distributed server or requester.
- Information about buffer pools.

Because the BSDS is essential to recovery in the event of subsystem failure, during installation DB2 automatically creates two copies of the BSDS and, if space permits, places them on separate volumes.

The BSDS can be duplexed to ensure availability.

Related tasks:

 [Managing the log and the bootstrap data set \(DB2 Administration Guide\)](#)

Buffer pools

Buffer pools are areas of virtual storage that temporarily store pages of table spaces or indexes.

When an application program accesses a row of a table, DB2 places the page that contains that row in a buffer. Access to data in this temporary storage is faster than accessing data on a disk. If the required data is already in a buffer, the application program does not need to wait for it to be retrieved from disk, so the time and cost of retrieving the page is reduced.

Buffer pools require monitoring and tuning. Buffer pool sizes are critical to the performance characteristics of an application or group of applications that access data in those buffer pools.

You can specify default buffer pools for user data and for indexes. A special type of buffer pool that is used only in Parallel Sysplex data sharing is the *group buffer pool*, which resides in the coupling facility. Group buffer pools reside in a special PR/SM™ LPAR logical partition called a *coupling facility*, which enables several DB2 subsystems to share information and control the coherency of data.

Buffer pools reside in the DBM1 address space. The maximum size of a buffer pool is 16 TB.

Data definition control support database

The *data definition control support* (DDCS) database refers to a user-maintained collection of tables that are used by data definition control support to restrict the submission of specific DB2 DDL (data definition language) statements to selected application identifiers (plans or collections of packages).

This database is automatically created during installation. After this database is created, you must populate the tables to use this facility. The system name for this database is DSNRGFDB.

The resource limit facility

The *resource limit facility* (sometimes abbreviated RLF) enables you to control the amount of processor resources that are used by SQL statements.

GUPI

Resource limits apply to the following types of SQL statements:

- SELECT
- INSERT
- UPDATE
- MERGE
- TRUNCATE
- DELETE

Resource limits apply only to dynamic SQL statements. Resource limits apply to SQL statement regardless of whether they are issued locally or remotely. The resource limit facility does not control static SQL statements regardless of whether they are issued locally or remotely, and no limits apply to primary or secondary authorization IDs that have installation SYSADM or installation SYSOPR authority.

You can establish a single limit for all users, different limits for individual users, or both. You can choose to have these limits applied before the statement is executed through *predictive governing*, or while a statement is running, through *reactive governing*. You can also use reactive and predictive governing in combination. You define these limits in one or more *resource limit tables*, named DSNRLSTxx or DSNRLMTxx, depending on the monitoring purpose.

Work file database

Use the *work file database* as storage for processing SQL statements that require working space, such as that required for a sort.

The work file database is used as storage for DB2 work files for processing SQL statements that require working space (such as the space that is required for a sort), and as storage for created global temporary tables and declared global temporary tables.

DB2 creates a work file database and some table spaces in it for you at installation time. You can create additional work file table spaces at any time. You can drop, re-create, and alter the work file database or the table spaces in it, or both, at any time.

In a non-data-sharing environment, the work file database is named DSNDB07. In a data sharing environment, each DB2 member in the data sharing group has its own work file database.

You can also use the work file database for all temporary tables.

DB2 and data integrity

Referential integrity ensures data integrity by enforcing rules with referential constraints, check constraints, and triggers. You can rely on constraints and triggers to ensure the integrity and validity of your data, rather than relying on individual applications to do that work.

Constraints

Constraints are rules that control values in columns to prevent duplicate values or set restrictions on data added to a table.

Constraints fall into the following three types:

- Unique constraints
- Referential constraints
- Check constraints

Unique constraints

A *unique constraint* is a rule that the values of a key are valid only if they are unique in a table.

Unique constraints are optional and can be defined in the CREATE TABLE or ALTER TABLE statements with the PRIMARY KEY clause or the UNIQUE clause. The columns specified in a unique constraint must be defined as NOT NULL. A unique index enforces the uniqueness of the key during changes to the columns of the unique constraint.

A table can have an arbitrary number of unique constraints, with at most one unique constraint defined as a primary key. A table cannot have more than one unique constraint on the same set of columns.

A unique constraint that is referenced by the foreign key of a referential constraint is called the *parent key*.

Referential constraints

DB2 ensures referential integrity between your tables when you define referential constraints.

Referential integrity is the state in which all values of all foreign keys are valid. Referential integrity is based on *entity integrity*. Entity integrity requires that each entity have a unique key. For example, if every row in a table represents relationships for a unique entity, the table should have one column or a set of columns that provides a unique identifier for the rows of the table. This column (or set of columns) is called the parent key of the table. To ensure that the parent key does not contain duplicate values, a unique index must be defined on the column or columns that constitute the parent key. Defining the parent key is called entity integrity.

A *referential constraint* is the rule that the nonnull values of a foreign key are valid only if they also appear as values of a parent key. The table that contains the parent key is called the *parent table* of the referential constraint, and the table that contains the foreign key is a *dependent* of that table.

The relationship between some rows of the DEPT and EMP tables, shown in the following figure, illustrates referential integrity concepts and terminology. For example, referential integrity ensures that every foreign key value in the DEPT column of the EMP table matches a primary key value in the DEPTNO column of the DEPT table.

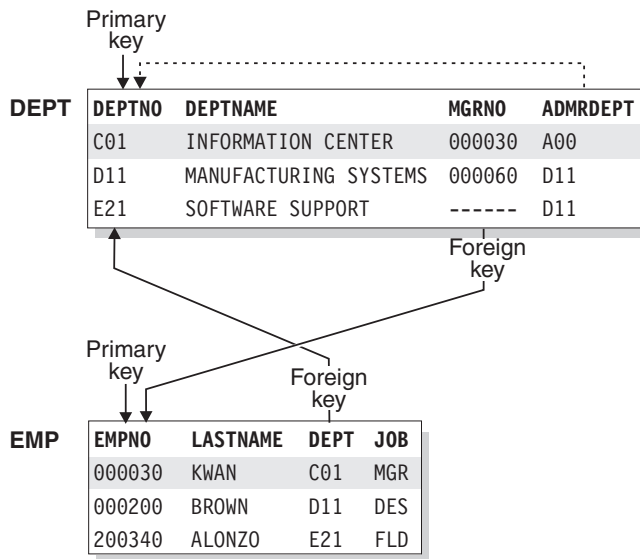

Figure 6. Referential integrity of DEPT and EMP tables

Two parent and dependent relationships exist between the DEPT and EMP tables.

- The foreign key on the DEPT column establishes a parent and dependent relationship. The DEPT column in the EMP table depends on the DEPTNO in the DEPT table. Through this foreign key relationship, the DEPT table is the parent of the EMP table. You can assign an employee to no department (by specifying a null value), but you cannot assign an employee to a department that does not exist.
- The foreign key on the MGRNO column also establishes a parent and dependent relationship. Because MGRNO depends on EMPNO, EMP is the parent table of the relationship, and DEPT is the dependent table.

You can define a primary key on one or more columns. A primary key that includes two or more columns is called a *composite key*. A foreign key can also include one or more columns. When a foreign key contains multiple columns, the corresponding primary key must be a composite key. The number of foreign key columns must be the same as the number of columns in the parent key, and the data types of the corresponding columns must be compatible. (The sample project activity table, DSN8A10.PROJECT, is an example of a table with a primary key on multiple columns, PROJNO, ACTNO, and ACSTDATE.)

A table can be a dependent of itself; this is called a *self-referencing table*. For example, the DEPT table is self-referencing because the value of the administrative department (ADMRDEPT) must be a department ID (DEPTNO). To enforce the self-referencing constraint, DB2 requires that a foreign key be defined.

Similar terminology applies to the rows of a parent-and-child relationship. A row in a dependent table, called a *dependent row*, refers to a row in a parent table, called a *parent row*. But a row of a parent table is not always a parent row—perhaps nothing refers to it. Likewise, a row of a dependent table is not always a dependent row—the foreign key can allow null values, which refer to no other rows.

Referential constraints are optional. You define referential constraints by using CREATE TABLE and ALTER TABLE statements.

DB2 enforces referential constraints when the following actions occur:

- An INSERT statement is applied to a dependent table.
- An UPDATE statement is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A MERGE statement that includes an insert operation is applied to a dependent table.
- A MERGE statement that includes an update operation is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A DELETE statement is applied to a parent table. All affected referential constraints and all delete rules of all affected relationships must be satisfied in order for the delete operation to succeed.
- The LOAD utility with the ENFORCE CONSTRAINTS option is run on a dependent table.
- The CHECK DATA utility is run.

Another type of referential constraint is an *informational referential constraint*. This type of constraint is not enforced by DB2 during normal operations. An application process should verify the data in the referential integrity relationship. An informational referential constraint allows queries to take advantage of materialized query tables.

The order in which referential constraints are enforced is undefined. To ensure that the order does not affect the result of the operation, there are restrictions on the definition of delete rules and on the use of certain statements. The restrictions are specified in the descriptions of the SQL statements CREATE TABLE, ALTER TABLE, INSERT, UPDATE, MERGE, and DELETE.

The rules of referential integrity involve the following concepts and terminology:

parent key

A primary key or a unique key of a referential constraint.

parent table

A table that is a parent in at least one referential constraint. A table can be defined as a parent in an arbitrary number of referential constraints.

dependent table

A table that is a dependent in at least one referential constraint. A table can be defined as a dependent in an arbitrary number of referential constraints. A dependent table can also be a parent table.

descendent table

A table that is a dependent of another table or a table that is a dependent of a descendent table.

referential cycle

A set of referential constraints in which each associated table is a descendent of itself.

parent row

A row that has at least one dependent row.

dependent row

A row that has at least one parent row.

descendent row

A row that is dependent on another row or a row that is a dependent of a descendent row.

self-referencing row

A row that is a parent of itself.

self-referencing table

A table that is both parent and dependent in the same referential constraint. The constraint is called a *self-referencing constraint*.

A temporal referential constraint can be defined for a table that contains a BUSINESS_TIME period. The PERIOD BUSINESS_TIME clause is used in both the FOREIGN KEY clause and the REFERENCES clause to indicate that there must not be a row in the child table for which the period of time represented by the BUSINESS_TIME period value for that row is not contained in the BUSINESS_TIME period of one or more corresponding rows in the parent table. Unlike normal referential constraints, it is not necessary that there be exactly one corresponding row in the parent table where the BUSINESS_TIME period contains the BUSINESS_TIME period of the child row. As long as the BUSINESS_TIME period of a row in the child table is contained in the union of the BUSINESS_TIME periods of two or more contiguous matching rows in the parent table, the temporal referential constraint is satisfied.

Additionally, the following indexes must be defined:

- A unique index on the parent table with the BUSINESS_TIME WITHOUT OVERLAPS clause.
- A non-unique index on the child table with the BUSINESS_TIME WITH OVERLAPS clause. Alternatively, the index on the child table, can be defined without the BUSINESS_TIME WITH OVERLAPS clause if the end of the index key includes the end column followed by the begin column of the BUSINESS_TIME period (both in ascending order).

The following rules provide referential integrity:

insert rule

A nonnull insert value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is null if any component of the value is null.

update rule

A nonnull update value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is treated as null if any component of the value is null.

delete rule

Controls what happens when a row of the parent table is deleted. The choices of action, made when the referential constraint is defined, are RESTRICT, NO ACTION, CASCADE, or SET NULL. SET NULL can be specified only if some column of the foreign key allows null values.

More precisely, the delete rule applies when a row of the parent table is the object of a delete or propagated delete operation and that row has dependents in the dependent table of the referential constraint. A *propagated delete* refers to the situation where dependent rows are deleted when parent rows are deleted. Let P denote the parent table, let D denote the dependent table, and let p denote a parent row that is the object of a delete or propagated delete operation. If the delete rule is:

- RESTRICT or NO ACTION, an error occurs and no rows are deleted.
- CASCADE, the delete operation is propagated to the dependent rows of p in D .

- SET NULL, each nullable column of the foreign key of each dependent row of *p* in *D* is set to null.

Each referential constraint in which a table is a parent has its own delete rule, and all applicable delete rules are used to determine the result of a delete operation. Thus, a row cannot be deleted if it has dependents in a referential constraint with a delete rule of RESTRICT or NO ACTION or the deletion cascades to any of its descendents that are dependents in a referential constraint with the delete rule of RESTRICT or NO ACTION.

The deletion of a row from parent table *P* involves other tables and can affect rows of these tables:

- If *D* is a dependent of *P* and the delete rule is RESTRICT or NO ACTION, *D* is involved in the operation but is not affected by the operation and the deletion from the parent table *P* does not take place.
- If *D* is a dependent of *P* and the delete rule is SET NULL, *D* is involved in the operation and rows of *D* might be updated during the operation.
- If *D* is a dependent of *P* and the delete rule is CASCADE, *D* is involved in the operation and rows of *D* might be deleted during the operation. If rows of *D* are deleted, the delete operation on *P* is said to be propagated to *D*. If *D* is also a parent table, the actions described in this list apply, in turn, to the dependents of *D*.

Any table that can be involved in a delete operation on *P* is said to be *delete-connected* to *P*. Thus, a table is delete-connected to table *P* if it is a dependent of *P* or a dependent of a table to which delete operations from *P* cascade.

➡ Department table (DSN8A10.DEPT) (Introduction to DB2 for z/OS)

➡ Employee table (DSN8A10.EMP) (Introduction to DB2 for z/OS)

➡ Project activity table (DSN8A10.PROJECT) (Introduction to DB2 for z/OS)

➡ Referential constraints (DB2 Application programming and SQL)

Check constraints

A *check constraint* is a rule that specifies the values that are allowed in one or more columns of every row of a base table.

Like referential constraints, check constraints are optional and you define them by using the CREATE TABLE and ALTER TABLE statements. The definition of a check constraint restricts the values that a specific column of a base table can contain.

A table can have any number of check constraints. DB2 enforces a check constraint by applying the restriction to each row that is inserted, loaded, or updated. One restriction is that a column name in a check constraint on a table must identify a column of that table.

Example: You can create a check constraint to ensure that all employees earn a salary of \$30 000 or more:

```
CHECK (SALARY >= 30000)
```

Related concepts:

➡ Check constraints (DB2 Application programming and SQL)

Triggers

A *trigger* defines a set of actions that are executed when a delete, insert, or update operation occurs on a specified table or view. When such an operation is executed, the trigger is said to be *activated*.

You can use triggers along with referential constraints and check constraints to enforce data integrity rules. Triggers are more powerful than constraints because you can use them to do the following things:

- Update other tables
- Automatically generate or transform values for inserted or updated rows
- Invoke functions that perform operations both inside and outside of DB2

For example, assume that you need to prevent an update to a column when a new value exceeds a certain amount. Instead of preventing the update, you can use a trigger. The trigger can substitute a valid value and invoke a procedure that sends a notice to an administrator about the attempted invalid update.

You define triggers with the CREATE TRIGGER statement.

Triggers move the business rule application logic into the database, which results in faster application development and easier maintenance. The business rule is no longer repeated in several applications, and the rule is centralized to the trigger. For example, DB2 can check the validity of the changes that any application makes to a salary column, and you are not required to change application programs when the logic changes.

There are a number of criteria that are defined when creating a trigger, which are used to determine when a trigger should be activated.

- The *subject table* defines the table or view for which the trigger is defined.
- The *trigger event* defines a specific SQL operation that modifies the subject table. The operation could be a delete, insert, or update.
- The *trigger activation time* defines whether the trigger should be activated before or after the trigger event is performed on the subject table.

The statement that causes a trigger to be activated includes a set of *affected rows*. These are the rows of the subject table that are being deleted, inserted or updated. The *trigger granularity* defines whether the actions of the trigger are to be performed once for the statement, or once for each of the rows in the set of affected rows.

The *trigger action* consists of an optional search condition and a set of SQL statements that are executed whenever the trigger is activated. The SQL statements are only executed if no search condition is specified, or the specified search condition evaluates to true.

The triggered action can refer to the values in the set of affected rows. This is supported through the use of *transition variables*. Transition variables use the names of the columns in the subject table, qualified by a specified name that identifies whether the reference is to the old value (prior to the update) or the new value (after the update). The new value can also be changed using an assignment in a before update or insert trigger.

Another means of referring to the values in the set of affected rows is by using *transition tables*. Transition tables also use the names of the columns of the subject table, but have a name specified that allows the complete set of affected rows to be

treated as a table. Transition tables can only be used in after triggers, and cannot be modified. Separate transition tables can be defined for old and new values.

Multiple triggers can be specified for a combination of table, event, or activation time. The order in which the triggers are activated is the same as the order in which they were created. Thus, the most recently created trigger is the last trigger that is activated.

The activation of a trigger might cause *trigger cascading*. This is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers, or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which might result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing significant change to the database as a result of a single delete, insert or update statement.

The actions that are performed in the trigger are considered to be part of the operation that caused the trigger to be executed.

- The database manager ensures that the operation and the triggers that are executed as a result of that operation either all complete or are all backed out. Operations that occurred prior to the triggering operation are not affected.
- The database manager effectively checks all constraints (except for a constraint with a RESTRICT delete rule) after the operation and the associated triggers have been executed.

 [Creation of triggers \(Introduction to DB2 for z/OS\)](#)

Application processes, concurrency, and recovery

All SQL programs execute as part of an *application process*. An application process involves the execution of one or more programs, and it is the unit to which DB2 allocates resources and locks.

Different application processes might involve the execution of different programs, or different executions of the same program. The means of initiating and terminating an application process are dependent on the environment.

Locking, commit, and rollback

More than one application process might request access to the same data at the same time. Furthermore, under certain circumstances, an SQL statement can execute concurrently with a utility on the same table space. *Locking* is used to maintain data integrity under such conditions, preventing, for example, two application processes from updating the same row of data simultaneously.

DB2 implicitly acquires locks to prevent uncommitted changes made by one application process from being perceived by any other. DB2 will implicitly release all locks it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A *commit* operation releases locks acquired by the application process and commits database changes made by the same process.

DB2 provides a way to *back out* uncommitted changes made by an application process. This might be necessary in the event of a failure on the part of an

application process, or in a *deadlock* situation. An application process, however, can explicitly request that its database changes be backed out. This operation is called *rollback*.

The interface used by an SQL program to explicitly specify these commit and rollback operations depends on the environment. If the environment can include recoverable resources other than DB2 databases, the SQL COMMIT and ROLLBACK statements cannot be used. Thus, these statements cannot be used in an IMS, CICS, or WebSphere environment.

Unit of work

A *unit of work* is a recoverable sequence of operations within an application process. A unit of work is sometimes called a *logical unit of work*.

At any time, an application process has a single unit of work, but the life of an application process can involve many units of work as a result of commit or full rollback operations.

A unit of work is initiated when an application process is initiated. A unit of work is also initiated when the previous unit of work is ended by something other than the end of the application process. A unit of work is ended by a commit operation, a full rollback operation, or the end of an application process. A commit or rollback operation affects only the database changes made within the unit of work it ends. While these changes remain uncommitted, other application processes are unable to perceive them unless they are running with an isolation level of uncommitted read. The changes can still be backed out. Once committed, these database changes are accessible by other application processes and can no longer be backed out by a rollback. Locks acquired by DB2 on behalf of an application process that protects uncommitted data are held at least until the end of a unit of work.

The initiation and termination of a unit of work define *points of consistency* within an application process. A point of consistency is a claim by the application that the data is consistent. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds have been added to the second account is consistency reestablished. When both steps are complete, the commit operation can be used to end the unit of work, thereby making the changes available to other application processes. The following figure illustrates this concept.

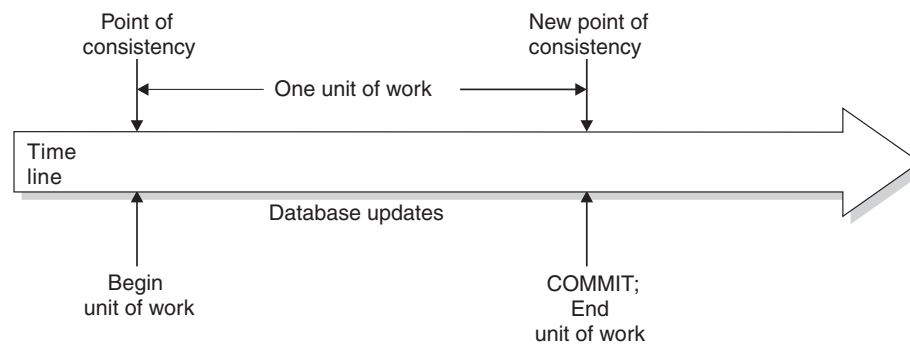

Figure 7. Unit of work with a commit operation

Unit of recovery

A *DB2 unit of recovery* is a recoverable sequence of operations executed by DB2 for an application process.

If a unit of work involves changes to other recoverable resources, the unit of work will be supported by other units of recovery. If relational databases are the only recoverable resources used by the application process, then the scope of the unit of work and the unit of recovery are the same and either term can be used.

Rolling back work

DB2 can back out all changes made in a unit of recovery or only selected changes. Only backing out all changes results in a point of consistency.

Rolling back all changes

The SQL ROLLBACK statement without the TO SAVEPOINT clause specified causes a full rollback operation. If such a rollback operation is successfully executed, DB2 backs out uncommitted changes to restore the data consistency that existed when the unit of work was initiated.

That is, DB2 undoes the work, as shown in the following figure:

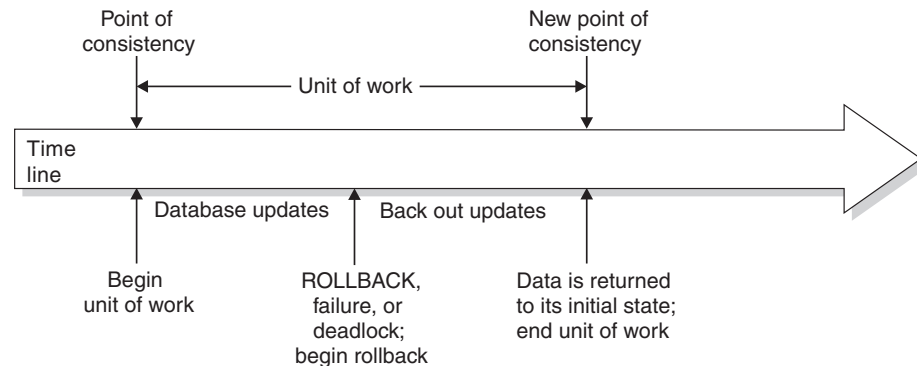

Figure 8. Rolling back all changes from a unit of work

Rolling back selected changes using savepoints

A *savepoint* represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set.

For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the SQL RELEASE SAVEPOINT statement to delete a savepoint. The following figure illustrates this concept.

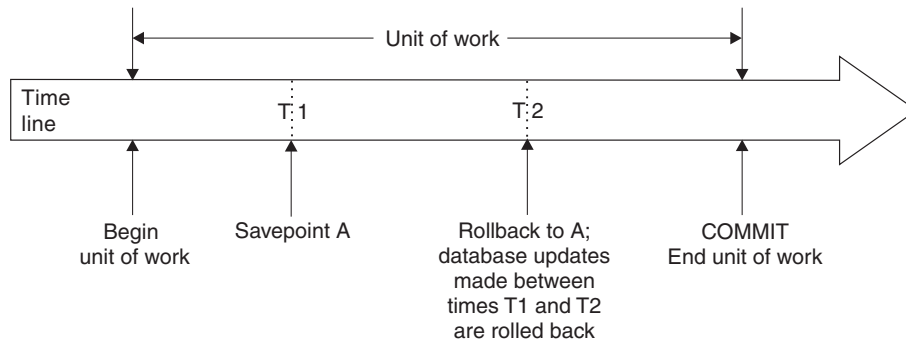

Figure 9. Rolling back changes to a savepoint within a unit of work

Packages and application plans

A *package* contains control structures that DB2 uses when it runs SQL statements. An *application plan* relates an application process to a local instance of DB2 and specifies processing options.

Packages are produced during program preparation. You can think of the control structures as the bound or operational form of SQL statements. All control structures in a package are derived from the SQL statements that are embedded in a single source program.

An application plan contains one or both of the following elements:

- A list of package names

DB2 applications require an application plan. Packages make application programs more flexible and easier to maintain.

Example: The following figure shows an application plan that contains two packages. Suppose that you decide to change the SELECT statement in package AA to select data from a different table. In this case, you need to bind only package AA again and not package AB.

GUPI

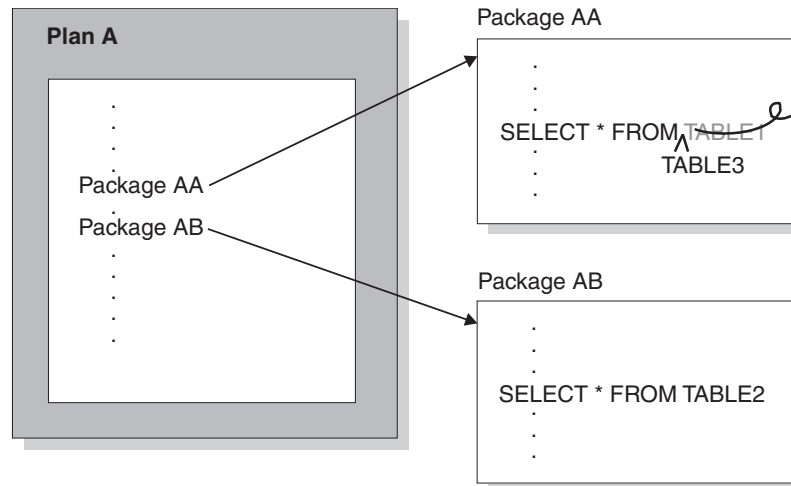

Figure 10. Application plan and packages

GUPI

In general, you create plans and packages by using the DB2 commands `BIND PLAN` and `BIND PACKAGE`.

A *trigger package* is a special type of package that is created when you execute a `CREATE TRIGGER` statement. A trigger package executes only when the trigger with which it is associated is activated.

Packages for JDBC, SQLJ, and ODBC applications serve different purposes that you can read more about later in this information.

“`SET CURRENT PACKAGESET`” on page 2192

Routines

A *routine* is an executable SQL object. The two types of routines are functions and stored procedures.

Functions

A *function* is a routine that can be invoked from within other SQL statements and that returns a value or a table.

Functions are classified as either SQL functions or external functions. SQL functions are written using SQL statements, which are also known collectively as SQL procedural language. External functions reference a host language program. The host language program can contain SQL, but does not require SQL.

You define functions by using the CREATE FUNCTION statement. You can classify functions as built-in functions, user-defined functions, or cast functions that are generated for distinct types. Functions can also be classified as aggregate, scalar, or table functions, depending on the input data values and result values.

A *table function* can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table that is created through a CREATE TABLE statement. Table functions can be qualified with a schema name.

Related tasks:

- Defining a user-defined function (DB2 Application programming and SQL)
 - “Functions” on page 219
 - “Types of functions” on page 219

Procedures

A *procedure*, also known as a stored procedure, is a routine that you can call to perform operations that can include SQL statements.

Procedures are classified as either SQL procedures or external procedures. SQL procedures contain only SQL statements. External procedures reference a host language program that might or might not contain SQL statements.

DB2 for z/OS supports the following types of procedures:

External stored procedures

External stored procedures are procedures that are written in a host language and can contain SQL statements. The source code for an external stored procedure is separate from the definition. You can write an external stored procedure in Assembler, C, C++, COBOL, Java, REXX, or PL/I. All programs must be designed to run using Language Environment®. Your COBOL and C++ stored procedures can contain object-oriented extensions.

External SQL procedures

External SQL procedures are procedures whose body is written in SQL. DB2 supports them by generating an associated C program for each procedure. All SQL procedures that were created prior to Version 9.1 are external SQL procedures. Starting in Version 9.1, you can create an external SQL procedure by specifying FENCED or EXTERNAL in the CREATE PROCEDURE statement.

Native SQL procedures

Native SQL procedures are procedures whose body is written in SQL. For native SQL procedures, DB2 does not generate an associated C program. Starting in Version 9.1, all SQL procedures that are created without the FENCED or EXTERNAL options in the CREATE PROCEDURE statement are native SQL procedures. You can create native SQL procedures in one step. Native SQL statements support more functions and usually provide better performance than external SQL statements.

SQL control statements are supported in SQL procedures. Control statements are SQL statements that allow SQL to be used in a manner similar to writing a program in a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL procedures provide the same benefits as procedures in a host language. That is, a common piece of code needs to be written and maintained only once and can be called from several programs.

SQL procedures provide additional benefits when they contain SQL statements. In this case, SQL procedures can reduce or eliminate network delays that are associated with communication between the client and server and between each SQL statement. SQL procedures can improve security by providing a user the ability to invoke only a procedure instead of providing them with the ability to execute the SQL that the procedure contains.

You define procedures by using the CREATE PROCEDURE statement.

Sequences

A *sequence* is a stored object that simply generates a sequence of numbers in a monotonically ascending (or descending) order. A sequence provides a way to have DB2 automatically generate unique integer primary keys and to coordinate keys across multiple rows and tables.

A sequence can be used to exploit parallelization, instead of programmatically generating unique numbers by locking the most recently used value and then incrementing it.

Sequences are ideally suited to the task of generating unique key values. One sequence can be used for many tables, or a separate sequence can be created for each table requiring generated keys. A sequence has the following properties:

- Guaranteed, unique values, assuming that the sequence is not reset and does not allow the values to cycle
- Monotonically increasing or decreasing values within a defined range
- Can increment with a value other than 1 between consecutive values (the default is 1).
- Recoverable. If DB2 should fail, the sequence is reconstructed from the logs so that DB2 guarantees that unique sequence values continue to be generated across a DB2 failure.

Values for a given sequence are automatically generated by DB2. Use of DB2 sequences avoids the performance bottleneck that results when an application implements sequences outside the database. The counter for the sequence is incremented (or decremented) independently of the transaction. In some cases, gaps can be introduced in a sequence. A gap can occur when a given transaction increments a sequence two times. The transaction might see a gap in the two numbers that are generated because there can be other transactions concurrently incrementing the same sequence. A user might not realize that other users are

drawing from the same sequence. Furthermore, it is possible that a given sequence can appear to have generated gaps in the numbers, because a transaction that might have generated a sequence number might have rolled back or the DB2 subsystem might have failed. Updating a sequence is not part of a transaction's unit of recovery.

A sequence is created with a CREATE SEQUENCE statement. A sequence can be referenced using a *sequence-reference*. A sequence reference can appear most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value, or the previously generated value.

Although there are similarities, a sequence is different than an identity column. A sequence is an object, whereas an identity column is a part of a table. A sequence can be used with multiple tables, but an identity column is tied to a single table.

“CREATE SEQUENCE” on page 1693

User-defined types

A *user-defined data type* is a data type that is defined to the database using a CREATE statement.

A *distinct type* is a user-defined type that shares its internal representation with a built-in data type (its source type), but is considered to be a separate and incompatible data type for most operations. A distinct type is created with an SQL CREATE TYPE (distinct) statement. A distinct type can be used to define a column of a table, or a parameter of a routine.

“CREATE TYPE (distinct)” on page 1830

Distributed data

The database managers in a distributed relational database communicate and cooperate with each other in a way that allows a DB2 application program to use SQL to access data at any of the interconnected computer systems.

A *distributed relational database* consists of a set of tables and other objects that are spread across different, but interconnected, computer systems. Each computer system has a relational database manager, such as DB2, that manages the tables in its environment. The database managers communicate and cooperate with each other in a way that allows a DB2 application program to use SQL to access data at any of the computer systems. The DB2 subsystem where the application plan is bound is known as the *local DB2 subsystem*. Any database server other than the local DB2 subsystem is considered a *remote database server*, and access to its data is a distributed operation.

Distributed relational databases are built on formal requester-server protocols and functions. An *application requester* component supports the application end of a connection. It transforms an application's database request into communication protocols that are suitable for use in the distributed database network. These requests are received and processed by an *application server* component at the database server end of the connection. Working together, the application requester

and application server handle the communication and location considerations so that the application is isolated from these considerations and can operate as if it were accessing a local database.

For more information on Distributed Relational Database Architecture™ (DRDA®) communication protocols, see *Open Group Technical Standard, DRDA Version 3 Vol. 1: Distributed Relational Database Architecture*.

Connections

A *connection* is an association between an application process and a local or remote database server. Connections are managed by applications.

An application process must be connected to the application server facility of a database manager before SQL statements that reference tables or views can be executed. An application can use the CONNECT statement to establish a connection to a database server and make that database server the current server of the application process.

Commit processing: When DB2 for z/OS acts as a requester, it negotiates with the database server during the connection process to determine how to perform commits. If the remote server does not support two-phase commit protocol, DB2 downgrades to perform one-phase commits. Otherwise, DB2 always performs two-phase commits, which allow applications to update one or more databases in a single unit of work and are more reliable than one-phase commits. Two-phase commit is a two-step process:

1. First, all database managers involved in the same unit of work are pooled to determine whether they are ready to commit.
2. Then, if all database managers respond positively, they are directed to execute commit processing. If all database managers do not respond positively, they are directed to execute backout processing.

DB2 can also provide coordination for transactions that include both two-phase commit resources and one-phase commit resources. If an application has multiple connections to several different database servers, and if any of the connections are one-phase commit connections, then only one database that is involved in the transaction can be updated. The connections to all the other databases that are involved in the transaction are read-only.

Supported SQL statements and clauses: For the most part, an application can use the statements and clauses that are supported by the database manager of the current server, even though that application might be running via the application requester of a database manager that does not support some of those statements and clauses. Restrictions to this general rule for DB2 for z/OS are documented in *IBM DB2 SQL Reference for Cross-Platform Development*.

To execute a static SQL statement that references tables or views, the bound form of the statement is taken from a package that the database manager previously created through a bind operation or when a version of a native SQL procedure was defined.

Distributed unit of work

The *distributed unit of work facility* provides for the remote preparation and execution of SQL statements.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server. Any number of database servers can participate in the same unit of work, and any number of connections can exist between an application process and a database server. A commit or rollback operation that does not specify a savepoint ends the unit of work.

Connection management

How connections are managed depends on what states the SQL connection and the application process are in.

At any time:

- An SQL connection is in one of the following states:
 - Current and held
 - Current and release-pending
 - Dormant and held
 - Dormant and release-pending
- An application process is in the connected or unconnected state, and has a set of zero or more SQL connections. Each SQL connection is uniquely identified by the name of the database server at the other end of the connection. Only one SQL connection is active (current) at a time.

Initial state of an application process: An application process is initially in the connected state, and it has exactly one SQL connection. The server of that connection is the local DB2 subsystem.

Initial state of an SQL connection: An SQL connection is initially in the current and held state.

The following figure shows the state transitions:

Figure 11. State transitions for an SQL connection and an application process connection in a distributed unit of work

SQL connection states

If an application process successfully executes a CONNECT statement, the SQL connection states of the connections change.

If an application process successfully executes a CONNECT statement:

- The current connection is placed in the dormant and held state.
- The new connection is placed in the current and held state.
- The location name is added to the set of existing connections.

If the location name is already in the set of existing connections, an error is returned.

An SQL connection in the dormant state is placed in the current state using:

- The SET CONNECTION statement, or
- The CONNECT statement, if the SQLRULES(DB2) bind option is in effect.

When an SQL connection is placed in the current state, the previously-current SQL connection, if any, is placed in the dormant state. No more than one SQL connection in the set of existing connections of an application process can be current at any time. Changing the state of an SQL connection from current to dormant or from dormant to current has no effect on its held or release-pending state.

An SQL connection is placed in the release-pending state by the RELEASE statement. When an application process executes a commit operation, every

release-pending connection of the process is ended. Changing the state of an SQL connection from held to release-pending has no effect on its current or dormant state. Thus, an SQL connection in the release-pending state can still be used until the next commit operation. No way exists to change the state of a connection from release-pending to held.

Application process connection states

In a distributed unit of work, an application process can be in a connected or unconnected state. Depending on the state, the application process can execute only certain SQL statements successfully.

A connection to a different database server can be established by the explicit or implicit execution of a CONNECT statement. The following rules apply:

- An application process cannot have more than one SQL connection to the same database server at the same time.
- When an application process executes a SET CONNECTION statement, the specified location name must be in the set of existing connections of the application process.
- When an application process executes a CONNECT statement and the SQLRULES(STD) bind option is in effect, the specified location must not be in the set of existing connections of the application process.

If an application process has a current SQL connection, the application process is in a *connected* state. The CURRENT SERVER special register contains the name of the database server of the current SQL connection. The application process can execute SQL statements that refer to objects managed by that server. If the server is a DB2 subsystem, the application process can also execute certain SQL statements that refer to objects managed by a DB2 subsystem with which that server can establish a connection.

An application process in an unconnected state enters a connected state when it successfully executes a CONNECT or SET CONNECTION statement.

If an application process does not have a current SQL connection, the application process is in an *unconnected* state. The CURRENT SERVER special register contains blanks. The only SQL statements that can be executed successfully are CONNECT, RELEASE, COMMIT, ROLLBACK, and any of the following local SET statements.

- SET CONNECTION
- SET CURRENT APPLICATION ENCODING SCHEME
- SET CURRENT PACKAGE PATH
- SET CURRENT PACKAGESET
- SET *host-variable* = CURRENT APPLICATION ENCODING SCHEME
- SET *host-variable* = CURRENT PACKAGESET
- SET *host-variable* = CURRENT SERVER

Because the application process is in an unconnected state, a COMMIT or ROLLBACK statement is processed by the local DB2 subsystem.

An application process in a connected state enters an unconnected state when its current SQL connection is intentionally ended, or the execution of an SQL statement is unsuccessful because of a failure that causes a rollback operation at the current server and loss of the SQL connection. SQL connections are intentionally ended when an application process successfully executes a commit operation and either of the following are true:

- The SQL connection is in the release-pending state.
- The SQL connection is not in the release-pending state, but it is a remote connection and either of the following are true:
 - The DISCONNECT(AUTOMATIC) bind option is in effect
 - The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection

An implicit CONNECT to a default DB2 subsystem is executed when an application process executes an SQL statement other than COMMIT, CONNECT TO, CONNECT RESET, SET CONNECTION, RELEASE, or ROLLBACK, and if all of the following conditions apply:

- The CURRENTSERVER bind option was specified when creating the application plan of the application process and the identified server is not the local DB2.
- An explicit CONNECT statement has not already been successfully or unsuccessfully executed by the application process.
- An implicit connection has not already been successfully or unsuccessfully executed by the application process. An implicit connection occurs as the result of execution of an SQL statement that contains a three-part name in a package that is bound with the DBPROTOCOL(DRDA) option.

If the implicit CONNECT fails, the application process is placed in an *unconnected* state.

When a connection is ended, all resources that were acquired by the application process through the connection and all resources that were used to create and maintain the connection are returned to the connection pool. For example, if application process *P* placed the connection to application server *X* in the release-pending state, all cursors of *P* at *X* are closed and returned to the connection pool when the connection is ended during the next commit operation.

When a connection is ended as a result of a communications failure, the application process is placed in an unconnected state.

All connections of an application process are ended when the process ends.

Remote unit of work

The *remote unit of work facility* also provides for the remote preparation and execution of SQL statements, but in a much more restricted fashion than the distributed unit of work facility.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server, and all SQL statements in the same unit of work must be executed by the same database server. However, unlike a distributed unit of work, an application process can have only one connection at a time. The process cannot connect to a new server until it executes a commit or rollback operation on the current server to end that unit of work. This restricts the situations in which a CONNECT statement can be executed.

Connection management

How connections are managed depends on what states the SQL connection and the application process are in.

An application process is in one of four states at any time:

- Connectable and connected
- Unconnectable and connected
- Connectable and unconnected
- Unconnectable and unconnected

Initial state of an application process: An application process is initially in the connectable and connected state. The database server to which the application process is connected is determined by a product-specific option that might involve an implicit CONNECT operation. An implicit connect operation cannot occur if an implicit or explicit connect operation has already successfully or unsuccessfully occurred. Thus, an application process cannot be implicitly connected to a database server more than once. Other rules for implicit connect operations are product-specific.

Figure 12 shows the state transitions:

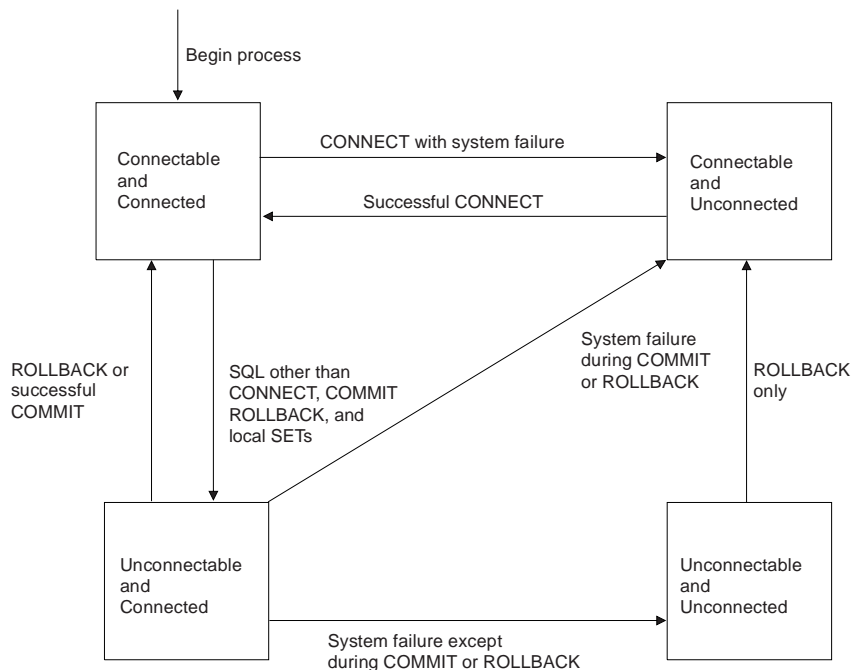

Figure 12. State transitions for an application process connection in a remote unit of work

In the following descriptions of application process connections, CONNECT can mean:

- CONNECT TO
- CONNECT RESET
- CONNECT *authorization*

It cannot mean CONNECT with no operand, which is used to return information about the current server.

Consecutive CONNECT statements can be executed successfully because CONNECT does not remove an application process from the connectable state. A CONNECT statement does not initiate a new unit of work; a unit of work is initiated by the first SQL statement that accesses data. CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT,

COMMIT, RELEASE, ROLLBACK, or SET CONNECTION. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

Connectable and connected state: In the connectable and connected state, an application process is connected to a database server, and CONNECT statements that target the current server can be executed. An application process re-enters this state when either of the following is true:

- The process completes a rollback or a successful commit from an unconnectable and connected state.
- The process successfully executes a CONNECT statement from a connectable and unconnected state.

Unconnectable and connected state: In the unconnectable and connected state, an application process is connected to a database server, and only a CONNECT statement with no operands can be executed. An application process enters this state from a connectable and connected state when it executes any SQL statement other than CONNECT, COMMIT, or ROLLBACK.

Connectable and unconnected state: In the connectable and unconnected state, an application process is not connected to a database server. The only SQL statement that can be executed is CONNECT. An application process enters this state if any of the following is true:

- The process does not successfully execute a CONNECT statement from a connectable and connected state.
- The process executes a COMMIT statement when the SQL connection is in a release-pending state.
- A system failure occurs during a COMMIT or ROLLBACK from an unconnectable and connected state.
- The process executes a ROLLBACK statement from an unconnectable and unconnected state.

Other product-specific reasons can also cause an application process to enter the connectable and unconnected state.

Unconnectable and unconnected state: In the unconnectable and unconnected state, an application process is not connected to a database server and CONNECT statements cannot be executed. The only SQL statement that can be executed is ROLLBACK. An application process enters this state from an unconnectable and connected state as a result of a system failure, except during a COMMIT or ROLLBACK, at the server.

Character conversion

A *string* is a sequence of bytes that can represent characters. Within a string, all the characters are represented by a common encoding representation. In some cases, it might be necessary to convert these characters to a different encoding representation. The process of conversion is known as *character conversion*.

Character conversion, when required, is automatic, and when successful, it is transparent to the application.

In client/server environments, character conversion can occur when an SQL statement is executed remotely. Consider, for example, the following two cases. In either case, the data could have a different representation at the sending and receiving systems.

- The values of data sent from the requester to the current server
- The values of data sent from the current server to the requester

Conversion can also occur during string operations on the same system, as in the following examples:

- An overriding CCSID is specified.
For example, an SQL statement with a descriptor, which requires an SQLDA. In the SQLDA, the CCSID is in the SQLNAME field for languages other than REXX, and in the SQLCCSID field for REXX. (For more information, see “SQL descriptor area (SQLDA)” on page 2366). A DECLARE VARIABLE statement can also be issued to associate a CCSID with the host variables into which data is retrieved from a table.
- The value of the ENCODING bind option or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for a native SQL procedure (static SQL statements) or the CURRENT APPLICATION ENCODING SCHEME special register (for dynamic SQL) is different than encoding scheme of the data being retrieved.
- A mixed character string is assigned to an SBCS column or host variable.
- An SQL statement refers to data that is defined with different CCSIDs.

The text of an SQL statement is also subject to character conversion because it is a character string.

The following list defines some of the terms used for character conversion.

ASCII Acronym for American Standard Code for Information Interchange, an encoding scheme used to represent characters. The term ASCII is used throughout this information to refer to IBM-PC Data or ISO 8-bit data.

character set

A defined set of characters, a character being the smallest component of written language that has semantic value. For example, the following character set appears in several code pages:

- 26 nonaccented letters A through Z
- 26 nonaccented letters a through z
- digits 0 through 9
- . , ; ? () ' " / - _ & + % * = < >

code page

A set of assignments of characters to code points. For example, in EBCDIC, “A” is assigned code point X'C1', and “B” is assigned code point X'C2'. In Unicode UTF-8, “A” is assigned code point X'41', and “B” is assigned code point X'42'. Within a code page, each code point has only one specific meaning.

code point

A unique bit pattern that represents a character. It is a numerical index or position in an encoding table used for encoding characters.

coded character set

A set of unambiguous rules that establishes a character set and the

one-to-one relationships between the characters of the set and their coded representations. It is the assignment of each character in a character set to a unique numeric code value.

coded character set identifier (CCSID)

A two-byte, unsigned binary integer that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

EBCDIC

Acronym for Extended Binary-Coded Decimal Interchange Code, an encoding scheme used to represent character data, a group of coded character sets that consist of 8 bit coded characters. EBCDIC coded character sets use the first 64 code positions (X'00' to X'3F') for control codes. The range X'41' to X'FE' is used for single-byte characters. For double-byte characters, the first byte is in the range X'41' to X'FE' and the second byte is also in the range X'41' to X'FE', while X'4040' represents a double-byte space.

encoding scheme

A set of rules used to represent character data. All string data stored in a table must use the same encoding scheme and all tables within a table space must use the same encoding scheme, except for global temporary tables, declared temporary tables, and work file table spaces. DB2 supports these encoding schemes:

- ASCII
- EBCDIC
- Unicode

substitution character

A unique character that is substituted during character conversion for any characters in the source encoding representation that do not have a match in the target encoding representation.

Unicode

A universal encoding scheme for written characters and text that enables the exchange of data internationally. It provides a character set standard that can be used all over the world. It provides the ability to encode all characters used for the written languages of the world and treats alphabetic characters, ideographic characters, and symbols equivalently because it specifies a numeric value and a name for each of its characters. It includes punctuation marks, mathematical symbols, technical symbols, geometric shapes, and dingbats. DB2 supports these two encoding forms:

- UTF-8: Unicode Transformation Format, a 8 bit encoding form designed for ease of use with existing ASCII-based systems. UTF-8 can encode any of the Unicode characters. A UTF-8 character is 1,2,3, or 4 bytes in length. A UTF-8 data string can contain any combination of SBCS and MBCS data, including supplementary characters. The CCSID value for data in UTF-8 format is 1208. UTF-8 has multiple code points for spaces, including the '20'X single-byte space that DB2 uses for padding UTF-8 data.
- UTF-16: Unicode Transformation Format, a 16 bit encoding form designed to provide code values for over a million characters and a superset of UCS-2. UTF-16 can encode any of the Unicode characters. In UTF-16 encoding, characters are 2 bytes in length, except for supplementary characters, which take two 2 byte string units per character. The CCSID value for data in UTF-16 format is 1200. UTF-16 has multiple code points for spaces, including the '0020'X single-byte space that DB2 uses for padding UTF-16 data.

Character data (CHAR, VARCHAR, and CLOB) is encoded in Unicode UTF-8. Character strings are also used for mixed data (that is a mixture of single-byte characters and multi-byte characters) and for data that is not associated with any character set (called bit data). Graphic data (GRAPHIC, VARGRAPHIC, and DBCLOB) is encoded in Unicode UTF-16. For a comparison of some UTF-8 and UTF-16 code points for some sample characters, see Figure 15 on page 50. This table shows how a UTF-8 character can be 1 to 4 bytes in length, a non-supplementary UTF-16 character is 2 bytes in length, and how a supplementary character in either UTF-8 or UTF-16 takes two 2 byte code points.

Character conversion can affect the results of several SQL operations. In this information, the effects are described in:

“Conversion rules for string assignment” on page 129

“Conversion rules for comparisons” on page 137

“Character conversion in set operations and concatenations” on page 1128

Character sets and code pages

Even with the same encoding scheme, different CCSIDs exist, and the same code point can represent a different character in different CCSIDs. Furthermore, a byte in a character string does not necessarily represent a character from a single-byte character set (SBCS).

The following figure shows how a typical character set might map to different code points in two different code pages.

code page: pp1 (ASCII)

| | 0 | 1 | 2 | 3 | 4 | 5 | | E | F |
|---|---|---|---|---|---|---|--|---|---|
| 0 | | | | 0 | @ | P | | À | |
| 1 | | | | 1 | A | Q | | À | α |

Coded character sets and CCSIDS

IBM's character data representation architecture (CDRA) deals with the differences in string representation and encoding. The *Coded Character Set Identifier (CCSID)* is a key element of this architecture. A CCSID is a 2 byte (unsigned) binary number that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

A CCSID is an attribute of strings, just as length is an attribute of strings. All values of the same string column have the same CCSID.

Character conversion is described in terms of CCSIDs of the source and target. With DB2 for z/OS, two methods are used to identify valid source and target combinations and to perform the conversion from one coded character set to another:

- DB2 catalog table SYSIBM.SYSSTRINGS
Each row in the catalog table describes a conversion from one coded character set to another.
- z/OS support for Unicode
For more information about the conversion services that are provided, including a complete list of the IBM-supplied conversion tables, see *z/OS Support for Unicode: Using Conversion Services*.

In some cases, no conversion is necessary even though the strings involved have different CCSIDs.

Different types of conversions might be supported by each database manager. Round-trip conversions attempt to preserve characters in one CCSID that are not defined in the target CCSID so that if the data is subsequently converted back to the original CCSID, the same original characters result. Enforced subset match conversions do not attempt to preserve such characters. Which type of conversion is used for a specific source and target CCSID is product-specific.

For more information on character conversion, see *DB2 Installation Guide*.

Determining the encoding scheme and CCSID of a string

An encoding scheme and a CCSID are attributes of strings, just as length is an attribute of strings. All values of the same string column have the same encoding scheme and CCSID.

Every string has an encoding scheme and a CCSID that identifies the manner in which the characters in the string are encoded. Strings can be encoded in ASCII, EBCDIC, or Unicode.

The CCSID that is associated with a string value depends on the SQL statement in which the data is referenced and the type of expression. Table 4 on page 52 describes the rules for determining the CCSID that is associated with a string value. Use the Type 1 rules when the SQL statement meets the following conditions:

- The SQL statement operates with a single set of CCSIDs (SBCS, mixed, and graphic). An SQL statement that does not contain any of the following items operates with a single set of CCSIDs:
 - References to columns from multiple tables or views that are defined with CCSIDs from more than one set of CCSIDs (SBCS, mixed, and graphic)
 - Graphic hexadecimal (GX) or hexadecimal Unicode (UX) string constants
 - References to the XMLCLOB built-in function
 - Cast specifications with a CCSID clause
 - User-defined table functions
- The SQL statement is not one of the following statements:
 - CALL statement
 - SET assignment statement
 - SET special register
 - VALUES statement
 - VALUES INTO statement
- One of the following built-in functions is not referenced:
 - XMLSERIALIZE
 - GETVARIABLE
 - DECRYPT_CHAR
 - DECRYPT_DB
 - DECRYPT_BIT
 - NORMALIZE_STRING
 - ASCII_CHAR
 - CHAR
 - ASCII_STR (or ASCIISTR)
 - EBCDIC_CHAR
 - EBCDIC_STR
 - UNICODE_STR (or UNISTR)

Use the Type 2 rules when the statement does not meet the conditions for Type 1 rules.

Table 4. Rules for determining the CCSID that is associated with string data

| Source of the string data | Type 1 rules | Type 2 rules |
|--|---|---|
| String constant | <p>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant.</p> <p>The CCSID is the appropriate character string CCSID for the encoding scheme.</p> | The CCSID is the appropriate character string CCSID for the application encoding scheme. ¹ |
| Datetime constant | <p>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant.</p> <p>Otherwise, the default EBCDIC encoding scheme is used for the string constant.</p> <p>The CCSID is the appropriate character string CCSID for the encoding scheme.</p> | The CCSID is the appropriate character string CCSID for the application encoding scheme. ¹ |
| Hexadecimal string constant (X'...') | <p>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant.</p> <p>Otherwise, the default EBCDIC encoding scheme is used for the string constant.</p> <p>The CCSID is the appropriate graphic string CCSID for the encoding scheme.</p> | The CCSID is the appropriate character string CCSID for the application encoding scheme. ¹ |
| Graphic string constant (G'...') | <p>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the graphic string constant.</p> <p>Otherwise, the default EBCDIC encoding scheme is used for the graphic string constant.</p> <p>The CCSID is the graphic string CCSID for the encoding scheme.</p> | The CCSID is the graphic string CCSID for the application encoding scheme. ¹ |
| Graphic hexadecimal constant (GX'...') | Not applicable. | The CCSID is the graphic string CCSID for the application encoding scheme, which must be ASCII or EBCDIC. |
| Hexadecimal Unicode string constant (UX'....') | Not applicable. | The CCSID is 1200 (UTF-16). |
| Special register | <p>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the special register.</p> <p>Otherwise, the default EBCDIC encoding scheme is used for the special register.</p> <p>The CCSID is the appropriate character string CCSID for the encoding scheme.</p> | The CCSID is the appropriate CCSID for the application encoding scheme. ¹ |
| Column of a table | The CCSID is the CCSID that is associated with the column of the table. | The CCSID is the CCSID that is associated with the column of the table. |

Table 4. Rules for determining the CCSID that is associated with string data (continued)

| Source of the string data | Type 1 rules | Type 2 rules |
|--|--|---|
| Column of a view | The CCSID is the CCSID of the column of the result table of the fullselect of the view definition. | The CCSID is the CCSID of the column of the result table of the fullselect of the view definition. |
| Expression | The CCSID is the CCSID of the result of the expression. | The CCSID is the CCSID of the result of the expression. |
| Result of a built-in function | <p>If the description of the function, in Chapter 4, "Built-in functions," on page 321, indicates what the CCSID of the result is, the CCSID is that CCSID.</p> <p>Otherwise, if the description of the function refers to this table for the CCSID, the CCSID is the appropriate CCSID of the CCSID set that is used by the statement for the data type of the result.</p> | <p>If the description of the function, in Chapter 4, "Built-in functions," on page 321, indicates what the CCSID of the result is, the CCSID is that CCSID.</p> <p>Otherwise, if the description of the function refers to this table for the CCSID, the CCSID is the appropriate CCSID of the application encoding scheme for the data type of the result.¹</p> |
| Parameter of a user-defined routine | The CCSID is the CCSID that was determined when the function or procedure was created. | The CCSID is the CCSID that was determined when the function or procedure was created. |
| The expression in the RETURN statement of a CREATE statement for a user-defined SQL scalar function | If the expression in the RETURN statement is string data, the encoding scheme is the same as for the parameters of the function. The CCSID is determined from the encoding scheme and the attributes of the data. | The CCSID is determined from the CCSID of the result of the expression specified in the RETURN statement. |
| String host variable | <p>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the host variable.</p> <p>Graphic variables are an exception if the table or view is EBCDIC or ASCII and the value of the MIXED DATA field on the DSNTIPF panel is NO. In this case, the Unicode encoding scheme is used for the graphic host variable.</p> <p>Otherwise, the default EBCDIC encoding scheme is used for the host variable.</p> <p>The CCSID is the appropriate CCSID for the data type of the host variable.</p> | <p>At package prepare time, the CCSID is the appropriate CCSID for the data type of the host variable for the application encoding scheme.</p> <p>Graphic variables are an exception if the application or encoding scheme is EBCDIC or ASCII and the value of the MIXED DATA field on the DSNTIPF panel is NO. In this case, the Unicode encoding scheme is used for the graphic host variable.</p> <p>At run time, the CCSID specified in the declare variable statement, or as an override in the SQLDA. Otherwise, the CCSID is the appropriate CCSID for the data type of the host variable for the application encoding scheme.</p> |
| <p>Note: If the context is within a check constraint or trigger package, the CCSID is the appropriate CCSID for Unicode instead of the application encoding scheme.</p> | | |

The following examples show how these rules are applied.

Example 1: Assume that the default encoding scheme for the installation is EBCDIC and that the installation does not support mixed and graphic data. The following statement conforms to the rules for Type 1 in Table 4 on page 52. Therefore, the X'40' is interpreted as EBCDIC SBCS data because the statement references a table that is in EBCDIC. The CCSID for X'40' is the default EBCDIC SBCS CCSID for the installation.

```
SELECT * FROM EBCDIC_TABLE WHERE COL1 = X'40';
```

the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank.

Example 2: The following statement references data from two different tables that use different encoding schemes. This statement does not conform to the rules for Type 1 statements in Table 4 on page 52. Therefore, the rules for Type 2 statements are used. The CCSID for X'40' is dependent on the current application encoding scheme. Assuming that the current application encoding scheme is EBCDIC, X'40' represents a single EBCDIC blank.

```
SELECT * FROM EBCDIC_TABLE, UNICODE_TABLE WHERE COL1 = X'40';
```

as with Example 1, the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank. If the current application encoding scheme were ASCII or Unicode, X'40' would represent something different and the results of the query would be different.

Expanding conversions

An *expanding conversion* occurs when the length of the converted string is greater than that of the source string.

For example, an expanding conversion occurs when an ASCII mixed data string that contains DBCS characters is converted to EBCDIC mixed data. To prevent the loss of data on expanding conversions, use a varying-length string variable with a maximum length that is sufficient to contain the expansion.

Expanding conversions also can occur when string data is converted to or from Unicode. It can also occur between UTF-8 and UTF-16, depending on the data being converted. UTF-8 uses 1, 2, 3, or 4 bytes per character. UTF-16 uses 2 bytes per character, except for supplementary characters, which use two 2 byte code points for each character. If UTF-8 were being converted to UTF-16, a 1 byte character would be expanded to 2 bytes.

Contracting conversions

A *contracting conversion* occurs when the length of the converted string is smaller than that of the source string.

For example, a contracting conversion occurs when an EBCDIC mixed data string that contains DBCS characters is converted to ASCII mixed data due to the removal of shift codes.

Contracting conversions also can occur when string data is converted to or from Unicode data. It can also occur between UTF-8 and UTF-16, depending on the data being converted.

Chapter 2. Language elements

An understanding of the basic syntax of SQL and language elements that are common to many SQL statements can be helpful in using SQL with DB2 for z/OS.

The following topics provide information about these language elements:

- “Characters”
- “Tokens” on page 56
- “Identifiers” on page 57
- “Naming conventions” on page 59
- “SQL path” on page 65
- “Qualification of unqualified object names” on page 67
- “Aliases and synonyms” on page 68
- “Authorization IDs, roles, and authorization names” on page 72
- “Data types” on page 80
- “Promotion of data types” on page 108
- “Casting between data types” on page 109
- “Assignment and comparison” on page 119
- “Rules for result data types” on page 143
- “Constants” on page 147
- “Special registers” on page 155
- “Column names” on page 202
- “Variables” on page 208
- “Host structures in PL/I, C, and COBOL” on page 217
- “Host-variable arrays in PL/I, C, C++, and COBOL” on page 218
- “Functions” on page 219
- “Expressions” on page 228
- “Predicates” on page 279
- “Search conditions” on page 305
- “Options affecting SQL” on page 306
- “Mappings from SQL to XML” on page 315

Characters

The basic symbols of keywords and operators in the SQL language are *characters* that are classified as letters, digits, or special characters.

- A *letter* is any of the 26 uppercase (A through Z) and 26 lowercase (a through z) letters of the English alphabet.¹
- A *digit* is any one of the characters 0 through 9.
- A *special character* is any character other than a letter or a digit.

1. Letters also include three code points reserved as alphabetic extenders for national languages (\$, #, and @ in the United States). These three code points (X'5B', X'7B', and X'7C') should be avoided because they represent different characters depending on the CCSID.

Tokens

The basic syntactical units of the SQL language are called *tokens*. A token consists of one or more characters of which none are blanks, control characters, or characters within a string constant or delimited identifier.

Tokens are classified as *ordinary* or *delimiter* tokens:

- An *ordinary token* is a numeric constant, an ordinary identifier, a host identifier, or a keyword.

Examples:

1 .1 +2 SELECT E 3

- A *delimiter token* is a string constant, a delimited identifier, an operator symbol, or any of the special characters shown in the syntax diagrams. A question mark (?) is also a delimiter token when it serves as a parameter marker, as explained in "PREPARE" on page 2083.

Examples:

, 'string' "fld1" = .

Spaces

A *space* is a sequence of one or more blank characters.

Control characters

A *control character* is a special character that is used for string alignment. Treated similar to a space, a control character does not cause a particular action to occur. The following table shows the control characters that DB2 recognizes and their hexadecimal values.

In an SQL procedure, a *new line control character* is a special character that is used for a new line. The carriage return, new line or next line, and line feed (new line) characters, or the combination of carriage return followed by new line characters, and the combination of carriage return followed by line feed characters, as shown in the following table, are the new line control characters for SQL procedures.

Table 5. Hexadecimal values for the control characters that DB2 recognizes

| Control character | EBCDIC hex value | Unicode hex value |
|-----------------------|------------------|-------------------|
| Tab | 05 | 09 |
| Form feed | 0C | 0C |
| Carriage return | 0D | 0D |
| New line or next line | 15 | C285 |
| Line feed (new line) | 25 | 0A |

Tokens, other than string constants and certain delimited identifiers, must not include a control character or space. A control character or space can follow a token. A delimiter token, control character, or a space must follow every ordinary token. If the syntax does not allow a delimiter token to follow an ordinary token, a control character or a space must follow that ordinary token.

Comments

Dynamic SQL statements can include SQL comments. Static SQL statements can include host language comments or SQL comments. Comments can be specified wherever a space can be specified, except within a delimiter token or between the keywords EXEC and SQL. In Java, SQL comments are not allowed within embedded Java expressions. There are two types of SQL comments:

simple comments

Simple comments are introduced with two consecutive hyphens (--). Simple comments cannot continue past the end of the line. For additional information, see “SQL comments” on page 1158.

bracketed comments

Bracketed comments are introduced with /* and end with */. A bracketed comment can continue past the end of the line. For additional information, see “SQL comments” on page 1158.

Uppercase and lowercase

A token in an SQL statement can include lowercase letters, but lowercase letters in an ordinary token are folded to uppercase. However, lowercase letters are folded to uppercase in a C or Java program only if the appropriate precompiler option is specified. Delimiter tokens are never folded to uppercase.

Example: The following two statements, after folding, are equivalent:

```
select * from DSN8A10.EMP where lastname = 'Smith';
SELECT * FROM DSN8A10.EMP WHERE LASTNAME = 'Smith';
```

Identifiers

An *identifier* is a token used to form a name. An identifier in an SQL statement is an SQL identifier or a host identifier.

See “Limits in DB2 for z/OS” on page 2300 for the identifier length limits that DB2 imposes.

SQL identifiers

SQL identifiers can be *ordinary identifiers* or *delimited identifiers*.

Ordinary identifiers

An *ordinary identifier* is an uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character.

An ordinary identifier should not be a reserved word. If a reserved word is used as an identifier in SQL, it must be specified in uppercase and must be a delimited identifier or specified in a host variable. For a list of reserved words, see “Reserved schema names and reserved words” on page 2307.

SQL ordinary identifiers can contain DBCS characters unless otherwise specified. However, an SQL ordinary identifier cannot contain a mixture of SBCS and DBCS characters.

The following list shows the rules for forming SQL ordinary identifiers:

- The UTF-8 representation of the name must not exceed 128 bytes.
- Continuation to the next line is not allowed.

If the SQL ordinary identifier contains DBCS characters, the following additional rules apply:

- The identifier, if encoded in EBCDIC, must start with a shift-out (X'0E') and end with a shift-in (X'0F'). There must be an even number of bytes between the shift-out and the shift-in. An odd-numbered byte between those shifts must not be a shift-out. DBCS blanks (X'4040' in EBCDIC) are not acceptable between the shift-out and the shift-in.
- The identifiers are not folded to uppercase or changed in any other way.

Example: The following example is an ordinary identifier:

SALARY

Delimited identifiers

A *delimited identifier* is a sequence of one or more characters enclosed within escape characters.

The escape character is the quotation mark (")² except for:

- Dynamic SQL when the field SQL STRING DELIMITER on installation panel DSNTIPF is set to the quotation mark (") and either of these conditions is true:
 - DYNAMICRULES run behavior applies. For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.
 - DYNAMICRULES bind, define, or invoke behavior applies and installation panel field USE FOR DYNAMIC RULES is YES.

In this case, the escape character is the apostrophe (').

However, for COBOL application programs, if DYNAMICRULES run behavior does not apply and installation panel field USE FOR DYNAMICRULES is NO, a COBOL compiler option specifies whether the escape character is the quotation mark or apostrophe.

- Static SQL in COBOL application programs. A COBOL compiler option specifies whether the escape character is the quotation mark (") or the apostrophe (').

A delimited identifier can be used when the sequence of characters does not qualify as an ordinary identifier. Such a sequence, for example, could be an SQL reserved word, or it could begin with a digit. Two consecutive escape characters are used to represent one escape character within the delimited identifier. A delimited identifier that contains EBCDIC DBCS characters also must contain the necessary shift characters.

Leading and embedded blanks in the sequence are significant. Trailing blanks in the sequence are not significant. The length of a delimited identifier does not include the starting and ending escape characters. Embedded escape characters (that appear as two characters) are counted in the length as a single character.

Example: If the escape character is the quotation mark, the following example is a delimited identifier:

"VIEW"

Host identifiers

A *host identifier* is a name declared in the host program.

2. In CCSID 1026 and CCSID 1155, the code point for the quotation mark can be X'7F' or X'FC'. However, if the beginning delimiter is X'7F', the ending delimiter must also be X'7F'. If the beginning delimiter is X'FC', ending delimiter must also be X'FC'.

The rules for forming a host identifier are the rules of the host language. In non-Java programs, do not use names beginning with 'DB2', 'SQ'³, 'SQL', 'sql', 'RDI', or 'DSN' because precompilers generate host variable names that begin with these characters. In Java, do not use names beginning with '__sJT_'.

Restrictions for distributed access

To use certain identifiers in distributed access, those identifiers need to be restricted to certain characters.

DB2's internal processing of distributed access must sometimes convert the identifiers for *authorization-name*, *procedure-name*, and *schema-name* between CCSIDs. If there is any possibility that these identifiers will be used in distributed access, restrict the identifiers to characters whose representation in Unicode UTF-8 have code points in the range 0 through 127. You do not need to enter the identifiers in Unicode; this restriction refers to conversion that DB2 performs internally.

Naming conventions

The rules for forming a name depend on the type of the object designated by the name.

The syntax diagrams use different terms for different types of names. The following list defines these terms.

accelerator-name

An unqualified name that identifies an accelerator-only table. An accelerator name is 1 to 8 uppercase characters or digits. The name must be unique within the DB2 subsystem or data sharing group.

alias-name

A qualified or unqualified name that designates an alias, table, or view. The unqualified form of *alias-name* is an SQL identifier. An unqualified *alias-name* in an SQL statement is implicitly qualified by the default schema. The qualified form is a *schema-name* followed by a period and an SQL identifier.

See "Aliases and synonyms" on page 68 for additional information about aliases.

authorization-name

An SQL identifier that designates a set of privileges. It can also designate a user, a group of users, or a role. For a user or a group of users, DB2 does not control this property. For a role, DB2 does control this property. See "Authorization IDs, roles, and authorization names" on page 72 for the distinction between an authorization name and an authorization ID.

aux-table-name

A qualified or unqualified name that designates an auxiliary table. The rules for the name are the same as the rules for *table-name*. See *table-name*.

bpname

A name that identifies a buffer pool. The following list shows the names of the different buffer pool sizes.

4KB BP0, BP1, BP2, ..., BP49

8KB BP8K0, BP8K1, BP8K2, ..., BP8K9

16KB BP16K0, BP16K1, BP16K2, ..., BP16K9

3. 'SQ' is allowed in C, COBOL, and REXX.

32KB BP32K, BP32K1, BP32K2, ..., BP32K9

built-in-type

A qualified or unqualified name that identifies an IBM-supplied data type. A qualified name is SYSIBM followed by a period and the name of the built-in data type. An unqualified name has an implicit qualifier, the schema name, which is determined by the rules in “Qualification of unqualified object names” on page 67.

catalog-name

An SQL identifier that designates an integrated catalog facility catalog. The identifier must start with a letter and must not include special characters.

clone-table-name

A qualified or unqualified name that designates the name of a clone table. See the definition of *table-name* for more information about qualification of table names.

collection-id

An SQL identifier that identifies a collection of packages, such as a collection ID as a qualifier for a package ID. Refer to *DB2 Command Reference* for naming conventions.

column-name

A qualified or unqualified name that designates a column of a table or view.

A qualified column name is a qualifier followed by a period and an SQL identifier. The qualifier is a table name, a view name, a synonym, an alias, or a correlation name. The unqualified column name is an SQL identifier.

constraint-name

An SQL identifier that designates a primary key, check, referential, or unique constraint on a table.

correlation-name

An SQL identifier that designates a table, a view, or individual rows of a table or view.

context-name

An unqualified SQL identifier that designates a trusted context.

cursor-name

An SQL identifier that designates an SQL cursor. In SQLJ, *cursor-name* is a host variable (with no indicator variable) that identifies an instance of an iterator.

database-name

An SQL identifier that designates a database. The identifier must start with a letter and must not include special characters.

descriptor-name

A host identifier that designates an SQL descriptor area (SQLDA). See “Host variables” on page 208 for a description of a host identifier. A descriptor name never includes an indicator variable.

distinct-type-name

A qualified or unqualified name that designates a distinct type.

A qualified distinct type name is a two-part name. The first part is the schema name of the distinct type. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified distinct type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the distinct type appears as described by the rules in “Unqualified distinct type, function, procedure, and specific names” on page 68.

external-program-name

A name that specifies the program that runs when the function is invoked or the procedure name is specified in a CALL statement.

function-name

A qualified or unqualified name that designates a user-defined function, a cast function that was generated when a distinct type was created, or a built-in function.

A qualified function name is a two-part name. The first part is the schema name of the function. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified function name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Unqualified distinct type, function, procedure, and specific names” on page 68.

host-label

A token that designates a label in a host program.

host-variable

A sequence of tokens that designates a host variable. A host variable includes at least one host identifier, as explained in “Host variables” on page 208.

index-name

A qualified or unqualified name that designates an index.

A qualified index name is an authorization ID or schema name followed by a period and an SQL identifier.

An unqualified index name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 67.

For an index on a declared temporary table, the qualifier must be SESSION.

location-name

An SQL identifier that designates the name of a location. A location name is 1 to 16 bytes, does not include alphabetic extenders, lowercase letters, or Katakana characters. The characters allowed in the delimited form are the same as those allowed in the ordinary form.

mask-name

A qualified or unqualified name that designates a mask.

A qualified mask name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified mask name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined

by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 67.

package-name

A qualified or unqualified name that designates a package. The unqualified form of a *package-name* is an SQL identifier. A *package-name* must not be a delimited identifier that includes lowercase letters or special characters. A *package-name* in an SQL statement must be qualified. In some contexts outside of SQL, a package name can be specified as an unqualified name.

parameter-name

An SQL identifier that designates a parameter in an SQL procedure or SQL function.

permission-name

A qualified or unqualified name that designates a permission.

A qualified permission name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified permission name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 67.

plan-name

An SQL identifier that designates an application plan. The identifier must not be a delimited identifier that includes lowercase letters or special characters.

procedure-name

A qualified or unqualified name that designates a stored procedure.

A fully qualified procedure name is a three-part name. The first part is a location name that identifies the DBMS at which the procedure is stored. The second part is the schema name of the stored procedure. The third part is an SQL identifier. A period must separate each of the parts in a qualified name.

A two-part procedure name is implicitly qualified with the location name of the current server. The first part is the schema name of the stored procedure. The second part is an SQL identifier. A period must separate the two parts.

A one part, or unqualified, procedure name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears, as described by the rules in “Qualification of unqualified object names” on page 67.

The SQL identifier in a qualified or unqualified name must not be an asterisk (*).

profile-name

An SQL identifier that corresponds to a RACF profile name.

program-name

An SQL identifier that designates an exit routine.

role-name

An unqualified SQL identifier that designates a role. The identifier cannot begin with the characters SYS and cannot be ACCESSCTRL, DATAACCESS, DBADM, DBCTRL, DBMAINT, NONE, NULL, PACKADM, PUBLIC, SECADM, or SQLADM.

routine-version-id

An SQL identifier of up to 64 EBCDIC bytes that designates a version of a routine. The UTF-8 representation of the identifier must not exceed 122 bytes.

savepoint-name

An unqualified SQL identifier that designates a savepoint.

schema-name

An SQL identifier that provides a logical grouping for SQL objects. A *schema-name* is used as a qualifier of the name of SQL objects.

seclabel-name

A string that corresponds to the value of the RACF security label. It is recommended that name not include national characters (@ (X'7C'), # (X'7B'), or \$ (X'5B')). If the table is a Unicode table and the security label name does include national characters, an error might be issued if substitution occurs when DB2 converts the value from EBCDIC to Unicode.

sequence-name

A qualified or unqualified name that designates a sequence.

A qualified sequence name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified sequence name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67.

server-name

An SQL identifier that designates an application server. The identifier must start with a letter and must not include lowercase letters or special characters.

specific-name

A qualified or unqualified name that designates a unique name for a user-defined function.

A qualified specific name is a two-part name. The first part is the schema name. The second part is an SQL identifier, and it must not be an asterisk (*). A period must separate each of the parts.

An unqualified specific name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Unqualified distinct type, function, procedure, and specific names” on page 68.

A specific name can be used to identify a function to alter, comment on, drop, grant privileges on, revoke privileges from, or be the source function for another function. A specific name cannot be used to invoke a function. In addition to being used in certain SQL statements, a specific name must be used in DB2 commands to uniquely identify a function.

SQL-condition-name

An SQL identifier that designates a condition in an SQL function or an SQL procedure.

SQL-label

An SQL identifier that designates a label in an SQL function or an SQL procedure.

SQL-parameter-name

A qualified or unqualified name that designates a parameter in the SQL routine body of an SQL function or SQL procedure. The unqualified form of an *SQL-parameter-name* is an SQL identifier. The qualified form is a *function-name* or *procedure-name* followed by a period and an SQL identifier.

SQL-variable-name

A qualified or unqualified name that designates a variable in an SQL routine body. The unqualified form of an *SQL-variable-name* is an SQL identifier. The qualified form is an *SQL-label* followed by a period (.) and an SQL identifier.

statement-name

An SQL identifier that designates a prepared SQL statement.

stogroup-name

An SQL identifier that designates a storage group.

synonym

An SQL identifier that designates a synonym, a table, or a view. The table or view must exist at the current server. A qualified name is never interpreted as a synonym.

See “Aliases and synonyms” on page 68 for additional information about synonyms.

table-name

A qualified or unqualified name that designates a table.

A fully qualified table name is a three-part name. The first part is a location name that designates the DBMS at which the table is stored. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part table name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified table name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the rules set forth in “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67. For a declared temporary table, the qualifier (the second part in a three-part name and the first part in a two-part name) must be SESSION. For complete details on specifying a name when a declared temporary table is defined and then later referring to that declared temporary table in other SQL statements, see “DECLARE GLOBAL TEMPORARY TABLE” on page 1858.

table-space-name

An SQL identifier that designates a table space of an identified database. The identifier must start with a letter and must not include special characters. If a database is not identified, DSNDB04 is implicit.

trigger-name

A qualified or unqualified name that designates a trigger.

A qualified trigger name is a two-part name. The first part is the schema name of the trigger. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified trigger name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67.

view-name

A qualified or unqualified name that designates a view.

A fully qualified view name is a three-part name. The first part is a location name that designates the DBMS where the view is defined. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part view name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified view name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67.

XML-attribute-name

An identifier that is used as an XML attribute name.

XML-element-name

An identifier that is used as an XML element name.

SQL path

The *SQL path* is an ordered list of schema names. DB2 uses the path to resolve the schema name for certain unqualified object names that appear in any context other than as the main object of an ALTER, CREATE, DROP, COMMENT, GRANT, RENAME, or REVOKE statement.

DB2 uses the path to resolve the schema name for the following object names:

- data types (both built-in types and distinct types)
- functions
- stored procedures

Searching through the path from left to right, DB2 implicitly qualifies the object name with the first schema name in the SQL path that contains the same object with the same unqualified name for which the user has appropriate authorization. For functions, DB2 uses a process called function resolution in conjunction with the SQL path to determine which function to choose because several functions with the same name and number of parameters but different parameter data types might be defined in the same schema or other schemas in the SQL path. (For details, see “Function resolution” on page 221.) For procedures, DB2 selects a matching procedure name only if the number of parameters is also the same.

The SQL path does not apply to unqualified procedure names in ASSOCIATE LOCATOR and DESCRIBE PROCEDURE statements. For these statements, an implicit schema name is not generated.

For an example of how DB2 uses the SQL path to resolve the schema name, assume that the SQL path is SMITH, XGRAPHIC, SYSIBM, and that an unqualified distinct type name MYTYPE was specified. DB2 looks for MYTYPE first in schema SMITH, then XGRAPHIC, and then SYSIBM.

The PATH option establishes the SQL path that is used to resolve:

- Unqualified data type and function names in static SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name as an identifier token (CALL *procedure-name*)

If the PATH option was not specified when the plan or package was created or last rebound or when native SQL procedure was defined or last changed, the default value of the SQL path is: SYSIBM, SYSFUN, SYSPROC, *plan or package qualifier*.

The CURRENT PATH special register determines the SQL path used to resolve:

- Unqualified data type and function names in dynamic SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name in a host variable (CALL *host-variable*)

Generally, the initial value of the CURRENT PATH special register is one of the following:

- The value of the PATH option
- "SYSIBM", "SYSFUN", "SYSPROC", *value of CURRENT SQLID special register* if the PATH option was not specified.

If schema "SYSIBM", "SYSFUN", "SYSPROC" is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path; if all are not specified, they are assumed in the order of "SYSIBM", "SYSFUN", "SYSPROC".

For example, assume that the SQL path is explicitly specified as SYSIBM, GEORGIA, SMITH. As implicitly assumed schemas, SYSFUN and SYSPROC are added to the beginning of the explicit path effectively making the path:

SYSFUN, SYSPROC, SYSIBM, GEORGIA, SMITH

For more information about the SQL path for dynamic SQL, see "CURRENT PATH" on page 181 and "SET PATH" on page 2209.

Resolution of unqualified object names

Most object names are implicitly or explicitly qualified with a schema name. Synonyms are an exception.

A synonym has a single part name. When DB2 encounters an unqualified name, DB2 must determine which object to process. This process is called *name resolution*.

When DB2 encounters a single part name in a context where an alias, table, view, or synonym can be specified, DB2 first checks to see if the name refers to a synonym that is defined by the current user.

Qualification of unqualified object names

Unqualified object names, other than synonyms, are implicitly qualified. The rules for qualifying a name differ depending on the type of object that the name identifies.

Unqualified alias, index, JAR file, sequence, table, trigger, and view names

Unqualified alias, index, JAR file, sequence, table, trigger, and view names are implicitly qualified by the default schema.

The default schema is determined as follows:

- For static SQL statements, the default schema is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE or ALTER statement for a SQL routine. If this option is not in effect for the plan, package, or native SQL procedure, the default schema is the authorization ID of the owner of the plan, package, or native SQL procedure.
- For dynamic SQL statements, the behavior as specified by the combination of the DYNAMICRULES option and the run time environment determines the default schema. (For a list of these behaviors and the DYNAMICRULES values that determine them, see Table 6 on page 75).
 - If *DYNAMICRULES run behavior* applies, the default schema is the schema in the CURRENT SCHEMA special register. Run behavior is the default.
 - If *bind behavior* applies, the default schema is the identifier that is implicitly or explicitly specified in the QUALIFIER option, as explained for static SQL statements.
 - If *define behavior* applies, the default schema is the owner of the function or stored procedure (the owner is the definer).
 - If *invoke behavior* applies, the default schema is the authorization ID of the invoker of the function or stored procedure.

Exception: For bind, define, and invoke behavior, the default schema of PLAN_TABLE, DSN_STATEMENT_TABLE, and DSN_FUNCTION_TABLE (output from the EXPLAIN statement) is always the value in special register CURRENT SQLID.

Unqualified distinct type, function, procedure, and specific names

The qualification of unqualified distinct type, function, stored procedure, and specific names depends on the SQL statement in which the unqualified name appears.

- If an unqualified name is the main object of an ALTER, CREATE, COMMENT, DROP, GRANT, or REVOKE statement, the name is implicitly qualified with a schema name as follows:
 - In a static statement, the implicit schema name is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE or ALTER statement for a SQL routine. If this option is not in effect for the package or procedure, the implicit qualifier is the authorization ID of the owner of the package or procedure.
 - In a dynamic statement, the implicit schema name is the schema in the CURRENT SCHEMA special register.
- Otherwise, the implicit schema name for the unqualified name is determined as follows:
 - For distinct type names, DB2 searches the SQL path and selects the first schema in the path such that the distinct type exists in the schema and the user has authorization to use the distinct type.
 - For function names, DB2 uses the SQL path in conjunction with function resolution, as described in “Function resolution” on page 221.
 - For stored procedure names in CALL statements, DB2 searches the SQL path and selects the first schema in the path such that the schema contains a procedure with the same name and number of parameters and the user has authorization to use the procedure.
 - For stored procedure names in ASSOCIATE LOCATORS and DESCRIBE PROCEDURE statements, DB2 does not use the SQL path because an implicit schema name is not generated for these statements.

For information about the SQL path, see “SQL path” on page 65.

Aliases and synonyms

A table or view can be referred to in an SQL statement by its name, by an alias that has been defined for its name, or by a synonym that has been defined for its name. Thus, aliases and synonyms can be thought of as alternative names for tables and views.

Important: Use aliases instead of synonyms. Synonyms are similar to aliases but are supported only for compatibility with previous releases. Aliases behave the same for the DB2 family of products. **Recommendation:** When writing new SQL statements or creating portable applications, use aliases instead. IBM has no current plans to remove support for synonyms from DB2 for z/OS; however the use of synonyms is discouraged.

An alias can be defined at a local server and can refer to a table or view that is at the current server or a remote server. The alias name can be used wherever the table name or view name can be used to refer to the table or view in an SQL statement. The rules for forming an alias name are the same as the rules for forming a table name or a view name, as explained below. A fully qualified alias name (a three-part name) can refer to an alias at a remote server. However, the table or view identified by the alias at the remote server must exist at the remote server.

An alias name designates an alias when it is preceded by the keyword `ALIAS`, as in `CREATE ALIAS`, `DROP ALIAS`, `COMMENT ON ALIAS`, and `LABEL ON ALIAS`. In all other contexts, an alias name designates a table or view. For example, `COMMENT ON ALIAS A` specifies a comment about the alias `A`, whereas `COMMENT ON TABLE A` specifies a comment about the table or view designated by `A`.

A synonym designates a synonym when it is preceded by the keyword `SYNONYM`, as in `CREATE SYNONYM` and `DROP SYNONYM`. In all other contexts, a synonym designates a local table or view and can be used wherever the name of a table or view can be used in an SQL statement.

Statements that use three-part names and refer to distributed data result in DRDA access to the remote site. DRDA access for three-part names is used when the plan or package that contains the query to distributed data is bound with bind option `DBPROTOCOL(DRDA)`, or the value of field `DATABASE PROTOCOL` on installation panel `DSNTIP5` is `DRDA`. When an application program uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names. Also, each alias needs to be defined at the local site. An alias at a remote site can refer to yet another server as long as a referenced alias eventually refers to a table or view.

The option of referencing a table or view by an alias or a synonym is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements. But they can be referred to in an SQL statement, with two exceptions: a local alias cannot be used in the `CREATE ALIAS` statement, and a synonym cannot be used in the `CREATE SYNONYM` statement. If an alias is used in the `CREATE SYNONYM` statement, it must identify a table or view at the current server. The synonym is defined on the name of that table or view. If a synonym is used in the `CREATE ALIAS` statement, the alias is defined on the name of the table or view identified by the synonym.

The effect of using an alias or a synonym in an SQL statement is that of text substitution. For example, if `A` is an alias for table `Q.T`, one of the steps involved in the preparation of `SELECT * FROM A` is the replacement of `'A'` by `'Q.T'`. Likewise, if `S` is a synonym for `Q.T`, one of the steps involved in the preparation of `SELECT * FROM S` is the replacement of `'S'` by `'Q.T'`.

The differences between aliases and synonyms are as follows:

- Authorization or the `CREATE ALIAS` privilege is required to define an alias. No authorization is required to define a synonym.
- An alias can be defined on the name of a table or view, including tables and views that are not at the current server. A synonym can only be defined on the name of a table or view at the current server.
- An alias can be defined on an undefined name. A synonym can only be defined on the name of an existing table or view.
- Dropping a table or view has no effect on its aliases. But dropping a table or view does drop its synonyms.
- An alias is a qualified name that can be used by any authorization ID. A new alias cannot have the same fully qualified name as an existing alias, table, or view, and a new unqualified alias name cannot have the same name as an existing synonym.

- A synonym is an unqualified name that can only be used by the owner of the synonym. A new synonym cannot have the same name as an existing synonym, or the unqualified name of an existing alias, table, or view.
- An alias defined at one DB2 subsystem can be used at another DB2 subsystem. A synonym can only be used at the DB2 subsystem where it is defined.
- When an alias is used, an error occurs if the name that it designates is undefined or is the name of an alias at the current server. (The alias can represent another alias at a different server, which can represent yet another alias at yet another server as long as eventually a referenced alias represents a table or view.) When a synonym is used, this error cannot occur.
- A synonym cannot be created in a trusted context that has ROLE AS OBJECT OWNER in effect.

Authorization, privileges, permissions, masks, and object ownership

Users (as identified by an authorization ID) can successfully execute SQL statements only if they have the authority to perform the specified operation. For example, to create a table, a user must be authorized to create tables.

The two forms of authorization are administrative authority and privileges.

Administrative authority

The holder of administrative authority is charged with the task of controlling DB2 and is responsible for the safety and integrity of the data.

Those with SYSADM authority implicitly have all privileges on all objects and control who will have access to DB2 and the extent of this access.

Those with SECADM authority manage security policies by enforcing row and column access control for tables that contain sensitive data. They define row permissions and column masks, which describe how tables that use row or column access controls should be accessed and which determine whether a trigger or a user-defined function is considered secure for those tables.

Privileges

Privileges are those activities that a user is allowed to perform. Authorized users can create objects, have access to objects that they own, and can pass on privileges on the objects that they own to other users by using the GRANT statement. Privileges can be granted to specific users or to PUBLIC. PUBLIC specifies that a privilege is granted to all users (including to future users).

The REVOKE statement can be used to revoke previously granted privileges.

Row permissions and column masks

A *row permission* is a database object that expresses an access control rule for a row of a specific table. A row permission is in the form of a search condition that describes to which rows users have access. Row permissions are applied after table privileges (like SELECT or INSERT) are checked.

A *column mask* is a database object that expresses an access control rule for a specific column in a table. A column mask is in the form of a CASE

expression that describes to which column values users have access. Column masks are applied after table privileges (like SELECT or INSERT) are checked.

Row permissions and column masks can be created, changed, and dropped only by those with SECADM authority by using the CREATE MASK, CREATE PERMISSION, and DROP statements. The definition of a permission or a mask can reference other objects. Those with SECADM authority do not need additional privileges to reference those objects, such as SELECT privilege to retrieve from a table or EXECUTE privilege to invoke a user-defined function, in the definition of the row permission or column mask. Multiple row permissions and column masks can be created for a table. Only one column mask can be created for each column in a table. A row permission or a column mask can be created before row or column access control is enforced for a table. The definition of the row permission and the column mask is stored in the DB2 catalog. However, the permission and the mask do not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to enforce row access control or the ACTIVATE COLUMN ACCESS CONTROL clause is used to enforce column access control on the table.

When an ALTER TABLE statement is used to explicitly activate row access control for a table, a default row permission is implicitly created for the table which prevents all access to the table. After row access controls have been activated for a table, if the table is referenced explicitly in a data change statement and if multiple row permissions are defined for the table, a row access control search condition is derived by using the logical OR operator with the search condition of each defined row permission.

When an ALTER TABLE statement is used to explicitly activate column access control for a table, access to the table is not restricted. However, if the table is referenced in a data change statement, all column masks that have been created for the table are applied to mask the column values that are referenced in the output of the queries or to determine the column values that are used in the data change statements.

The authorization ID or role for the statement does not need authority to reference objects that are specified in the definition of the row permission or column mask.

Object ownership

When an object is created, one authorization ID is assigned ownership of the object. Ownership means that the user is authorized to reference the object in any applicable SQL statement. The privileges on the object can be granted by the owner, and cannot be revoked from the owner. Owners of views only receive the level of privileges that they have on the underlying table or view. The owner of the object that is being created is determined as follows:

- If the schema qualifier is not explicitly specified, the owner depends on how the CREATE statement is issued:
 - If the CREATE statement is embedded in a program, the owner of the object that is being created is the authorization ID that serves as the implicit qualifier for unqualified object names. This is the authorization ID that is in the QUALIFIER option when the plan, package, or native SQL procedure (that contains the CREATE statement) is created or last changed. If the QUALIFIER option is not used, the owner of the object is the authorization ID in the OWNER option when the plan, package, or native SQL procedure is created or

last changed. If the OWNER option is not used, the owner is the owner of the plan, package, or native SQL procedure. If the plan or package was last bound in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, a role is the owner.

- If the CREATE statement is dynamically prepared, the owner of the object that is being created is the authorization ID of the process.
- If the CREATE statement is execute in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the role of the primary authorization ID is the owner.
- If the schema qualifier is explicitly specified, the owner depends on the type of object that is being created unless the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause. When the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the object is determined as follows:
 - If the CREATE statement is embedded in a program, the role that owns the plan or package is the owner of the object.
 - If the CREATE statement is dynamically prepared, the primary authorization ID is the owner.

If the schema qualifier is explicitly specified, and the CREATE statement is not executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner depends on the type of object that is being created: :

- For an alias, auxiliary table, created global temporary table, table, or view, the owner of the object that is being created is the same as the explicit schema name.
- For a user-defined distinct type, user-defined function, procedure, sequence, JAR files, or trigger, the owner of the object that is being created is the authorization ID of the process.

The rules that determine ownership of row permissions and column masks are the same as those that determine ownership of objects like user-defined distinct types, user-defined functions, procedures, sequences, JAR files, or trigger.

The owner of a row permission or a column mask does not have implicit owner privileges. Only users with SECADM authority can manage and maintain row permissions and column masks.

Authorization IDs, roles, and authorization names

Processes can successfully execute SQL statements only if they have the necessary authority. A process derives this authority from its authorization IDs. An authorization ID can also designate a user, a group of users, or a role.

An *authorization ID* is a character string that is associated with a process that is checked to determine the authority to perform a specified operation.

DB2 does not control the association of users to user groups. However, DB2 does control the association between users and roles when a trusted context is defined.

DB2 uses authorization IDs to provide authorization checking of SQL statements.

Whenever a connection is established between DB2 and a process, DB2 obtains an authorization ID and passes it to the authorization connection or sign-on exit

routine. The list of one or more authorization IDs that is returned by the exit routine are used as the authorization IDs of the process. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

Every process has exactly one primary authorization ID. Any other authorization IDs of a process are secondary authorization IDs. The use of these authorization IDs depends on the type of process (bind process, application process, or process involved in the creation of objects).

Primary authorization ID

An authorization ID that is used to establish a connection between DB2 and an application process.

Secondary authorization ID

An authorization ID that is associated with a primary authorization ID.

Secondary authorization IDs include all the authorization IDs that have been associated with a primary authorization ID by the connection or sign-on authorization exit routine, the CURRENT SQLID (when different from the primary authorization ID), and other authorization IDs like the stored procedure definer and call package owner for stored procedure package checking.

Authorization ID of the process

The user's primary and secondary authorization IDs. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

A *role* is a database entity that groups together one or more privileges. A role is available only when the process is run in a trusted context. Users are associated with a role in the definition of a trusted context.

A trusted context can have a default role, specific roles for individual users, or no roles at all. A user in a trusted context can have only one active role. This is the role that is specifically defined for the user or the default role of the trusted context. The following restrictions apply to roles:

- A role cannot be a primary authorization ID.
- A role cannot be set by using a SET CURRENT SQLID statement.
- A role can be the schema qualifier of an object. However, when it is used as a schema qualifier, a role is considered to be a character string and does not add any implicit schema privileges (ALTERIN, CREATEIN, or DROPIN) to this role.
- A role must already exist for privileges to be granted to it.

The role that is in effect for a user is considered to be one of the secondary authorization IDs of the user.

Do not confuse an *authorization-name* that is specified in an SQL statement with an authorization ID of a process.

Example: Assume that SMITH is your TSO logon, DYNAMICRULES run behavior is in effect, and you execute the following statements interactively:

```
CREATE TABLE TDEPT LIKE DSN8A10.DEPT;  
GRANT SELECT ON TDEPT TO KEENE;
```

Also assume that your site has not replaced the default exit routine for connection authorization and that you have not executed the SET CURRENT SQLID

statement. Thus, when the GRANT statement is prepared and executed by SPUIFI, the SQL authorization ID is SMITH. KEENE is an authorization name that is specified in the GRANT statement.

Authorization to execute the GRANT statement is checked against SMITH. The authorization rule is that the privilege set that is designated by SMITH must include the SELECT privilege with the GRANT option on SMITH.TDEPT. No check that involves KEENE is performed. If the GRANT statement specifies a role, the existence of the role is checked.

Authorization IDs and schema names

An authorization ID that has the same name as the name of a schema implicitly has certain privileges for that schema.

If an authorization ID is not a role and has the same name as the name of a schema, that authorization ID implicitly has the following privileges for that schema:

- CREATEIN privilege
- ALTERIN privilege
- DROPIN privilege

Authorization IDs and statement preparation

The authorization ID that is specified as the owner of the plan or package must be one of the authorization IDs of the bind process. The owner can be set to any value if one of the authorization IDs of the bind process has SYSADM or SYSCTRL authority.

A process that creates a plan or package is called a *bind process*. The connection with DB2 is the result of the execution of a BIND or REBIND subcommand. Both subcommands allow for the specification of the authorization ID of the owner of the plan or package.

BINDAGENT can specify an owner other than himself (or one of his representatives), but it has to be someone that granted him BINDAGENT. The default owner for BIND is the primary authorization ID. The default owner for REBIND is the previous owner of the plan or package (ownership is unchanged if an owner is not explicitly specified). If the BIND or REBIND is performed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the plan or package is a role. If the OWNER bind option is specified, the role that is specified in it is the owner, otherwise the role that performs the bind or rebind becomes the owner.

The authorization ID that is used for the authorization checking of embedded SQL statements is that of the owner of the plan or package. If the application is bound in a trusted context using the ROLE AS OBJECT OWNER clause, the authorization ID that is used for authorization checking is the role that owns the plan or package, otherwise the authorization ID is the authorization ID of the owner of the plan or package. If an embedded SQL statement refers to tables or views at a DB2 subsystem other than the one at which the plan or package is bound, the authorization checking is deferred until run time. For more information on this, see “Authorization IDs and remote execution” on page 78.

If VALIDATE(BIND) is specified, the privileges required to use or manipulate objects at the DB2 subsystem at which the plan or package is bound must exist at

bind time. If the privileges or the referenced objects do not exist and SQLERROR(NOPACKAGE) is in effect, the bind operation is unsuccessful. If SQLERROR(CONTINUE) is specified, then the bind is successful and any statements in error are flagged. If any statements in error are flagged, an error will occur when you attempt to execute them at run time.

If a plan or package is bound with VALIDATE(RUN), authorization checking is still performed at bind time, but the referenced objects and the privileges required to use these objects need not exist at this time. If any privilege required for a statement does not exist at bind time, an authorization check is performed whenever the statement is first executed within a unit of work, and all privileges required for the statement must exist at that time. If any privilege does not exist, execution of the statement is unsuccessful. When the authorization check is performed at run time, it is performed against the plan or package owner, not the SQL authorization ID. For the effect of this option on cursors, see “DECLARE CURSOR” on page 1846.

Authorization IDs and dynamic SQL

The bind option DYNAMICRULES determines the authorization ID that is used for checking authorization when dynamic SQL statements are processed. The set of values for the authorization ID and other dynamic SQL attributes is called the *dynamic SQL statement behavior*. The four possible behaviors are run, bind, define, and invoke.

This discussion applies to dynamic SQL statements that refer to objects at the current server. For those that refer to objects elsewhere, see “Authorization IDs and remote execution” on page 78.

In addition to determining the authorization ID, DYNAMICRULES also controls other dynamic SQL attributes such as the implicit qualifier that is used for unqualified alias, index, sequence, table, trigger, and view names; the source for application programming options; and whether certain SQL statements can be invoked dynamically.

As the following table shows, the combination of the value of the DYNAMICRULES option and the run time environment determines which of the four SQL statement behavior is used. DYNAMICRULES(RUN), which implies run behavior, is the default.

Table 6. How DYNAMICRULES and the run time environment determine dynamic SQL statement behavior

| DYNAMICRULES value | Behavior of dynamic SQL statements | |
|--------------------|------------------------------------|---|
| | Stand-alone program environment | User-defined function or stored procedure environment |
| RUN | Run behavior | Run behavior |
| BIND | Bind behavior | Bind behavior |
| DEFINERUN | Run behavior | Define behavior |
| DEFINEBIND | Bind behavior | Define behavior |
| INVOKERUN | Run behavior | Invoke behavior |

Table 6. How DYNAMICRULES and the run time environment determine dynamic SQL statement behavior (continued)

| DYNAMICRULES value | Behavior of dynamic SQL statements | |
|--------------------|------------------------------------|---|
| | Stand-alone program environment | User-defined function or stored procedure environment |
| INVOKEBIND | Bind behavior | Invoke behavior |

Note: BIND and RUN values can be specified for packages, plans, and native SQL procedures. The other values can be specified for packages and native SQL procedures but not for plans.

In the following behavior descriptions, a package that *runs under* a user-defined function or stored procedure package is a package whose associated program meets one of the following conditions:

- The program is called by a user-defined function or stored procedure.
- The program is in a series of nested calls that start with a user-defined function or stored procedure.

Run behavior

DB2 uses the authorization IDs of the application process and the SQL authorization ID (the value of special register CURRENT SQLID) for authorization checking of dynamic SQL statements. If the process is running in a trusted context with a role associated with the primary authorization ID, the authorization IDs of the application process include this role.

A process that uses a plan and its associated packages is called an *application process*. At any time, the SQL authorization ID is the value of CURRENT SQLID. This SQL special register can be initialized by the connection or sign-on exit routine. If the exit routine does not set a value, the initial value of CURRENT SQLID is the primary authorization ID of the process. You can use the SQL statement SET CURRENT SQLID to change the value of CURRENT SQLID. Unless some authorization ID of the process has SYSADM authority, the new value must be one of the authorization IDs of the process. Thus, CURRENT SQLID usually contains either the primary authorization ID of the process or one of its secondary authorization IDs. The CURRENT SQLID cannot contain a role.

Privilege set: If the dynamically prepared statement is other than an ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, or REVOKE statement, each privilege required for the statement can be a privilege designated by any authorization ID of the process. Therefore, the privilege set is the union of the set of privileges held by each authorization ID of the process. When the process is running in a trusted context with a role, the authorization IDs of the process include this role.

If the dynamic SQL statement is an ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, or REVOKE statement, the only authorization ID that is used for authorization checking is the SQL authorization ID. Therefore, the privilege set is the privileges held by that single authorization ID of the process. If the process is running in a trusted context using the ROLE AS OBJECT OWNER clause for the a CREATE, GRANT, or REVOKE statement, the single authorization ID of the process that is checked is the role that is in effect.

Implicit qualification: As explained under “Qualification of unqualified object names” on page 67, when an SQL statement is dynamically prepared, the values of the CURRENT SCHEMA special register is used as the implicit qualifier. For example, it is used as the implicit qualifier for all unqualified tables, aliases, views, indexes, and sequences.

Bind behavior

The same rules that are used to determine the authorization ID for static (embedded) statements are used for dynamic statements. DB2 uses the authorization ID of the owner of the package or plan for authorization checking of dynamic SQL statements, as explained in detail under “Authorization IDs and statement preparation” on page 74.

Privilege set: The privilege set is the privileges that are held by the owner of the package or plan.

Implicit qualification: The identifier specified in the QUALIFIER option of the bind command that is used to bind the SQL statements, or the CREATE PROCEDURE or ALTER PROCEDURE statement that is used to create a version of an SQL procedure is the implicit qualifier for all unqualified tables, views, aliases, indexes, and sequences. If the QUALIFIER option was not used when the plan, package, or native SQL procedure was created or last changed, the implicit qualifier is the owner of the plan, package, or native SQL procedure.

Define behavior

Define behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or *runs under* a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(DEFINEBIND) or DYNAMICRULES(DEFINERUN). DB2 uses the authorization ID of the stored procedure or user-defined function owner (the definer) for authorization checking of dynamic SQL statements in the application package.

Privilege set: The privilege set is the privileges that are held by the authorization ID of the owner.

Implicit qualification: The stored procedure or user-defined function owner is also the implicit qualifier. For example, the owner is the implicit qualifier for unqualified table, view, alias, index, and sequence names.

Invoke behavior

Invoke behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or *runs under* a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(INVOKEBIND) or DYNAMICRULES(INVOKERUN). DB2 uses the stored procedure or user-defined function invoker for authorization checking of dynamic SQL statements in the application package. The invoker can also be a role.

Privilege set: The privilege set is the privileges that are held by the invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked. This includes the role of the primary authorization ID, if running in a trusted context with a role. In that case, the privilege set is the union of the set of privileges held by each authorization ID of the process.

Implicit qualification: The stored procedure or user-defined function invoker is also the implicit qualifier. For example, it is the implicit qualifier for unqualified table, view, alias, index, and sequence names. The invoker can also be a role.

Restricted statements when run behavior does not apply: When bind, define, or invoke behavior is in effect, you cannot use the following dynamic SQL statements: ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, and REVOKE.

Authorization IDs and remote execution

The authorization rules for remote execution depend on whether the distributed operation is DRDA access with a DB2 for z/OS server and requester. DRDA access with a server and requester other than DB2 can also effect the authorization rules for remote execution.

DRDA access with DB2 for z/OS only

To prepare and execute SQL statements using DRDA access, certain privileges are required by the package owner and additional privileges are required by the user who invokes the application.

Any static statement executed using DRDA access is in a package bound at a server other than the local DB2 subsystem. Before the package can be bound, its owner must have the BINDADD privilege and the CREATE IN privilege for the package's collection. Also required are enough privileges to execute the package's static SQL statements that refer to data on that server. All these privileges are recorded in the DB2 catalog of the server, not in the catalog of the local DB2 subsystem. Such privileges must be granted by GRANT statements executed at the server. This allows the server to control the creation and use of packages that are run from other DBMSs.

A user who invokes an application that has a plan at the local DB2 subsystem must have the EXECUTE privilege on the plan recorded in the DB2 catalog of the local subsystem. If that application uses a package that is bound at a DB2 server other than the local DB2 requester, the EXECUTE privilege on the package must also be recorded in the DB2 catalog of the server. The ID that must hold the authorization to run the package at the DB2 server depends on the value of the PRIVATE_PROTOCOL subsystem parameter at the DB2 server:

- If PRIVATE_PROTOCOL is set to NO, EXECUTE authority on the package must be explicitly granted to the primary user ID or an associated secondary ID at the DB2 server. If the local requester application invokes a stored procedure that resides at the DB2 server, EXECUTE authority on the stored procedure package must be explicitly granted at the DB2 server to the owner of the package that issues the CALL statement if either of the following is true:
 - The owner of the stored procedure does not have the authority to execute the remote stored procedure package.
 - The CALL statement is in the form of CALL: host-variable and neither the primary user ID nor an associated secondary ID has the authority to execute the remote stored procedure package.
- If PRIVATE_PROTOCOL is not set to NO, EXECUTE authority on the package must be explicitly granted to the local requester plan owner at the DB2 server.

The plan owner needs no other privilege to execute the package. If the local requester application invokes a stored procedure that resides at the DB2 server, EXECUTE authority on the stored procedure package must be explicitly granted at the DB2 server to the DB2 requester plan owner of the application that issues the CALL statement if either of the following is true:

- The owner of the stored procedure does not have the authority to execute the remote stored procedure package.
- The CALL statement is in the form of CALL: host-variable and neither the primary user ID nor an associated secondary ID has the authority to execute the remote stored procedure package.

EXECUTE authority is also required to use a package for a user-defined function, trigger, or stored procedure that resides at the DB2 server. However, except as previously described for a specific stored procedure case, the PRIVATE_PROTOCOL subsystem parameter is not used to determine the ID that is required to hold the EXECUTE privilege on that package. In the case of trigger packages, the authorization ID of the SQL statement that activates the trigger must have the EXECUTE privilege on the trigger. Again, all these privileges must be recorded in the DB2 catalog of the server.

Having the appropriate privileges recorded as described above allows the execution of the static SQL statements in the package, and the execution of dynamic SQL statements if DYNAMICRULES bind, define, or invoke behavior is in effect. If DYNAMICRULES run behavior is in effect, the authorization rules for dynamic SQL statements is different. Authorization for the execution of dynamic SQL statements must come from the set of authorization IDs that are derived during connection processing, and, if the process is running in a trusted connection, the role that is in effect. An application goes through connection processing when it first connects to a server or when it reuses a CICS or IMS thread that has a different primary authorization ID.

If an application uses Recoverable Resources Manager Services attachment facility (RRSAF) and has no plan, authority to execute the package is determined in the same way as when the requester is not DB2 for z/OS.

“DRDA access with a server or requester other than DB2”

Related tasks:

➡ Checking authorization at a DB2 database server (Managing Security)

DRDA access with a server or requester other than DB2

Specific privileges are required depending on whether DB2 is the server or the requester involved in DRDA access.

DB2 for z/OS as the server: If the requester is not a DB2 for z/OS subsystem, there is no DB2 application plan involved. In this case, the privilege set of the authorization ID, which is determined by the DYNAMICRULES behavior, must have the EXECUTE privilege on the package. Dynamic SQL statements in the package are executed according to the DYNAMICRULES behavior, as described in “Authorization IDs and dynamic SQL” on page 75.

DB2 for z/OS as the requester: The authorization rules for remote execution are those of the server.

Authorization ID translations

When certain authorization IDs are sent to a remote DBMS, those authorization IDs might undergo translation before being used.

Translation can occur for a primary authorization ID, the authorization ID of the owner of an application plan, or the authorization ID of the owner of a package. For example, a user known as SMITH at the local DBMS could be known, after translation, as JONES at the server. Likewise, a package owner known as GRAY could be known as WINTERS at the server. If so, JONES or WINTERS would be used, instead of SMITH or GRAY, to determine the authorization ID for dynamic SQL statements in the package. If the DYNAMICRULES run behavior applies, JONES, who is executing the dynamic statement at the server, is used. If DYNAMICRULES bind behavior applies, WINTERS, the package owner at the server, is used.

Two sets of communications database (CDB) catalog tables control the translations. One set is at the local DB2, and the other set is at the remote DB2. Translation can take place at either or both sites.

Related concepts:

-  Communications database for the requester (Managing Security)
-  Communications database for the server (Managing Security)

Other security measures

Even if DB2 authority requirements are satisfied, other security measures can be in effect when distributed data is accessed.

The fact that DB2 authority requirements are satisfied does not guarantee that a user has access to a given server. Other security measures can also come into play. For example, requests to execute remote SQL statements could be denied based on Resource Access Control Facility (RACF) considerations. Developing such security measures is discussed in *DB2 Administration Guide*.

Data types

DB2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

The smallest unit of data that can be manipulated in SQL is called a *value*. How values are interpreted depends on the data type of their source. The sources of values are:

- Columns
- Constants
- Expressions
- Functions
- Special registers
- Variables (such as host variables, SQL variables, parameter markers, and parameters of routines)

The following topics describes the built-in data types and distinct types.

Figure 16 on page 81 shows the built-in data types that DB2 supports.

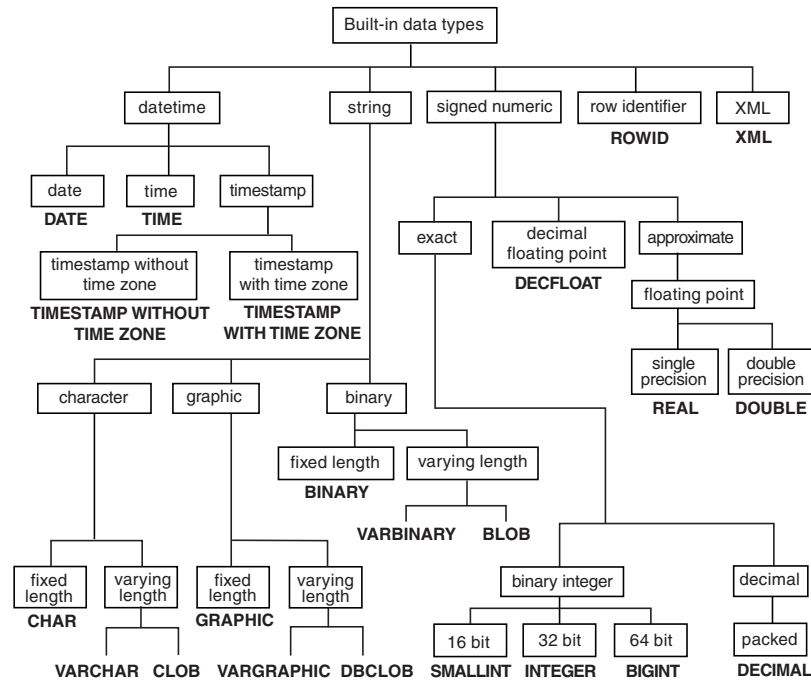

Figure 16. Built-in data types supported by DB2

Nulls

All data types include the null value. Distinct from all nonnull values, the null value is a special value that denotes the absence of a (nonnull) value.

Although all data types include the null value, some sources of values cannot provide the null value. For example, constants, columns that are defined as NOT NULL, and special registers cannot contain null values; the COUNT and COUNT_BIG functions cannot return a null value; and ROWID columns cannot store a null value although a null value can be returned for a ROWID column as the result of a query.

Numbers

The numeric data types are categorized as exact numerics: binary integer and decimal; decimal floating point; and approximate numerics: floating-point

Binary integer includes small integer, large integer, and big integer. Binary numbers are exact representations of integers. Decimal numbers are exact representations of real numbers. Binary and decimal numbers are considered exact numeric types. Decimal floating point numbers include DECFLOAT(16) and DECFLOAT(34), which are capable of representing either 16 or 34 significant digits. Floating-point includes single precision and double precision. Floating-point numbers are approximations of real numbers and are considered approximate numeric types.

All numbers have a sign, a precision, and a scale. If a column value is zero, the sign is positive. Decimal floating point has distinct values for a number and the same number with various exponents (for example: 0.0, 0.00, 0.0E5, 1.0, 1.00, 1.0000). The precision is the total number of binary or decimal digits excluding the

sign. The scale is the total number of binary or decimal digits to the right of the decimal point. If there is no decimal point, the scale is zero.

Small integer (SMALLINT)

A *small integer* is a binary integer with a precision of 15 bits. The range of small integers is -32768 to +32767.

Large integer (INTEGER)

A *large integer* is a binary integer with a precision of 31 bits.

The range of large integers is -2147483648 to +2147483647.

Big integer (BIGINT)

A *big integer* is a binary integer with a precision of 63 bits.

The range of big integers is -9223372036854775808 to +9223372036854775807.

Single precision floating-point (REAL)

A *single precision floating-point* number is a short (32 bits) floating-point number.

The range of single precision floating-point numbers is about $-7.2E+75$ to $7.2E+75$. In this range, the largest negative value is about $-5.4E-79$, and the smallest positive value is about $5.4E-079$.

Double precision floating-point (DOUBLE or FLOAT)

A *double precision floating-point* number is a long (64 bits) floating-point number.

The range of double precision floating-point numbers is about $-7.2E+75$ to $7.2E+75$. In this range, the largest negative value is about $-5.4E-79$, and the smallest positive value is about $5.4E-079$.

Decimal (DECIMAL or NUMERIC)

A *decimal* number is a packed decimal number with an implicit decimal point.

The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits.

All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is $-n$ to $+n$, where n is the largest positive number that can be represented with the applicable precision and scale. The maximum range is $1 - 10^{31}$ to $10^{31} - 1$.

Decimal floating-point (DECFLOAT)

A *decimal floating-point* value is an IEEE 754r number with a decimal point. The position of the decimal point is stored in each decimal floating-point value.

The maximum precision is 34 digits.

The range of a decimal floating point number is either 16 or 34 digits of precision, and an exponent range of respectively 10^{-383} to 10^{+384} or 10^{-6143} to 10^{+6144} .

In addition to the finite numbers, decimal floating point numbers are able to represent one of the following named special values:

- Infinity - a value that represents a number whose magnitude is infinitely large.

- Quiet NaN - a value that represents undefined results which does not cause an invalid number condition.
- Signaling NaN - a value that represents undefined results which will cause an invalid number condition if used in any numerical operation.

When a number has one of these special values, its coefficient and exponent are undefined. The sign of an infinity is significant (that is, it is possible to have both positive and negative infinity). The sign of a NaN has no meaning for arithmetic operations. INF can be used in place of INFINITY.

Numeric host variables

Numeric host variables can be defined in all languages with a few exceptions.

Binary integer variables can be defined in all host languages.

Floating-point variables can be defined in all host languages. All languages, except Java, support System/390[®] floating-point format. Assembler, C, C++, PL/I, and Java also support IEEE floating-point format. In assembler, C, C++, and PL/I programs, the SQL processing option FLOAT tells DB2 whether floating-point variables contain data in System/390 floating-point format or IEEE floating-point format. The contents of floating-point host variables must match the format that is specified with the FLOAT SQL processing option.

Decimal variables can be defined in all host languages except Fortran.

In COBOL, decimal numbers can be represented in the following formats:

- Packed decimal format, denoted by USAGE PACKED-DECIMAL or COMP-3
- External decimal format, denoted by USAGE DISPLAY with SIGN LEADING SEPARATE
- NATIONAL decimal format denoted by USAGE NATIONAL and SIGN LEADING SEPARATE

Decimal floating-point variables can be defined in Assembler, C, C++, PL/I, and Java.

String representations of numeric values

String representations of numeric values can be used in some contexts. A valid string representation of a numeric value must conform to the rules for numeric constants.

The encoding scheme in use determines what type of strings can be used for string representation of numeric values. For ASCII and EBCDIC, a string representation of a numeric value must be a character string. For UNICODE, a string representation of a numeric value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a numeric value is when the encoding scheme is UNICODE.

When a decimal number is cast to a string (for example, using a CAST specification), the implicit decimal point is replaced by the default decimal separator character that is in effect when the statement is prepared.

When a string is cast to a decimal value (for example, using a CAST specification), the default decimal separator character in effect when the statement was prepared is used to interpret the string.

When a floating point or decimal floating-point number is cast to a string (for example, using a CAST specification), or a string is cast to a floating point or decimal floating-point number, the decimal separator character must be a period (.).

For more information, see “Constants” on page 147.

Subnormal numbers and underflow

The decimal floating-point data type has a set of non-zero numbers that fall outside the range of normal decimal floating-point values. These numbers are called subnormal.

Non-zero numbers whose adjusted exponents are less than E_{\min}^4 are called subnormal numbers. These subnormal numbers are accepted as operands for all operations and can result from any operation. If a result is subnormal before any rounding occurs, the subnormal condition is returned.

For a subnormal result, the minimum values of the exponent becomes $E_{\min} - (\text{precision} - 1)$, called E_{tiny} , where precision is the working precision. If necessary, the result will be rounded to ensure that the exponent is no smaller than E_{tiny} . If the result becomes inexact during rounding, an underflow condition is returned. A subnormal result does not always return the underflow condition but will always return the subnormal condition.

When a number underflows to zero during a calculation, its exponent will be E_{tiny} . The maximum value of the exponent is unaffected.

The maximum value of the exponent for subnormal numbers is the same as the minimum value of the exponent which can arise during operations that do not result in subnormal numbers. This occurs where the length of the coefficient in decimal digits is equal to the precision.

Character strings

A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

Default CCSIDs

The value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

The following table shows how the value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

Table 7. Default CCSIDs for character strings

| Encoding scheme | Value of MIXED DATA field | Default attribute |
|-----------------|---------------------------|---|
| ASCII or EBCDIC | NO | Character: SBCS |
| | | The value of the ASCII CCSID or EBCDIC CCSID field on installation panel determines the system CCSID for SBCS data. |

Table 7. Default CCSIDs for character strings (continued)

| Encoding scheme | Value of MIXED DATA field | Default attribute |
|-----------------|---------------------------|---|
| ASCII or EBCDIC | YES | Character: MIXED The value of the ASCII CCSID or EBCDIC CCSID field on installation panel DSNTIPF determines the system CCSID for SBCS data, MIXED, and graphic data. |
| Unicode | Not applicable | Character: MIXED The CCSIDs are: <ul style="list-style-type: none"> • 367 for SBCS data • 1208 for MIXED data • 1200 for graphic data |

Fixed-length character strings

When fixed-length character string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length character string, the length attribute must be between 1 and 255 inclusive.

Varying-length character strings

The types of varying-length character strings are VARCHAR and *character large object (CLOB)*. A CLOB is a type of LOB. A CLOB column is useful for storing large amounts of character data, such as documents written with a single character set.

When varying-length character strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute except for C NUL-terminated strings. Actual values might have a smaller value. For varying-length character strings, the length specifies the number of bytes.

For a VARCHAR string, the length attribute must be between 1 and 32704. For a VARCHAR column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in Maximum record size the description of the CREATE TABLE statement. For a CLOB string, the length attribute must be between 1 and 2 147 483 647 inclusive. (2 147 483 647 is 2 gigabytes minus 1 byte.) For more information about CLOBs, see “Large objects (LOBs)” on page 96.

Character string variables

Character string variables follow specific rules for use in host languages.

- Fixed-length character string variables can be used in all languages except REXX and Java. In C, CHAR string variables are limited to a length of 1.
- Varying-length character string variables can be used in all host languages with the following exceptions:
 - Fortran: varying-length non-LOB character strings cannot be used.
 - Assembler, C, and COBOL: varying-length non-LOB strings are simulated as described in *DB2 Application Programming and SQL Guide*. In C, NUL-terminated strings can also be used.
 - REXX: CLOBs and DBCLOBs cannot be used.

Character string encoding schemes

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

Each character string is further defined as one of the following subtypes:

Bit data

Data that is not associated with a coded character set and, therefore, is never converted. The CCSID for bit data is X'FFFF' (65535). The bytes do not represent characters.

Bit data is a form of character data. The pad character is a blank for assignments to bit data; the pad character is X'00' for assignments to binary data. It is recommended that binary data be used instead of character for bit data.

If both operands in a predicate are EBCDIC, both operands are padded with X'40'. Otherwise, both operands are padded with X'20'. For example, if both operands are ASCII, or if one operand is ASCII and the other operand is EBCDIC, both are padded with X'20'.

SBCS data

Data in which every character is represented by a single byte. Each SBCS string has an associated CCSID. If necessary, an SBCS string is converted before it is used in an operation with a character string that has a different CCSID.

Mixed data

Data that can contain a mixture of characters from a single-byte character set (SBCS) and a multiple-byte character set (MBCS). Each mixed string has an associated CCSID. If necessary, a mixed string is converted before an operation with a character string that has a different CCSID. If a mixed data string contains an MBCS character, it cannot be converted to SBCS data.

EBCDIC mixed data can contain shift characters, which are not MBCS data.

When the encoding scheme is Unicode or the DB2 installation is defined to support mixed data, DB2 recognizes MBCS sequences within mixed data string when performing character sensitive operations. These operations include parsing, character conversion, and the pattern matching specified by the LIKE predicate.

Character strings with a CLOB data type can only be SBCS or MIXED. BLOB should be used for binary strings.

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

- ASCII reserves a set of code points for SBCS characters and another set as the first half of DBCS characters. When it encounters the first half of a DBCS character, the system reads the next byte in order to obtain the complete character.
- EBCDIC makes use of two special code points:
 - A shift-out character (X'0E') to introduce a string of DBCS characters.
 - A shift-in character (X'0F') to end a string of DBCS characters.

DBCS sequences within mixed data strings are recognized as the string is read from left to right. At any time, the reading of the string is in SBCS mode or DBCS mode. In SBCS mode, which is the initial mode, any byte other than a

shift-out is interpreted as an SBCS character. When a shift-out is read, the mode switches to DBCS mode. In DBCS mode, the next byte and every second byte after that byte is interpreted as the first byte of a DBCS character unless it is a shift character. If the byte is a shift-out, an error occurs. If the byte is a shift-in, the mode returns to SBCS mode. An error occurs if the mode is still DBCS mode after processing the last byte of the string. Because of the shift characters, EBCDIC mixed data requires more storage than ASCII mixed data.

- UTF-8 is a varying-length encoding of byte sequences. The high bits indicate the part of the sequence to which a byte belongs. The first byte indicates the number of bytes to follow in a byte sequence.

Examples

The same mixed data character string can be represented as character and hexadecimal data in different encoding schemes.

For the same mixed data character string, the following table shows character and hexadecimal representations of the character string in different encoding schemes. In EBCDIC, the shift-out and shift-in characters are needed to delineate the double-byte characters.

Table 8. Example of a character string in different encoding schemes

| Data type and encoding scheme | Character representation | Hexadecimal representation (with spaces separating each character) |
|-------------------------------|--------------------------|--|
| 9 bytes in ASCII | gen ki | 8CB3 67 65 6E 8B43 6B 69 |
| 13 bytes in EBCDIC | gen ki | 0E 4695 0F 87 85 95 0E 45B9 0F 92 89 |
| 11 bytes in Unicode UTF-8 | gen ki | E58583 67 65 6E E6B097 6B 69 |

Because of the differences of the representation of mixed data strings in ASCII, EBCDIC, and Unicode, mixed data is not transparently portable. To minimize the effects of these differences, use varying-length strings in applications that require mixed data and operate on ASCII, EBCDIC, and Unicode data.

String unit specifications

The ability to specify string units for certain built-in functions and on the CAST specification allows you to process string data in a more "character-based manner" than a "byte-based manner". The string unit determines the length in which the operation is to occur. You can specify CODEUNITS32, CODEUNITS16, or OCTETS as the units for the operation.

CODEUNITS32

Specifies that Unicode UTF-32 is the units for the operation.

CODEUNITS32 is useful when an application wants to process data in a simple fixed-length format and needs the same answer regardless of the storage format of the data (ASCII, EBCDIC, UTF-8, or UTF-16). Although the answers are in terms of CODEUNITS32, the data is not converted to UTF-32 to perform the function.

CODEUNITS16

Specifies that Unicode UTF-16 is the units for the operation.

CODEUNITS16 is useful when an application wants to know how many double-byte characters are in a string.

OCTETS

Specifies that bytes are the units for the operation. OCTETS is often used when an application is interested in allocation buffer space or when operations need to use simple byte processing.

Determining the length of a string by counting in string units (CODEUNITS16 or CODEUNITS32) or bytes (OCTETS) can result in different answers. When OCTETS is specified, the length of a string is determined by simply counting the number of bytes in the string. Counting by CODEUNITS16 or CODEUNITS32 gives the same answer unless the data contains supplementary characters. For information about the difference between CODEUNITS16 and CODEUNITS32 when the data contains supplementary characters, see “Difference between CODEUNITS16 and CODEUNITS32” on page 89.

Example: Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The first two queries, which count the length of the string in CODEUNITS32 and CODEUNITS16, returns the same value, 6. The third query, which counts the length of the string in OCTETS, returns the value 7. These values are the length of the string as expressed in the string units that are specified.

```
SELECT CHARACTER_LENGTH(NAME, CODEUNITS32)
  FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME, CODEUNITS16)
  FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME, OCTETS)
  FROM T1 WHERE NAME = 'Jürgen';
```

The following table shows the UTF-8, UTF-16, and UTF-32 representations of 'Jürgen'.

| Format | Representation of the name 'Jürgen' |
|--------|---|
| UTF-8 | x'4AC3BC7267656E' |
| UTF-16 | x'004A00FC007200670065006E' |
| UTF-32 | x'0000004A000000FC0000007200000067000000650000006E' |

The bold highlighting in the table demonstrates how the representation of the character *ü* in 'Jürgen' differs between the three string units:

- The UTF-8 representation of the character *ü* is X'C3BC'. In UTF-8, characters that are not in the Latin-1 subset (essentially a through z, A through Z, and 0 through 9), such as accented characters or Japanese characters, are represented by multiple bytes.
- The UTF-16 representation of the character *ü* is X'00FC'. In UTF-16, each character is represented in 2 bytes. UTF-16 supplementary characters take two 2-byte code points.
- The UTF-32 representation of the character *ü* is X'000000FC'. In UTF-32, each character is represented in 4 bytes.

Specifying the string units on a built-in function does not affect the data type or the CCSID of the result of the function. If necessary, DB2 converts the data to Unicode for evaluation when CODEUNITS32 or CODEUNITS16 is specified. DB2 always evaluates the data in the encoding scheme of the output data when OCTETS is specified. For more information about the data types and CCSIDs of the results of functions, see the description of each function.

Differences between the way that characters are represented in ASCII, EBCDIC, and Unicode can affect the results of your queries.

Example: Assume that NAME is a VARCHAR(128) column, encoded in EBCDIC (CCSID 37), that contains the value 'Mit freundlichen Grüßen, Jürgen'. The following query returns the string 'Mit freundlichen Grüß':

```
SELECT SUBSTRING(C1,1,21,CODEUNITS16)
FROM T1 WHERE C1 = 'Mit freundlichen Grüßen, Jürgen';
```

The following table shows the result data in more detail:

| Format | Representation of 'Mit freundlichen Grüß' |
|--------|--|
| EBCDIC | D489A340869985A4958493898388859540C799 DC59 |
| UTF-8 | 4D697420667265756E646C696368656E204772 C3BCC39F |
| UTF-16 | 004D0069007400200066007200650075006E0064006C0069006300680065006E002000470072 00FC00DF |

The bold highlighting in the table shows that the representation of the characters *ii* and *ß* in UTF-8 and UTF-16 each require two bytes. If OCTETS had been specified on the SUBSTRING function to have the string evaluated in UTF-8 bytes instead of EBCDIC OCTETS or CODEUNITS16, the result would have been 'Mit freundlichen Grü'. The character *ß* would have been lost.

Difference between CODEUNITS16 and CODEUNITS32:

CODEUNITS16 and CODEUNITS32 return the same answer unless the data contains supplementary characters.

A supplementary character is represented as two UTF-16 code units or one UTF-32 code unit. In UTF-8, a non-supplementary character is represented by 1 to 3 bytes and a supplementary character is represented by 4 bytes. In UTF-16, a non-supplementary character is represented by one CODEUNIT16 code unit or 2 bytes, and a supplementary character is represented by two CODEUNIT16 code units or 4 bytes. In UTF-32, a character is represented by one CODEUNIT32 code unit or 4 bytes. Thus, CODEUNITS16 and CODEUNITS32 return different answers when the data contains supplementary characters.

Example 1: The following table shows the hexadecimal values for the mathematical bold capital A and the Latin capital letter A. The mathematical bold capital A is a supplementary character that is represented by 4 bytes in UTF-8, UTF-16, and UTF-32.

| Character | UTF-8 representation | UTF-16 representation | UTF-32 representation |
|-----------------------------|----------------------|-----------------------|-----------------------|
| Unicode value \u1D400 - 'A' | X'F09D9080' | X'D835DC00' | X'0001D400' |
| MATHEMATICAL BOLD CAPITAL A | | | |
| Unicode value \u0041 - 'A' | X'41' | X'0041' | X'00000041' |
| LATIN CAPITAL LETTER A | | | |

Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following similar queries return different answers:

```

-- Query:                                -- Returns the value:
SELECT CHARACTER_LENGTH(C1,CODEUNITS32) FROM T1;    -- 1
SELECT CHARACTER_LENGTH(C1,CODEUNITS16) FROM T1;    -- 2
SELECT CHARACTER_LENGTH(C1,OCTETS) FROM T1;        -- 4

```

Example 2: Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following similar queries return different answers.

```

-- Query:                                -- Returns the value:
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS32)) FROM T1;    -- X'F09D9080'
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS16)) FROM T1;    -- X'20'
SELECT HEX(SUBSTRING(C1,1,2,CODEUNITS16)) FROM T1;    -- X'F09D9080'
SELECT HEX(SUBSTRING(C1,1,1,OCTETS)) FROM T1;        -- X'20'
SELECT HEX(SUBSTR(C1,1,1)) FROM T1;                  -- X'F0'

```

The value X'20' is the pad (blank) character.

Determining the length attribute of the final result:

When CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying specific formulas depending on which function is specified.

To determine the final result of a function or the CAST specification, DB2 might need to use an intermediate result string if CODEUNITS32 or CODEUNITS16 is specified, depending on the encoding scheme of the data:

- ASCII and EBCDIC data require the use of a UTF-16 intermediate result string when either CODEUNITS32 or CODEUNITS16 is specified.
- UTF-8 data requires the use of a UTF-16 intermediate result string only when CODEUNITS16 is specified.

Regardless of whether an intermediate string is used, when CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying the formulas that are described in the following table. The length attributes that are calculated at each step in the formulas are measured in bytes, unless indicated otherwise.

Table 9. Formulas for the length attribute of the final result string

| Function | Determination of the length attribute of the string ¹ |
|--------------------|---|
| CAST specification | Follow these three steps to determine the length attribute of the final result: |
| CHAR | 1. Length of the intermediate string (IML) |
| CLOB | When CODEUNITS32 or CODEUNITS16 is specified: |
| DBCLOB | <ul style="list-style-type: none"> If the source string is not in Unicode CCSID 1200, 1208, or 367, convert the source string to CCSID 1200, using the formulas in Table 33 on page 141 to determine the result length of the intermediate string (IML). |
| GRAPHIC | <ul style="list-style-type: none"> If source string is in Unicode CCSID 1208 or 367, and CODEUNITS16 is specified, convert the source string to CCSID 1200, using the formulas in Table 33 on page 141 to determine the result length of the intermediate string (IML). |
| VARCHAR | <ul style="list-style-type: none"> Otherwise, the intermediate string is the same as the source string. |
| VARGRAPHIC | When OCTETS is specified: |
| | <ul style="list-style-type: none"> If the CCSID of the source string is different from the CCSID of the result of the function, convert the source string to the CCSID of the result of the function, using the formulas in Table 33 on page 141 to determine the result length of the intermediate string (IML). Otherwise, the intermediate string is the same as the source string. <p>Exception: For the GRAPHIC and VARGRAPHIC function, if the source string is EBCDIC, the source is widened with prefix X'42' before the source string is converted to CCSID 1200 and the length of the intermediate string is determined.</p> |
| | 2. Result length attribute of the intermediate string (r1) |
| | The result length (r1) of the intermediate string depends on whether a <i>length</i> argument was explicitly specified. |
| | If <i>length</i> was not specified, the result length (r1) attribute is: |
| | r1 = IML |
| | If <i>length</i> was specified, the result length (r1) attribute is: |
| | IF (ol * n) < r_IML THEN |
| | r1 = ol * n |
| | ELSE |
| | IF intermediate string is in CCSID 1200 (UTF-16) THEN |
| | r1 = MIN(ol * n , IML + (r * 2)) |
| | ELSE |
| | r1 = MIN(ol * n , IML + r) |
| | Where: |
| | <ul style="list-style-type: none"> ol = original <i>length</i> argument, expressed in the specified string units n = 4 bytes for CODEUNITS32 2 bytes for CODEUNITS16 IML = length of the intermediate string r_IML = IML rounded up to next multiple of n r = ol - (r_IML/n), expressed in the specified string units <p>The calculation for r is an estimate of the difference between the <i>length</i> argument and the estimated number of characters of the input argument, expressed in the specified string units.</p> |
| | 3. Length of the final result string (the result of the function) |
| | The result length attribute of the final string is determined by converting the result length (r1) of the intermediate string to the CCSID of the result of the function, using the formulas in Table 33 on page 141, if CCSID conversion is necessary. Otherwise, the result length attribute of the final string is r1. |

Table 9. Formulas for the length attribute of the final result string (continued)

| Function | Determination of the length attribute of the string ¹ |
|-------------------|---|
| CHARACTER_LENGTH | <p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> <li data-bbox="464 300 1409 384">1. Length of the intermediate string (IML) The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).) <li data-bbox="464 405 1409 510">For the LOCATE, LOCATE_IN_STRING, and POSITION functions, this applies to both the <i>source-string</i> and <i>search-string</i>. If the CCSIDs of intermediate strings for the converted <i>source-string</i> and <i>search-string</i> differ, the intermediate string for the <i>search-string</i> is converted to the CCSID of intermediate string for the <i>source-string</i>. <li data-bbox="464 531 1409 594">2. Result length attribute of the intermediate string (r1) The result length (r1) attribute is always 4 (the length of an integer): $r1 = 4$ <li data-bbox="464 636 1409 699">3. Length of the final result string (the result the function) The length of the final result of the function is always an integer. |
| INSERT OVERLAY | <p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> <li data-bbox="464 762 1409 972">1. Length of the intermediate string (IML) The length of the intermediate string (IML) for both the <i>source-string</i> and the <i>insert-string</i> is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).) If the CCSIDs of the intermediate strings for the converted <i>source-string</i> and <i>insert-string</i> differ, the intermediate string for the <i>insert-string</i> is converted to the CCSID of the intermediate string for the <i>source-string</i>. <li data-bbox="464 993 1409 1308">2. Result length attribute of the intermediate string (r1) The result length (r1) attribute of the intermediate string depends on whether the start and length arguments are constants. If the <i>start</i> and <i>length</i> arguments are both constants, the result length attribute is: $r1 = L1 - \text{MIN} (\text{MAX} (0, L1 - (V2 - 1) * n), V3 * m) + L4$ If at least one argument (the <i>start</i> or <i>length</i> argument) is not a constant, the result length attribute is: $r1 = L1 + L4$ Where: <ul style="list-style-type: none"> • L1 and L4 are the length attributes of the intermediate strings of the <i>source-string</i> and <i>insert-string</i>, respectively. • V2 and V3 are the <i>start</i> and <i>length</i> values, respectively, expressed in the specified string units. <p>m= 1 if the intermediate string of the <i>source-string</i> is not CCSID 1200 (UTF-16) 2 if the intermediate string of the <i>source-string</i> is CCSID 1200 (UTF-16)</p> <p>n= 4 bytes for CODEUNITS32 2 bytes for CODEUNITS16</p> <li data-bbox="464 1665 1409 1770">3. Length of the final result string (the result the function) The length of the final result is the same as the length of the final result for the CAST specification. (See Length attribute of the final result string (the result of the function).) |

Table 9. Formulas for the length attribute of the final result string (continued)

| Function | Determination of the length attribute of the string ¹ |
|---------------|---|
| LEFT RIGHT | <p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> 1. Length of the intermediate string (IML) The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).) 2. Result length attribute of the intermediate string (r1) The result length (r1) attribute is the same as the length of the intermediate string: $r1 = IML$ 3. Length of the final result string (the result of the function) The result length attribute of the final string is determined by converting the result length (r1) of the intermediate string to the CCSID of the result of the function, using the formulas in Table 33 on page 141, if CCSID conversion is necessary. Otherwise, the result length attribute of the final string is r1. The result length attribute of the final string is: $MIN(\text{length of source string, length of CCSID converted string})$ |
| SUBSTRING | <p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> 1. Length of the intermediate string (IML) The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).) 2. Result length attribute of the intermediate string (r1) The result length (r1) of the intermediate string depends on whether a <i>length</i> argument was explicitly specified. If <i>length</i> was not specified, the result length (r1) attribute is: $r1 = IML$ If <i>length</i> was specified, the result length (r1) attribute is: $r1 = MIN(o1 * n, IML)$ Where: <ul style="list-style-type: none"> o1 = original <i>length</i> argument, expressed in the specified string units n = 4 bytes for CODEUNITS32 2 bytes for CODEUNITS16 IML = length of the intermediate string 3. Length of the final result string (the result of the function) The length of the final result string is the same as for LEFT built-in function. |

Note:

- The final value of the calculation for each length attribute (IML, r1, and the final result of the function) is limited by the maximum length of the function or by the maximum length of the corresponding data type of the result, whichever is applicable. Each length attribute is expressed in terms of bytes.

Example 1: Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,10,CODEUNITS32) as COL1 FROM T1;
```

DB2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from Table 33 on page 141, $X * 2$) is $26 * 2$. Thus, the length of the intermediate string is 52 bytes (IML = 52).
2. The CHAR function is evaluated against the first 10 UTF-32 characters in this string. The result length attribute is 40 bytes ($r1 = o1 * n$ or $10 * 4$) because $o1 * n < r_IML$ or $40 < 52$.
3. The 40 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from Table 33 on page 141, $X * .5$) is $40 * .5$. Thus, the length of the final result of the functions is 20 bytes.

Example 2: This example is similar to the first example, except that the specified length for the function is 20 instead of 10. Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,20,CODEUNITS32) as COL1 FROM T1;
```

DB2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from Table 33 on page 141, $X * 2$) is $26 * 2$. Thus, the length of the intermediate result string is 52 bytes (IML = 52).
2. The CHAR function is evaluated against the first 20 UTF-32 characters in this intermediate string. However, because the estimated number of characters in the intermediate string, as expressed in the specified string units, is only 13 characters (r_IML/n or $52/4$), the intermediate string must be padded with 7 padding characters to satisfy the 20 characters that are requested ($r = o1 - (r_IML/n)$ or $20 - 13$). In Unicode 1200 (UTF-16), each padding character takes 2 bytes.
The result length attribute is then calculated to be 66 bytes ($r1 = \text{MIN}(o1 * n, \text{IML} + (r * 2))$ or $\text{MIN}(20 * 4, 52 + 14)$) because $o1 * n < r_IML$ or $80 < 52$ is not true.
3. The 66 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from Table 33 on page 141, $X * .5$) is $66 * .5$. Thus, the length of the final result of the function is 33 bytes.

Graphic strings

A *graphic string* is a sequence of double-byte characters.

The length of the string is the number of characters in the sequence. Like character strings, graphic strings can be empty. An empty string should not be confused with the null value.

Fixed-length graphic strings

When fixed-length graphic string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a fixed-length graphic string, the length attribute must be between 1 and 127 inclusive. A fixed-length graphic string column can also be called a GRAPHIC column.

Varying-length graphic strings

The types of varying-length graphic strings are VARGRAPHIC and *double-byte character large object* (DBCLOB). DBCLOB is a type of LOB. A DBCLOB column is

useful for storing large amounts of double-byte character data, such as documents written with a single double-byte character set.

When varying-length graphic strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual values might have a smaller value. For a varying-length graphic string, the length attribute must be between 1 and 16352.

For a varying-length graphic string column, the maximum for the length attribute is determined by the record size associated with the table, as described Maximum record size in the description of the CREATE TABLE statement. For a DBCLOB string, the length attribute must be between 1 and 1 073 741 823 inclusive. In UTF-16, although supplementary characters use two 2-byte code points, supplementary characters are still considered double-byte characters. For more information about DBCLOBs, see “Large objects (LOBs)” on page 96.

Graphic string variables

Graphic string variables must follow certain rules.

Variables with a graphic string type cannot be defined in Fortran. In addition, graphic string variables follow these rules:

- Fixed-length graphic string host variables can be defined in all host languages, except REXX and Java. In C, fixed-length graphic-string variables are limited to a length of 1.
- Varying-length graphic string variables can be defined in all host languages, with the exception of DBCLOBs which cannot be used in REXX.

Graphic string encoding schemes

Each graphic string can be further defined as either double-byte data or Unicode data.

Double-byte data

Data in which every character is represented by a character from the double-byte character set (DBCS) that does not include shift-out or shift-in characters. Each double-byte graphic string has an associated ASCII or EBCDIC CCSID.

Unicode data

Data that contains characters represented by two bytes, except supplementary characters, which take two 2-byte code points per character. Each Unicode graphic string is encoded using UTF-16. The CCSID for UTF-16 is 1200.

String units in built-in functions

When working with graphic strings, you can specify the string unit in which the operation is to take place for certain built-in functions and the CAST specification. The string unit determines the length in which the operation is to occur.

For more information about string units, see “String unit specifications” on page 87.

Binary strings

A *binary string* is a sequence of bytes.

The length of a binary string is the number of bytes in the sequence. Binary strings are not associated with any CCSID. There are three binary string data types: BINARY, VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT).

Fixed-length binary strings

The type of fixed-length binary strings is BINARY. When fixed-length binary string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length binary string, the length attribute must be between 1 and 255 inclusive.

Varying-length binary strings

The types of varying-length binary strings are VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT)

When varying-length binary strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual length values might have a smaller value than the length attribute value. For varying-length binary strings, the actual length specifies the number of bytes in the string.

For a VARBINARY string, the length attribute must be between 1 and 32704. For a VARBINARY string column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in "Maximum record size" on the description of the CREATE TABLE statement. Like a varying-length character string, varying-length binary string could be an empty string.

A binary string column is useful for storing non-character data, such as encoded or compressed data, pictures, voice, and mixed media. Another use is to hold structured data for exploitation by distinct types, user-defined functions, and stored procedures. Note, that although binary strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BINARY, BLOB, VARBINARY built-in functions and CAST specification can be used to change a FOR BIT DATA character string into a binary string.

Large objects (LOBs)

The term *large object* (LOB) refers to any of the following data types: CLOB, DBCLOB, or BLOB.

CLOB A *character large object* (CLOB) is a varying-length string with a maximum length of 2 147 483 647 bytes (2 gigabytes minus 1 byte). A CLOB is designed to store large SBCS data or mixed data, such as lengthy documents. For example, you can store information such as an employee resume, the script of a play, or the text of novel in a CLOB. Alternatively, you can store such information in UTF-8 in a mixed CLOB. A CLOB is a varying-length character string.

DBCLOB

A *double-byte character large object* (DBCLOB) is a varying-length string with a maximum length of 1 073 741 823 double-byte characters. A DBCLOB is designed to store large DBCS data. For example, you could store the information mentioned for CLOB (an employee resume, the script for a play, or the text of a novel) in UTF-16 in a DBCLOB. A DBCLOB is a varying-length graphic string.

BLOB A *binary large object* (BLOB) is a varying-length string with a maximum

length of 2 147 483 647 bytes (2 gigabytes minus 1 byte). A BLOB is designed to store non-traditional data such as pictures, voice, and mixed media. BLOBs can also store structured data for use by distinct types and user-defined functions. A BLOB is a binary string.

Although BLOB strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BLOB function can be used to change a FOR BIT DATA character string into a BLOB string.

Restrictions using LOBs

With a few exceptions, you can use LOBs in the same contexts in which you can use other varying-length strings.

The following table shows the contexts in which LOBs cannot be used.

Table 10. Contexts in which LOBs cannot be used

| Context of usage | LOB (CLOB, DBCLOB, or BLOB) |
|--|---|
| A GROUP BY clause | Not allowed |
| An ORDER BY clause | Not allowed |
| A CREATE INDEX statement that creates an index using an expression | Not allowed except when the index is created using an expression, in which case an inline LOB column can be referenced as the source data type for the SUBSTR and SUBSTRING built-in functions. |
| A SELECT DISTINCT statement | Not allowed |
| A MERGE statement | Cannot be used in the context of an INCLUDE <i>column-name</i> clause |
| A subselect of a set operation except UNION ALL | Not allowed |
| Predicates | Cannot be used in any predicate except EXISTS, LIKE, and NULL. This restriction includes a <i>simple-when-clause</i> in a CASE expression. <i>expression</i> WHEN <i>expression</i> in a <i>simple-when-clause</i> is equivalent to a predicate with <i>expression=expression</i> . |
| The definition of primary, unique, and foreign keys | Not allowed |
| Check constraints | Not allowed |

Manipulating LOBs using locators

A LOB locator is a host variable with a value that represents a single LOB value in the database server. LOB locators provide a mechanism for you to easily manipulate very large objects in application programs without having to store the entire LOB value on the client machine where the application program might be running.

Because LOB values can be very large, the transfer of these values from the database server to host variables in client application programs can be time consuming. Also, application programs typically process LOB values a piece at a time, rather than as a whole. For these cases, the application can use a *large object locator* (LOB locator) to reference the LOB value.

For example, when selecting a LOB value, an application program could handle the value in either of these two ways:

- Select the entire LOB value and place it into an equally large host variable. This method is acceptable if the application program is going to process the entire LOB value at once.
- Select the LOB value into a LOB locator. Then, using the LOB locator, the application program can issue subsequent database operations on the LOB value (such as using it as a parameter to the scalar functions SUBSTR, CONCAT, COALESCE, LENGTH, doing an assignment, searching the LOB value with LIKE or POSSTR, or using it as a parameter to a user-defined function or procedure) by supplying the LOB locator value as input. The resulting output of the LOB locator operation, for example, the amount of data that is assigned to a client host variable, would then typically be a small subset of the input LOB value.

LOB locators can also represent more than just base values; they can also represent the value associated with a LOB expression. For example, a LOB locator might represent the value associated with:

```
SUBSTR(lob_value_1 CONCAT lob_value_2 CONCAT lob_value_3 , 42, 6000000)
```

For non-locator-based host variables in an application program, when a null value is selected into that host variable, the indicator variable is set to -1, signifying that the value is null. For LOB locators, however, the meaning of indicator variables is slightly different. Because a LOB locator host variable itself can never be null, a negative indicator variable value indicates that the LOB value represented by the LOB locator is null. The null information is kept local to the client by virtue of the indicator variable value (the server does not track null values with valid LOB locators).

A LOB locator represents a value, not a row or location in the database. Therefore, after a value is selected into a LOB locator, no action that is subsequently performed on the original row or table will affect the value that is referenced by the LOB locator. The value associated with a LOB locator is valid until the transaction ends, or until the LOB locator is explicitly freed, whichever comes first.

A LOB locator is also not a database type, and it is never stored in the database. As a result, it cannot participate in views or check constraints. However, values for the SQLTYPE field of the SQLDA exist for LOB locators so that they can be described within an SQLDA structure that is used by FETCH, OPEN, CALL and EXECUTE statements.

For more information about manipulating LOBs with LOB locators, see *DB2 Application Programming and SQL Guide*.

Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

Moreover, strings can represent datetime values, as discussed in “String representations of datetime values” on page 101.

Date

A *date* is a three-part value (year, month, and day) designating a point in time using the Gregorian calendar, which is assumed to have been in effect from the year 1 A.D.

⁴ The range of the year part is 0001 to 9999. The range of the month part is 1 to 12. The range of the day part is 1 to 28, 29, 30, or 31, depending on the month and year.

The internal representation of a date is a string of 4 bytes. Each byte consists of two packed decimal digits. The first 2 bytes represent the year, the third byte the month, and the last byte the day.

The length of a DATE column as described in the catalog is the internal length, which is 4 bytes. The length of a DATE column as described in the SQLDA is the external length, which is 10 bytes unless a date exit routine was specified when your DB2 subsystem was installed. (Writing a date exit routine is described in *DB2 Administration Guide*.) In that case, the string format of a date can be up to 255 bytes in length. Accordingly, DCLGEN⁵ defines fixed-length string variables for DATE columns with a length equal to the value of the field LOCAL DATE LENGTH on installation panel DSNTIP4, or a length of 10 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

Time

A *time* is a three-part value (hour, minute, and second) designating a time of day using a 24-hour clock. The range of the hour part is 0 to 24. The range of the minute and second parts is 0 to 59. If the hour is 24, the minute and second parts are both zero.

The internal representation of a time is a string of 3 bytes. Each byte consists of two packed decimal digits. The first byte represents the hour, the second byte the minute, and the last byte the second.

The length of a TIME column as described in the catalog is the internal length which is 3 bytes. The length of a TIME column as described in the SQLDA is the external length which is 8 bytes unless a time exit routine was specified when the DB2 subsystem was installed. (Writing a time exit routine is described in *DB2 Administration Guide*.) In that case, the string format of a time can be up to 255 bytes in length. Accordingly, DCLGEN⁵ defines fixed-length string variables for TIME columns with a length equal to the value of the field LOCAL TIME LENGTH on installation panel DSNTIP4, or a length of 8 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

Timestamp

A *timestamp* is a six-part or seven-part value (year, month, day, hour, minute, second, and optional fractional second) with an optional time zone specification, that represents a date and time.

The time portion of a timestamp value can include a specification of fractional seconds. The number of digits in the fractional seconds portion is specified using

4. Historical dates do not always follow the Gregorian calendar. Dates between 1582-10-04 and 1582-10-15 are accepted as valid dates although they never existed in the Gregorian calendar.

5. DCLGEN is a DB2 DSN subcommand for generating table declarations for designated tables or views. The declarations are stored in z/OS data sets, for later inclusion in DB2 source programs.

an attribute in the range from 0 to 12 with a default of 6. The time zone is the difference in hours and minutes between local time and UTC. The range of the hour offset is -12 to 14, and the minute offset is 00 to 59. The optional time zone is specified in the format \pm th:tm, with values ranging from -12:59 to +14:00. A timestamp data type is `TIMESTAMP WITHOUT TIME ZONE` (generically referred to as `TIMESTAMP`) or `TIMESTAMP WITH TIME ZONE`.

TIMESTAMP WITHOUT TIME ZONE

The internal representation of a timestamp is a string of 7 to 13 bytes, each of which consists of two packed decimal digits. The first 4 bytes represent the date, the next 3 bytes the time, and the remaining bytes the fractional seconds based on the precision of the timestamp.

The length of a `TIMESTAMP WITHOUT TIME ZONE` column as described in the catalog is the internal length, which is 7 to 13 bytes.

The length of a `TIMESTAMP WITHOUT TIME ZONE` column as described in the `SQLDA` is between 19 and 32 bytes, which corresponds to the length for the character-string representation of the value. For example, a 19 byte character-string representation has no fractional seconds; a 26 byte character-string representation has 6 digits of fractional seconds; and a 29 byte character-string representation has 9 digits of fractional seconds.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

TIMESTAMP WITH TIME ZONE

The external representation of a `TIMESTAMP WITH TIME ZONE` value is the local timestamp followed by the time zone offset. For example, New York is 5 hours behind London during standard time, so New York time "8:15" on 2010-02-10 can be represented as '2010-02-10-08.15.00-5:00'. This timestamp with time zone value represents a UTC value '2010-02-10-13.15.00', which is derived by subtracting the time zone offset from local timestamp.

The internal representation of a timestamp is a string of 9 to 15 bytes that contains the UTC timestamp followed by the time zone. Each byte consists of 2 packed decimal digits. The first byte consists of two packed decimal digits representing time zone hour and the first bit is used to represent the sign of the time zone offset. The second byte of time zone, representing the time zone minute, also consists of two packed decimal digits. For example, time zone "-3:30" is represented as X'8330' and time zone "5:30" is represented as X'0530'.

The length of a `TIMESTAMP WITH TIME ZONE` column as described in the catalog is the internal length, which is between 9 to 15 bytes (a 7 to 13 bytes timestamp followed by 2 bytes time zone).

The length of a `TIMESTAMP WITH TIME ZONE` column as described in the `SQLDA` is the external length, which is between 147 and 160 bytes and corresponds to the length for the character-string representation of the value. For example, a 147 byte character representation has no fractional seconds, and a 160 byte character-string representation has 12 digits of fractional seconds, where the time zone component is 7 bytes.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB. `DCLGEN` therefore defines 147 to 160 byte, varying-length string variables for `TIMESTAMP WITH TIME ZONE` columns.

Datetime host variables

Character-string host variables are normally used to contain date, time, and timestamp values. However, date, time, and timestamp host variables can also be specified in Java as `java.sql.Date`, `java.sql.Time`, and `java.sql.Timestamp`, respectively.

String representations of datetime values

Dates, times, and timestamp values can be represented by strings. For many host languages, there are no special SQL constants for datetime values and, except for Java, no host variables with a data type of date, time, or timestamp. Thus, to be retrieved, a datetime value must be assigned to a string variable.

Values whose data types are `DATE`, `TIME`, `TIMESTAMP WITHOUT TIME ZONE`, or `TIMESTAMP WITH TIME ZONE` are represented in a form that is transparent to the user of SQL. Dates, times, and timestamps (with or without time zones) can also be represented by strings. These representations directly concern the SQL user because, for many host languages there are no special SQL constants or host variables with a data type for `DATE`, `TIME`, `TIMESTAMP WITHOUT TIME ZONE`, or `TIMESTAMP WITH TIME ZONE` values (for variables with Java). Thus, to be retrieved, a datetime value must be assigned to a string variable. The format of the resulting string depends on the default date format and the default time format that is in effect when the statement is prepared.

Each datetime value is assigned an encoding scheme. This encoding scheme is used when the datetime value is converted from its internal form to the string representation in the form of the mixed CCSID if the field `MIXED DATA` is `YES` on installation panel `DSNTIPF`. Otherwise the `SBCS` CCSID of the assigned encoding scheme is used. For Unicode, the mixed CCSID is always used. The following table shows how the encoding scheme is determined:

Table 11. The encoding scheme of datetime values

| Datetime expression | Result encoding scheme |
|---------------------|--|
| Columns | The same encoding scheme as the table that contains the column |
| Host variables | If the statement references: <ul style="list-style-type: none">• A single encoding scheme - The same encoding scheme• Multiple encoding schemes - The application encoding scheme |
| Special registers | If the statement references: <ul style="list-style-type: none">• A single encoding scheme - The same encoding scheme• Multiple encoding schemes - The application encoding scheme |
| Expressions | If the statement references: <ul style="list-style-type: none">• A single encoding scheme - The same encoding scheme• Multiple encoding schemes - The application encoding scheme |

For ASCII and EBCDIC, a string representation of a datetime value must be a character string. For Unicode, a string representation of a datetime value can be

either a character string or a graphic string. Thus, the only time a graphic string can be used for a datetime value is when the encoding scheme is Unicode.

In host languages other than Java, a datetime value must be assigned to a string variable. When a date or time is assigned to a string variable, the string format is determined by a precompiler option or subsystem parameter. When a string representation of a datetime value is used in other operations, it is converted to a datetime value. However, this can be done only if the string representation is recognized by DB2 or an exit provided by the installation and the other operand is a compatible datetime value. An input string representation of a date or time with LOCAL specified must have an actual length that is not greater than 255 bytes.

Datetime values that are represented by strings can appear in contexts that require values whose data types are DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE. A string representation of a date, time or timestamp (with or without time zone) can be passed as an argument to the DATE, TIME, TIMESTAMP, or TIMESTAMP_TZ function to obtain a datetime value. A CAST specification can also be used to turn a character representation of a date, time, or timestamp (with or without time zone) into a datetime value.

Date strings:

A string representation of a date is a string that starts with a digit and has a length of at least 8 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the month and day portions.

The following table shows the valid string formats for dates. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. For an installation-defined date string format, the format and length must have been specified when DB2 was installed. They cannot be listed here.

Table 12. Formats for string representations of dates

| Format name | Abbreviation | Date format | Example |
|---|--------------|--------------------------------------|------------|
| International Standards Organization | ISO | yyyy-mm-dd | 1987-10-12 |
| IBM USA standard | USA | mm/dd/yyyy | 10/12/1987 |
| IBM European standard | EUR | dd.mm.yyyy | 12.10.1987 |
| Japanese industrial standard Christian era | JIS | yyyy-mm-dd | 1987-10-12 |
| Installation-defined | LOCAL | Any installation- defined form | — |

Time strings:

A string representation of a time is a string that starts with a digit, and has a length of at least 4 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the hour part of the time; seconds can be omitted entirely. If you choose to omit seconds, an implicit specification of 0 seconds is assumed. Thus 13.30 is equivalent to 13.30.00.

The following table shows the valid string formats for times. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. In the case of an

installation-defined time string format, the format and length must have been specified when your DB2 subsystem was installed. They cannot be listed here.

Table 13. Formats for string representations of times

| Format name | Abbreviation | Time format | Example |
|---|------------------|-------------------------------|----------|
| International Standards Organization ¹ | ISO ¹ | hh.mm.ss | 13.30.05 |
| IBM USA standard | USA | hh:mm AM or PM | 1:30 PM |
| IBM European standard | EUR | hh.mm.ss | 13.30.05 |
| Japanese industrial standard Christian era | JIS | hh:mm:ss | 13:30:05 |
| Installation-defined | LOCAL | Any installation-defined form | — |

Note: 1. This is an earlier version of the ISO format. JIS can be used to get the current ISO format.

In the USA format:

- The minutes can be omitted, thereby specifying 00 minutes. For example, 1 PM is equivalent to 1:00 PM.
- The letters A, M, and P can be lowercase.
- A single blank must precede the AM or PM.
- The hour must not be greater than 12 and cannot be 0 except for the special case of 00:00 AM.

Using the ISO format of the 24-hour clock, the correspondence between the USA format and the 24-hour clock is as follows:

- 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
- 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
- 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
- 12:00 AM (midnight) corresponds to 24.00.00
- 00:00 AM (midnight) corresponds to 00.00.00

Timestamp strings:

A string representation of a timestamp is a character or graphic string that starts with a digit and has a length of at least 16 characters.

The character or graphic string must contain a value that conforms to one of the formats listed in “Datetime constants” on page 150, subject to the following rules:

- leading blanks are not allowed
- trailing blanks can be included
- leading zeros can be omitted from the month, day, hour, and time zone hour elements of the timestamp. An implicit specification of 0 is assumed for any digit that is omitted.
- the hour can be 24 if the minutes, seconds, and any fractional seconds are all zeroes.
- leading zeros must be included for the minute, second, and time zone minute elements of the timestamp.

- the number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted.
- the separator character that follows the seconds element can be omitted if fractional seconds are not included.
- an optional single blank can be included between the time and the time zone.
- an optional time zone can be included, in one of the following formats:
 - \pm th:tm, with values ranging from -24:00 to +24:00. A value of -0:00 is treated the same as a value of +0:00.
 - \pm th, with values ranging from -24 to +24, and an implicit specification of 00 is assumed for the time zone minute element.
 - uppercase Z to specify UTC

If a string representation of a timestamp is implicitly cast to a value with a timestamp data type, the timestamp precision is assumed to be 6, regardless of the number of digits of fractional seconds in the string. Beyond the sixth digit that represents fractional seconds, the digits are truncated and the missing digits are assumed to be zeros. For example, 1990-3-2-8.30.00.10 is equivalent to 1990-03-02-08.30.00.100000. A string representation of a timestamp can be given a different timestamp precision by explicitly casting the value to a timestamp with a specified precision or, in the case of a constant, preceding the string with the `TIMESTAMP` keyword (for example, `TIMESTAMP 2007-03-28-14.50.35.123;` has the `TIMESTAMP(3)` data type).

If a string representation of a timestamp is implicitly cast to a `TIMESTAMP WITHOUT TIME ZONE` value, the string must not contain a time zone.

SQL statements also support the ODBC or JDBC string representation of a timestamp as an input value only. The ODBC and JDBC string representation of a timestamp has the form `yyyy-mm-dd hh:mm:ss.nnnnnn`.

LOCAL date and time exits: For `LOCAL`, the date exit for ASCII data is `DSNXVDTA`, the date exit for EBCDIC is `DSNXVDTX`, and the date exit for Unicode is `DSNXVDTU`. For `LOCAL`, the time exit for ASCII data is `DSNXVTMA`, the time exit for EBCDIC is `DSNXVTMX`, and the time exit for Unicode is `DSNXVTMU`.

Determination of the implicit time zone

DB2 uses the `IMPLICIT_TIMEZONE` parameter of `DSNHDECP` to implicitly determine the time zone to associate with a value that does not have a time zone on assignment to a `TIMESTAMP WITH TIME ZONE` column or variable.

The `IMPLICIT_TIMEZONE` parameter of `DSNHDECP` is used to support operations that combine `TIMESTAMP WITHOUT TIME ZONE` values and `TIMESTAMP WITH TIME ZONE` values and indicates the time zone to associate with `TIMESTAMP WITHOUT TIME ZONE` values. For example, on assignment of a value that does not have time zone information (the `TIMESTAMP WITHOUT TIME ZONE` data type, or a string representation of a timestamp without a time zone) to a `TIMESTAMP WITH TIME ZONE` target such as a column or variable, DB2 implicitly determines the time zone to associate with the value. The implicit time zone is determined as follows:

- If `IMPLICIT_TIMEZONE` is not specified or is specified as `CURRENT`, the implicit time zone is the value of the `CURRENT TIME ZONE` special register.
- If `IMPLICIT_TIMEZONE` is specified as `SESSION`, the implicit time zone is the value of the `SESSION TIME ZONE` special register.

- If `IMPLICIT_TIMEZONE` is specified as a character string in the format of `'±th:tm'`, the implicit time zone is the time zone value represented by the character string.

Restrictions on the use of local datetime formats

Certain restrictions apply on the use of date and time values as input, as output, and for use in binding a package.

The following rules apply to the character-string representation of dates and times:

For input: In distributed operations, DB2 as a server uses its local date or time routine to evaluate host variables and constants. This means that character-string representation of dates and times can be:

- One of the standard formats
- A format recognized by the server's local date/time exit

For output: With DRDA access, DB2 as a server returns date and time host variables in the format defined at the server. To have date and time host variables returned in another format, use `CHAR(date-expression, XXXX)` where `XXXX` is `JIS`, `EUR`, `USA`, `ISO`, or `LOCAL` to explicitly specify the specific format.

For BIND PACKAGE COPY: When binding a package using the `COPY` option, DB2 uses the `ISO` format for output values unless the `SQL` statement explicitly specifies a different format. Input values can be specified in the format described previously.

Row ID values

A *row ID* is a value that uniquely identifies a row in a table. A column or a host variable can have a row ID data type.

A ROWID column enables queries to be written that navigate directly to a row in the table because the column implicitly contains the location of the row. Each value in a ROWID column must be unique. Although the location of the row might change, for example across a table space reorganization, DB2 maintains the internal representation of the row ID value permanently. When a row is inserted into the table, DB2 generates a value for the ROWID column unless one is supplied. If a value is supplied, it must be a valid row ID value that was previously generated by DB2 and the column must be defined as `GENERATED BY DEFAULT`. Users cannot update the value of a ROWID column.

The internal representation of a row ID value is transparent to the user. The value is never subject to character conversion because it is considered to contain BIT data. The length of a ROWID column as described in the `LENGTH` column of catalog table `SYSCOLUMNS` is the internal length, which is 17 bytes. The length as described in the `LENGTH2` column of catalog table `SYSCOLUMNS` is the external length, which is 40 bytes.

A ROWID column can be either user-defined or implicitly generated by DB2. You can use the `CREATE TABLE` statement or the `ALTER TABLE` statement to define a ROWID column. If you define a LOB column in a table and the table does not have a ROWID column, DB2 implicitly generates a ROWID column. DB2:

- Creates the column with a name of `DB2_GENERATED_ROWID_FOR_LOBSnn`.
DB2 appends `nn` only if the column name already exists in the table, replacing `nn` with `'00'` and incrementing by `'1'` until the name is unique within the row.
- Defines the column as `GENERATED ALWAYS`.

- Appends the column to the end of the row after all the other explicitly defined columns.

An implicitly hidden ROWID column is called *a hidden ROWID column*. A hidden ROWID column is not visible in SQL statements unless you refer to the column directly by name. For example, assume that DB2 generated a hidden ROWID column named DB2_GENERATED_ROWID_FOR_LOBS for table MYTABLE. The result table for a SELECT * statement for table MYTABLE would not contain that ROWID column. However, the result table for SELECT COL1, DB2_GENERATED_ROWID_FOR_LOBS would include the hidden ROWID column.

If you add a ROWID column to a table that already has a hidden ROWID column, DB2 ensures that the corresponding values in each column are identical. If the ROWID column that you add is defined as GENERATED BY DEFAULT, DB2 changes the attribute of the hidden ROWID column to GENERATED BY DEFAULT.

For information about using row IDs, see *DB2 Application Programming and SQL Guide*.

XML values

An XML value represents well-formed XML in the form of an XML document, XML content, or a sequence of XML nodes.

An XML value that is stored in a table as the value of a column that is defined with the XML data type must be a well-formed XML document. XML values are processed in an internal representation that is not comparable to any string value. The only predicates that can be applied to the XML data type are the XMLEXISTS predicate and the NULL predicate.

An XML value can be transformed into a serialized string value that represents the XML document by using the XMLSERIALIZE function. Similarly, a string value that represents an XML document can be transformed to an XML value by using the XMLPARSE function.

The XML data type has a variable length and allows for a wide range of sizes. Although data of this type has no defined maximum length, it does have an effective maximum length limit when treated as a serialized string value that represents XML. The maximum effective length is the same as the DB2 limit for a LOB data value. DB2 treats XML string data in a similar manner as LOB data to accommodate very large XML values. Thus, XML values are constrained by the same maximum length limit as LOB data. Unlike the LOB data type which has a LOB locator type, there is no XML locator type.

Restrictions when using XML values: With a few exceptions, you can use XML values in the same contexts in which you can use other data type. XML values cannot be used in the following contexts:

- SELECT lists that are preceded by the DISTINCT clause
- GROUP BY clauses
- ORDER BY clauses
- A subselect of a fullselect with a set operator that is not UNION ALL
- Basic predicates, quantified predicates, BETWEEN predicates, DISTINCT predicates, IN predicates, or LIKE predicates
- Aggregate functions with the DISTINCT keyword

- Primary, unique, or foreign keys
- CREATE TYPE statements

No host languages have any built-in support for an XML data type.

Distinct types

A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its *source type*), but is considered to be a separate and incompatible data type for most operations.

For example, the semantics for a picture type, a text type, and an audio type that all use the built-in data type BLOB for their internal representation are quite different. A distinct type is created with the SQL statement CREATE TYPE.

For example, the following statement creates a distinct type named AUDIO:

```
CREATE TYPE AUDIO AS BLOB (1M);
```

Although AUDIO has the same representation as the built-in data type BLOB, it is a separate data type that is not comparable to a BLOB or to any other data type. This inability to compare AUDIO to other data types allows functions to be created specifically for AUDIO and assures that these functions cannot be applied to other data types.

The name of a distinct type is qualified with a schema name. The implicit schema name for an unqualified name depends on the context in which the distinct type appears. If an unqualified distinct type name is used:

- In a CREATE TYPE statement or the object of DROP, COMMENT, GRANT, or REVOKE statement, DB2 uses the normal process of qualification by authorization ID to determine the schema name.
- In any other context, DB2 uses the SQL path to determine the schema name. DB2 searches the schemas in the path, in sequence, and selects the first schema in the path such that the distinct type exists in the schema and the user has authorization to use the data type. For a description of the SQL path, see “SQL path” on page 65.

A distinct type does not automatically acquire the functions and operators of its source type because they might not be meaningful. (For example, it might make sense for a “length” function of the AUDIO type to return the length in seconds rather than in bytes.) Instead, distinct types support *strong typing*. Strong typing ensures that only the functions and operators that are explicitly defined on a distinct type can be applied to that distinct type. However, a function or operator of the source type can be applied to the distinct type by creating an appropriate user-defined function. The user-defined function must be sourced on the existing function that has the source type as a parameter. For example, the following series of SQL statements shows how to create a distinct type named MONEY based on data type DECIMAL(9,2), how to define the + operator for the distinct type, and how the operator might be applied to the distinct type:

```
CREATE TYPE MONEY AS DECIMAL(9,2);
CREATE FUNCTION "+"(MONEY,MONEY)
  RETURNS MONEY
  SOURCE SYSIBM."+"(DECIMAL(9,2),DECIMAL(9,2));
CREATE TABLE SALARY_TABLE
  (SALARY MONEY,
   COMMISSION MONEY);
SELECT SALARY + COMMISSION FROM SALARY_TABLE;
```

A distinct type is subject to the same restrictions as its source type. For example, if a CLOB value is not allowed as input to a function, you cannot specify a distinct type that is based on a CLOB as input.

The comparison operators are automatically generated for distinct types, except those that are based on a CLOB, DBCLOB, or BLOB. In addition, DB2 automatically generates functions for every distinct type that support casting from the source type to the distinct type and from the distinct type to the source type. For example, for the AUDIO type created above, these are generated cast functions:

```
FUNCTION schema-name.BLOB (schema-name.AUDIO) RETURNS SYSIBM.BLOB (1M)
FUNCTION schema-name.AUDIO (SYSIBM.BLOB (1M)) RETURNS schema-name.AUDIO
```

Promotion of data types

Data types can be classified into groups of related data types. Within such groups, an order of precedence exists in which one data type is considered to precede another data type. This precedence enables DB2 to support the *promotion* of one data type to another data type that appears later in the precedence order.

For example, DB2 can promote the data type CHAR to VARCHAR and the data type INTEGER to DOUBLE PRECISION; however, DB2 cannot promote a CLOB to a VARCHAR.

DB2 considers the promotion of data types when:

- Performing function resolution (see “Function resolution” on page 221)
- Casting distinct types (see “Casting between data types” on page 109)
- Assigning built-in data types to distinct types (see “Distinct type assignments” on page 131)

For each data type, the following table shows the precedence list (in order) that DB2 uses to determine the data types to which the data type can be promoted. The table indicates that the best choice is the same data type and not promotion to another data type. The table also shows data types that are considered equivalent during the promotion process. For example, CHARACTER and GRAPHIC are considered to be equivalent data types.

Table 14. Precedence of data types

| Data type ^{1,2} | Data type precedence list (in best-to-worst order) |
|--------------------------|--|
| SMALLINT ³ | SMALLINT, INTEGER, BIGINT, decimal, real, double, DECFLOAT |
| INTEGER ³ | INTEGER, BIGINT, decimal, real, double, DECFLOAT |
| BIGINT ³ | BIGINT, decimal, real, double, DECFLOAT |
| decimal ³ | decimal, real, double, DECFLOAT |
| real | real, double, DECFLOAT |
| double | double, DECFLOAT |
| DECFLOAT | DECFLOAT |
| CHAR or GRAPHIC | CHAR or GRAPHIC, VARCHAR or VARGRAPHIC, CLOB or DBCLOB |
| VARCHAR or VARGRAPHIC | VARCHAR or VARGRAPHIC, CLOB or DBCLOB |
| CLOB or DBCLOB | CLOB or DBCLOB |
| BINARY | BINARY, VARBINARY, BLOB |

Table 14. Precedence of data types (continued)

| Data type ^{1,2} | Data type precedence list (in best-to-worst order) |
|-----------------------------|---|
| VARBINARY | VARBINARY, BLOB |
| BLOB | BLOB |
| DATE | DATE |
| TIME | TIME |
| TIMESTAMP WITHOUT TIME ZONE | TIMESTAMP WITHOUT TIME ZONE or TIMESTAMP WITH TIME ZONE |
| TIMESTAMP WITH TIME ZONE | TIMESTAMP WITHOUT TIME ZONE or TIMESTAMP WITH TIME ZONE |
| ROWID | ROWID |
| XML | XML |
| A distinct type | The same distinct type |

Notes:

1. The data types in lowercase letters represent the following data types:

decimal

DECIMAL(*p,s*) or NUMERIC(*p,s*)

real

REAL or FLOAT(*n*) where *n* is not greater than 21

double

DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(*n*) where *n* is greater than 21

2. Other synonyms for the listed data types are considered to be the same as the synonym listed.
3. Real and double are checked for function resolution purposes only. Additionally, the number of significant digits (even for DECFLOAT(16)), and the exponent range of DECFLOAT exceeds that of real and double (double has 16 significant digits). Therefore, DECFLOAT values will not be promoted to real or double.

Casting between data types

There are many occasions when a value with a given data type needs to be *cast* (changed) to a different data type or to the same data type with a different length, precision, or scale.

Data type promotion is one example where the promotion of one data type to another data type requires that the value be cast to the new data type. A data type that can be changed to another data type is *castable* from the source data type to the target data type.

The casting of one data type to another can occur implicitly or explicitly. The cast functions, CAST specification, or XMLCAST specification can be used to explicitly change a data type, depending on the data types involved. In addition, when a sourced user-defined function is created, the data types of the parameters of the source function must be castable to the data types of the function that is being created.

If truncation occurs when a character or graphic string is cast to another data type, a warning occurs if any non-blank characters are truncated. This truncation behavior is similar to retrieval assignment of character or graphic strings. See “Retrieval assignment” on page 128.

If truncation occurs when casting to a binary string, an error is returned.

For casts that involve a distinct type as either the data type to be cast to or from, Table 15 shows the supported casts.

For casting a parameter marker or NULL value to the XML data type, the CAST specification can be used. XML input can also be specified for the CAST specification when the result data type is XML.

Table 15. Supported casts when a distinct type is involved

| Data type ... | Is castable to data type ... |
|---|---|
| Distinct type <i>DT</i> | Source data type of distinct type <i>DT</i> |
| Source data type of distinct type <i>DT</i> | Distinct type <i>DT</i> |
| Distinct type <i>DT</i> | Distinct type <i>DT</i> |
| Data type <i>A</i> | Distinct type <i>DT</i> where <i>A</i> is promotable to the source data type of distinct type <i>DT</i> (see “Promotion of data types” on page 108) |
| INTEGER | Distinct type <i>DT</i> if <i>DT</i> 's source data type is SMALLINT |
| DOUBLE | Distinct type <i>DT</i> if <i>DT</i> 's source data type is REAL |
| VARCHAR | Distinct type <i>DT</i> if <i>DT</i> 's source data type is CHAR or GRAPHIC |
| VARGRAPHIC | Distinct type <i>DT</i> if <i>DT</i> 's source data type is GRAPHIC or CHAR |
| VARBINARY | Distinct type <i>DT</i> if <i>DT</i> 's source data type is BINARY |

When a distinct type is involved in a cast, a cast function that was generated when the distinct type was created is used. How DB2 chooses the function depends on whether function notation or CAST specification syntax is used. (For details, see “Function resolution” on page 221 and “CAST specification” on page 254, respectively.) Function resolution is similar for both. However, in CAST specification, when an unqualified distinct type is specified as the target data type, DB2 first resolves the schema name of the distinct type and then uses that schema name to locate the cast function.

For casts between built-in data types, the following table shows the supported casts.

Table 16. Supported casts between built-in data types

| Cast from data type – | To data type ¹ | | | | | | | | | | | | | | | | | | | |
|-----------------------------------|--------------------------------------|---------------------------------|----------------------------|---------------------------------|---------------------------------|------------------|----------------------------|---------------------------------|------------------|------------------|----------------------------|---------------------------------|---------------------------------|---------------------------------|---|------------------|---------------------------------|------------------|---|--|

| BLOB | | | | | | | | | | | | | | Y | Y | Y | | | | |
| DATE | | | | | | | Y | Y | | | | | | | | | Y | | Y | |
| TIME | | | | | | | Y | Y | | | | | | | | | | Y | | |
| TIMESTAMP WITHOUT TIME ZONE | | | | | | | Y | Y | | | | | | | | | Y | Y | Y | Y |

Table 16. Supported casts between built-in data types (continued)

| Cast from data type - | To data type ¹ | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------------------------|---------------------------|--|--|--|--|--|---------|---|--|--|--|--|--------|--|--|--|--|--|---------|---|---|--|--|--|-----------|---|---|---|---|
| | SMALLINT | | | | | | INTEGER | | | | | | BIGINT | | | | | | DECIMAL | | | | | | TIMESTAMP | | | | |
| TIMESTAMP WITH TIME ZONE | | | | | | | Y | Y | | | | | | | | | | | | | | | | | | Y | Y | Y | Y |
| ROWID | | | | | | | Y | Y | | | | | | | | | | | Y | Y | Y | | | | | | | | Y |
| XML | | | | | | | | | | | | | | | | | | | | | | | | | | | | | Y |

Note:

1. Other synonyms for the listed data types are considered to be the same as the synonym listed. Some exceptions exist when the cast involves character string data if the subtype is FOR BIT DATA.
2. The result length for these casts is 3 * LENGTH(graphic string).
3. These data types are castable between each other only if the data is Unicode.

Table 17 shows where to find information about the rules that apply when casting to the identified target data types.

Table 17. Rules for casting to a data type

| Target data type | Rules |
|------------------|------------------------------|
| SMALLINT | “SMALLINT” on page 577 |
| INTEGER | “INTEGER or INT” on page 468 |
| BIGINT | “BIGINT” on page 360 |
| DECIMAL | “DECIMAL or DEC” on page 419 |
| NUMERIC | “DECIMAL or DEC” on page 419 |
| REAL | “REAL” on page 549 |

Table 17. Rules for casting to a data type (continued)

| Target data type | Rules |
|-----------------------------------|---|
| DOUBLE | "DOUBLE_PRECISION or DOUBLE" on page 430 |
| DECFLOAT | "DECFLOAT" on page 412 |
| CHAR | "CHAR" on page 370 |
| VARCHAR | "VARCHAR" on page 641 |
| CLOB | "CLOB" on page 381 |
| GRAPHIC | "GRAPHIC" on page 451 |
| VARGRAPHIC | "VARGRAPHIC" on page 658 |
| DBCLOB | "DBCLOB" on page 408 |
| BINARY | "BINARY" on page 362 |
| VARBINARY | "VARBINARY" on page 639 |
| BLOB | "BLOB" on page 366 |
| DATE | "DATE" on page 397 |
| TIME | "TIME" on page 597 |
| TIMESTAMP WITHOUT TIME ZONE | <p>If the source data type is a character or graphic string, see "TIMESTAMP" on page 598, where one operand is specified. If the string contains a time zone, an error is returned.</p> <p>If the source data type is a DATE, the timestamp is composed of the specified date and a time of 00:00:00.</p> <p>If the source is a TIMESTAMP WITH TIME ZONE, the resulting timestamp is the timestamp without time zone element of the specified datetime value, which is the local timestamp in the corresponding time zone. For example: cast('2008-04-12-07.30.00.0-6:00' as TIMESTAMP) returns 2008-04-12-07.30.00.0.</p> <p>If the source type is a TIMESTAMP WITHOUT TIME ZONE the timestamp is the specified value.</p> |
| TIMESTAMP WITH TIME ZONE | <p>If the source data type is a character or graphic string or TIMESTAMP WITHOUT TIME ZONE, see "TIMESTAMP_TZ" on page 613, where one operand is specified. If the string contains a time zone, an error is returned.</p> <p>If the source type is a TIMESTAMP WITH TIME ZONE, the timestamp is the specified value.</p> |
| ROWID | "ROWID" on page 564 |

Table 18. The derived length of an argument when a built-in scalar function is invoked and implicit casting is required.

| Source data type | Target data type | | | | VAR- GRAPHIC | CLOB | DBCLOB | BLOB | TIME STAMP (precision) | DECFLOAT |
|------------------|------------------|---------|---------|-----|-----------------|------|--------|------|------------------------------|----------|

| TIME-STAMP(<i>p</i>) WITH TIME ZONE | If <i>p</i> =0 then 148, otherwise 149+ <i>p</i> | If <i>p</i> =0 then 148, otherwise 149+ <i>p</i> | If <i>p</i> =0 then 148, otherwise 149+ <i>p</i> | If <i>p</i> =0 then 148, otherwise 149+ <i>p</i> | | | | | |

Casting non-XML values to XML values

Table 19. Supported Casts from Non-XML Values to XML Values

| Source Data Type | Target Data Type | |
|------------------|------------------|---------------------------|
| | XML | Resulting XML Schema Type |
| SMALLINT | Y | xs:short |
| INTEGER | Y | xs:int |
| BIGINT | Y | xs:long |
| DECIMAL | Y | xs:decimal |
| DECFLOAT | N | |
| REAL | N | |
| FLOAT | Y | xs:double |
| DOUBLE | Y | xs:double |
| CHAR | Y | xs:string |
| VARCHAR | Y | xs:string |
| CLOB | Y | xs:string |
| GRAPHIC | Y | xs:string |
| VARGRAPHIC | Y | xs:string |
| DBCLOB | Y | xs:string |
| BINARY | N | |
| VARBINARY | N | |
| BLOB | N | |

Table 19. Supported Casts from Non-XML Values to XML Values (continued)

| Source Data Type | Target Data Type | |
|-----------------------------|------------------|---------------------------|
| | XML | Resulting XML Schema Type |
| character type FOR BIT DATA | N | |
| DATE | N | |
| TIME | N | |
| TIMESTAMP WITHOUT TIME ZONE | N | |
| TIMESTAMP WITH TIME ZONE | N | |
| ROWID | N | |
| distinct type | N | |

When character string values are cast to XML values, the resulting `xs:string` atomic value cannot contain illegal XML characters. If the input character string is not in Unicode, the input characters are converted to Unicode.

Casting XML values to non-XML values

An `XMLCAST` from an XML value to a non-XML value can be described as two casts: an XQuery cast that converts the source XML value to a target XQuery data type that corresponds to the SQL target type, followed by a cast from the corresponding XQuery data type to the actual SQL type. The target XQuery data type is an XML schema data type like `xs:decimal` or `xs:string`, as shown in the follow table.

An `XMLCAST` is supported if the target type has a corresponding XQuery target type that is supported, and if there is a supported XQuery cast from the type of the source value to the corresponding XQuery target type. The target type that is used in the XQuery cast is based on the corresponding XQuery target type and might contain some additional restrictions.

The following table lists the XQuery types that result from such conversion.

Table 20. Supported Casts from XML Values to Non-XML Values

| Target Data Type | Source Data Type | |
|------------------|------------------|----------------------------------|
| | XML | Corresponding XQuery Target Type |
| SMALLINT | Y | <code>xs:integer</code> |
| INTEGER | Y | <code>xs:integer</code> |
| BIGINT | Y | <code>xs:integer</code> |
| DECIMAL | Y | <code>xs:decimal</code> |
| DECFLOAT | Y | <code>xs:double</code> |
| REAL | Y | <code>xs:double</code> |
| FLOAT | Y | <code>xs:double</code> |
| DOUBLE | Y | <code>xs:double</code> |
| CHAR | Y | <code>xs:string</code> |
| VARCHAR | Y | <code>xs:string</code> |
| CLOB | Y | <code>xs:string</code> |
| GRAPHIC | Y | <code>xs:string</code> |

Table 20. Supported Casts from XML Values to Non-XML Values (continued)

| Target Data Type | Source Data Type | |
|-----------------------------|------------------|----------------------------------|
| | XML | Corresponding XQuery Target Type |
| VARGRAPHIC | Y | xs:string |
| DBCLOB | Y | xs:string |
| BINARY | N | |
| VARBINARY | N | |
| BLOB | N | |
| character type FOR BIT DATA | N | |
| DATE | Y | xs:date |
| TIME | Y | xs:time |
| TIMESTAMP | Y | xs:dateTime |
| ROWID | N | |
| distinct type | N | |

The following restrictions are in effect when a value is cast from an XQuery target data type to a target SQL data type:

- If the target type is one of the character or graphic string types, the resulting XML value is converted, if necessary, to the CCSID of the target data type using the rules described in “Conversion rules for string assignment” on page 129, before it is converted to the target type with a limited length. Truncation occurs if the specified length limit is smaller than the length of the resulting string after CCSID conversion. A warning occurs if any non-blank characters are truncated. If the target type is a fixed-length string type (CHAR or GRAPHIC) and the specified length of the target type is greater than the length of the resulting string from CCSID conversion, blanks are padded at the end. This truncation and padding behavior is similar to retrieval assignment of character or graphic strings.
- If the target type is DOUBLE or REAL and the source XML value after the XQuery cast is an xs:double value of INF, -INF, or NaN, an error is returned. If the source value is an xs:double negative zero, the value is converted to positive zero. If the source value is beyond the range of the target data type, an overflow error is returned. If the source value contains more significant digits than the precision of the target data type, the source value is rounded to the precision of the target data type.
- If the target type is DECFLOAT and the source XML value is an xs:double value of INF, -INF, or NaN, the result will be the corresponding special DECFLOAT values INF, -INF, or NaN. If the source value is an xs:double negative zero, the result is negative zero. If the target type is DECFLOAT(16) and the source value is beyond the range of DECFLOAT(16), an overflow error is returned. If the source value has more than 16 significant digits, the value is rounded according to the ROUNDING mode that is in effect. This rounding behavior is the same as what is used during the cast of DECFLOAT(34) to DECFLOAT(16).
- If the target type is DECIMAL, the resulting xs:decimal value is converted, if necessary, to the precision and scale of the target data type. The necessary number of leading zeros is added or removed. In the fractional part of the number, the necessary number of trailing zeros is added or the necessary number of digits is eliminated. This truncation behavior is similar to the behavior of the cast from DECIMAL to DECIMAL.

- If the target type is DATE, TIME, or TIMESTAMP WITHOUT TIME ZONE, the resulting XML value is adjusted to UTC time and the time zone component is removed. If the source does not include a time zone and the target data type is TIMESTAMP WITH TIME ZONE, zeroes are used for the time zone component. If the target type is TIME and the resulting XML value contains a seconds component with non-zero digits after the decimal point, those digits are truncated. If the target type is DATE or timestamp, the year part of the resulting xs:date or xs:dateTime value must be in the range of 0001 to 9999. If the target type is timestamp and the precision of the target timestamp is less than 12, the fractional seconds part of the xs:dateTime value will be truncated to the target timestamp precision.

Implicit cast from numeric data to string data

When DB2 implicitly casts a numeric value to a string value, the target type is VARCHAR value which is then compatible with other character string or graphic string data types.

The length attribute and the CCSID attribute of the result of the cast are determined in the same way as the VARCHAR function. When GRAPHIC or VARGRAPHIC data types are involved, the encoding scheme must be UNICODE. The following table shows the target type and length:

Table 21. Target type and length attribute for implicit cast from numeric types to string types

| Source data type | Target data type |
|--------------------|-------------------------------|
| SMALLINT | VARCHAR(6) |
| INTEGER | VARCHAR(11) |
| BIGINT | VARCHAR(20) |
| NUMERIC or DECIMAL | VARCHAR(<i>precision</i> +2) |
| REAL | VARCHAR(24) |
| FLOAT | VARCHAR(24) |
| DOUBLE | VARCHAR(24) |
| DECFLOAT | VARCHAR(42) |

Implicit conversion from a numeric value to a string value can happen during:

- Assignment (where the source value is a number and the target operand is a character string or graphic string data type).
Among assignment statements, implicit casting is not supported for the SET statements for special registers, the RETURNS clause and RETURN statement for functions, and the SQL control statements: RETURN, SIGNAL, and RESIGNAL.
- Application of concatenation operators (CONCAT and ||)
- Application of set operators.

Implicit conversion is not supported in the following cases:

- One operand of a set operator is a numeric value and the other operand is a string value
- A numeric value is compared to or assigned to a string value that is the result of a fullselect which included a set operator

Implicit cast from string data to numeric data

When DB2 implicitly casts a character string or graphic string value to a numeric value, the target type is DECFLOAT(34) which is compatible with other numeric data types.

When GRAPHIC or VARGRAPHIC data types are involved, the encoding scheme must be UNICODE. The following table shows the target type and length:

Table 22. Target type and length attribute for implicit cast from string types to numeric types

| Source data type | Target data type |
|--|------------------|
| CHAR | DECFLOAT(34) |
| VARCHAR | DECFLOAT(34) |
| GRAPHIC | DECFLOAT(34) |
| VARGRAPHIC | DECFLOAT(34) |
| CHAR FOR BIT DATA or VARCHAR FOR BIT DATA | N/A |
| BINARY | N/A |
| VARBINARY | N/A |
| BLOB | N/A |
| CLOB | N/A |
| DBCLOB | N/A |

Implicit conversion from a string value to a numeric value can happen during:

- Assignment (where the source value is a character string or graphic string and the target operand is a numeric data type).
- Comparisons

When a character string or graphic string value is compared with a numeric value, DB2 implicitly converts the string value to DECFLOAT(34) and applies numeric comparison rule between the DECFLOAT(34) value and the other numeric value.

- Basic predicates, quantified predicates, and DISTINCT predicates (one operand is numeric value and the other operand is character string or graphic string value)

Numeric is the dominant data type. The character or graphic string value is cast to DECFLOAT(34) value.

- BETWEEN predicates

Numeric is the dominant data type. If any of the three operands is a numeric value, DB2 implicitly casts the character or graphic string operands to DECFLOAT data type.

- IN predicates

Numeric is the dominant data type. If any of the operands is a numeric value, DB2 implicitly casts the character or graphic string operands to DECFLOAT data type.

- Searched-when-clause of CASE expression

Pair-wise comparison is performed. Implicit cast of each pair follows the same rule as for a basic predicate. Implicit string and numeric cast is supported on searched-when-clause of CASE expression.

– Search conditions in SQL control statements (one operand is numeric value and the other operand is character string or graphic string value)
 The search condition can appear in SQL control statements like the CASE statement, the IF statement, the REPEAT statement, and the WHILE statement. For comparisons in the search condition, numeric is the dominant data type. The character string or graphic string value is cast to a DECFLOAT(34) value. Implicit string and numeric cast is supported on the *searched-when-clause* of the CASE statement.

- Arithmetic operators (unary arithmetic operators + and - and infix arithmetic operators +, -, *, and /)
 If the operand of unary arithmetic operators is of a character string or graphic string data type, that operand is implicitly cast to DECFLOAT(34). For infix arithmetic operators, if one operand is a numeric value or both operands are character or graphic string values, DB2 implicitly casts the character string or graphic string operand to the DECFLOAT data type.

Implicit conversion is not supported in the following cases:

- One operand of a set operator is a string value and the other operand is a numeric value
- A string value is compared to or assigned to a numeric value that is the result of a fullselect which included a set operator

Assignment and comparison

The basic operations of SQL are assignment and comparison.

Assignment operations are performed during the execution of statements such as CALL, INSERT, UPDATE, MERGE, FETCH, SELECT INTO, SET *host-variable* or SET *assignment-statement*, and VALUES INTO statements. In addition, when a function is invoked or a stored procedure is called, the arguments of the function or stored procedure are assigned. Comparison operations are performed during the execution of statements that include predicates and other language elements such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

The basic rule for both operations is that data types of the operands must be compatible. The compatibility rule also applies to other operations that are described under “Rules for result data types” on page 143.

The following table shows the compatibility of data types for assignments and comparisons for numeric data types.

Table 23. Compatibility of data types for assignments and comparisons with numeric data types. Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Binary integer | Decimal number | Floating point | Decimal floating point |
|------------------------|----------------|----------------|----------------|------------------------|
| Binary integer | Y | Y | Y | Y |
| Decimal number | Y | Y | Y | Y |
| Floating point | Y | Y | Y | Y |
| Decimal floating point | Y | Y | Y | Y |
| Character string | 1 | 1 | 1 | 1 |
| Graphic string | 2 | 2 | 2 | 2 |

Table 23. Compatibility of data types for assignments and comparisons with numeric data types (continued). Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Binary integer | Decimal number | Floating point | Decimal floating point |
|-----------------------------|----------------|----------------|----------------|------------------------|
| Binary string | N | N | N | N |
| Date | N | N | N | N |
| Time | N | N | N | N |
| Timestamp without time zone | N | N | N | N |
| Timestamp with time zone | N | N | N | N |
| Row ID | N | N | N | N |
| Distinct type | 3 | 3 | 3 | 3 |
| XML ⁴ | N | N | N | N |

Notes:

1. LOBs and bit data are not supported.
2. LOBs are not supported.
3. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 131.
4. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

The following table shows the compatibility of data types for assignments and comparisons for string data types.

Table 24. Compatibility of data types for assignments and comparisons with string data types. Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Character string | Graphic string | Binary string |
|-----------------------------|------------------|------------------|----------------|
| Binary integer | 7 | 7 | N |
| Decimal number | 7 | 7 | N |
| Floating point | 7 | 7 | N |
| Decimal floating point | 7 | 7 | N |
| Character string | Y | Y ^{4,5} | N ³ |
| Graphic string | Y ^{4,5} | Y | N |
| Binary string | N ³ | N | Y |
| Date | 1 | 1,4 | N |
| Time | 1 | 1,4 | N |
| Timestamp without time zone | 1 | 1,4 | N |
| Timestamp with time zone | 1 | 1,4 | N |
| Row ID | N | N | N |
| Distinct type | 2 | 2 | 2 |
| XML ⁶ | N | N | N |

Table 24. Compatibility of data types for assignments and comparisons with string data types (continued). Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Character string | Graphic string | Binary string |
|--|------------------|----------------|---------------|
| Notes: | | | |
| 1. The compatibility of datetime values is limited to assignment and comparison: <ul style="list-style-type: none"> • Datetime values can be assigned to string columns and to string variables that are not LOB values, as explained in “Datetime assignments” on page 130. • A valid string representation of a date can be assigned to a date column or compared to a date. • A valid string representation of a time can be assigned to a time column or compared to a time. • A valid string representation of a timestamp(without or with time zone) can be assigned to a timestamp column(without or with time zone) or compared to a timestamp(without or with time zone). | | | |
| 2. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 131. | | | |
| 3. All character strings, even those with subtype FOR BIT DATA, are not compatible with binary strings. | | | |
| 4. On assignment and comparison from Graphic to Character, the resulting length in bytes is 3 * (LENGTH(<i>graphic-string</i>)), depending on the CCSIDs. | | | |
| 5. Character strings with subtype FOR BIT DATA are not compatible with Graphic Data. | | | |
| 6. Character and graphic strings, including LOBs, can be assigned to XML columns. However, XML cannot be assigned to a character or graphic string column. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates. | | | |
| 7. LOBs and bit data are not supported. | | | |

The following table shows the compatibility of data types for assignments and comparisons for date, time, and timestamp data types.

Table 25. Compatibility of data types for assignments and comparisons with date, time, and timestamp (without or with time zone) data types. Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Date | Time | Timestamp without time zone | Timestamp with time zone |
|-----------------------------|------|------|-----------------------------|--------------------------|
| Binary integer | N | N | N | N |
| Decimal number | N | N | N | N |
| Floating point | N | N | N | N |
| Decimal floating point | N | N | N | N |
| Character string | Y | Y | Y | Y |
| Graphic string | 2 | 2 | 2 | 2 |
| Binary string | N | N | N | N |
| Date | Y | N | N | N |
| Time | N | Y | N | N |
| Timestamp without time zone | N | N | Y | Y |
| Timestamp with time zone | N | N | Y | Y |
| Row ID | N | N | N | N |
| Distinct type | 1 | 1 | 1 | 1 |
| XML ³ | N | N | N | N |

Table 25. Compatibility of data types for assignments and comparisons with date, time, and timestamp (without or with time zone) data types (continued). Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Date | Time | Timestamp without time zone | Timestamp with time zone |
|--|------|------|-----------------------------|--------------------------|
| Notes: | | | | |
| 1. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 131. | | | | |
| 2. On assignment and comparison from Graphic to Character, the resulting length in bytes is 3 * (LENGTH(<i>graphic-string</i>)), depending on the CCSIDs. | | | | |
| 3. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates. | | | | |

The following table shows the compatibility of data types for assignments and comparisons for row ID, XML, and distinct data types.

Table 26. Compatibility of data types for assignments and comparisons with row ID, XML, and distinct data types. Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

| Operand | Row ID | XML ² | Distinct type |
|-----------------------------|--------------|------------------|----------------|
| Binary integer | N | N | ¹ |
| Decimal number | N | N | ¹ |
| Floating point | N | N | ¹ |

| XML ² | N | Y | N |

Notes:

1. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 131.
2. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

Compatibility with a column that has a field procedure is determined by the data type of the column, which applies to the decoded form of its values.

A basic rule for assignment operations is that a null value cannot be assigned to:

- A column that cannot contain null values
- A non-Java host variable that does not have an associated indicator variable

For a host variable that does have an associated indicator variable, a null value is assigned by setting the indicator variable to a negative value. See “Host variables” on page 208 for a discussion of indicator variables.

- A Java host variable that is a primitive type

For a Java host variable that is not a primitive type, the value of that variable is set to a Java null value.

Numeric assignments

The basic rule for numeric assignments is that the whole part of a decimal or integer number cannot be truncated. If necessary, the fractional part of a decimal number is truncated.

Decimal or integer to floating-point

Because floating-point numbers are only approximations of real numbers, the result of assigning a decimal or integer number to a floating-point column or variable might not be identical to the original number.

Floating-point or decimal to integer

When a single precision floating-point number is converted to integer, rounding occurs on the seventh significant digit, zeros are added to the end of the number, if necessary, starting from the seventh significant digit, and the fractional part of the number is eliminated. When a double precision floating-point or decimal number is converted to integer, the fractional part of the number is eliminated.

Example 1: The following example shows single precision floating-point numbers converted to an integer:

| Floating-point number: | Results when assigned to an integer column or host variable: |
|------------------------|---|
| 2.0000045E6 | 2000000 |
| 2.00000555E8 | 200001000 |

Example 2: The following example shows a double precision floating-point number converted to an integer:

| Floating-point number: | Results when assigned to an integer column or host variable: |
|------------------------|---|
| 2.0000045E6 | 2000004 |
| 2.00000555E8 | 200000555 |

Example 3: The following example shows a decimal number converted to an integer:

| Decimal number: | Results when assigned to an integer column or host variable: |
|-----------------|---|
| 2000004.5 | 2000004 |
| 200000555.0 | 200000555 |

Decimal to decimal

When a decimal number is assigned to a decimal column or variable, the number is converted, if necessary, to the precision and the scale of the target.

The necessary number of leading zeros is added or eliminated, and, in the fractional part of the number, the necessary number of trailing zeros is added, or the necessary number of trailing digits is eliminated.

Decimal to DECFLOAT

When a decimal number is assigned to a DECFLOAT column or variable, the number is converted to the precision (16 or 34) of the target. Leading zeros are eliminated.

Depending on the precision and scale of the decimal number, and the precision of the target, the value might be rounded to fit.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Integer to decimal

When an integer is assigned to a decimal column or variable, the number is converted first to a temporary decimal number and then, if necessary, to the precision and scale of the target.

The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer.

Integer to DECFLOAT

When an integer is assigned to a DECFLOAT column or variable, the number is converted first to a temporary decimal number and then to DECFLOAT.

The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer. The decimal number is then converted to DECFLOAT using the rules for "Decimal to DECFLOAT."

Floating-point to floating-point

When a single precision floating-point number is assigned to a double precision floating-point column or variable, the single precision data is padded with eight hex zeros. When a double precision floating-point number is assigned to a single precision floating-point column or variable, the double precision data is converted and rounded up on the seventh hex digit.

In assembler, C, or C++ applications that are prepared with the FLOAT(IEEE) SQL processing option, floating-point constants and values in host variables are assumed to have IEEE floating-point format. All floating-point data is stored in DB2 in System/390 floating-point format. Therefore, when the FLOAT(IEEE) SQL processing option is in effect, DB2 performs the following conversions:

- When a number in short or long IEEE floating-point format is assigned to a single-precision or double-precision floating-point column, DB2 converts the number to System/390 floating-point format.
- When a single-precision or double-precision floating-point column value is assigned to a short or long floating-point host variable, DB2 converts the column value to IEEE floating-point format.

Floating-point to decimal

When a single precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number.

When a single precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision

6 by rounding on the seventh decimal digit. Twenty five zeros are then appended to the number to bring the precision to 31. Because of rounding, a number less than 0.5×10^{-6} is reduced to 0.

When a double precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 15, and then, if necessary, truncated to the precision and scale of the target. In this conversion, zeros are added to the end of the number, if necessary, to bring the precision to 16. The number is then rounded (using floating-point arithmetic) on the sixteenth decimal digit to produce a 15-digit number. Because of rounding, a number less in magnitude than 0.5×10^{-15} is reduced to 0. If the decimal number requires more than 15 digits to the left of the decimal point, an error is reported. Otherwise, the scale is given the largest possible value that allows the whole part of the number to be represented without loss of significance.

The following examples show the effect of converting a double precision floating-point number to decimal:

Example 1: The floating-point number, .123456789098765E-05 in decimal notation is, .00000123456789098765. Rounding adds 5 in the 16th position, so the number becomes .00000123456789148765 and truncates the result to .000001234567891. Zeros are then added to the end of a 31-digit result, and the number becomes .0000012345678910000000000000000.

Example 2: The floating-point number, 1.2339999999999E+01 in decimal notation is, 12.33999999999900. Rounding adds 5 in the 16th position, so the number becomes 12.33999999999905 and truncates the result to 12.3399999999990. Zeros are then added to the end of a 31-digit result and the number becomes 12.3399999999990000000000000000000.

Floating point to DECFLOAT

When a single or double precision floating-point number is assigned to a DECFLOAT column or variable, the number is first converted to a temporary string representation of the floating point number. The string representation of the number is then converted to DECFLOAT.

DECFLOAT to integer

When a DECFLOAT is assigned to a binary integer column or variable, the fractional part of the number is lost.

Example 1: The following example shows decimal floating-point numbers converted to an integer:

| | |
|--------------------------------|--|
| Decimal floating-point number: | Results when assigned to an integer column or host variable: |
| 2.0000045E6 | 2000004 |
| 2.00000555E8 | 200000555 |

DECFLOAT to decimal

When a DECFLOAT value is assigned to a decimal column or variable, the DECFLOAT value is converted, if necessary, to the precision and the scale of the target.

During the assignment, the necessary number of leading zeros is added and, in the fractional part of the number, the necessary number of trailing zeros is added, or rounding occurs.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Example 1: The following example shows decimal floating-point numbers converted to a decimal value:

| | |
|--------------------------------|--|
| Decimal floating-point number: | Results when assigned to an decimal(15,0) column or host variable: |
| 2.0000045E6 | 2000005 |
| Decimal floating-point number: | Results when assigned to an decimal(15,2) column or host variable: |
| 2.0000045E6 | 2000004.50 |
| 2.00000555E8 | 200000555.00 |

DECFLOAT to floating-point

Because floating-point numbers are only approximations of real numbers, the result of assigning a DECFLOAT value to a floating-point column or variable might not be identical to the original number.

The DECFLOAT value is first converted to a string representation, and is then converted to floating-point number.

DECFLOAT(16) to DECFLOAT(34)

When a DECFLOAT(16) is assigned to a DECFLOAT(34) column or variable, the exponent of the source is converted to the corresponding exponent in the result format, and the coefficient is extended by appending zeros on the left.

DECFLOAT(34) to DECFLOAT(16)

When a DECFLOAT(34) is assigned to a DECFLOAT(16) column or variable, the exponent of the source is converted to the corresponding exponent in the result format.

The source coefficient is rounded to the precision of the target.

For static SQL statements, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

To COBOL integers

Assignment to COBOL integer variables uses the full size of the integer.

Thus, the value placed in the COBOL data item might be out of the range of values.

COBOL supports some data types with no SQL equivalent (BINARY decimal and DISPLAY decimal data items, for example). In most cases, you can use COBOL statements to convert between the unsupported COBOL data types and the data types that SQL supports.

For DB2 for z/OS, the only BINARY numeric variables allowed as HOST variable are integer binary variables. The only DECIMAL host variables supported by SQL are packed decimal host variables.

Example 1: If COL1 contains a value of 12345, the following statements cause the value 12345 to be placed in A, even though A has been defined with only 4 digits:

```
01 A PIC S9999 BINARY.  
EXEC SQL SELECT COL1  
      INTO :A  
      FROM TABLEX  
END-EXEC.
```

Example 2: The following COBOL statement results in 2345 being placed in A:

```
MOVE 12345 TO A.
```

String assignments

There are two types of string assignments; storage assignment and retrieval assignment.

- *Storage assignment* is when a value is assigned to a column or a parameter of a function or stored procedure.
- *Retrieval assignment* is when a value is assigned to a variable.

The rules differ for storage and retrieval assignment.

Binary string assignment

Binary string assignment involves assignment at both the storage and the retrieval of binary strings.

Storage assignment:

The length of a string that is assigned to a column or transition variable must not be greater than the length attribute of the column or parameter. If the string is longer than the length attribute of that column or transition variable, an error is returned.

When the string is assigned to a fixed-length binary string column or parameter of a function or procedure, and the length of the string is less than the length attribute of that column or parameter, the string is padded to the right with the necessary number of binary zeros.

Retrieval assignment:

The length of a string that is assigned to a variable can be greater than the length attribute of the variable. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the string is truncated on the right by the necessary number of bytes. When this occurs, a warning is returned.

Character and graphic string assignment

The rules for storage and retrieval assignment apply when both the source and the target are strings.

When a datetime data type is involved, see “Datetime assignments” on page 130. For the special considerations that apply when a distinct type is involved in an assignment, especially to a variable, see “Distinct type assignments” on page 131.

Storage assignment:

The basic rule for character storage assignment is that the length of a string that is assigned to a column or transition variable must not be greater than the length attribute of the column or transition variable.

Trailing blanks are included in the length of the string. When the length of the string is greater than the length attribute of the column or the parameter, the following actions occur:

- If all of the trailing characters that must be truncated to make a string fit the target are blanks and the string is a character or graphic string, the string is truncated and assigned without warning.
- Otherwise, the string is not assigned and an error occurs to indicate that at least one of the excess characters is non-blank.

When a string is assigned to a fixed-length column or parameter and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of SBCS or DBCS blanks. The pad character is always a blank even for columns or parameters that are defined with the FOR BIT DATA attribute.

Retrieval assignment:

The length of a string that is assigned to a host variable can be greater than the length attribute of the variable. When the length of the string is greater than the length of the variable, the string is truncated on the right by the necessary number of SBCS or DBCS characters.

When truncation occurs, the value is assigned to the SQLWARN1 field of the SQLCA. Furthermore, if an indicator variable is provided and the source of the value is not a LOB, the indicator variable is set to the original length of the string. The truncation result of an improperly formed mixed string is unpredictable.

When a character string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of blanks. The pad character is always a blank even for strings defined with the FOR BIT DATA attribute.

When a string of length n is assigned to a varying-length string variable with a maximum length greater than n , the characters after the n th character of the variable are undefined.

Assignments involving mixed data strings

A mixed data string that contains MBCS characters cannot be assigned to an SBCS column, SBCS parameter, or SBCS variable.

The following rules apply when a mixed data string is assigned to a variable and the string is longer than the length attribute of the variable:

- If the string is not well-formed mixed data, it is truncated as if it were BIT or graphic data.
- If the string is well-formed mixed data, it is truncated on the right such that it is well-formed mixed data with a length that is the same as the length attribute of the variable and the number of characters lost is minimal.

Assignments involving C NUL-terminated strings

A C NUL-terminated string variable that is referenced in a CONNECT statement does not need to contain a NUL. Otherwise, DB2 enforces the convention that the value of a NUL-terminated string variable, either character or graphic, is NUL-terminated.

An input variable that does not contain a NUL will cause an error. A value that is assigned to an output variable will always be NUL-terminated even if a character must be truncated to make room for the NUL.

When a string of length n is assigned to a C NUL-terminated string variable with a length greater than $n+1$, the rules depend on whether the source string is a value of a fixed-length string or a varying-length string:

- If the source is a fixed-length string and the value of field PAD NUL-TERMINATED on installation panel DSNTIP4 is YES, the string is padded on the right with $x-n-1$ blanks, where x is the length of the variable. The padded string is then assigned to the variable and a NUL is appended at the end of the variable. If the value of field PAD NUL-TERMINATED is NO, the string is assigned to the first n bytes of the variable and a NUL is appended at the end of the variable.
- If the source is a varying-length string, the string is assigned to the first n bytes of the variable and a NUL is appended at the end of the variable.

Conversion rules for string assignment

A character or graphic string that is assigned to a column or variable is first converted, if necessary, to the coded character set of the target. Conversion is necessary only if certain conditions apply.

Conversion is necessary only if all the following are true:

- The CCSIDs of string and target are different.
- Neither CCSID is X'FFFF' (neither the string nor the target is defined as BIT data).
- The string is neither null nor empty.

An error occurs if:

- The SYSSTRINGS table is used but contains no information about the pair of CCSIDs and DB2 cannot do the conversion through z/OS support for Unicode.
- A character of the string cannot be converted and the operation is assignment to a column or to a host variable that has no indicator variable. For example, a DBCS character cannot be converted to a variable with an SBCS CCSID.

A warning occurs if:

- A character of the string is converted to a substitution character. A *substitution character* is the character that is used when a character of the source character set is not part of the target character set. For example, assuming an EBCDIC target character set, if the source character set includes Katakana characters and the target character set does not, a Katakana character is converted to the EBCDIC SUB X'3F'.
- A character of the string cannot be converted and the operation is assignment to a variable that has an indicator variable. For example, a DBCS character cannot be converted if the variable has an SBCS CCSID. In this case, the string is not assigned to the variable and the indicator variable is set to -2.

Datetime assignments

A string value that is assigned to a date, time, or timestamp column, variable, or parameter must be a valid string representation of a date, a time, or a timestamp.

A value that is assigned to a date column, a date variable, or a date parameter must be a date or a valid string representation of a date.

A date can be assigned only to the following items:

- a date column
- a character-string column
- a character-string variable

A value that is assigned to a time column, a time variable, or a time parameter must be a time or a valid string representation of a time.

A time can be assigned only to the following items:

- a time column
- a character-string column
- a character-string variable

A value that is assigned to a timestamp column, a timestamp variable, or a timestamp parameter must be a timestamp, a timestamp constant, a valid string representation of a timestamp, or a valid string representation of a date. When a string representation of a date is assigned to a timestamp target, the DB2 database manager inserts zeroes for the time portion of the timestamp target.

A timestamp can be assigned only to the following items:

- a timestamp column
- a character-string or graphic-string column
- a timestamp variable
- a character-string or graphic-string variable

A valid string representation of a datetime value must not be a BLOB, CLOB, or DBCLOB. A datetime value cannot be assigned to a column that has a field procedure. If the timestamp precision of the target is less than the timestamp precision of the assigned value, the extra fractional seconds are truncated.

When a datetime value is assigned to a character-string variable or column, it is converted to its string representation. Leading zeros are not omitted from any part of the date, time, or timestamp. The required length of the target varies depending on the format of the string representation. If the length of the fixed length character-string target is greater than required, it is padded on the right with blanks. If the length of the target is less than required, the result depends on the type of datetime value involved, and the type of the target.

When a datetime value is assigned to a timestamp variable or column, it is converted to the target timestamp data type. If the source data type is not the same as the target data type, the source value is implicitly cast to the target data type. DB2 might implicitly cast data types during assignments that involve a distinct type.

- If the target is not a variable and has a character-string or graphic-string data type (except for BLOB, CLOB, or DBCLOB), truncation is not allowed. The length of the column must be at least the following values:

- 10 for a **DATE**
- 8 for a **TIME**
- 19 for a **TIMESTAMP WITHOUT TIME ZONE** with a precision of 0, 20+p with precision of *p*
- Sufficient to include the time zone (truncation is not allowed), for a **TIMESTAMP WITH TIME ZONE**
- When the target is a character-string or graphic-string variable, the following rules apply:
 - **For a date:** The length of the variable must not be less than 10.
 - **For a time:** If the USA format is used, the length of the variable must not be less than 8. This format does not include seconds.
If the ISO, EUR, or JIS format is used, the length of the variable must not be less than 5. If the length is 5, 6, or 7, the seconds part of the time is omitted from the result and SQLWARN1 is set to 'W'. In this case, the seconds part of the time is assigned to the indicator variable if one is provided, and, if the length is 6 or 7, the value is padded with blanks so that it is a valid string representation of a time.
 - **For a timestamp:** The length of the variable must not be less than 19. If the source is **TIMESTAMP WITH TIME ZONE**, the length of the variable must be sufficient to include the time zone, truncation is not allowed.
 - If the length is between 19 and 31, the timestamp is truncated like a string, which causes the omission of one or more digits of the fractional seconds part of a timestamp.
 - If the length is 20, the trailing decimal point is excluded so that the value is a valid string representation of a timestamp with precision 0.

Row ID assignments

A row ID value can be assigned only to a column, parameter, or host variable with a row ID data type.

For the value of the ROWID column, the column must be defined as GENERATED BY DEFAULT and the column must have a unique, single-column index. The value that is specified for the column must be a valid row ID value that was previously generated by DB2.

XML assignments

XML data can be assigned to a column, but when the target is not a column, the XML data type can only be assigned to another XML data type.

When the target is a column (for example, data change statements), the source can be the XML data type, or CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, DBCLOB, BINARY, VARBINARY, or BLOB data types. When the source is not XML data, the source is implicitly parsed as if the XMLPARSE function is invoked with the STRIP WHITESPACE option. If the source data is graphic data, the encoding scheme must be Unicode.

All other data types cannot be assigned to a target of the XML data type.

Distinct type assignments

The rules that apply to the assignments of distinct types to host variables are different than the rules for all other assignments that involve distinct types.

Assignments to host variables: The assignment of distinct type to a host variable is based on the source data type of the distinct type. Therefore, the value of a distinct type is assignable to a host variable only if the source data type of the distinct type is assignable to the host variable.

Example: Assume that distinct type AGE was created with the following SQL statement:

```
CREATE TYPE AGE AS SMALLINT;
```

When the statement was executed, DB2 also generated these cast functions:

```
AGE (SMALLINT) RETURNS AGE
AGE (INTEGER) RETURNS AGE
SMALLINT (AGE) RETURNS SMALLINT
```

Next, assume that column STU_AGE was defined in table STUDENTS with distinct type AGE. Now, consider this valid assignment of a student's age to host variable HV_AGE, which has an INTEGER data type:

```
SELECT STU_AGE INTO :HV_AGE FROM STUDENTS WHERE STU_NUMBER = 200;
```

The distinct type value is assignable to host variable HV_AGE because the source data type of the distinct type (SMALLINT) is assignable to the host variable (INTEGER). If distinct type AGE had been based on a character data type such as CHAR(5), the above assignment would be invalid because a character type cannot be assigned to an integer type.

Assignments other than to host variables: A distinct type can be the source or target of an assignment. Assignment is based on whether the data type of the value to be assigned is castable to the data type of the target. (Table 15 on page 110 shows which casts are supported when a distinct type is involved). Therefore, a distinct type value can be assigned to any target other than a host variable when:

- The target of the assignment has the same distinct type, or
- The distinct type is castable to the data type of the target

Any value can be assigned to a distinct type when:

- The value to be assigned has the same distinct type as the target, or
- The data type of the assigned value is castable to the target distinct type

Example: Assume that the source data type for distinct type AGE is SMALLINT:

```
CREATE TYPE AGE AS SMALLINT;
```

Next, assume that two tables TABLE1 and TABLE2 were created with four identical column descriptions:

```
AGECOL    AGE
SMINTCOL  SMALLINT
INTCOL    INTEGER
DECCOL    DEC(6,2)
```

Using the following SQL statement and substituting various values for X and Y to insert values into various columns of TABLE1 from TABLE2, the following table shows whether the assignments are valid. DB2 uses assignment rules in this INSERT statement to determine if X can be assigned to Y.

```
INSERT INTO TABLE1 (Y)
SELECT X FROM TABLE2;
```

Table 27. Assessment of various assignments for example INSERT statement

| X (column in TABLE2) | Y (column in TABLE1) | Valid | Reason |
|----------------------|----------------------|-------|--|
| AGECOL | AGECOL | Yes | Source and target are same distinct type |
| SMINTCOL | AGECOL | Yes | SMALLINT can be cast to AGE |
| INTCOL | AGECOL | Yes | INTEGER can be cast to AGE (because AGE's source type is SMALLINT) |
| DECCOL | AGECOL | No | DECIMAL cannot be cast to AGE |
| AGECOL | SMINTCOL | Yes | AGE can be cast to its source type of SMALLINT |
| AGECOL | INTCOL | No | AGE cannot be cast to INTEGER |
| AGECOL | DECCOL | No | AGE cannot be cast to DECIMAL |

Assignments to LOB locators

When a LOB locator is used, it can refer only to LOB data. If a LOB locator is used for the first fetch of a cursor, LOB locators must be used for all subsequent fetches.

Numeric comparisons

Numbers are compared algebraically, that is, with regard to sign. For example, -2 is less than +1. When numbers of different data types are compared, certain rules are in effect as to how the comparison is performed.

If one number is an integer and the other is decimal, the comparison is made with a temporary copy of the integer, which has been converted to decimal.

When decimal numbers with different scales are compared, the comparison is made with a temporary copy of one of the numbers that has been extended with trailing zeros so that its fractional part has the same number of digits as the other number.

If one number is double precision floating-point and the other is integer, decimal, or single precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to double precision floating-point. However, if a single precision floating-point number is compared with a floating-point constant, the comparison is made with a single precision form of the constant.

Two floating-point numbers are equal only if the bit configurations of their normalized forms are identical.

If one number is DECFLOAT and the other number is integer, decimal, single precision floating-point, or double precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to DECFLOAT.

If one number is DECFLOAT(16) and the other number is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison.

Additionally, the DECFLOAT data type supports both positive and negative zero. Positive and negative zero have different binary representations, but the equal (=) predicate will return true for comparisons of positive and negative zero.

The functions, COMPARE_DECFLOAT and TOTALORDER can be used to perform comparisons at a binary level. For example, for a comparison of 2.0<>2.00.

The DECFLOAT data type also supports the specification of negative and positive NaN (quiet and signaling), and negative and positive infinity. From an SQL perspective, infinity = infinity, NaN = NaN, and sNaN = sNaN.

The following rules are the comparison rules for these special values:

- Infinity compares equal only to infinity of the same sign (positive or negative)
- NaN compares equal only to NaN of the same sign (positive or negative)
- sNaN compares equal only to sNaN of the same sign (positive or negative)

The ordering among the different special values is as follows: -NAN < -SNAN < -INFINITY < 0 < INFINITY < SNAN < NAN

String comparisons

String comparisons can occur with binary string, character strings, and graphic strings.

Binary string comparisons

Binary string comparisons are always performed according to the binary values.

Two binary strings are equal only if the lengths of the two strings are identical. If the strings are equal up to the length of the shorter string length, the shorter string is considered less than the longer string even when the remaining bytes in the longer string are hexadecimal zeros. This is illustrated in the following table:

Table 28. Binary string comparison where one operand is longer because of hexadecimal zeros

| Hexadecimal value of the first operand | relationship | Hexadecimal value of the second operand |
|--|--------------|---|
| X'4100' | < | X'410000' |
| X'4100' | < | X'42' |
| X'4100' | = | X'4100' |
| X'4100' | > | X'41' |
| X'4100' | > | X'400000' |

Binary strings cannot be compared to character strings (even FOR BIT DATA) unless the character string is cast to a binary string.

Character and graphic string comparisons

Two strings are compared by comparing the corresponding bytes of each string. If the strings do not have the same length, the comparison is made with a temporary copy of the shorter string that has been padded on the right with blanks so that it has the same length as the other string.

Two strings are equal if they are both empty or if all corresponding bytes are equal. An empty string is equal to a blank string. If two strings are not equal, their relationship (that is, which has the greater value) is determined by the comparison of the first pair of unequal bytes from the left end of the strings. This comparison is made according to the collating sequence associated with the encoding scheme of the data. For ASCII data, characters A through Z (both upper and lowercase)

have a greater value than characters 0 through 9. For EBCDIC data, characters A through Z (both upper and lowercase) have a lesser value than characters 0 through 9.

Varying-length strings with different lengths are equal if they differ only in the number of trailing blanks. In operations that select one value from a collection of such values, the value selected is arbitrary. The operations that can involve such an arbitrary selection are DISTINCT, MAX, MIN, and references to a grouping column. See the description of GROUP BY for further information about the arbitrary selection involved in references to a grouping column.

Related concepts:

 [Objects with different CCSIDs in the same SQL statement \(DB2 Internationalization Guide\)](#)

String comparisons with field procedures:

The rules for string comparisons with field procedures depend on the values being compared.

If a column with a field procedure is compared with the value of a variable or a constant, the variable or constant is encoded by the field procedure before the comparison is made. If the comparison operator is LIKE, the variable or constant is not encoded and the column value is decoded.

If a column with a field procedure is compared with another column, that column must have the same field procedure and both columns must have the same CCSID set. The comparison is performed on the encoded form of the values in the columns. If the encoded values are numeric, their data types must be identical; if they are strings, their data types must be compatible.

If two encoded strings of different lengths are compared, the shorter is temporarily padded with encoded blanks so that it has the same length as the other string.

In a CASE expression, if a column with a field procedure is used as the *result-expression* in a THEN or ELSE clause, all other columns that are used as *result-expressions* must have the same field procedure. Otherwise, no column used in a *result-expression* can name a field procedure.

Datetime comparisons

| A date, time, or timestamp value can be compared with another value of the same
| data type, a datetime constant of the same data type, or with a string
| representation of a value of that data type. Additionally, a `TIMESTAMP WITHOUT`
| `TIME ZONE` value can be compared with a `TIMESTAMP WITH TIME ZONE`
| value.

| All comparisons are chronological, which means the further a point in time is from
| January 1, 0001, the greater the value of that point in time. The time 24:00:00
| compares greater than the time 00:00:00.

| Comparisons that involve `TIME` values and string representations of time values
| always include seconds. If the string representation omits seconds, zero seconds
| are implied.

| Comparisons that involve timestamp values are evaluated according to the
| following rules:

- When comparing timestamp values with different precisions, the higher precision is used for the comparison and any missing digits for fractional seconds are assumed to be zero.
- When comparing a `TIMESTAMP WITH TIME ZONE` value to a `TIMESTAMP WITHOUT TIME ZONE` value, the `TIMESTAMP WITHOUT TIME ZONE` value is cast to `TIMESTAMP WITH TIME ZONE` before the comparison is made.
- When comparing two `TIMESTAMP WITH TIME ZONE` values, the comparison is made using the UTC representations of the values. Two `TIMESTAMP WITH TIME ZONE` values are considered equal if they represent the same instance in UTC, regardless of the time zone offsets that are stored in the values. For example, '1999-04-15-08.00.00-08:00' (8:00 a.m. Pacific Standard Time) is the same as '1999-04-15-11.00.00-05:00' (11:00 a.m. Eastern Standard Time).
- When comparing a timestamp value with a string representation of a timestamp, the string representation is first converted to the data type of the timestamp operand. With the exception that the converted value has a precision of 12. If the timestamp operand is `TIMESTAMP WITHOUT TIME ZONE`, the string must not contain a specification of time zone.
- Timestamp comparisons are chronological without regard to representations that might be considered equivalent. For example, the following predicate is true:
`TIMESTAMP('1990-02-23-00.00.00') > '1990-02-22-24.00.00'`

Example 1: Table `TABLE1` has 2 columns: `C1`, which is defined as `TIMESTAMP WITH TIME ZONE`; and `C2`, which is defined as `TIMESTAMP WITHOUT TIME ZONE`:

```
CREATE TABLE TABLE1 (C1 TIMESTAMP WITH TIME ZONE, C2 TIMESTAMP);
```

A row is inserted into the table with the following `INSERT` statement. The input values are provided by character-string representations of a timestamp with a time zone.

```
INSERT INTO TABLE1 VALUES ( '2007-11-05-08.00.00-08:00', '2007-11-05-08.00.00');
```

Assuming that the implicit time zone is `-5:00`, the following `SELECT` statement will not return any rows. The string representation of the `TIMESTAMP WITHOUT TIME ZONE` value is cast to a `TIMESTAMP WITH TIME ZONE` value, which results in a timestamp with time zone value of '2007-11-05-08.00.00-05:00' for column `C2`. The comparison predicate is false because the two values are not equal.

```
SELECT 1 FROM TABLE1 WHERE C1 = C2;
```

Example 2: When a `TIMESTAMP WITHOUT TIME ZONE` value is compared with a string representation of a `TIMESTAMP WITHOUT TIME ZONE` or a `TIMESTAMP WITH TIME ZONE` value, the string representation is cast to `TIMESTAMP WITHOUT TIME ZONE` (regardless of whether the string contains a time zone). The comparison is performed using the two `TIMESTAMP WITHOUT TIME ZONE` values. Assume that `string_hv` contains a timestamp with time zone value of '2007-11-05-08.00.00-08:00'. The string value is cast to a `TIMESTAMP WITHOUT TIME ZONE` value of '2007-11-05-08.00.00', which is compared with the value that is stored in column `C2`. The following `SELECT` statement returns a single row because a row exists in the table with a timestamp without time zone value of '2007-11-05-08.00.00'.

```
SELECT 1 FROM TABLE1 WHERE C2 = :string_hv;
```

Row ID comparisons

A value with a row ID type can only be compared to another row ID value.

The comparison of the row ID values is based on their internal representations. The maximum number of bytes that are compared is 17 bytes, which is the number of bytes in the internal representation. Therefore, row ID values that differ in bytes beyond the 17th byte are considered to be equal.

XML comparisons

The XML data type cannot be directly compared to any data type, including the XML data type. The method for doing comparison is through the use of the XMLEXISTS predicate.

Conversion rules for comparisons

When two strings are compared, one of the strings is first converted, if necessary, to the coded character set of the other string. Conversion is necessary only if certain rules apply.

Conversion is necessary only if all of the following are true:

- The CCSIDs of the two strings are different.
- Neither CCSID is X'FFFF' (neither string is defined as a binary string).
- The string selected for conversion is neither null nor empty.
- The following conversion tables (Table 30 on page 139 or Table 31 on page 139) indicate when conversion is necessary.

The string selected for conversion depends on the type of the operands. For the purpose of CCSID determination, string expressions in a statement are divided into 6 types, as described in the following table.

Table 29. Operand types

| Type of operand | CCSID of the operand type |
|-------------------|---|
| Columns | CCSID from the containing table |
| String constants | CCSID associated with the application encoding scheme. For dynamic statements, this is the CURRENT APPLICATION ENCODING SCHEME special register. For static statements, this is the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures.. |
| Special registers | CCSID associated with the application encoding scheme. For dynamic statements, this is the CURRENT APPLICATION ENCODING SCHEME special register. For static statements, this is the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures. |
| Host variables | CCSID specified in the DECLARE VARIABLE statement, associated with the application encoding scheme, or specified in SQLDAID or SQLDA |

Table 29. Operand types (continued)

| Type of operand | CCSID of the operand type |
|-------------------------------------|--|
| Derived value based on a column | <p data-bbox="613 258 1419 369">CCSID derived from the source of the derived value. A derived value based on a column is an expression whose source is directly or indirectly based on columns. The CCSID of such an expression is the CCSID derived from its source.</p> <p data-bbox="613 401 753 428">For example:</p> <ul data-bbox="613 436 1419 1192" style="list-style-type: none"> <li data-bbox="613 436 1419 520">• The CCSID of SUBSTR(column_1, 5, length(column_2)) is the CCSID of column_1. Note that the CCSID of column_2 has no influence on the CCSID of SUBSTR. <li data-bbox="613 531 1419 594">• The CCSID of column_1 'ABC' is the CCSID of column_1, derived from the rules described in Table 30 on page 139. <li data-bbox="613 604 1419 688">• The CCSID of column_1 GX'42C1' is the DBCS CCSID from the CCSID set of column_1, derived from the rules described in Table 30 on page 139 and Table 31 on page 139. <li data-bbox="613 699 1419 783">• The CCSID of COALESCE(EBCDIC_column_1, ASCII_column_1) is the UNICODE CCSID, derived from the rules described in Table 30 on page 139. <li data-bbox="613 793 1419 856">• The CCSID of CAST(string_column_1 AS GRAPHIC(10)) is the DBCS CCSID from the CCSID set of string_column_1. <li data-bbox="613 867 1419 951">• The CCSID of CAST(EBCDIC_string_column_1 AS VARCHAR(10) CCSID UNICODE) is the UNICODE CCSID derived from the rules described in Table 30 on page 139. <li data-bbox="613 961 1419 1045">• The CCSID of CASE WHEN(1=1) THEN '1' ELSE ASCII_column_1 END is the CCSID of ASCII_column_1, derived from the rules described in Table 30 on page 139. <li data-bbox="613 1056 1419 1140">• The CCSID of CASE WHEN(1=1) THEN EBCDIC_column_1 ELSE ASCII_column_1 END is the UNICODE CCSID derived from the rules described in Table 30 on page 139. <li data-bbox="613 1150 1419 1192">• The CCSID of a scalar fullselect (SELECT column_1 FROM table_1) is the CCSID of column_1. |
| Derived value not based on a column | <p data-bbox="613 1209 1419 1320">CCSID derived from the source of the derived value. A derived value not based on a column is an expression whose source is not directly or indirectly based on any column. The CCSID of such an expression is the CCSID derived from its source.</p> <ul data-bbox="613 1331 1419 1713" style="list-style-type: none"> <li data-bbox="613 1331 1419 1415">• For example, the CCSID of SUBSTR('ABDC', 1, length('AB')) is the CCSID of the string constant 'ABCD'. Note that the CCSID of column_1 has no influence on the CCSID of SUBSTR. <li data-bbox="613 1425 1419 1488">• the CCSID of user_defined_function1(column1) is the output CCSID defined by user_defined_function1. <li data-bbox="613 1499 1419 1562">• the CCSID of the cast function of distinct type, shape, is the CCSID of distinct type, shape. <li data-bbox="613 1572 1419 1656">• the CCSID of CURRENT SQLID UX'0041' is the UNICODE DBCS CCSID, derived from the rules described in Table 30 on page 139 and Table 31 on page 139. <li data-bbox="613 1667 1419 1713">• the CCSID of CAST('abc' as CHAR(10) CCSID UNICODE) is the UNICODE CCSID. |

The following table shows which operand supplies the target CCSID set when the comparison is part of an SQL statement involving multiple tables with different CCSID sets.

Table 30. Operand that supplies the CCSID for character conversion

| First operand | Second operand | | | | Derived value based on a column | Derived value not based on a column |
|-------------------------------------|----------------|-----------------|------------------|------------------|---------------------------------|-------------------------------------|
| | Column value | String constant | Special register | Host variable | | |
| Column value | 1 | first operand | first operand | first operand, 2 | 1 | first operand |
| String constant | second operand | 1 | 1 | 1 | second operand | 1 |
| Special register | second operand | 1 | 1 | 1 | second operand | 1 |
| Host variable | second operand | 1 | 1 | 1 | second operand, 2 | 1 |
| Derived value based on a column | 1 | first operand | first operand | first operand, 2 | 1 | first operand |
| Derived value not based on a column | second operand | 1 | 1 | 1 | second operand | 1 |

Note:

1. If the CCSID sets are different, both operands are converted, if necessary, to Unicode. SBCS and Mixed are converted to UTF-8. DBCS is converted to UTF-16. See the next table to determine which operand supplies the CCSID for character conversion.
2. If the encoding scheme that is in effect for the statement is EBCDIC or ASCII, the host variable is Unicode graphic, and the value of the field MIXED DATA on installation panel DSNTIPF is NO, the column or the derived value that is based on a column supplies the target CCSID set.

The following table shows which operand is selected for conversion when both operands are based on a column or are not based on a column as represented in the previous table.

Table 31. Operand that supplies the CCSID for character conversion when both operands are based or not based on a column

| First operand | Second operand | | |
|---------------|----------------------------|-----------------------------|----------------|
| | SBCS data | Mixed data | DBCS data |
| SBCS data | | second operand ¹ | second operand |
| Mixed data | first operand ¹ | | second operand |
| DBCS data | first operand | first operand | |

Note:

1. For ASCII and EBCDIC data, the conversion depends on the value of the field MIXED DATA on installation panel DSNTIPF at the DB2 that does the comparison. If MIXED DATA = YES, the SBCS operand is converted to MIXED. If MIXED DATA = NO, the MIXED operand is converted to SBCS

For example, assume a comparison of the form:

string-constant-SBCS =derived-value-not-based-on-column-DBCS

Assume that the operands have different encoding schemes. First look at Table 30 on page 139. The relevant table entry is in the third row and second column. The value for this entry shows that if the CCSID sets are different, the operands are converted to Unicode. The first operand (string-constant-SBCS) is converted to UTF-8 (Mixed) if it is not already Unicode. In addition, the second operand (derived-value-not-based-on-column-DBCS) is converted to UTF-16 (Unicode DBCS) if necessary. After the operands have been converted to Unicode, Table 31 on page 139 is used to determine which operand supplies the specific CCSID for the conversion. The relevant table entry is in the second row and third column. It indicates that the second operand (derived-value-not-based-on-column-DBCS) determines the CCSID because DBCS data takes precedence over Mixed data.

An error occurs if a character of the string cannot be converted, the SYSSTRINGS table is used but contains no information about the pair of CCSIDs of the operands being compared, or DB2 cannot do the conversion through z/OS support for Unicode. A warning occurs if a character of the string is converted to a substitution character.

A derived value based on a column is an expression that includes columns that affects the result CCSID of the expression. For example, in the expression `COL1 || 'abc'`, `COL1` determines the result CCSID. Therefore, the expression `COL1 || 'abc'` is considered to be a derived value based on a column that continues to give the column precedence in any further comparisons. The expression `CASE WHEN COL1 > 1 THEN 'abc' ELSE 'def' END` contains a column that does not affect the result CCSID of the expression and is therefore not considered to be a derived value based on a column.

The following table defines which expressions are considered to be a derived value based on a column.

Table 32. Derived values based on a column

| Expression | Condition |
|---|--|
| <code>expression1 expression2</code> | <code>expression1</code> or <code>expression2</code> is a column or a derived value based on a column |
| <code>CASE when-clause THEN result-expression ELSE result-expression END</code> | any <code>result-expression</code> is a <i>string-expression</i> that is a column or derived value based on a column |
| <code>CAST(expression as data-type)</code> | <code>expression</code> is a <i>string-expression</i> that is a column or a derived value based on a column and <code>data-type</code> is a string data type |
| Scalar-fullselect: <code>(SELECT expression FROM table)</code> | <code>expression</code> is a <i>string-expression</i> that is a column or a derived value based on a column and <code>data-type</code> is a string data type |

When a statement contains multiple CCSID sets, if the length of one of the strings changes after CCSID conversion, the string becomes a varying-length string. That is, the data type becomes VARCHAR, CLOB, VARGRAPHIC, or DBCLOB. The following table shows the worse case resulting lengths of CCSID conversion, where X is length in bytes.

Table 33. Worst case result length of CCSID conversion, where X represents LENGTH(string in bytes)

| From CCSID | To CCSID | | | | | | | | | |
|------------|----------|--------------------|--------|------------------|--------------------|------|------------------|----------------|--------|-----|
| | EBCDIC | | | ASCII | | | Unicode | | | |
| | SBCS | Mixed | DBCS | SBCS | Mixed | DBCS | SBCS | UTF-8 | UTF-16 | |
| EBCDIC | SBCS | X | X | X*2 ¹ | X | X | X*2 ¹ | X ¹ | X*3 | X*2 |
| | Mixed | X | X | X*2 ¹ | X | X | X*2 ¹ | X ¹ | X*3 | X*2 |
| | DBCS | X*0.5 ¹ | X+2 | X | X*0.5 ¹ | X | X | X*0.5 | X*1.5 | X |
| ASCII | SBCS | X | X | X*2 ¹ | X | X | X*2 ¹ | X ¹ | X*3 | X*2 |
| | Mixed | X | X*1.8 | X*2 ¹ | X | X | X*2 ¹ | X ¹ | X*3 | X*2 |
| | DBCS | X*0.5 ¹ | X+2 | X | X*0.5 ¹ | X | X | X*0.5 | X*1.5 | X |
| Unicode | SBCS | X | X | X*2 | X | X | X*2 | X | X | X*2 |
| | UTF-8 | X | X*1.25 | X | X | X | X | X | X | X*2 |
| | UTF-16 | X*0.5 | X+2 | X | X*0.5 | X | X | X*0.5 | X*1.5 | X |

Note:

1. Because of the high probability of data loss, IBM does not provide conversion tables for this combination of two CCSIDs and data subtypes.

Distinct type comparisons

A value with a distinct type can only be compared to another value with exactly the same type because distinct types have strong typing, which means that a distinct type is compatible only with its own type.

To compare a distinct type to a value with a different data type, the distinct type value must be cast to the data type of the comparison value or the comparison value must be cast to the distinct type. For example, because constants are built-in data types, a constant can be compared to a distinct type value only if it is first cast to the distinct type or vice versa.

The following table shows examples of valid and invalid comparisons, assuming the following SQL statements were used to define two distinct types AGE_TYPE and CAMP_DATE and table CAMP_ROSTER table.

```
CREATE TYPE AGE_TYPE AS INTEGER;
CREATE TYPE CAMP_DATE AS DATE;
CREATE TABLE CAMP_ROSTER
( NAME          VARCHAR(20),
  ATTENDEE_NUMBER INTEGER NOT NULL,
  AGE           AGE_TYPE,
  FIRST_CAMP_DATE CAMP_DATE,
  LAST_CAMP_DATE CAMP_DATE,
  BIRTHDATE    DATE);
```

Table 34. Examples of valid and invalid comparisons involving distinct types

| SQL statement | Valid | Reason |
|--|-------|--|
| Distinct types with distinct types | | |
| SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE < LAST_CAMP_DATE; | Yes | Both values are the same distinct type. |
| Distinct types with columns of the same source data type | | |
| SELECT * FROM CAMP_ROSTER WHERE AGE > ATTENDEE_NUMBER; | No | A distinct type cannot be compared to integer. |

Table 34. Examples of valid and invalid comparisons involving distinct types (continued)

| SQL statement | Valid | Reason |
|--|-------|---|
| SELECT * FROM CAMP_ROSTER WHERE INTEGER(AGE) > ATTENDEE_NUMBER; | Yes | The distinct type is cast to an integer, making the comparison of two integers. |
| SELECT * FROM CAMP_ROSTER WHERE CAST(AGE AS INTEGER) > ATTENDEE_NUMBER; | | |
| SELECT * FROM CAMP_ROSTER WHERE AGE > AGE_TYPE(ATTENDEE_NUMBER); | Yes | Integer ATTENDEE_NUMBER is cast to the distinct type AGE_TYPE, making both values the same distinct type. |
| SELECT * FROM CAMP_ROSTER WHERE AGE > CAST(ATTENDEE_NUMBER as AGE_TYPE); | | |
| Distinct types with constants | | |
| SELECT * FROM CAMP_ROSTER WHERE AGE IN (15,16,17); | No | A distinct type cannot be compared to a constant. |
| SELECT * FROM CAMP_ROSTER WHERE INTEGER(AGE) IN (15,16,17); | Yes | The distinct type is cast to the data type of constants, making all the values in the comparison integers. |
| SELECT * FROM CAMP_ROSTER WHERE AGE IN (AGE_TYPE(15),AGE_TYPE(16),AGE_TYPE(17)); | Yes | Constants are cast to distinct type AGE_TYPE, making all the values in the comparison the same distinct type. |
| SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > '06/12/99'; | No | A distinct type cannot be compared to a constant. |
| SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > CAST('06/12/99' AS CAMP_DATE); | No | The string constant '06/12/99', a VARCHAR data type, cannot be cast directly to distinct type CAMP_DATE, which is based on a DATE data type. As illustrated in the next row, the constant must be cast to a DATE data type and then to the distinct type. |
| SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > CAST(DATE('06/12/1999') AS CAMP_DATE); | Yes | The string constant '06/12/99' is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a string constant to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the string constant must first be cast to a DATE, TIME, or TIMESTAMP data type. |
| Distinct types with host variables | | |
| SELECT * FROM CAMP_ROSTER WHERE AGE BETWEEN :HV_INTEGER AND :HV_INTEGER2; | No | The host variables have integer data types. A distinct type cannot be compared to an integer. |
| SELECT * FROM CAMP_ROSTER WHERE AGE BETWEEN CAST(:HV_INTEGER AS AGE_TYPE) AND AGE_TYPE(:HV_INTEGER2); | Yes | The host variables are cast to distinct type AGE_TYPE, making all the values the same distinct type. |
| SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > :HV_VARCHAR; | No | The host variable has a VARCHAR data type. A distinct type cannot be compared to a VARCHAR. |
| SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > CAST(DATE(:HV_VARCHAR) AS CAMP_DATE); | Yes | The host variable is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a VARCHAR host variable to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the host variable must first be cast to a DATE, TIME, or TIMESTAMP data type. |

Rules for result data types

Rules that are applied to the operands of an operation determine the data type of the result. Certain rules apply in certain situations and apply depending on the data type of operands.

The rules apply to:

- Corresponding columns in set operations (UNION, INTERSECT, or EXCEPT)
- Result expressions of a CASE expression
- Arguments of the scalar functions COALESCE, IFNULL, MAX, and MIN
- Expression values of the IN list of an IN predicate
- Arguments of a BETWEEN predicate, except if the data types of all operands are numeric
- Arguments for the aggregation group ranges in OLAP specifications

For the result data type of expressions that involve the operators '/', '*', '+' and '-', see "Expressions with arithmetic operators" on page 230.

For the result data type of expressions that involve the CONCAT operator, see "Expressions with the concatenation operator" on page 237.

Evaluation of the operands of an operation determines the data type of the result. If an operation has more than one pair of operands, DB2 determines the result type of the first pair, uses this result type with the next operand to determine the next result type, and so on. The last intermediate result type and the last operand determine the result type of the operation.

With the exception of the COALESCE function, the result of an operation can be null unless the operands do not allow nulls.

If the data type and attributes of any operand column are not the same as those of the result, the operand column values are converted to conform to the data type and attributes of the result. The conversion operation is exactly the same as if the values were assigned to the result. For example:

- If one operand column is CHAR(10), and the other operand column is CHAR(5), the result is CHAR(10), and the values derived from the CHAR(5) column are padded on the right with five blanks.
- If the whole part of a number cannot be preserved then an error is returned.

"Conversion rules for comparisons" on page 137

Numeric operands

Numeric types are compatible only with other numeric types.

Table 35. Result data types with numeric operands

| One operand | Other operand | Data type of the result |
|-------------|---------------|-------------------------|
| SMALLINT | SMALLINT | SMALLINT |
| INTEGER | INTEGER | INTEGER |
| INTEGER | SMALLINT | INTEGER |
| BIGINT | SMALLINT | BIGINT |
| BIGINT | INTEGER | BIGINT |

Table 35. Result data types with numeric operands (continued)

| One operand | Other operand | Data type of the result |
|------------------|--|---|
| BIGINT | BIGINT | BIGINT |
| DECIMAL(w,x) | SMALLINT | DECIMAL(p,x) where $p = x + \max(w-x, 5)^1$ |
| DECIMAL(w,x) | INTEGER | DECIMAL(p,x) where $p = x + \max(w-x, 11)^1$ |
| DECIMAL(w,x) | BIGINT | DECIMAL(p,x) where $p = x + \max(w-x, 19)^1$ |
| DECIMAL(w,x) | DECIMAL(y,z) | DECIMAL(p,s) where $p = \max(x, z) + \max(w-x, y-z)^1$ $s = \max(x, z)$ |
| REAL | REAL | REAL |
| REAL | DECIMAL, BIGINT, INTEGER, or SMALLINT | DOUBLE |
| REAL | BIGINT | DOUBLE |
| DOUBLE | DOUBLE, REAL, DECIMAL, BIGINT, INTEGER, or SMALLINT | DOUBLE |
| DECFLOAT(n) | SMALLINT | DECFLOAT(n) |
| DECFLOAT(n) | INTEGER | DECFLOAT(n) |
| DECFLOAT(n) | BIGINT | DECFLOAT(34) |
| DECFLOAT(n) | DECIMAL($\leq 16,s$) | DECFLOAT(n) |
| DECFLOAT(n) | DECIMAL($> 16,s$) | DECFLOAT (34) |
| DECFLOAT(n) | REAL | DECFLOAT(n) |
| DECFLOAT(n) | DOUBLE | DECFLOAT(n) |
| DECFLOAT(n) | DECFLOAT(m) | DECFLOAT($\max(n,m)$) |

Notes:

1. Precision cannot exceed 31.

Character and graphic string operands

Character and graphic strings are compatible with other character and graphic strings as long as there is a conversion between their corresponding CCSIDs.

Table 36. Result data types with string operands

| One operand | Other operand | Data type of the result |
|----------------|----------------------------------|---|
| CHAR(x) | CHAR(y) | CHAR(z) where $z = \max(x, y)$ |
| GRAPHIC(x) | CHAR(y) | VARGRAPHIC(y) where $y >$ maximum length of a graphic |
| GRAPHIC(x) | CHAR(y) | GRAPHIC(z) where $z = \max(x, y)$ |
| VARCHAR(x) | VARCHAR(y) or CHAR(y) | VARCHAR(z) where $z = \max(x, y)$ |

Table 36. Result data types with string operands (continued)

| One operand | Other operand | Data type of the result |
|---------------|---|--------------------------------------|
| VARCHAR(x) | GRAPHIC(y) | VARGRAPHIC(z) where $z = \max(x, y)$ |
| VARGRAPHIC(x) | VARGRAPHIC(y), GRAPHIC(y), VARCHAR(y), or CHAR(y) | VARGRAPHIC(z) where $z = \max(x, y)$ |
| CLOB(x) | CLOB(y), VARCHAR(y), or CHAR(y) | CLOB(z) where $z = \max(x, y)$ |
| CLOB(x) | GRAPHIC(y) or VARGRAPHIC(y) | DBCLOB(z) where $z = \max(x, y)$ |
| DBCLOB(x) | CHAR(y), VARCHAR(y), CLOB(y), GRAPHIC(y), VARGRAPHIC(y), or DBCLOB(y) | DBCLOB(z) where $z = \max(x, y)$ |

Character string subtypes are determined as indicated in the following table:

Table 37. Result data types with character string operands

| One operand | Other operand | Data type of the result |
|-------------|-----------------------------|-------------------------|
| Bit data | Mixed, SBCS, or bit data | Bit data |
| Mixed data | Mixed or SBCS data | Mixed data |
| SBCS data | SBCS data | SBCS data |

Binary string operands

Binary strings are compatible with other binary strings. Binary strings include BINARY, VARBINARY, and BLOB.

Table 38. Result data types with binary string operands

| One operand | Other operand | Data type of the result |
|--------------|---|-------------------------------------|
| BINARY(x) | BINARY(y) | BINARY(z) where $z = \max(x, y)$ |
| VARBINARY(x) | BINARY(y) or VARBINARY(y) | VARBINARY(z) where $z = \max(x, y)$ |
| BLOB(x) | BINARY(y), VARBINARY(y), or BLOB(y) | BLOB(z) where $z = \max(x, y)$ |

Datetime operands

A date, time, or timestamp value is compatible with another value of the same type or any string expression that contains a valid string representation of the same type.

A DATE type is compatible with another DATE type or any string expression that contains a valid string representation of a date. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is DATE.

A TIME type is compatible with another TIME type or any string expression that contains a valid string representation of a time. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is TIME.

A timestamp type is compatible with another timestamp type, a timestamp constant, or any string expression that contains a valid string representation of a timestamp. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is a timestamp as determined in the following table.

Table 39. Result data types with datetime operands

| One operand | Other operand | Data type of the result |
|---|---|---|
| TIMESTAMP(<i>x</i>) WITHOUT TIME ZONE | TIMESTAMP(<i>y</i>) WITHOUT TIME ZONE | TIMESTAMP(max(<i>x</i> , <i>y</i>)) WITHOUT TIME ZONE |
| TIMESTAMP(<i>x</i>) WITHOUT TIME ZONE | CHAR(<i>y</i>) or VARCHAR(<i>y</i>) | TIMESTAMP(<i>x</i>) WITHOUT TIME ZONE ¹ |
| TIMESTAMP(<i>x</i>) WITH TIME ZONE | TIMESTAMP(<i>y</i>) WITH TIME ZONE | TIMESTAMP(max(<i>x</i> , <i>y</i>)) WITH TIME ZONE |
| TIMESTAMP(<i>x</i>) WITH TIME ZONE | CHAR(<i>y</i>) or VARCHAR(<i>y</i>) | TIMESTAMP(<i>x</i>) WITH TIME ZONE |
| TIMESTAMP(<i>x</i>) WITH TIME ZONE | TIMESTAMP(<i>y</i>) WITHOUT TIME ZONE | TIMESTAMP(max(<i>x</i> , <i>y</i>)) WITH TIME ZONE |

Note: If one operand is TIMESTAMP(*x*) WITHOUT TIME ZONE and the other operand is CHAR(*y*) or VARCHAR(*y*), the result data type is TIMESTAMP(*x*) WITHOUT TIME ZONE even if the string representation contains a time zone.

If both operands are in the same encoding scheme, the result is in that encoding scheme. Otherwise the result is in the application encoding scheme.

Row ID operands

A row ID data type is compatible only with itself. The result has a row ID data type.

XML operands

XML data is compatible only with other XML data. The data type of the result is XML.

Other data types can be treated as an XML data type by using the CAST specification or XMLPARSE functions to cast character, graphic, or binary data to XML data.

Distinct type operands

A distinct type is compatible only with itself. The data type of the result is the distinct type.

Constants

A *constant* (also called a *literal*) specifies a value. Constants are classified as string constants or numeric constants. Numeric constants are further classified as integer, floating-point, decimal, or decimal floating-point. String constants are classified as character, graphic, or binary.

All constants have the attribute NOT NULL. A negative sign in a numeric constant with a value of zero is ignored, except for a decimal floating-point constant.

Constants have a built-in data type. Therefore, an operation that involves a constant and a distinct type requires that the distinct type be cast to the built-in data type of the constant or the constant be cast to the distinct type. For example, see Table 34 on page 141, which contains an example of casting data types to compare a constant to a distinct type.

Integer constants

An *integer constant* specifies an integer as a signed or unsigned number with a maximum of 19 digits that does not include a decimal point.

The data type of an integer constant is large integer if its value is within the range of a large integer. The data type of an integer constant is big integer if its value is outside the range of a large integer, but within the range of a big integer. A constant that is defined outside the range of big integer values is considered a decimal constant.

Examples:

64 -15 +100 32767 720176

In syntax diagrams, the term *integer* is used for a large integer constant that must not include a sign.

Floating-point constants

A *floating-point constant* specifies a double-precision floating-point number as two numbers separated by an E.

The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point. The value of the constant is the product of the first number and the power of 10 specified by the second number. It must be within the range of floating-point numbers. The number of characters in the constant must not exceed 30. Excluding leading zeros, the number of digits in the first number must not exceed 17 and the number of digits in the second must not exceed 2.

Examples: The following floating-point constants represent the numbers '150', '200000', -0.22, and '500':

15E1 2.E5 -2.2E-1 +5.E+2

Decimal constants

A *decimal constant* is a signed or unsigned number of no more than 31 digits and either includes a decimal point or is not within the range of binary integers.

The precision is the total number of digits, including those, if any, to the right of the decimal point. The total includes all leading and trailing zeros. The scale is the number of digits to the right of the decimal point, including trailing zeros.

Examples: The following decimal constants have, respectively, precisions and scales of 5 and 2; 4 and 0; 2 and 0; and 23 and 2:

025.50 1000. -15. +37589333333333333333.33

Decimal floating-point constants

A *decimal floating-point constant* specifies a decimal floating-point number as two numbers separated by an E. The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point.

The value of the constant is the product of the first number and the power of 10 specified by the second number. The value must be within the range of DECFLOAT(34). The number of characters in the constant must not exceed 42. Excluding leading zeros, the number of digits in the first number must not exceed 34 and the number of digits in the second number must not exceed 4.

A constant that is specified as two numbers separated by an E is a decimal-floating point constant only if the value is outside the range of a floating-point constant. A constant that is specified as a number that does not contain an E, and has more than 31 digits, is also a decimal-floating point constant.

In addition to numeric constants, the following special values can be used to specify decimal-floating point special values:

- INF or INFINITY - represents infinity
- NAN - represents quiet not-a-number
- SNAN - represents signaling not-a-number

The special values can be any combination of uppercase or lowercase letters and can be preceded by an operational sign (+ or -).

SNAN results in a warning or exception when it is used in a numerical operation; NAN does not. SNAN can be used in non-numerical operations without causing a warning or exception. For example, SNAN can be used in the VALUES list of an insert operation or as a constant used in a comparison in a predicate.

When the special values are used in a predicate, the following order of precedence applies:

-NAN < -SNAN < -INFINITY < -0 < 0 < INFINITY < SNAN < NAN

Examples: The following decimal floating-point constants represent the numbers 123456789012345678, sNaN, and negative infinity:

123456789012345678E0 SNAN -INFINITY

When one of the special values is used in a context where it could be interpreted as an identifier, such as a column name, cast a string constant that represents the special value to decimal-floating point.

```
CAST ('snan' AS DECFLOAT)
CAST ('INF' AS DECFLOAT)
CAST ('Nan' AS DECFLOAT)
```

Character string constants

A *character string constant* specifies a varying-length character string. There are two forms of character string constant.

- A sequence of characters that starts and ends with a string delimiter, which is either an apostrophe (') or a quotation mark ("). For the factors that determine which is applicable, see "Apostrophes and quotation marks as string delimiters" on page 311. This form of string constant specifies the character string contained between the string delimiters. The number of bytes between the delimiters must not be greater than 32704. The limit of 32704 refers to the length (in bytes) of the UTF-8 representation of the string. If you produced the string in a CCSID other than UTF-8 (for example, an EBCDIC CCSID), the length of the UTF-8 representation might differ from the length of the string's representation in the source CCSID. Two consecutive string delimiters are used to represent one string delimiter within the character string.
- An X followed by a sequence of characters that starts and ends with a string delimiter. This form of a character string constant is also called a *hexadecimal constant*. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704. A hexadecimal digit is a digit or any of the letters A through F. If the MIXED DATA subsystem parameter is set to YES, hexadecimal digits in a hexadecimal constant must be specified in upper case. Otherwise, an error might be returned when SQL statements are processed. Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents a character. A hexadecimal constant allows you to specify characters that do not have a keyboard representation.

Examples:

```
'12/14/1985' '32' 'DON'T CHANGE' X'FFFF' ''
```

The right most string in the example (") represents an empty character string constant, which is a string of zero length.

A character string constant is classified as mixed data if it includes a DBCS substring. In all other cases, a character string constant is classified as SBCS data. For information about the CCSID that is assigned to the constant, see "Determining the encoding scheme and CCSID of a string" on page 51. A mixed string constant can be continued from one line to the next only if the break occurs between single byte characters. A Unicode string is always considered mixed regardless of the content of the string.

For Unicode, character constants can be assigned to UTF-8 and UTF-16. The form of the constant does not matter. Typically, character string constants are used only with character strings, but they also can be used with graphic UTF-16 data. However, hexadecimal constants are just character data. Thus, hexadecimal constants being used to insert data into UTF-16 data strings should be in UTF-8 format, not UTF-16 format. For example, if you wanted to insert the number 1 into a UTF-16 column, you would use X'31', not X'0031'. Even though X'0031' is a UTF-16 value, DB2 treats it as two separate UTF-8 code points. Thus, X'0031' would become X'00000031'.

Binary string constants

A binary-string constant specifies a varying-length binary string.

A binary-string constant is formed by specifying a BX followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704.

A hexadecimal digit is a digit or any of the letters A through F (upper case or lower case). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents one byte. Note that this representation is similar to the representation of the character-constant that uses the X" form; however binary-string constant and character-string constant are not compatible and the X" form can not be used to specify a binary-string constant, just as the BX" form cannot be used to specify a character-string constant.

Examples of binary-string constants:

BX'0000' BX'C141C242' BX'FF00FF01FF'

Datetime constants

A *datetime constant* is a character string constant of a particular format.

Character-string constants are described under "Character string constants" on page 149.

For information about the valid string formats, see "String representations of datetime values" on page 101.

Typically, character-string constants are used to represent constant datetime values in assignments and comparisons. However, the ANSI/ISO SQL standard form of a datetime constant can be used to specifically denote the constant as a datetime constant instead of a character-string constant. The format for the ANSI/ISO SQL standard datetime constants are as follows:

DATE *string-constant*

string-constant must contain a value that conforms to one of the valid formats for string representations of dates, subject to the following rules:

- leading blanks are not allowed.
- leading zeros can be omitted from the month and day elements of the date. An implicit specification of 0 is assumed for any digit that is omitted.
- leading zeros must be included for the year element of the date.
- trailing blanks can be included.

The data type of the value is DATE.

TIME *string-constant*

string-constant must contain a value that conforms to one of the valid formats for string representations of times, subject to the following rules:

- leading blanks are not allowed.
- leading zeros can be omitted from the hour elements of the time.
- the seconds element of the time can be omitted.
- trailing blanks can be included.
- if the USA format is not used and the minutes and seconds are all zeros, the hour can be 24.
- If the format is USA, the following additional rules apply:

- the minutes element of the time can be omitted. For example, 1 PM is equivalent to 1:00 PM.
- the letters A, M, and P can be specified in lowercase.
- a single blank must precede the AM or PM.
- the hour must not be greater than 12 and cannot be 0 except when the time is specified as 00:00 AM.

An implicit specification of 0 is assumed for any digit that is omitted.

The correspondence between the USA format and the ISO format (24-hour clock) is as follows:

- 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
- 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
- 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
- 12:00 AM (midnight) corresponds to 24.00.00
- 00:00 AM (midnight) corresponds to 00.00.00

The data type of the value is TIME.

TIMESTAMP *string-constant*

string-constant must contain a value that conforms to one of the formats listed in the following tables, subject to the following rules:

- leading blanks are not allowed.
- trailing blanks can be included.
- leading zeros can be omitted from the month, day, hour, and time zone hour elements of the timestamp. An implicit specification of 0 is assumed for any digit that is omitted.
- leading zeros must be included for the minute, second, and time zone minute elements of the timestamp
- the hour can be 24 if the minutes, seconds, and any fractional seconds are all zeroes.
- the separator character that follows the seconds element can be omitted if fractional seconds are not included.
- the number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted. The number of digits of fractional seconds determines the precision of the timestamp value.
- an optional single blank can be included between the time and the time zone elements.
- an optional time zone can be included, in one of the following formats:
 - \pm h:tm, with values ranging from -24:00 to +24:00. A value of -0:00 is treated the same as +0:00.
 - \pm th, with values ranging from -24 to +24 (an implicit specification of 00 is assumed for the time zone minute element)
 - uppercase Z to specify UTC

The data type of the value depends on the content of the string constant (where p is the number of digits of fractional seconds in the constant):

- **TIMESTAMP(p) WITHOUT TIME ZONE** if the content of the string constant conforms to the rules in the Table 40 on page 152 table.
- **TIMESTAMP(p) WITH TIME ZONE** if the content of the string constant conforms to the rules in the Table 41 on page 152 table.

Table 40. Formats used to specify a value for a data type of **TIMESTAMP WITHOUT TIME ZONE**

| Description | TIMESTAMP(0) WITHOUT TIME ZONE ¹³ | TIMESTAMP(p) WITHOUT TIME ZONE ²³ |
|--|---|--|
| Blank between date and time portions and colons in time portion. | <ul style="list-style-type: none"> • yyyy-mm-dd hh:mm:ss • yyyy-mm-dd hh:mm:ss. | yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn |
| Minus sign between date and time portions and periods in time portion. | <ul style="list-style-type: none"> • yyyy-mm-dd-hh.mm.ss • yyyy-mm-dd-hh.mm.ss. | yyyy-mm-dd- hh.mm.ss.nnnnnnnnnnnn |
| Blank between date and time portions and periods in time portion. | <ul style="list-style-type: none"> • yyyy-mm-dd hh.mm.ss • yyyy-mm-dd hh.mm.ss. | yyyy-mm-dd hh.mm.ss.nnnnnnnnnnnn |

Notes:

1. No fractional seconds; shown with and without optional trailing period after seconds
2. *p* is the number of digits of fractional seconds. *nnnnnnnnnnnn* can range from 1 to 12 instances of *n*
3. As an additional format, the character T can be substituted as the separator between the date and time portions of the value.

Table 41. Formats used to specify a value for a data type of **TIMESTAMP WITH TIME ZONE**

| Description | TIMESTAMP(0) WITH TIME ZONE ¹³ | TIMESTAMP(p) WITH TIME ZONE ²³ |
|--|--|---|
| Blank between date and time portions and colons in time portion, no space between time and time zone. | <ul style="list-style-type: none"> • yyyy-mm-dd hh:mm:ss±th:tm • yyyy-mm-dd hh:mm:ss±th • yyyy-mm-dd hh:mm:ss.±th:tm • yyyy-mm-dd hh:mm:ss.±th | <ul style="list-style-type: none"> • yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th |
| Minus sign between date and time portions and periods in time portion. | <ul style="list-style-type: none"> • yyyy-mm-dd-hh.mm.ss±th:tm • yyyy-mm-dd-hh.mm.ss±th • yyyy-mm-dd-hh.mm.ss.±th:tm • yyyy-mm-dd-hh.mm.ss.±th | <ul style="list-style-type: none"> • yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn ±th |
| Blank between date and time portions, colons in time portion, blank between fractional seconds and sign for time zone. | <ul style="list-style-type: none"> • yyyy-mm-dd hh:mm:ss ±th:tm • yyyy-mm-dd hh:mm:ss ±th • yyyy-mm-dd hh:mm:ss. ±th:tm • yyyy-mm-dd hh:mm:ss. ±th | <ul style="list-style-type: none"> • yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th |
| Blank between date and time portions and periods in time portion. | <ul style="list-style-type: none"> • yyyy-mm-dd hh.mm.ss±th:tm • yyyy-mm-dd hh.mm.ss±th • yyyy-mm-dd hh.mm.ss.±th:tm • yyyy-mm-dd hh.mm.ss.±th | <ul style="list-style-type: none"> • yyyy-mm-dd hh.mm.ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd hh.mm.ss.nnnnnnnnnnnn ±th |

Table 41. Formats used to specify a value for a data type of `TIMESTAMP WITH TIME ZONE` (continued)

| Description | TIMESTAMP(0) WITH TIME ZONE ¹³ | TIMESTAMP(p) WITH TIME ZONE ²³ |
|--|---|---|
| Notes: | | |
| 1. No fractional seconds; shown with and without optional trailing period after seconds | | |
| 2. <i>p</i> is the number of digits of fractional seconds. <i>nnnnnnnnnnnnnn</i> can range from 1 to 12 instances of <i>n</i> | | |
| 3. As an additional format, the character T can be substituted as the separator between the date and time portions of the value. | | |

Graphic string constants

A *graphic string constant* specifies a varying-length graphic string.

In EBCDIC environments, the forms of graphic string constants are shown in the following figure. (Shift-in and shift-out characters for EBCDIC data are discussed in “Character strings” on page 84.)⁶

| Context | Graphic String Constant | Empty String | Example |
|--------------------|--|--|----------------------------------|
| PL/I | <code>␣'dbcs-string'G_{s1}</code> <code>␣'dbcs-string'_{s1}G</code> | <code>␣''G_{s1}</code> <code>␣''_{s1}G</code> | <code>␣'元氣'G_{s1}</code> |
| | G represents a DBCS G (X'42C7') | | |
| | ' represents a DBCS apostrophe (X'427D') | | |
| All other contexts | <code>G'␣dbcs-string_{s1}'</code> <code>N'␣dbcs-string_{s1}'</code> | <code>G'␣_{s1}'</code> <code>G''</code> <code>g'␣_{s1}'</code> <code>g''</code> <code>N'␣_{s1}'</code> <code>N''</code> <code>n'␣_{s1}'</code> <code>n''</code> | <code>G'␣元氣_{s1}'</code> |

Figure 17. Graphic string constants in EBCDIC

In SQL statements and in host language statements in a source program, graphic string constants cannot be continued from one line to the next. A graphic string constant must be short enough so that its UTF-8 representation requires no more than 32704 bytes.

DB2 supports two types of hexadecimal graphic string constants.

- `UX'xxxx'` represents a string of graphic Unicode UTF-16 characters, where *x* is a hexadecimal digit. The number of digits must be a multiple of 4 and must not exceed 32704. Each group of 4 digits represents a single UTF-16 graphic character. For example, the UX constant for 'ABC' is `UX'004100420043'`.

6. The PL/I form of graphic string constants is supported only in static SQL statements.

- GX'xxxx' represents a string of graphic characters, where *x* is a hexadecimal digit. The number of digits must be a multiple of 4. Each group of 4 digits represents a single double-byte graphic character. The hexadecimal shift-in and shift-out ('OE'X and 'OF'X), which apply to EBCDIC only, are not included in the string.

If the MIXED DATA installation option is set to NO, a GX constant cannot be used. Instead, a UX constant should be used. A GX constant cannot be used when the encoding scheme is UNICODE.

For information about the CCSID that is assigned to a graphic string constant, including UX'xxxx' and GX'xxxx' string constants, see “Determining the encoding scheme and CCSID of a string” on page 51.

Special registers

A special register is a storage area that is defined for an application process by DB2 and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

The special registers can be referenced as follows:

special registers

| |

Notes:

- 1 The SQL standard uses the form with the underline.
- 2 The ENCRYPTION PASSWORD special register can only be explicitly referenced in the SET ENCRYPTION PASSWORD statement. It is used implicitly used by the encryption and decryption functions.

General rules for special registers

Changing register values

A commit operation might cause special registers to be re-initialized. Whether a special register is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see “CURRENT SQLID” on page 191.

A rollback operation has no effect on the values of special registers. Nor does any SQL statement, with the following exceptions:

- SQL SET statements can change the values of the following special registers:
 - CURRENT APPLICATION ENCODING SCHEME
 - CURRENT DEBUG MODE
 - CURRENT DECFLOAT ROUNDING MODE
 - CURRENT DEGREE
 - CURRENT EXPLAIN MODE
 - CURRENT GET_ACCEL_ARCHIVE
 - CURRENT LOCALE LC_CTYPE
 - CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
 - CURRENT OPTIMIZATION HINT
 - CURRENT PACKAGE PATH
 - CURRENT PACKAGESET
 - CURRENT PATH
 - CURRENT PRECISION
 - CURRENT QUERY ACCELERATION
 - CURRENT REFRESH AGE
 - CURRENT ROUTINE VERSION
 - CURRENT RULES
 - CURRENT SCHEMA
 - CURRENT SQLID⁷
 - ENCRYPTION PASSWORD
 - SESSION TIME ZONE
- SQL CONNECT statements can change the value of CURRENT SERVER.

Determining register values

You can use various statements to determine the value of a special register. For instance, a SELECT statement, a SET statement, the VALUES statement (if the statement is within a trigger action) will provide the value of a special register. The following examples find the value of the CURRENT PRECISION special register:

7. If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see DYNAMICRULES bind option (DB2 Commands).

```
SELECT CURRENT PRECISION FROM SYSIBM.SYSDUMMY1;  
SET :hv = CURRENT PRECISION  
VALUES(CURRENT PRECISION)
```

CCSIDS for register values

Special registers that contain character strings have an associated CCSID. The particular CCSID depends on the context in which the special register is referenced. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Datetime special registers

The datetime registers are named CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP. Datetime special registers are stored in an internal format. When two or more of these registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. A datetime special register is implicitly specified when it is used to provide the default value of a datetime column.

If the SQL statement in which a datetime special register is used is in a user-defined function or stored procedure that is within the scope of a trigger, DB2 uses the timestamp for the triggering SQL statement to determine the special register value.

The values of these special registers are based on:

- The time-of-day clock of the processor for the server executing the SQL statement
- The TIMEZONE parameter for this processor. The TIMEZONE parameter is in SYS1.PARMLIB(CLOCKXX).

To evaluate the references when the statement is being executed, a single reading from the time-of-day clock is incremented by the number of hours, minutes, and seconds specified by the TIMEZONE parameter. The values derived from this are assumed to be the local date, time, or timestamp, where local means local to the DB2 that executes the statement. This assumption is correct if the clock is set to local time and the TIMEZONE parameter is zero or the clock is set to UTC (Coordinated Universal Time) and the TIMEZONE parameter gives the difference from UTC.

Because the datetime special registers and the CURRENT TIMEZONE special register depend on the parameter PARMTZ(SYS1.PARMLIB(CLOCKXX)), their values are affected if the local time at the server is changed by the z/OS system command SET CLOCK. The values of the CURRENT DATE and CURRENT TIMESTAMP special registers might be affected if the local date at the server is changed by the system command SET DATE⁸.

Where special registers are processed

In distributed applications, CURRENT APPLICATION ENCODING SCHEME, CURRENT SERVER, and CURRENT PACKAGESET are processed locally. All other special registers are processed at the server.

8. Whether the SET DATE command affects these special registers depends on the system level and the program temporary fix (PTF) level of the system.

CURRENT APPLICATION ENCODING SCHEME

CURRENT APPLICATION ENCODING SCHEME specifies which encoding scheme is to be used for dynamic statements. It allows an application to indicate the encoding scheme that is used to process data. This register is not supported in REXX applications or in stored procedures written in REXX.

The value contained in the special register is a character representation of a CCSID. Although you can use the values ASCII, EBCDIC, or UNICODE to set the special register, what is stored in the special register is a character representation of the numeric CCSID that corresponds to the value used in the SET CURRENT APPLICATION ENCODING SCHEME statement. The value ASCII, EBCDIC, or UNICODE is not stored. The CCSID_ENCODING scalar function can be used to get a value of ASCII, EBCDIC, or UNICODE from a numeric CCSID value.

The data type is CHAR(8). If necessary, the value is padded on the right with blanks so that its length is 8 bytes.

For stored procedures and user-defined functions, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is determined by the value of the ENCODING bind option for the package that is associated with the procedure or function, or by the APPLICATION ENCODING SCHEME option of the CREATE FUNCTION, ALTER FUNCTION, CREATE PROCEDURE, or ALTER PROCEDURE statement for a compiled SQL function or a native SQL procedure. If the option was not specified, the initial value is the value of the field DEFAULT APPLICATION ENCODING SCHEME field on installation panel DSNTIPF.

For triggers, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is the value of field DEFAULT APPLICATION ENCODING SCHEME on installation panel DSNTIPF.

Example: The CURRENT APPLICATION ENCODING SCHEME special register can be used like any other special register:

```
EXEC SQL VALUES(CURRENT APPLICATION ENCODING SCHEME) INTO :HV1;  
EXEC SQL INSERT INTO T1 VALUES (CURRENT APPLICATION ENCODING SCHEME);  
EXEC SQL SET :HV1 = CURRENT APPLICATION ENCODING SCHEME;  
EXEC SQL SELECT C1 FROM T1 WHERE C1 = CURRENT APPLICATION ENCODING SCHEME;
```

Related reference:

“SET CURRENT APPLICATION ENCODING SCHEME” on page 2173

CURRENT CLIENT_ACCTNG

CURRENT CLIENT_ACCTNG contains the value of the accounting string from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- DB2Connection.setDB2ClientAccountingInformation(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

The value for the accounting string will be obtained first from the accounting string that is set by the SET_CLIENT_ID function, AUTH SIGNON function, or the Set Client Information (sqleseti) API, or alternatively from the accounting token set by RRSAF if accounting string has not been set.

In a distributed environment, if the value set by the API exceeds 200 bytes, it is truncated to 200 bytes.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

Example: Get the current value of the accounting string for this connection.

```
SET :ACCT_STRING = CURRENT CLIENT_ACCTNG
```

Related concepts:

WLM_SET_CLIENT_INFO stored procedure

[➤](#) sqle_client_info data structure

CURRENT CLIENT_APPLNAME

CURRENT CLIENT_APPLNAME contains the value of the application name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The default application name varies, depending on the connection:

- If the connection is from a remote application client driver, the default is the application name as supplied by the driver. Default values set by the IBM Data Server Driver for JDBC and SQLJ can be obtained from the DatabaseMetaData.getClientInfoProperties method.
- If the connection is from a remote DB2 10 for z/OS application, the default varies depending on which attachment facility is used:

TSO attachment facility

The default application name is one of the following cases:

- The TSO logon user ID when the application runs in TSO foreground using TSO online applications like SPUFI.
- The job name when the application runs in TSO background using TSO batch applications like DSNTEP2.

RRS attachment facility interface

The correlation ID that is provided at the call of the RRS DSNRLI SIGNON function.

Call attachment facility

The job name.

CICS attachment facility

The first 8 bytes of the correlation ID. In particular the correlation ID is a 12-byte string for a CICS transaction, where the first 8 bytes are used as the default application name.

IMS Attachment facility

An 8-byte string, the Program Specification Block (PSB) name, or the program name.

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- `SQL_CLIENT_INFO_APPLNAME` (sqleseti)
- `DB2Connection.setDB2ClientApplicationInformation(String info)`
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client application name is explicitly set, it overwrites the default application name described above and is used as the client application name.

In a distributed environment, if the value set by the API exceeds 32 bytes, it is truncated to 32 bytes.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

Example: Select the departments that are allowed to use the application that is being used in this connection.

```
SELECT DEPT
FROM DEPT_APPL_MAP
WHERE APPL_NAME = CURRENT CLIENT_APPLNAME
```

CURRENT_CLIENT_USERID

CURRENT_CLIENT_USERID contains the value of the client user ID from the client information that is specified for the connection.

The default client user ID is the primary authorization ID used to establish the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_USERID (sqleseti)
- DB2Connection.setDB2ClientUser(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client user ID is explicitly set, it overwrites the primary authorization id described above and is used as the client user ID.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

In a distributed environment, if the value set by the API exceeds 16 bytes, it is truncated to 16 bytes.

Example: Find out in which department the current client user ID works.

```
SELECT DEPT
FROM DEPT_USERID_MAP
WHERE USER_ID = CURRENT_CLIENT_USERID
```

CURRENT CLIENT_WRKSTNNAME

CURRENT CLIENT_WRKSTNNAME contains the value of the workstation name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The default workstation name varies, depending on the connection:

- If the connection originates from a DB2 10 for z/OS requester, it is the client host name.
- If the connection is from a remote application client driver, it is the client host name where the request is submitted. Default values that are set by the IBM Data Server Driver for JDBC and SQLJ can be obtained from the DatabaseMetaData.getClientInfoProperties method.
- If the connection is from a remote DB2 10 for z/OS application, the default varies depending on which attachment facility is used:

TSO attachment facility

The default workstation name is one of the following cases:

- The default workstation name is 'TSO' when the application runs in TSO foreground with TSO online applications like SPUFI.
- The default workstation name is 'BATCH' when the application runs in TSO background with TSO batch applications like DSNTEP2.

RRS attachment facility interface

The default workstation name is 'RRSAF'

Call attachment facility

The default workstation name is 'DB2CALL'.

CICS attachment facility

The default workstation name is the CICS region name.

IMS Attachment facility

The default workstation name is IMS region ID.

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_WRKSTNNAME (sqleseti)
- DB2Connection.setDB2ClientWorkstation(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client workstation name is explicitly set, it overwrites the default workstation name described above and is used as the client workstation name.

In a distributed environment, if the value set by the API exceeds 18 bytes, it is truncated to 18 bytes.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

Example: Get the name of the workstation that is being used in this connection.

```
SET :WS_NAME = CURRENT CLIENT_WRKSTNNAME
```

CURRENT DATE

The CURRENT DATE special register specifies a date that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT TIME or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.⁹

The value of CURRENT DATE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199. For other applications, the date is derived by the DB2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT_DATE is equivalent to specifying CURRENT DATE.

Example: Display the average age of employees.

```
SELECT AVG(YEAR(CURRENT DATE - BIRTHDATE))
FROM DSN8A10.EMP;
```

9. Except for the case of a non-atomic multiple row INSERT or MERGE statement.

CURRENT DEBUG MODE

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option when certain routines are created. The DEBUG MODE option specifies whether the routine should be built with the ability to run in debugging mode.

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option of the following statements:

- ALTER FUNCTION for a new version of an SQL scalar function
- ALTER PROCEDURE for a new version of a native SQL procedure
- CREATE FUNCTION for an SQL scalar function
- CREATE PROCEDURE for a Java procedure
- CREATE PROCEDURE for a native SQL procedure

The data type is VARCHAR(8). The following values are valid:

- ALLOW — Specifies that the routine can be run in debugging mode.
- DISALLOW — Specifies that the routine cannot be run in debugging mode. A subsequent ALTER statement can change the DEBUG MODE option to allow the routine to run in debugging mode.
- DISABLE — Specifies that the routine can never be run in debugging mode. When DISABLE is in effect, the routine cannot be changed to run in debugging mode. A subsequent ALTER statement cannot change the DEBUG MODE option to allow or disallow the routine to run in debugging mode.

The value of CURRENT DEBUG MODE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199. In other contexts the initial value of CURRENT DEBUG MODE is DISALLOW.

You can change the value of the CURRENT DEBUG MODE special register by running the SET CURRENT DEBUG MODE statement.

Example: Set the host variable DEBUG_MODE_OPT to the value of the CURRENT DEBUG MODE special register:

```
VALUES CURRENT DEBUG MODE INTO :DEBUG_MODE_OPT;
```

Related reference:

“SET CURRENT DEBUG MODE” on page 2174

CURRENT DECFLOAT ROUNDING MODE

CURRENT DECFLOAT ROUNDING MODE specifies the default rounding mode that is used for DECFLOAT values.

The data type is VARCHAR(128). The following rounding modes are supported:

- **ROUND_CEILING** — rounds the value towards positive infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by 1.
- **ROUND_DOWN** — rounds the value towards 0 (truncation). The discarded digits are ignored.
- **ROUND_FLOOR** — rounds the value towards negative infinity. If all of the discarded digits are zero or if the sign is positive the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1.
- **ROUND_HALF_DOWN** — rounds the value to the nearest value; if the values are equidistant, rounds the value towards zero. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.
- **ROUND_HALF_EVEN** — rounds the value to the nearest value; if the values are equidistant, rounds the value so that the final digit is even. If the discarded digits represents greater than half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 if its rightmost digit is odd (to make an even digit).
- **ROUND_HALF_UP** — rounds the value to the nearest value; if the values are equidistant, rounds the value away from zero. If the discarded digits represent greater than or equal to half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored.
- **ROUND_UP** — rounds the value away from 0. If all of the discarded digits are zero the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

The initial value of CURRENT DECFLOAT ROUNDING MODE is the value of the ROUNDING bind option or the native SQL procedure option. If the ROUNDING option is not specified, the initial value is the value of the DEF DECFLOAT ROUND MODE field on installation panel DSNTIPF.

The value of CURRENT DECFLOAT ROUNDING MODE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the CURRENT DECFLOAT ROUNDING MODE by executing the statement SET CURRENT DECFLOAT ROUNDING MODE.

Example: Set the DECFLOAT rounding mode to ROUND_CEILING:

```
SET CURRENT DECFLOAT ROUNDING MODE = 'ROUND_CEILING';
```

Related reference:

“SET CURRENT DECFLOAT ROUNDING MODE” on page 2176

CURRENT DEGREE

CURRENT DEGREE specifies the degree of parallelism for the execution of queries that are dynamically prepared by the application process.

The data type of the register is CHAR(3) and the only valid values are 1 (padded on the right with two blanks) and ANY.

If the value of CURRENT DEGREE is 1 when a query is dynamically prepared, the execution of that query will not use parallelism. If the value of CURRENT DEGREE is ANY when a query is dynamically prepared, the execution of that query can involve parallelism.

The initial value of CURRENT DEGREE is determined by the value of field CURRENT DEGREE on installation panel DSNTIP8. The default for the initial value of that field is 1 unless your installation has changed it to be ANY by modifying the value in that field. The initial value of CURRENT DEGREE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the statement SET CURRENT DEGREE.

CURRENT DEGREE is a register at the database server. Its value applies to queries that are dynamically prepared at that server and to queries that are dynamically prepared at another DB2 subsystem as a result of the use of a DB2 private connection between that server and that DB2 subsystem.

Example: The following statement inhibits parallelism:

```
SET CURRENT DEGREE = '1';
```

[Enabling parallel processing \(DB2 Performance\)](#)

[Disabling query parallelism \(DB2 Performance\)](#)

Related reference:

“SET CURRENT DEGREE” on page 2178

[CURRENT DEGREE field \(CDSSRDEF subsystem parameter\) \(DB2 Installation and Migration\)](#)

CURRENT EXPLAIN MODE

The CURRENT EXPLAIN MODE special register contains the values that control the EXPLAIN behavior in regards to eligible dynamic SQL statements.

This facility generates and inserts EXPLAIN information into the EXPLAIN tables. Possible values for the CURRENT EXPLAIN MODE special register are YES, NO, and EXPLAIN. The data type is VARCHAR(128).

NO Disable the ability to use EXPLAIN. No EXPLAIN information is kept. NO is the initial value of the EXPLAIN MODE special register.

YES

Enables the EXPLAIN facility and causes EXPLAIN information to be inserted into the EXPLAIN tables for eligible dynamic SQL statements after the statement is prepared and executed. All dynamic SQL statements are compiled and executed normally.

EXPLAIN

Enables the EXPLAIN facility and causes EXPLAIN information to be captured for any eligible dynamic SQL statement after the statement is prepared. This setting behaves similarly to YES, however, dynamic statements, except for SET statements, are not executed.

For values YES and EXPLAIN, prepared statements are not saved into the dynamic statement cache.

The initial value is NO. The initial value of CURRENT EXPLAIN MODE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

The value can be changed using the SET CURRENT EXPLAIN MODE statement.

Prerequisites for using CURRENT EXPLAIN MODE:

- Both the PLAN_TABLE and DSN_STATEMENT_CACHE_TABLE exist on the DB2 server and the table names are qualified with the current SQLID that is used when running the application.
- The Dynamic statement cache is enabled.
- The client application contains some explainable statements.

Required authorization for using CURRENT EXPLAIN MODE:

If CURRENT EXPLAIN MODE is set to YES or EXPLAIN, the privilege set for the underlying statement must have the necessary authorization to use the EXPLAIN facility.

When the EXPLAIN privilege is in effect and CURRENT EXPLAIN MODE is set to EXPLAIN, any SQLCODE that is returned due to the EXPLAIN privilege override any SQLCODE that is returned due to CURRENT EXPLAIN MODE being set to EXPLAIN.

Considerations when using the CURRENT EXPLAIN MODE special register to explain the acceleration of rowset queries:

A rowset query cannot be passed to an accelerator server for processing in the following cases:

- If the rowset query is run remotely
- If the rowset query is declared WITH RETURN
- If the rowset query is run under an SQL PL routine

| When a rowset query is run with EXPLAIN MODE YES or EXPLAIN
| MODE EXPLAIN, the EXPLAIN function indicates whether the local
| execution of a rowset cursor can be accelerated, depending on the content
| of the query. The EXPLAIN function will always indicate that remote
| rowset queries, rowset queries that are declared WITH RETURN, and
| rowset queries that run under an SQL PL routine cannot be accelerated.

| **Related reference:**

| "SET CURRENT EXPLAIN MODE" on page 2180

CURRENT GET_ACCEL_ARCHIVE

The CURRENT GET_ACCEL_ARCHIVE special register specifies whether a dynamic SQL query that references a table that is archived on an accelerator server uses the archived data. The special register does not apply to static SQL queries.

The data type is VARCHAR(255).

Valid values are:

NO Specifies that if a table is archived on an accelerator server, and a query references that table, the query does not use the data that is archived.

YES

Specifies that if a table is archived on an accelerator server, and a query references that table, the query uses the data that is archived.

The initial value of CURRENT GET_ACCEL_ARCHIVE is determined by one of the following settings:

- The value of DB2 subsystem parameter GET_ACCEL_ARCHIVE. The default for the initial value of that subsystem parameter is NO unless your installation has changed the value.
- If specified for the bind of a package, the GETACCELARCHIVE bind option. This behavior enables the GETACCELARCHIVE bind option to be used to specify the acceleration archive behavior for dynamic SQL queries and not only static SQL queries. This bind option does not have a default value.

The initial value of CURRENT GET_ACCEL_ARCHIVE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the SET CURRENT GET_ACCEL_ARCHIVE statement.

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The GET_ACCEL_ARCHIVE subsystem parameter
- The GETACCELARCHIVE bind option, if specified
- An explicit SET CURRENT GET_ACCEL_ARCHIVE statement

Example: The following statement sets the CURRENT GET_ACCEL_ARCHIVE special register so that when a table is archived on an accelerator server, the table reference does not include the archived data.

```
SET CURRENT GET_ACCEL_ARCHIVE=NO;
```

Related reference:

“SET CURRENT GET_ACCEL_ARCHIVE” on page 2182

CURRENT LOCALE LC_CTYPE

CURRENT LOCALE LC_CTYPE specifies the LC_CTYPE locale that will be used to execute SQL statements that use a built-in function that references a locale. Functions LCASE, UCASE, and TRANSLATE (with a single argument) refer to the locale when they are executed.

The data type is CHAR(50). If necessary, the value is padded on the right with blanks so that its length is 50 bytes. The following values are supported:

- blank — For a conversion to lowercase, SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z.

For a conversion to uppercase, SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin lowercase characters a-z are converted to full-width uppercase characters A-Z.

For optimal performance, specify a blank string unless your data must be processed by using rules that are defined by a specific locale.

- UNI — Case conversions use both the NORMAL and SPECIAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User's Guide and Reference). UNI cannot be used with EBCDIC data.
- locale name — The locale defines the rules for conversion to uppercase or lowercase characters. For information about locales and their naming conventions for EBCDIC data, see Locale naming conventions (XL C/C++ Programming Guide). For information about locales for Unicode and ASCII data, see z/OS Unicode Services User's Guide and Reference.

The initial value of CURRENT LOCALE LC_CTYPE is determined by the value of field LOCALE LC_CTYPE on installation panel DSNTIPF. The default for the initial value of that field is blank unless your installation has changed the value of that field. The initial value of CURRENT LOCALE LC_CTYPE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the statement SET CURRENT LOCALE LC_CTYPE.

Some examples of locales for EBCDIC data include:

```
Fr_BE
Fr_FR@EURO
En_US
Ja_JP
```

Example: Save the value of current register CURRENT LOCALE LC_CTYPE in host variable HV1, which is defined as VARCHAR(50).

```
EXEC SQL VALUES(CURRENT LOCALE LC_CTYPE) INTO :HV1;
```

Related concepts:

 [z/OS Unicode Services User's Guide and Reference](#)

Related reference:

“SET CURRENT LOCALE LC_CTYPE” on page 2183

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION specifies a value that identifies the types of objects that can be considered to optimize the processing of dynamic SQL queries. This register contains a keyword representing table types.

The data type is VARCHAR(255).

The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is determined by the value of field CURRENT MAINT TYPES on installation panel DSNTIP8. The default for the initial value of that field is SYSTEM unless your installation has changed the value of that field. The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement. The object types controlled by this special register are never considered by static embedded SQL queries.

Example: Set the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that all materialized query tables are considered.

```
SET CURRENT MAINTAINED TABLE TYPES ALL;
```

Related reference:

“SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION” on page 2185

CURRENT MEMBER

CURRENT MEMBER specifies the member name of a current DB2 data sharing member on which a statement is executing. The value of CURRENT MEMBER is a character string.

The data type is CHAR(8). If necessary, the member name is padded to the right with blanks so that its length is 8 bytes.

The value of a CURRENT MEMBER is a string of blanks when the application process is connected to a DB2 subsystem that is not a member of a data sharing group.

The SQL SET statement cannot change the value of CURRENT MEMBER.

Example: Use one of the following statements to set the host variable MEM to the name of the current DB2 member.

```
EXEC SQL SET :MEM = CURRENT MEMBER;  
EXEC VALUES (CURRENT MEMBER) into :MEM;
```

CURRENT OPTIMIZATION HINT

CURRENT OPTIMIZATION HINT specifies the user-defined optimization hint that DB2 should use to generate the access path for dynamic statements.

The data type is VARCHAR(128).

The value of the register identifies the rows in *owner*.PLAN_TABLE that DB2 uses to generate the access path. DB2 uses information in the rows in *owner*.PLAN_TABLE for which the value of the OPTHINT column matches the value of the CURRENT OPTIMIZATION special register. If the value of the register is an empty string or all blanks, DB2 uses normal optimization and ignores optimization hints. If the value of the register includes any non-blank characters and DB2 was installed without optimization hints enabled (field OPTIMIZATION HINTS on installation panel DSNTIP8), a warning occurs.

The initial value of CURRENT OPTIMIZATION HINT is the value of the OPTHINT bind option or of the native SQL procedure option. The initial value of CURRENT OPTIMIZATION HINT in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199. You can change the value of the special register by executing the statement SET CURRENT OPTIMIZATION HINT.

Example: Set the CURRENT OPTIMIZATION HINT special register so that DB2 uses the optimization plan hint that is identified by host variable *NOHYB* when generating the access path for dynamic statements.

```
SET CURRENT OPTIMIZATION HINT = :NOHYB
```

Related tasks:

-  Specifying access paths in a PLAN_TABLE instance (DB2 Performance)
-  Preparing to influence access paths (DB2 Performance)

Related reference:

“SET CURRENT OPTIMIZATION HINT” on page 2187

CURRENT PACKAGE PATH

CURRENT PACKAGE PATH specifies a value that identifies the path used to resolve references to packages that are used to execute SQL statements. This special register applies to both static and dynamic statements.

The data type is VARCHAR(4096). The value can be an empty or blank string, or a list of one or more collection IDs, where the collection IDs are enclosed in double quotation marks and separated by commas. Any quotation marks within the string are repeated as they are in any delimited identifier. The delimiters and commas are included in the length of the special register.

The initial value of CURRENT PACKAGE PATH is an empty string. The value is a list of collections only if the application process has explicitly specified a list of collections by means of the SET CURRENT PACKAGE PATH statement.

The initial value of CURRENT PACKAGE PATH in a user-defined function or procedure is inherited according to the rules in Table 43 on page 199.

When CURRENT PACKAGE PATH or CURRENT PACKAGESET is set, DB2 uses the values in these registers to resolve the collection for a package. The value of CURRENT PACKAGE PATH takes priority over CURRENT PACKAGESET. In a distributed environment, the value of CURRENT PACKAGE PATH at the remote server takes precedence of the value of CURRENT PACKAGE PATH at the local server (the requester). For more information on package resolution, see *DB2 Application Programming and SQL Guide*.

Example: In an application that is using SQLJ packages (in collection SQLJ1 and SQLJ2) and a JDBC package in DB2JAVA, set the CURRENT PACKAGE PATH special register to check SQLJ1 first, followed by SQLJ2, and DB2JAVA:

```
SET CURRENT PACKAGE PATH = SQLJ1, SQLJ2, DB2JAVA;
```

The following statement sets the host variable to the value of the resulting list:

```
SET :HVPKLIST = CURRENT PACKAGE PATH;
```

The value of the host variable would be "SQLJ1", "SQLJ2", "DB2JAVA".

Related reference:

"SET CURRENT PACKAGE PATH" on page 2188

CURRENT PACKAGESET

CURRENT PACKAGESET specifies an empty string, a string of blanks, or the collection ID of the package that will be used to execute SQL statements.

The data type is VARCHAR(128).

The initial value of CURRENT PACKAGESET is an empty string. The value is a collection ID only if the application process has explicitly specified a collection ID by means of the SET CURRENT PACKAGESET statement.

The initial value of CURRENT PACKAGESET in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

Example: Before passing control to another program, identify the collection ID for its package as ALPHA.

```
EXEC SQL SET CURRENT PACKAGESET = 'ALPHA';
```

Related reference:

“SET CURRENT PACKAGESET” on page 2192

CURRENT PATH

CURRENT PATH specifies the SQL path used to resolve unqualified data type names and function names in dynamically prepared SQL statements. It is also used to resolve unqualified procedure names that are specified as host variables in SQL CALL statements (CALL *host-variable*).

The data type is VARCHAR(2048).

The CURRENT PATH special register contains a list of one or more schema names, where each schema name is enclosed in delimiters and separated from the following schema by a comma (any delimiters within the string are repeated as they are in any delimited identifier). The delimiters and commas are included in the 2048 character length.

For information on when the SQL path is used to resolve unqualified names in both dynamic and static SQL statements and the effect of its value, see “SQL path” on page 65.

The initial value of the CURRENT PATH special register is determined from the first of one of the following sets of conditions that is met:

- If the CURRENT PATH special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment, the special register inherits the value from the invoking environment.
- If the connection is trusted, and both the role as object owner and qualifier options in effect, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "*role-name*" where *role-name* is the role that is associated with the user in the trusted context.
- Otherwise, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "*current-sqlid-value*".

If the value of the CURRENT SQLID special register changes after the initial value of PATH special register is established, the value of the PATH special register is unaffected when the CURRENT SQLID is updated. However, if a commit later occurs and a SET PATH statement has not been processed, the value of PATH special register is reinitialized taking into consideration the current value of the CURRENT SQLID special register.

You can change the value of the register by executing the statement SET PATH. For portability across the platforms, it is recommended that a SET PATH statement be issued at the beginning of an application.

Example: Set the special register so that schema SMITH is searched before the system schemas:

```
SET PATH = SMITH, SYSTEM PATH;
```

Related reference:

“SET PATH” on page 2209

CURRENT PRECISION

CURRENT PRECISION specifies the rules to be used when both operands in a decimal operation have precisions of 15 or less.

The data type of the register is CHAR(5).

Valid values for the CURRENT PRECISION special register include 'DEC15', 'DEC31', or 'Dpp.s' where 'pp' is either 15 or 31 and 's' is a number between 1 and 9. DEC15 specifies the rules that do not allow a precision greater than 15 digits, and DEC31 specifies the rules that allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15. If the form 'Dpp.s' is used, 'pp' represents the precision that will be used as the rules where DEC15 and DEC31 rules are used, and 's' represents the minimum divide scale to use for division operations. The separator used in the form 'Dpp.s' can be either the '.' or the ',' character, regardless of the setting of the default decimal point.

The initial value of CURRENT PRECISION is determined by the value of field DECIMAL ARITHMETIC on installation panel DSNTIP4. The default for the initial value is DEC15 unless your installation has changed it to be DEC31 by modifying the value in that field. The initial value of CURRENT PRECISION in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the statement SET CURRENT PRECISION.

CURRENT PRECISION only affects dynamic SQL. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC15 or D15.s, where 's' is a number between 1 and 9, DEC15 rules will apply. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC31 or D31.s, where 's' is a number between 1 and 9, DEC31 rules will apply. Preparation of a statement with DEC31 instead of DEC15 is more likely to result in an error, especially for division operations. Specification of CURRENT PRECISION in the form 'Dpp.s' where 'pp' is either 15 or 31 and 's' represents the minimum divide scale, will in some cases make division errors less likely when 'pp' is set to 31. For more information, see "Arithmetic with two decimal operands" on page 231.

Example 1: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic:

```
SET CURRENT PRECISION = 'DEC31';
```

Example 2: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic with a minimum divide scale of 3:

```
SET CURRENT PRECISION = 'D31.3';
```

Related reference:

"SET CURRENT PRECISION" on page 2194

CURRENT QUERY ACCELERATION

The CURRENT QUERY ACCELERATION special register specifies a value that identifies when DB2 sends dynamic SQL queries to an accelerator server and what DB2 does if the accelerator server fails. The special register does not apply to static SQL queries.

The data type is VARCHAR(255).

Valid values are:

NONE

Specifies that no queries are sent to an accelerator server.

ENABLE

Specifies that queries are accelerated only if DB2 determines that it is advantageous to do so. If an accelerator failure occurs while a query is running or if the accelerator returns an error, DB2 returns a negative SQLCODE to the application.

ENABLE WITH FAILBACK

Specifies that queries are accelerated only if DB2 determines that it is advantageous to do so. If the accelerator returns an error during the PREPARE or first OPEN for the query, DB2 executes the query without the accelerator. If the accelerator returns an error during a FETCH or a subsequent OPEN, DB2 returns the error to the user and does not execute the query.

ELIGIBLE

Specifies that queries are accelerated if they are eligible for acceleration. DB2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are executed by DB2. If an accelerator failure occurs while a query is running or if the accelerator returns an error, DB2 returns a negative SQLCODE to the application.

ALL

Specifies that queries are accelerated if they are eligible for acceleration. DB2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are not executed by DB2, and an SQL error is returned. If an accelerator failure occurs while a query is running or if the accelerator returns an error, DB2 returns a negative SQLCODE to the application.

The initial value of CURRENT QUERY ACCELERATION is determined by one of the following settings:

- The value of DB2 subsystem parameter QUERY_ACCELERATION. The default for the initial value of this subsystem parameter is NONE unless your installation has changed the value.
- If specified for the bind of a package, the QUERYACCELERATION bind option. This behavior enables the QUERYACCELERATION bind option to be used to specify the acceleration behavior for dynamic SQL queries and not only static SQL queries. This bind option does not have a default value.

The initial value of CURRENT QUERY ACCELERATION in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the SET CURRENT QUERY ACCELERATION statement.

| The precedence order (lowest to highest) for setting the value of the special register
| is as follows:

- | • The QUERY_ACCELERATION subsystem parameter
- | • The QUERYACCELERATION bind option, if specified
- | • An explicit SET CURRENT QUERY ACCELERATION statement

Example: The following statement sets the CURRENT QUERY ACCELERATION special register so that no query acceleration occurs.

```
SET CURRENT QUERY ACCELERATION NONE;
```

Related reference:

“SET CURRENT QUERY ACCELERATION” on page 2195

CURRENT REFRESH AGE

CURRENT REFRESH AGE specifies a timestamp duration value. This duration is the maximum duration since a REFRESH TABLE statement has been processed on a system-maintained REFRESH DEFERRED materialized query table such that the materialized query table can be used to optimize the processing of a query. This special register affects dynamic statement cache matching.

The data type of the register is DECIMAL(20,6). For a description of durations, see “Datetime operands and durations” on page 241.

If CURRENT REFRESH AGE has a value of 999999999999 (ANY), REFRESH DEFERRED materialized query tables are considered to optimize the processing of a dynamic SQL query. This value represents 9999 years, 99 months, 99 days, 99 hours, and 99 seconds.

The initial value of CURRENT REFRESH AGE is determined by the value of field CURRENT REFRESH AGE on installation panel DSNTIP8. The default for the initial value of that field is 0 unless your installation has changed it to ANY by modifying the value of that field. The initial value of CURRENT REFRESH AGE in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the SET CURRENT REFRESH AGE statement.

Example : The following example retrieves the current value of the CURRENT REFRESH AGE special register into the host variable, *CURMAXAGE*:

```
EXEC SQL VALUES (CURRENT REFRESH AGE) INTO :CURMAXAGE;
```

The value would be '999999999999.000000'.

Related reference:

“SET CURRENT REFRESH AGE” on page 2197

CURRENT ROUTINE VERSION

CURRENT ROUTINE VERSION specifies the version identifier that is to be used when invoking a native SQL procedure. CURRENT ROUTINE VERSION is used for CALL statements that use a host variable to specify the procedure name.

The data type of CURRENT ROUTINE VERSION is VARCHAR(64).

The initial value of CURRENT ROUTINE VERSION in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199. In other contexts the initial value of CURRENT ROUTINE VERSION is an empty string. An empty string indicates that a version identifier is not in effect for the SQL routine. When an SQL routine that does not have a version identifier in effect is invoked, the currently active version (as indicated in the catalog) of that routine is used.

You can change the value of the CURRENT ROUTINE VERSION by executing the statement SET CURRENT ROUTINE VERSION.

Setting the CURRENT ROUTINE VERSION special register to a version identifier might affect native SQL procedures that are invoked until the value of CURRENT ROUTINE VERSION is changed. If a version of an SQL procedure has a version identifier that matches the version identifier in the special register, that version of the SQL procedure is used when the SQL procedure is invoked. If an SQL procedure does not have a version identifier that matches the version identifier in the special register, the currently active version of the SQL procedure (as defined in the catalog) is used when the SQL procedure is invoked.

Example: Set the host variable *ROUTINE_VER* to the value of the CURRENT ROUTINE VERSION special register:

```
VALUES CURRENT ROUTINE VERSION INTO :ROUTINE_VER;
```

Related reference:

“SET CURRENT ROUTINE VERSION” on page 2199

CURRENT RULES

CURRENT RULES specifies whether certain SQL statements are executed in accordance with DB2 rules or the rules of the SQL standard.

The data type of the register is CHAR(3), and the only valid values are 'DB2' and 'STD'.

CURRENT RULES is a register at the database server. If the server is not the local DB2, the initial value of the register is 'DB2'. Otherwise, the initial value is the same as the value of the SQLRULES bind option. The initial value of CURRENT RULES in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

You can change the value of the register by executing the statement SET CURRENT RULES.

CURRENT RULES affects the statements listed in the following table. The table summarizes when the statements are affected and shows where to find detailed information. CURRENT RULES also affects whether DB2 issues an existence error (SQLCODE -204) or an authorization error (SQLCODE -551) when an object does not exist. For CURRENT RULES 'STD', DB2 issues an authorization error (SQLCODE -551) when an object does not exist instead of the existence error (SQLCODE -204).

Table 42. Summary of statements affected by CURRENT RULES

| Statement | What is affected | Details in topic |
|--------------|---|-----------------------------|
| ALTER TABLE | Enforcement of check constraints added. | "ALTER TABLE" on page 1304 |
| | Default value of the delete rule for referential constraints. | |
| | Whether DB2 creates LOB table spaces, auxiliary tables, and indexes on auxiliary tables for added LOB columns. | |
| | Whether DB2 creates an index for an added ROWID column that is defined with GENERATED BY DEFAULT. | |
| CREATE TABLE | Default value of the delete rule for referential constraints. | "CREATE TABLE" on page 1706 |
| | Whether DB2 creates LOB table spaces, auxiliary tables, and indexes on auxiliary tables for LOB columns if the table is explicitly created. | |
| | Whether DB2 creates an index for a ROWID column that is defined with GENERATED BY DEFAULT if the table is explicitly created. | |
| GRANT | Granting privileges to yourself. | "GRANT" on page 2000 |
| REVOKE | Revoking privileges from authorization IDs | "REVOKE" on page 2115 |

Example: Set CURRENT RULES so that a later ALTER TABLE statement is executed in accordance with the rules of the SQL standard:

```
SET CURRENT RULES = 'STD';
```

Related reference:

“SET CURRENT RULES” on page 2201

CURRENT SCHEMA

The CURRENT SCHEMA special register specifies the schema name used to qualify unqualified database object references in dynamically prepared SQL statements.

The data type is VARCHAR(128).

For information on when the CURRENT SCHEMA is used to resolve unqualified names in dynamic SQL statements and the effect of its value, see “Qualification of unqualified object names” on page 67.

The CURRENT SCHEMA special register contains a value that is a single identifier without delimiters.

The initial value of the special register is the value of CURRENT SQLID at the time the connection is established. If the connection is established as a trusted connection with a role as the object owner and qualifier, the initial value of the special register is the value of the role name that is associated with the user in the trusted context. The initial value of the special register in a user-defined function or procedure is inherited according to the rules in Table 43 on page 199.

The value of the special register can be changed by executing the SET SCHEMA statement. The value of CURRENT SCHEMA is the same as the value of CURRENT SQLID unless a SET SCHEMA statement has been issued specifying a different value. After a SET SCHEMA statement has been issued in an application, the values of CURRENT SCHEMA and CURRENT SQLID are separate. Therefore, if the value of CURRENT SCHEMA needs to be changed, a SET SCHEMA statement must be issued.

Specifying CURRENT_SCHEMA is equivalent to specifying CURRENT SCHEMA.

Example: Set the schema for object qualification to 'D123'.

```
SET SCHEMA = 'D123'
```

CURRENT SERVER

CURRENT SERVER specifies the location name of the current server.

The data type is CHAR(16). If necessary, the location name is padded on the right with blanks so that its length is 16 bytes.

The initial value of CURRENT SERVER depends on the CURRENTSERVER bind option. If CURRENTSERVER X is specified on the bind subcommand, the initial value is X. If the option is not specified, the initial value is the location name of the local DB2. The initial value of CURRENT SERVER in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199. The value of CURRENT SERVER is changed by the successful execution of a CONNECT statement.

The value of CURRENT SERVER is a string of blanks when either of the following conditions apply:

- The application process is in the unconnected state
- The application process is connected to a local DB2 subsystem that does not have a location name.

Example: Set the host variable CS to the location name of the current server.

```
EXEC SQL SET :CS = CURRENT SERVER;
```

CURRENT SQLID

CURRENT SQLID specifies the SQL authorization ID of the process.

The data type is VARCHAR(128).

The SQL authorization ID is:

- The authorization ID used for authorization checking on dynamically prepared CREATE, GRANT, and REVOKE SQL statements.
- The owner of a table space, database, storage group, or synonym created by a dynamically issued CREATE statement.

The initial value of CURRENT SQLID can be provided by the connection or sign-on exit routine. If not, the initial value is the primary authorization ID of the process. The value remains in effect until one of the following events occurs:

- The SQL authorization ID is changed by the execution of a SET CURRENT SQLID statement.
- A SIGNON or re-SIGNON request is received from a CICS transaction subtask or an IMS independent region.
- The DB2 connection is ended.
- When running in a trusted connection, the user is switched.

The initial value of CURRENT SQLID in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

CURRENT SQLID can only be referred to in an SQL statement that is executed by the current server.

CURRENT SQLID cannot be a role.

Example: Set the SQL authorization ID to 'GROUP34' (one of the authorization IDs of the process).

```
SET CURRENT SQLID = 'GROUP34';
```

CURRENT TIME

The CURRENT TIME special register specifies a time that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.¹⁰

The value of CURRENT TIME in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199. For other applications, the time is derived by the DB2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT_TIME is equivalent to specifying CURRENT TIME.

Example: Display information about all project activities and include the current date and time in each row of the result.

```
SELECT DSN8A10.PROJACT.*, CURRENT DATE, CURRENT TIME
FROM DSN8A10.PROJACT;
```

10. Except for the case of a non-atomic multiple row INSERT or MERGE statement.

CURRENT TIMESTAMP

The CURRENT TIMESTAMP special register specifies a timestamp that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIME within a single statement, all values are based on a single clock reading.¹¹

The value of CURRENT TIMESTAMP in a user-defined function or stored procedure is inherited according to the rules in Table 43 on page 199.

Specifying CURRENT_TIMESTAMP is equivalent to specifying CURRENT TIMESTAMP.

If you want a timestamp with a specified precision, the special register can be referenced as CURRENT_TIMESTAMP(*integer*), where *integer* can range from 0 to 12. The default precision is 6. SYSDATE can also be specified as a synonym for CURRENT_TIMESTAMP(0).

If you want a timestamp with a time zone, the special register can be referenced as CURRENT_TIMESTAMP(*integer*) WITH TIME ZONE, or CURRENT_TIMESTAMP WITH TIME ZONE. SYSTIMESTAMP can be specified as an alternative to CURRENT_TIMESTAMP(12) WITH TIME ZONE. The time zone is determined from the CURRENT TIME ZONE special register.

Note: If the CURRENT_TIMESTAMP special register is referenced in a timestamp with time zone context (for example, when compared with a timestamp with time zone column) the implicit time zone for the CURRENT_TIMESTAMP special register will be based on the implicit time zone system parameter, which could be a different value from the CURRENT TIME ZONE special register. To avoid misinterpretation of the time zone in this case, CURRENT_TIMESTAMP WITH TIME ZONE should be used.

Example 1: Display information about the full image copies that were taken in the last week.

```
SELECT * FROM SYSIBM.SYSCOPY
WHERE TIMESTAMP > CURRENT_TIMESTAMP - 7 DAYS;
```

Example 2: Insert a row into the IN_TRAY table. The value of the RECEIVED column should be a timestamp that indicates when the row was inserted. The values for the other three columns come from the host variables SRC (CHAR(8)), SUB (CHAR(64)), and TXT (VARCHAR(200)).

```
INSERT INTO IN_TRAY
VALUES (CURRENT_TIMESTAMP, :SRC, :SUB, :TXT)
```

Example 3: Retrieve the value of the CURRENT_TIMESTAMP special register with a precision of 8 and include the time zone:

```
SELECT CURRENT_TIMESTAMP(8) WITH TIME ZONE
FROM SYSIBM.SYSDUMMY1;
```

11. Except for the case of a non-atomic multiple row INSERT or MERGE statement.

CURRENT TIME ZONE

The CURRENT TIME ZONE special register specifies a value that contains the difference between UTC and local time as defined by the current server, if the SESSION TIME ZONE special register has not been set.

The local time difference for the current server is set by z/OS, in the CLOCKxx PARMLIB member.

The data type is DECIMAL(6,0).

The difference between UTC and local time at the current server is represented by a time duration. A time duration is a decimal number in which the first two digits are the number of hours, the next two digits are the number of minutes, and the last two digits are the number of seconds. The number of hours is adjusted, if necessary, to fit in the range between -24 and 24 exclusive.

Subtracting CURRENT TIME ZONE from a local time converts that local time to UTC.

CURRENT TIMEZONE can be specified as an alternative to CURRENT TIME ZONE.

Example: Select all the rows of the IN_TRAY table. Assume that the RECEIVED column is defined as TIMESTAMP WITHOUT TIME ZONE. Adjust the timestamp value in the RECEIVED column to UTC by subtracting the value of the CURRENT TIME ZONE special register.

```
SELECT RECEIVED - CURRENT TIME ZONE, SOURCE, SUBJECT, NOTE_TEXT  
FROM IN_TRAY;
```

Related information:

 [CLOCKxx \(time of day parameters\) \(MVS Initialization and Tuning Reference\)](#)

ENCRYPTION PASSWORD

The ENCRYPTION PASSWORD special register specifies the encryption password and the password hint (if one exists) that are used by the encryption and decryption built-in functions.

This special register can only be set, by using the SET ENCRYPTION PASSWORD statement, and cannot be referenced directly. The ENCRYPTION PASSWORD special register contains the value of the password that is used by the ENCRYPTION and DECRYPTION built-in functions to encrypt and decrypt data when a password is not explicitly specified as a function argument. The ENCRYPTION PASSWORD special register can also contain a password hint which is associated with the values that are encrypted using the encryption password. The password hint is a character string that is used to help in remembering the password. The GETHINT function is used to return the password hint for an encrypted value.

The initial value of the ENCRYPTION PASSWORD special register is the empty string (' ').

The initial value of the ENCRYPTION PASSWORD special register in a user-defined function or procedure is inherited from the invoking application. In other contexts, the initial value of the special register is the empty string.

The password is not related to DB2 authentication and is used only for data encryption.

Related reference:

“SET ENCRYPTION PASSWORD” on page 2204

SESSION_USER

SESSION_USER specifies the primary authorization ID of the process.

The data type is VARCHAR(128).

If SESSION_USER is referred to in an SQL statement that is executed at a remote DB2 and the primary authorization ID has been translated to a different authorization ID, SESSION_USER specifies the translated authorization ID. For an explanation of authorization ID translation, see *DB2 Administration Guide*. The value of SESSION_USER in a user-defined function or stored procedure is determined according to the rules in Table 43 on page 199.

USER can be specified as a synonym for SESSION_USER.

Example: Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = SESSION_USER;
```

SESSION TIME ZONE

The SESSION TIME ZONE special register specifies a value that identifies the time zone of the application process.

The data type is VARCHAR(128).

The time zone value is in the format of $\pm th:tm$. th represents the time zone hour offset. tm represents the time zone minute offset. Valid values for th are between -12 and +14. Valid values for tm are between 0 and 59. SESSION TIMEZONE can be specified as an alternative to SESSION TIME ZONE.

The initial value of the special register in a user-defined function or stored procedure is inherited according to the rules in “Special registers in a user-defined function or a stored procedure” on page 199. In other contexts the initial value of the special register represents the same time zone as the CURRENT TIME ZONE special register.

The value of the special register can be changed by executing the SET SESSION TIME ZONE statement. After a SET SESSION TIME ZONE statement has been processed, the values of the SESSION TIME ZONE and CURRENT TIME ZONE special register might not reflect the same value.

Example: Set the session time zone to '-8:00':

```
SET SESSION TIME ZONE = '-8:00';
```

Related reference:

“SET SESSION TIME ZONE” on page 2215

USER

USER specifies the primary authorization ID of the process. The data type is VARCHAR(128). SESSION_USER is the preferred spelling.

If USER is referred to in an SQL statement that is executed at a remote DB2 and the primary authorization ID has been translated to a different authorization ID, USER specifies the translated authorization ID. For an explanation of authorization ID translation, see *DB2 Administration Guide*. The value of USER in a user-defined function or stored procedure is determined according to the rules in Table 43 on page 199.

Example: Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = USER;
```

Special registers in a user-defined function or a stored procedure

You can use all special registers in a user-defined function or a stored procedure. However, you can modify only some of those special registers.

After a user-defined function or a stored procedure completes, DB2 restores all special registers to the values they had before invocation.

The following table shows information that you need when you use special registers in a user-defined function or stored procedure.

Table 43. Characteristics of special registers in a user-defined function or a stored procedure

| Special register | Initial value when INHERIT SPECIAL REGISTERS option is specified | Initial value when DEFAULT SPECIAL REGISTERS option is specified | Routine can use SET statement to modify? |
|---|--|--|--|
| CURRENT APPLICATION ENCODING SCHEME | The value of bind option ENCODING for the user-defined function or stored procedure package | The value of bind option ENCODING for the user-defined function or stored procedure package | Yes |
| CURRENT CLIENT_ACCTNG | Inherited from the invoking application | Inherited from the invoking application | Not applicable ⁵ |
| CURRENT CLIENT_APPLNAME | Inherited from the invoking application | Inherited from the invoking application | Not applicable ⁵ |
| CURRENT CLIENT_USERID | Inherited from the invoking application | Inherited from the invoking application | Not applicable ⁵ |
| CURRENT CLIENT_WRKSTNNAME | Inherited from the invoking application | Inherited from the invoking application | Not applicable ⁵ |
| CURRENT DATE | New value for each SQL statement in the user-defined function or stored procedure package ¹ | New value for each SQL statement in the user-defined function or stored procedure package ¹ | Not applicable ⁵ |
| CURRENT DEBUG MODE | Inherited from the invoking application | DISALLOW | Yes |
| CURRENT DECFLOAT ROUNDING MODE | Inherited from the invoking application | The value of bind option ROUNDING for the user-defined function or stored procedure package | Yes |
| CURRENT DEGREE | CURRENT DEGREE ² | The value of field CURRENT DEGREE on installation panel DSNTIP8 | Yes |
| CURRENT EXPLAIN MODE | Inherited from the invoking application | NO | Yes |
| CURRENT GET_ACCEL_ARCHIVE | Inherited from the invoking application | System default value | Yes |
| CURRENT LOCALE LC_CTYPE | Inherited from the invoking application | The value of field CURRENT LC_CTYPE on installation panel DSNTIPF | Yes |
| CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION | Inherited from the invoking application | System default value | Yes |

Table 43. Characteristics of special registers in a user-defined function or a stored procedure (continued)

| Special register | Initial value when INHERIT SPECIAL REGISTERS option is specified | Initial value when DEFAULT SPECIAL REGISTERS option is specified | Routine can use SET statement to modify? |
|----------------------------|--|---|--|
| CURRENT MEMBER | New value for each SET <i>host-variable</i> =CURRENT MEMBER statement | New value for each SET <i>host-variable</i> =CURRENT MEMBER statement | Not applicable ⁵ |
| CURRENT OPTIMIZATION HINT | The value of bind option OPTHINT for the user-defined function or stored procedure package or inherited from the invoking application ⁶ | The value of bind option OPTHINT for the user-defined function or stored procedure package | Yes |
| CURRENT PACKAGE PATH | An empty string if the routine was defined with a COLLID value; otherwise, inherited from the invoking application ⁴ | An empty string, regardless of whether a COLLID value was specified for the routine ⁴ | Yes |
| CURRENT PACKAGESET | Inherited from the invoking application ³ | Inherited from the invoking application ³ | Yes |
| CURRENT PATH | The value of bind option PATH for the user-defined function or stored procedure package or inherited from the invoking application ⁶ | The value of bind option PATH for the user-defined function or stored procedure package | Yes |
| CURRENT PRECISION | Inherited from the invoking application | The value of field DECIMAL ARITHMETIC on installation panel DSNTIP4 | Yes |
| CURRENT QUERY ACCELERATION | Inherited from the invoking application | System default value | Yes |
| CURRENT REFRESH AGE | Inherited from the invoking application | System default value | Yes |
| CURRENT ROUTINE VERSION | Inherited from the invoking application | The empty string | Yes |
| CURRENT RULES | Inherited from the invoking application | The value of bind option SQLRULES for the plan that invokes a user-defined function or stored procedure | Yes |
| CURRENT SCHEMA | Inherited from the invoking application | The value of CURRENT SCHEMA when the routine is entered | Yes |
| CURRENT SERVER | Inherited from the invoking application | Inherited from the invoking application | Yes |
| CURRENT SQLID | The primary authorization ID of the application process or inherited from the invoking application ⁷ | The primary authorization ID of the application process | Yes ⁸ |
| CURRENT TIME | New value for each SQL statement in the user-defined function or stored procedure package ¹ | New value for each SQL statement in the user-defined function or stored procedure package ¹ | Not applicable ⁵ |

Table 43. Characteristics of special registers in a user-defined function or a stored procedure (continued)

| Special register | Initial value when INHERIT SPECIAL REGISTERS option is specified | Initial value when DEFAULT SPECIAL REGISTERS option is specified | Routine can use SET statement to modify? |
|----------------------------------|--|--|--|
| CURRENT TIMESTAMP | New value for each SQL statement in the user-defined function or stored procedure package ¹ | New value for each SQL statement in the user-defined function or stored procedure package ¹ | Not applicable ⁵ |
| CURRENT TIMESTAMP WITH TIME ZONE | New value for each SQL statement in the user-defined function or stored procedure package ¹ | New value for each SQL statement in the user-defined function or stored procedure package ¹ | Not applicable ⁵ |
| CURRENT TIME ZONE | Inherited from the invoking application | Inherited from the invoking application | Not applicable ⁵ |
| ENCRYPTION PASSWORD | Inherited from the invoking application | Inherited from the invoking application | Yes |
| SESSION TIME ZONE | Inherited from the invoking application | The value of CURRENT TIME ZONE when the routine is entered | Yes |
| SESSION_USER or USER | Primary authorization ID of the application process | Primary authorization ID of the application process | Not applicable ⁵ |

Notes:

1. If the user-defined function or stored procedure is invoked within the scope of a trigger, DB2 uses the timestamp for the triggering SQL statement as the timestamp for all SQL statements in the package.
2. DB2 allows parallelism at only one level of a nested SQL statement. If you set the value of the CURRENT DEGREE special register to ANY, and parallelism is disabled, DB2 ignores the CURRENT DEGREE value.
3. If the routine definition includes a specification for COLLID, DB2 sets CURRENT PACKAGESET to the value of COLLID. If both CURRENT PACKAGE PATH and COLLID are specified, the CURRENT PACKAGE PATH value takes precedence and COLLID is ignored.
4. If the function definition includes a specification for PACKAGE PATH, DB2 sets CURRENT PACKAGE PATH to the value of PACKAGE PATH.
5. Not applicable because no SET statement exists for the special register.
6. If a program within the scope of the invoking program issues a SET statement for the special register before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, the special register contains the value that is set by the bind option for the user-defined function or stored procedure package.
7. If a program within the scope of the invoking program issues a SET CURRENT SQLID statement before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, CURRENT SQLID contains the authorization ID of the application process.
8. If the user-defined function or stored procedure package uses a value other than RUN for the DYNAMICRULES bind option, the SET CURRENT SQLID statement can be executed. However, it does not affect the authorization ID that is used for the dynamic SQL statements in the package. The DYNAMICRULES value determines the authorization ID that is used for dynamic SQL statements.

Column names

The meaning of a column name depends on its context.

A column name can be used to:

- Declare the name of a column, as in a CREATE TABLE statement.
- Specify the name of a column, as in a CREATE FUNCTION statement to name a column of the result table of a table function.
- Identify a column, as in a CREATE INDEX statement.
- Specify values of the column, as in the following contexts:
 - In an *aggregate function*, a column name specifies all values of the column in the group or intermediate result table to which the function is applied. (Groups and intermediate result tables are explained in Chapter 6, “Queries,” on page 1079.) For example, MAX(SALARY) applies the function MAX to all values of the column SALARY in a group.
 - In a *GROUP BY* or *ORDER BY* clause, a column name specifies all values in the intermediate result table to which the clause is applied. For example, ORDER BY DEPT orders an intermediate result table by the values of the column DEPT.
 - In an *expression*, a *search condition*, or a *scalar function*, a column name specifies a value for each row or group to which the construct is applied. For example, when the search condition CODE = 20 is applied to some row, the value specified by the column name CODE is the value of the column CODE in that row.
- Provide a column name for an expression to temporarily rename a column, as in the *correlation-clause* of a *table-reference* in a FROM clause or as in the AS clause in the *select-clause*.

Qualified column names

A qualifier for a column name can be a table name, a view name, an alias name, a synonym, or a correlation name. Whether a column name can be qualified depends, like its meaning, on its context.

- In some forms of the COMMENT and LABEL statements, a column name must be qualified. This is shown in the syntax diagrams.
- Where the column name specifies values of the column, a column name can be qualified at the user's option.
- In the column list of an INSERT statement, a column name can be qualified.
- In the *assignment-clause* of an UPDATE or a MERGE statement, a column name can be qualified.
- In all other contexts, a column name must not be qualified. This rule will be mentioned in the discussion of each statement to which it applies.

Where a qualifier is optional, it can serve two purposes. See “Column name qualifiers to avoid ambiguity” on page 203 and “Column name qualifiers in correlated references” on page 205 for details.

Correlation names

A *correlation name* can be defined in the FROM clause of a query and after the name of the target table or view in an UPDATE, MERGE, or DELETE statement.

For example, the following clause establishes Z as a correlation name for X.MYTABLE:

```
FROM X.MYTABLE Z
```

With Z defined as a correlation name for table X.MYTABLE, only Z should be used to qualify a reference to a column of X.MYTABLE in that SELECT statement.

A correlation name is associated with a table, view, nested table expression or table function only within the context in which it is defined. Hence, the same correlation name can be defined for different purposes in different statements. In a nested table expression or table function, a correlation name is required.

As a qualifier, a correlation name can be used to avoid ambiguity or to establish a correlated reference. It can also be used merely as a shorter name for a table or view. In the example, Z might have been used merely to avoid having to enter X.MYTABLE more than once.

Names that are specified in a FROM clause are either *exposed* or *non-exposed*. A correlation name is always an exposed name. A table name or view name is said to be exposed in that FROM clause if a correlation name is not specified. For example, in the following FROM clause, a correlation name is specified for EMPLOYEE, but not for DEPARTMENT; therefore, DEPARTMENT is an exposed name, and EMPLOYEE is not an exposed name:

```
FROM EMPLOYEE E, DEPARTMENT
```

The use of a correlation name in the FROM clause also allows the option of specifying a list of column names to be associated with the columns of the result table. As with a correlation name, the listed column names should be the names that are used to reference the columns in that SELECT statement. For example, assume that the name of the first column in the DEPT table is DEPTNO. Given this FROM clause in a SELECT statement:

```
FROM DEPT D (NUM,NAME,MGR,ANUM,LOC)
```

You should use D.NUM instead of D.DEPTNO to reference the first column of the table.

If a list of columns is specified, it must consist of as many names as there are columns in the *table-reference*. Each column must be unique and unqualified.

Column name qualifiers to avoid ambiguity

In the context of a function, a GROUP BY clause, an ORDER BY clause, an expression, or a search condition, a column name refers to values of a column in some table or view in a DELETE or UPDATE statement or *table-reference* in a FROM clause.

The tables, views, and *table-references*¹² that might contain the column are called the *object tables* of the context. Two or more object tables might contain columns with the same name. One reason for qualifying a column name is to designate the object from which the column comes. For information on avoiding ambiguity between SQL parameters and variables and column names, see “References to SQL parameters and SQL variables” on page 2321.

A nested table expression which is preceded by a TABLE keyword will consider *table-references* that precede it in the FROM clause as object tables. The *table-references* that follow it are not considered as object tables.

12. In the case of a *joined-table*, each *table-reference* within the *joined-table* is an object table.

Table designators: A qualifier that designates a specific object table is called a *table designator*. The clause that identifies the object tables also establishes the table designators for them. For example, the object tables of an expression in a SELECT statement are named in the FROM clause that follows it, as in the following statement:

```
SELECT DISTINCT Z.EMPNO, EMPTIME, PHONENO
FROM DSN8A10.EMP Z, DSN8A10.EMPPROJECT
WHERE WORKDEPT = 'D11'
AND EMPTIME > 0.5
AND Z.EMPNO = DSN8A10.EMPPROJECT.EMPNO;
```

Table designators in the FROM clause are established as follows:

- A name that follows a table or view name is both a correlation name and a table designator. Thus, Z is a table designator and qualifies the first column name in the select list.
- An exposed table or view name is a table designator. Thus, the qualified table name, Thus, the qualified table name, DSN8A10.EMPPROJECT is a table designator and qualifies the second column name in the select list.

Two or more object tables can be instances of the same table. In this case, distinct correlation names must be used to unambiguously designate the particular instance of the table. In the following example, the X and Y in the FROM clause are defined to refer, respectively, to the first and second instances of the DSN8A10.EMP table:

```
SELECT *
FROM DSN8A10.EMP X, DSN8A10.EMP Y;
```

Avoiding undefined or ambiguous references in DB2 SQL: When a column name refers to values of a column, the following situations result in errors:

- No object table contains a column with the specified name. The reference is undefined.
- The column name is qualified by a table designator, but the table named does not include a column with the specified name. Again, the reference is undefined.
- The name is unqualified and more than one object table includes a column with that name. The reference is ambiguous.

Avoid ambiguous references by qualifying a column name with a uniquely defined table designator. If the column is contained in several object tables with different names, the table names can be used as designators. Ambiguous references can also be avoided without the use of the table designator by giving unique names to the columns of one of the object tables using the column name list following the correlation name.

Two or more object tables can be instances of the same table. A FROM clause that includes *n* references to the same table should include at least *n* - 1 unique correlation names.

For example, in the following FROM clause X and Y are defined to refer, respectively, to the first and second instances of the table EMP.

```
SELECT X.LASTNAME, Y.LASTNAME
FROM DSN8A10.EMP X, DSN8A10.EMP Y
WHERE Y.JOB = 'MANAGER'
AND X.WORKDEPT = Y.WORKDEPT
AND X.JOB <> 'MANAGER';
```

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name can be used. However, the qualifier used and the table used must be the same after fully qualifying the table name or view name and the table designator.

Example 1: If the authorization ID of the statement is CORPDATA, the following statement is valid:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT
FROM EMPLOYEE;
```

Example 2: If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE represents the table REGION.EMPLOYEE, but the qualifier for WORKDEPT represents a different table, CORPDATA.EMPLOYEE:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT      -- Incorrect
FROM EMPLOYEE;
```

Example 3: If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE in the select list represents the table REGION.EMPLOYEE, but the explicitly qualified table name in the FROM clause represents a different table, CORPDATA.EMPLOYEE.

```
SELECT EMPLOYEE.WORKDEPT                -- Incorrect
FROM CORPDATA.EMPLOYEE;
```

Column name qualifiers in correlated references

A reference to a column of a table identified at a higher level is called a *correlated reference*. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. It is good practice to use these unique correlation names to qualify column names.

A *subselect* is a form of a query that can be used as a component of various SQL statements. A *subquery* is a form of a fullselect that is enclosed within parenthesis. For example, a subquery can be used in a search condition. A fullselect that is used to retrieve a single value as an expression within a statement is called a *scalar fullselect* or a *scalar subquery*. A fullselect that is used in the FROM clause of a query is called a *nested table expression*.

A subquery can include search conditions of its own, and these search conditions can, in turn, include subqueries. Thus, an SQL statement can contain a hierarchy of subqueries. Those elements of the hierarchy that contain subqueries are said to be at a higher level than the subqueries they contain.

Every element of the hierarchy has a clause that establishes one or more table designators. This is the FROM clause, except in the highest level of an UPDATE, where it is the table or view being updated. A search condition of a subquery can reference not only columns of the tables identified by the FROM clause of its own element of the hierarchy, but also columns of tables identified at any level along the path from its own element to the highest level of the hierarchy.

A correlated reference to column C of table T can be of the form C, T.C, or Q.C, if Q is a correlation name defined for T. However, **a correlated reference in the form of an unqualified column name is not good practice**. The following explanation is based on the assumption that a correlated reference is always in the form of a qualified column name and that the qualifier is a correlation name.

A qualified column name, Q.C, is a correlated reference only if these three conditions are met:

- Q.C is used in a search condition or in a select list of a subquery.
- Q does not name a table used in the FROM clause of that subquery.
- Q does name a table used at some higher level.

Q.C refers to column C of the table or view at the level where Q is used as the table designator of that table or view. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. If Q is used to name a table at more than one level, Q.C refers to the lowest level that contains the subquery that includes Q.C.

If a correlation name is defined as the table designator of the table or view, but the table or view name is used as the column qualifier instead of the correlation name, an error is returned.

For example, in the following statement, the correlated reference X.WORKDEPT (in the last line) refers to the value of WORKDEPT in table DSN8A10.EMP at the level of the first FROM clause (which establishes X as a correlation name for DSN8A10.EMP). The statement lists employees who make less than the average salary for their department.

```
SELECT EMPNO, LASTNAME, WORKDEPT
       FROM DSN8A10.EMP X
       WHERE SALARY < (SELECT AVG(SALARY)
                       FROM DSN8A10.EMP
                       WHERE WORKDEPT = X.WORKDEPT);
```

The following example shows a correlated reference in the select list of the subquery.

```
SELECT T1.KEY1
       FROM BP1TBL T1
       GROUP BY T1.KEY1
       HAVING MAX(T1.KEY1) = (SELECT MIN(T1.KEY1) + MIN(T2.KEY1)
                             FROM BP2TBL T2);
```

Resolution of column name qualifiers and column names

The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved.

Names in a FROM clause are either *exposed* or *non-exposed*. A correlation name for a table name, view name, nested table expression, or reference to a table function is always exposed. A table name or a view name that is not followed by a correlation name is also exposed.

Although DB2 for z/OS does not enforce this rule strictly, in IBM SQL and ANSI/ISO SQL, the exposed names in a FROM clause must be unique, and the qualifier of a column name must be an exposed name. Therefore, for good programming practices, ensure that all exposed names are unique and that all qualified column names are qualified with the appropriate exposed name.

The rules for finding the referent of a column name qualifier are as follows:

1. Let Q be a one-, two-, or three-part name, and let Q.C denote a column name in subselect S. Q must designate a table or view identified in the statement that includes S and that table or view must have a column named C. An additional requirement differs for two cases:
 - If Q.C is not in a *search-condition* or S is not a subquery, Q must designate a table or view identified in the FROM clause of S. For example, if Q.C is in a SELECT clause, Q refers to a table or view in the following FROM clause.
 - If Q.C is in a *search-condition* and S is a subquery, Q must designate a table or view identified either in the FROM clause of S or in a FROM clause of a subselect that directly or indirectly includes S. For example, if Q.C is in a WHERE clause and S is the only subquery in the statement, the table or view that Q refers to is either in the FROM clause of S or the FROM clause of the subselect that includes S.
2. The same table or view can be identified more than once in the same statement. The particular occurrence of the table or view that Q refers to is determined by a procedure equivalent to the following steps:
 - a. The one- and two-part names in every FROM clause and the one- and two-part qualifiers of column names are expanded into a fully-qualified form.
 For example, if a dynamic SQL statement uses FROM Q and DYNAMICRULES run behavior (RUN) is in effect, Q is expanded to S.A.Q, where S is the value of CURRENT SERVER and A is the value of CURRENT SCHEMA. (If DYNAMICRULES bind behavior is in effect instead, A is the plan or package qualifier as determined during the bind process or the qualifier for the native SQL procedure as determined when the procedure was defined.) This step is later referred to as “name completion”. An error occurs if the first part of every name (the location) is not the same.
 - b. Q, now a three-part name, is compared with every name in the FROM clause of S. If Q.C is in a *search-condition* and S is a subquery, Q is next compared with every name in the FROM clause of the subselect that contains S. If that subselect is a subquery, Q is then compared with every name in the FROM clause of the subselect containing that subquery, and so on. If a FROM clause includes multiple names, the comparisons in that clause are made in order from left to right.
 - c. The referent of Q is selected by these rules:
 - If Q matches exactly one name, that name is selected.
 - If Q matches more than one name, but only one exposed name, that exposed name is selected.
 - If Q matches more than one exposed name, the first of those names is selected.
 - If Q matches more than one name, none of which are exposed names, the first of those names is selected.
 If Q does not match any name, or if the table or view designated by Q does not include a column named C, an error occurs.
 - d. Otherwise, Q.C is resolved to column C of the occurrence of the table or view identified by the selected name.
3. A warning occurs for any of these cases:
 - The selected name is not an exposed name.
 - The selected name is an exposed name that has an unexposed duplicate that appears before the selected name in the ordered list of names to which Q is compared.

- The selected name is an exposed name that has an exposed duplicate in the same FROM clause.
- Another name would have been selected had the matching been performed before name completion.

The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved. In the case of a searched UPDATE or DELETE statement, the first clause of the statement identifies the table or view to be updated or deleted. That clause can include a correlation name and, with regard to name resolution, is equivalent to the first FROM clause of a SELECT statement. For example, a subquery in the search condition of an UPDATE statement can include a correlated reference to a column of the updated rows.

The rules for column names in the ORDER BY clause are the same as other clauses.

Variables

A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements.

host variable

Host variables are defined by statements of a host language. For more information about how to refer to host variables, see “Host variables.”

transition variable

Transition variables are defined in a trigger and refer to either the old or new values of columns of the subject table or view of a trigger. For more information about how to refer to transition variables, see “CREATE TRIGGER” on page 1802.

SQL variable

SQL variables are defined by an SQL compound statement in an SQL function or SQL procedure. For more information about SQL variables, see “References to SQL parameters and SQL variables” on page 2252.

SQL parameter

SQL parameters are defined in an CREATE FUNCTION (SQL Scalar), CREATE FUNCTION (SQL table), or CREATE PROCEDURE (SQL) statement. For more information about SQL parameters, see “References to SQL parameters and SQL variables” on page 2252.

parameter marker

Parameter markers are specified in an SQL statement that is dynamically prepared, instead of variables, other than global variables. For more information about parameter markers, see Parameter markers in the PREPARE statement.

Unless otherwise noted, the term *variable* in syntax diagrams is used to describe where a host variable, transition variable, SQL variable, SQL parameter, or parameter marker can be used.

Host variables

Host variables are defined directly by statements of the host language or indirectly by SQL extensions. A *host-variable* in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead.

A *host variable* is either of these items that is referred to in an SQL statement:

- A variable in a host language such as a PL/I variable, C variable, Fortran variable, REXX variable, Java variable, COBOL data item, or Assembler language storage area
- A host language construct that was generated by an SQL precompiler from a variable declared using SQL extensions

Host variables are defined directly by statements of the host language or indirectly by SQL extensions as described in *DB2 Application Programming and SQL Guide*. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead. For more information about parameter markers, see "Variables in dynamic SQL" on page 211.

A host-variable in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables.

In PL/I, C, and COBOL, host variables can be referred to in ways that do not apply to Fortran and Assembler language. This is explained in "Host structures in PL/I, C, and COBOL" on page 217. The following applies to all host languages.

The term *host-variable*, as used in the syntax diagrams, shows a reference to a host variable. In a SET *host variable* statement and the INTO clause of a FETCH, SELECT INTO, or VALUES INTO statement, a host variable is an output variable to which a value is assigned by DB2. In a CALL statement, a host variable can be an output argument that is assigned a value after execution of the procedure, an input argument that provides an input value for the procedure, or both an input and output argument. In all other contexts, a host variable is an input variable which provides a value to DB2.

Non-Java variable references

The general form of a host variable reference in all languages other than Java is:

Each host identifier must be declared in the source program, except in a program written in REXX. The first host identifier designates the main variable; the second host identifier designates its indicator variable. The variable designated by the second host identifier must be a small integer. Indicator variables appear in two forms, normal indicator variables and extended indicator variables.

The purposes of normal indicator variable are to:

- Specify a non-null value. A 0 (zero), or positive value of the indicator variable specifies that the associated, first *host-identifier* provides the value of this host variable reference.
- Specify the null value. A negative value of the indicator variable specifies the null value.

In addition, on output, an indicator variable can indicate the following :

- A numeric conversion error (such as a divide by 0 or overflow) has occurred. A value of -2 for the indicator variable indicates a null result because of either numeric truncation or arithmetic warnings.
- A character could not be converted. A value of -2 for the indicator variable indicates a null result because of character string conversion warnings.
- No value was returned. A value of -3 for the indicator variable indicates a null result because the current row of the cursor is on a hole that is detected during a multiple row FETCH.
- Report the original length of a truncated string, if the string is not a LOB.
- Report the seconds portion of a time if the time is truncated on assignment to a host variable.

Extended indicator variables are limited to the input of host variables, and can specify the following:

- A non-null value. A 0 (zero), or positive value specifies that the associated, first *host-identifier* provides the value of this host variable reference.
- The null value. A -1, -2, -3, -4, or -6 value specifies the null value.
- The default value. A -5 value specifies that the target column for this host variable is to be set to its default value.
- An unassigned value. A -7 value specifies that the target column for this host variable is to be treated as if it had not been specified in the statement.

Extended indicator variables are only enabled if requested, and all indicator variables are otherwise normal indicator variables. Extended indicator variables are enabled when EXTENDEDINDICATOR(YES) is used, or when the **WITH EXTENDED INDICATORS** prepare attribute has been specified for the statement. In comparison to normal indicator variables, extended indicator variables have no additional restrictions for where the values for null and non-null can be used. There are no restrictions against using extended indicator variable values in indicator structures with host structures. There are no restrictions that result from the use of extended indicator variable values with host arrays in multiple-row statements. Restrictions on where the extended indicator variable values of default and unassigned are allowed apply uniformly, no matter how they are represented in the host application. The default and unassigned extended indicator variable values can only appear in limited, specified uses. Output indicator variables are never extended indicator variables.

When extended indicator variables are enabled, there are no restrictions against use of 0 (zero), or positive indicator variable values. However, negative indicator variable values outside the range -1 through -7 must not be specified. When extended indicator variables are enabled, the default and unassigned extended indicator values must not appear in contexts in which they are not supported.

When extended indicator variables are enabled, if the value of an extended indicator variable is greater than or equal to zero, the data type of the input host variable must be compatible with the data type of the target column. If the value of an extended indicator variable is less than zero, DB2 does not test for data type compatibility between the input host variable and the target column.

Java variable references

The general form of a host variable reference in Java is:

Each Java-identifier must be declared in the source program. The variable designated by the second Java-identifier is called an indicator variable and must be a short.

In Java, indicator variables are not always needed. Instead, instances of a Java class can be set to a null value. Variables defined as Java primitive types can not be set to a null value. When using an extended indicator variable, or when using a Java primitive type in assigning a null value or where the Java primitive type might be assigned null on output, indicator variables must be used.

If IN, OUT, or INOUT is not specified, the default depends on the context in which the variable is used. If the Java variable is used in an INTO clause, OUT is the default. Otherwise, IN is the default.

An SQL statement that refers to host variables must be within the scope of the declaration of those host variables. For host variables referred to in the SELECT statement of a cursor, the OPEN statement, and the DECLARE CURSOR statement have to be in the same scope.

All references to host variables must be preceded by a colon. If an SQL statement references a host variable without a preceding colon, the precompiler issues an error for the missing colon or interprets the host variable as an unqualified column name, which might lead to unintended results. The interpretation of a host variable without a colon as a column name occurs when the host variable is referenced in a context in which a column name can also be referenced.

Variables in dynamic SQL

In dynamic SQL statements, parameter markers are used instead of variables.

A *parameter marker* is a question mark (?) that represents a position in a dynamic SQL statement where the application will provide a value; that is, where a variable would be found if the statement string were a static SQL statement. The following examples show a static SQL statement that uses variables and a dynamic statement that uses parameter markers:

```
INSERT INTO DEPT VALUES (:HV_DEPTNO, :HV_DEPTNAME, :HV_MGRNO, :HV_ADMRDEPT)
INSERT INTO DEPT VALUES (?, ?, ?, ?)
```

For more information on parameter markers, see Parameter markers under the PREPARE statement.

LOB variables

Regular LOB variables (CLOB, DBCLOB, and BLOB), LOB locator variables and LOB file reference variables can be defined in all host languages with a few exceptions.

- Java supports file reference variables, but not locators for LOBs.

Where LOBs are allowed, the term meta-variable *variable* in a syntax diagram can refer to a regular variable, a locator variable, or a file reference variable. Because these variables are not native data types in host programming languages, SQL extensions are used, and the precompilers generate the host language constructs that are necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire LOB value and the performance benefit of delaying the transfer of data from the server is not required, a LOB locator or LOB file reference is not needed. However, it is often not acceptable to store an entire LOB value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire LOB value at one time is not acceptable, you can use one of the following alternatives:

- Referencing the LOB value using a LOB locator, and accessing portions of the value
- Storing the entire LOB value in a file, and using a LOB file reference to access the data

LOB locator variables

A LOB locator variable is a host variable that contains the locator representing a LOB value on the database server.

See “Manipulating LOBs using locators” on page 97 for information about how locators can be used to manipulate LOB values.

A locator variable in an SQL statement must identify a LOB locator variable described in the program according to the rules for declaring locator variables. This is always indirectly through an SQL statement. For example, in C:

```
static volatile SQL TYPE IS CLOB_LOCATOR *loc1;
```

The term *locator-variable*, as used in the syntax diagrams, shows a reference to a LOB locator variable. The meta-variable *locator-variable* can be expanded to include a *host-identifier* the same as that for *host-variable*.

Like all other host variables, a LOB locator variable can have an associated indicator variable. Indicator variables for LOB locator variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the locator host variable is unchanged. This means a locator can never represent a null value. However, when the indicator variable associated with a LOB locator is null, the value of the referenced LOB value is null.

If a locator variable does not currently represent any value, an error occurs when the locator variable is referenced.

When a transaction commits, LOB locators that were acquired by the transaction are released unless a HOLD LOCATOR statement was issued for the LOB locator. When the transaction ends, all LOB locators are released.

It is the application programmer's responsibility to guarantee that any LOB locator is used only in SQL statements that are executed at the same server that originally generated the LOB locator. For example, assume that a LOB locator is returned from one server and assigned to a LOB locator variable. If that LOB locator variable is subsequently used in an SQL statement that is executed at a different server unpredictable results will occur.

XML variables

An XML variable can be defined as a string or file reference variable. Regular XML variables and XML file reference variables can be defined in all host languages with a few exceptions.

- REXX supports file reference variables for XML.
- Java supports XML and file reference variables for XML.

XML variables can be declared as the following variable types:

Where XML variables are allowed, the meta-variable *variable* in a syntax diagram can refer to a regular variable or a file reference variable. Because these variables are not native data types in host programming languages, SQL extensions are used, and the precompilers generate the host language constructs that are necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire XML value and the performance benefit of delaying the transfer of data from the server is not required, an XML file reference is not needed. However, it is often not acceptable to store an entire XML value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire XML value at one time is not acceptable, portions of the value can be accessed, or the entire value can be stored in a file. When the entire value is stored in a file, an XML file reference can be used to access the data.

XML host variables can be declared as the following variable types:

- XML AS CLOB(*n*)
Declares a CLOB variable that contains XML data that is encoded in the CCSID for the variable.
- XML AS DBCLOB(*n*)
Declares a DBCLOB variable that contains XML data that is encoded in the graphic CCSID for the variable.
- XML AS BLOB(*n*)
Declares a BLOB variable that contains XML data that is encoded as specified within the data according to the XML 1.0 specification for determining encoding.
- XML AS CLOB_FILE
Declares a CLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.
- XML AS DBCLOB_FILE
Declares a DBCLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.
- XML AS BLOB_FILE
Declares a BLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

See “LOB or XML file reference variables” for additional information about file reference variables.

Although the application XML variable declaration includes a LOB type specification, the variable declarations all are considered to be the XML data type, not the LOB type that is used in the application declaration. The application might also use non-XML variables in place of XML variables. For example, when a prepared statement is executed, the application might use a character variable to replace an XML parameter marker in the statement.

Although the XML data type is incompatible with all other data types, both XML and non-XML data types can be used for input to and output from XML data. Applications can use either XML variables, character variables, or binary string variables for input and output in SQL statements for XML data.

The following table summarizes the conversions built-in data types (including XML) to and from the supported variable data types within embedded applications. The built-in data types are specified in the rows. A Y indicates that the built-in data type can be assigned to or assigned from the variable type.

Table 44. Application variable compatibility with the built-in data types for applications that contain embedded SQL

| built-in data type | application variable data type | | | | | |
|--------------------|--------------------------------|--|------------------------------------|-------------------------------|-----------------------------------|-------------------------------|
| | CHAR, VARCHAR, CLOB, CLOB_FILE | GRAPHIC, VARGRAPHIC, DBCLOB, DBCLOB_FILE | BINARY, VARBINARY, BLOB, BLOB_FILE | XML AS CLOB, XML AS CLOB_FILE | XML AS DBCLOB, XML AS DBCLOB_FILE | XML AS BLOB, XML AS BLOB_FILE |
| CHAR | Y | Y | | | | |
| VARCHAR | Y | Y | | | | |
| CLOB | Y | Y | | | | |
| GRAPHIC | Y | Y | | | | |
| VARGRAPHIC | Y | Y | | | | |
| DBCLOB | Y | Y | | | | |
| BINARY | | | Y | | | |
| VARBINARY | | | Y | | | |
| BLOB | | | Y | | | |
| XML | Y | Y | Y | Y | Y | Y |

LOB or XML file reference variables

File reference variables are used for direct file input and output for LOB and XML values (when the XML value is declared using XML AS *variable-type*), and can be defined in all host languages.

Because these are not native data types, SQL extensions are used and the DB2 precompiler or coprocessor generates the host language constructs necessary to represent each variable. In the case of REXX, LOB values are mapped to strings. See “XML variables” on page 213 for more information about XML host variables.

A file reference variable represents (rather than contains) the file, just as a LOB locator represents, rather than contains, the LOB data. Database queries, updates, and inserts can use file reference variables to store or to retrieve single column values.

As with all other host variables, file reference variables can have an associated indicator variable. Indicator variables for file reference variables behave in the same way as indicator variables for other data types. When a null value is returned from the database manager, the indicator variable is set, and the variable is unchanged. When the indicator variable that is associated with a file reference variable is null, the value of the referenced LOB or XML object is null. This means that a file reference variable can never point to a null value.

The length attribute of a file reference variable is assumed to be the maximum length of a LOB or XML object.

A file reference variable has the following properties:

Data type

BLOB, CLOB, or DBCLOB. This property is specified when the variable is declared using BLOB_FILE, CLOB_FILE, or DBCLOB_FILE.

Direction

This must be specified by the application program at run time (it is implicitly specified as part of the File options value). The direction can be either of the following:

Input Input is used as a source of data on an EXECUTE statement, an OPEN statement, an update operation, an insert operation, or a delete operation.

Output

Output is used as the target of data. For example, on a FETCH statement or a SELECT INTO statement.

File name

This must be specified by the application program at run time. It must be the complete path name of the file. Within an application, a file should only be referenced one time in a file reference variable.

File name length

This must be specified by the application program at run time. It is the length of the file name in bytes.

Data length

Sets the data length to the length of the new data that is written to the file. The length is in bytes. Data length is unused on input.

File options

Options are set by an INTEGER value in a field in the file reference variable structure. One of the following values must be specified in an application for each file reference variable before that file reference variable can be used in the application:

SQL_FILE_READ

This is a regular file that can be opened, read and closed. (The option is SQL-FILE-READ in COBOL, sql_file_read in FORTRAN, and READ in REXX.) SQL_FILE_READ is an input (from client to server) file option.

SQL_FILE_CREATE

Create a new file. If the file already exists, an error is returned. (The option is SQL-FILE-CREATE in COBOL, sql_file_create in FORTRAN, and CREATE in REXX.) SQL_FILE_CREATE is an output (from server to client) file option.

SQL_FILE_OVERWRITE

If an existing file with the specified name exists, it is overwritten; otherwise a new file is created. (The option is SQL-FILE-OVERWRITE in COBOL, `sql_file_overwrite` in FORTRAN, and OVERWRITE in REXX.). SQL_FILE_OVERWRITE is an output (from server to client) file option.

SQL_FILE_APPEND

If an existing file with the specified name exists, the output is appended to it; otherwise a new file is created. (The option is SQL-FILE-APPEND in COBOL, `sql_file_append` in FORTRAN, and APPEND in REXX.) SQL_FILE_APPEND is an output (from server to client) file option.

The encoding scheme CCSID of the file name is based on the encoding scheme of the application. The CCSID of the LOB or XML data (the contents of the file) can be set by the application by using a DECLARE *host-variable* CCSID statement if the CCSID of the LOB or XML data is different from the CCSID of the application. DB2 performs any character conversion that is required prior to insertion of the LOB or XML data into a table or writing of the LOB or XML data to a file.

Result set locator variables

A *result set locator variable* is a variable that contains the locator that identifies a stored procedure result set. A result set locator variable in an SQL statement must identify a result set locator variable described in the program according to the rules for declaring result set locator variables. This is always indirectly through an SQL statement.

For example, in C:

```
static volatile SQL TYPE IS RESULT_SET_LOCATOR VARYING *1oc1;
```

A result set locator variable in an SQL procedure is defined with the RESULT_SET_LOCATOR VARYING clause in a compound statement.

The meta-variable *rs-locator-variable*, as used in the syntax diagrams, shows a reference to a result set locator variable. A host variable that is a result set locator variable can have an association indicator variable. When the indicator variable that is associated with a result set locator is null, the referenced result set is not defined.

If a result set locator variable does not currently represent any stored procedure result set, an error occurs when the locator variable is referenced.

A commit operation destroys all open cursors that were declared in the stored procedure without the WITH HOLD option and the result set locators that are associated with those cursors. Otherwise, a cursor and its associated result set locator persist past the commit.

An application that is written in a programming language other than Java can access a result set that is returned from a stored procedure. A result set locator is used by the invoking application to access the result set. A result set locator value for a result set can be obtained from an ASSOCIATE LOCATOR statement or with the DESCRIBE PROCEDURE statement. For more information, see “ASSOCIATE LOCATORS” on page 1426 and “DESCRIBE PROCEDURE” on page 1912.

The result set locator value is specified on an `ALLOCATE CURSOR` statement to define a cursor in the invoking application and to associate it with a stored procedure result set. For more information, see “`ALLOCATE CURSOR`” on page 1159.

A `DESCRIBE CURSOR` statement can be used in the invoking application to obtain information on the characteristics of the columns of a stored procedure result set. For more information, see “`DESCRIBE CURSOR`” on page 1900.

The application can then access the rows of the result set using `FETCH` statements with the allocated cursor.

Host structures in PL/I, C, and COBOL

A *host structure* is a PL/I structure, C structure, or COBOL group that is referred to in an SQL statement.

Host structures are defined by statements of the host language, as explained in Overview of programming applications that access DB2 for z/OS data (DB2 Application programming and SQL). As used here, the term *host structure* does not include an `SQLCA` or `SQLDA`.

In Java and REXX, there is no equivalent to a host structure.

The form of a host structure reference is identical to the form of a host variable reference. The reference `:S1:S2` is a host structure reference if `S1` names a host structure. If `S1` designates a host structure, `S2` must be a small integer variable or an array of small integer variables. `S1` is the host structure and `S2` is its indicator array.

A host structure can be referred to in any context where a list of host variables can be referenced. A host structure reference is equivalent to a reference to each of the host variables contained within the structure in the order which they are defined in the host language structure declaration. The n th variable of the indicator array is the indicator variable for the n th variable of the host structure.

In PL/I, for example, if `V1`, `V2`, and `V3` are declared as the variables within the structure `S1`, the following two statements are equivalent:

```
EXEC SQL FETCH CURSOR1 INTO :S1;  
EXEC SQL FETCH CURSOR1 INTO :V1, :V2, :V3;
```

If the host structure has m more variables than the indicator array, the last m variables of the host structure do not have indicator variables. If the host structure has m fewer variables than the indicator array, the last m variables of the indicator array are ignored. These rules also apply if a reference to a host structure includes an indicator variable or a reference to a host variable includes an indicator array. If an indicator array or variable is not specified, no variable of the host structure has an indicator variable.

In addition to structure references, individual host variables or indicator variables in PL/I, C, and COBOL can be referred to by qualified names. The qualified form is a host identifier followed by a period and another host identifier. The first host identifier must name a structure, and the second host identifier must name a host variable at the next level within that structure.

In PL/I, C, and COBOL, the syntax of *host-variable* is:

In general, a *host-variable* in an expression must identify a host variable (not a structure) described in the program according to the rules for declaring host variables. However, there are a few SQL statements that allow a host variable in an expression to identify a structure, as specifically noted in the descriptions of the statements.

The following examples show references to host variables and host structures:

:V1 :S1.V1 :S1.V1:V2 :S1.V2:S2.V4

Host-variable arrays in PL/I, C, C++, and COBOL

A *host-variable array* is an array in which each element of the array contains a value for the same column. The first element in the array corresponds to the first value, the second element in the array corresponds to the second value, and so on.

Host-variable arrays can be referenced only in certain contexts: in a FETCH statement for a multiple-row fetch, in an INSERT statement for a multiple-row insert, or in a multiple-row MERGE statement. A host-variable array is designated in syntax diagrams as *host-variable-array*.

Host-variable arrays are defined by statements of the host language as explained in *DB2 Application Programming and SQL Guide*.

The form of a host-variable array reference is similar to the form of a host variable reference. The reference :COL1:COL1IND is a host-variable array reference if COL1 designates an array. If COL1 designates an array, COL1IND must be a one dimensional array of small integer host variables. The dimension of the host-variable array must be less than or equal to the dimension of the indicator array. If an indicator array is not specified, no variable of the main host-variable array has an indicator variable.

In PL/I, C, C++, and COBOL, the syntax of *host-variable-array* is:

In the following example, *COL1* is the main host-variable array and *COL1IND* is its indicator array. If *COL1* has 10 elements for fetching a single column of data for multiple rows of data, *COL1IND* must also have 10 entries.

```
EXEC SQL FETCH CURSOR FOR 5 ROWS INTO :COL1 :COL1IND;
```

Functions

A *function* is an operation denoted by a function name followed by zero or more operands that are enclosed in parentheses.

It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*. For example, a function can be passed with two input arguments that have date and time data types and return a value with a timestamp data type as the result.

Types of functions

There are several ways to classify functions. One way to classify functions is as built-in functions, user-defined functions, or cast functions that are generated for distinct types.

Built-in functions

Built-in functions are functions that come with DB2 for z/OS. These functions provide a single-value result.

Built-in functions include operator functions such as "+", aggregate functions such as AVG, and scalar functions such as SUBSTR. For a list of the built-in aggregate and scalar functions and information on these functions, see Chapter 4, "Built-in functions," on page 321.

The built-in functions are in schema SYSIBM.

The RANK, DENSE_RANK, and ROW_NUMBER specifications are sometimes referred to as built-in functions. Refer to "OLAP specification" on page 265 for more information on these specifications.

User-defined functions

User-defined functions are functions that are created using the CREATE FUNCTION statement and registered to the DB2 in the catalog. These functions allow users to extend the function of DB2 by adding their own or third party vendor function definitions.

A user-defined function is an SQL, external, or sourced function. An SQL function is defined to the database using only SQL statements. An external function is defined to the database with a reference to an external program that is executed when the function is invoked. A sourced function is defined to the database with a reference to a built-in function or another user-defined function. Sourced functions can be used to extend built-in aggregate and scalar functions for use on distinct types.

A user-defined function resides in the schema in which it was registered. The schema cannot be SYSIBM.

To help you define and implement user-defined functions, sample user-defined functions are supplied with DB2. You can also use these sample user-defined

functions in your application program just as you would any other user-defined function if the appropriate installation job has been run.

Related concepts:

“Sample user-defined functions” on page 2848

Related tasks:

 Defining a user-defined function (DB2 Application programming and SQL)

Generated user-defined functions for distinct types

Generated user-defined functions for distinct types (also called *cast functions*) are functions that DB2 automatically generates when a distinct type is created using the CREATE TYPE statement.

Cast functions support casting from the distinct type to the source type and from the source type to the distinct type. The ability to cast between the data types is important because a distinct type is compatible only with itself.

The generated cast functions reside in the same schema as the distinct type for which they were created. The schema cannot be SYSIBM.

Related reference:

“CREATE TYPE (distinct)” on page 1830

Additional way to classify functions

Another way to classify functions is as aggregate, scalar, or table functions, depending on the input data values and result values.

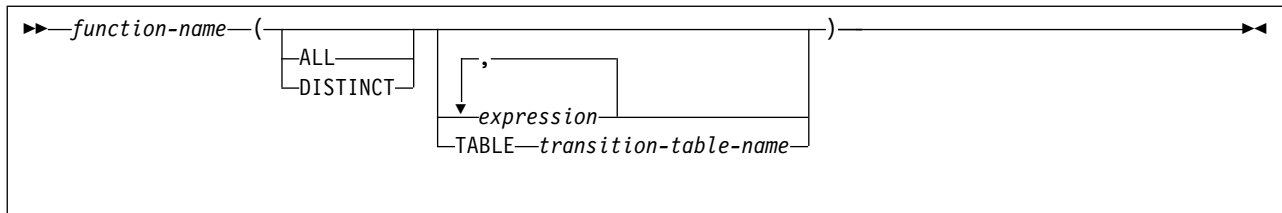

- An *aggregate function* receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Aggregate functions are sometimes called *column functions*. Built-in functions and user-defined sourced functions can be aggregate functions. Aggregate functions cannot be external user-defined function or SQL functions.
- A *scalar function* receives a single value for each argument and returns a single-value result. Built-in functions and user-defined functions, external, sourced, and SQL, can be scalar functions. The functions that are created for distinct types are also scalar functions.
- A *table function* returns a table for the set of arguments it receives. Each argument is a single value. A table function can only be referenced in the FROM clause of a subselect. A table function can be defined as an external or SQL function, but a table function cannot be a sourced function.

Table functions can be used to apply SQL language processing power to data that is not stored in the database or to allow access to such data as if it were stored in a table. For example, a table function can read a file or get data from the web and return a result table.

For a list of the aggregate, scalar, and table functions and information on these functions, see Chapter 4, “Built-in functions,” on page 321.

Function invocation

Each reference to a scalar or aggregate function (either built-in or user-defined) conforms to the following syntax:

In the above syntax, *expression* cannot include an aggregate function. See “Expressions” on page 228 for other rules for *expression*.

The **ALL** or **DISTINCT** keyword can only be specified for an aggregate function or a user-defined function that is sourced on an aggregate function.

When a function is invoked within a trigger body, the **TABLE** keyword can be specified to indicate that an argument is a trigger transition table. In this case, the corresponding parameter of the function must have been defined with the **TABLE LIKE** clause.

Table functions can be referenced only in the FROM clause of a subselect. For more information on referencing a table function, see the description of the “from-clause” on page 1091.

When the function is invoked, the value of each of its parameters is assigned using storage assignment, to the corresponding parameter of the function. Control is passed to external functions according to the calling conventions of the host language. When execution of a user-defined aggregate or scalar function is complete, the result of the function is assigned, using storage assignment, to the result data type. For information about assignment rules, see “Assignment and comparison” on page 119.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter defined as character FOR BIT DATA.

For compatibility with other SQL implementations, **UNIQUE** can be specified as a synonym for **DISTINCT** in aggregate functions.

Function resolution

After a function is invoked, DB2 must determine which function to execute. This process is called *function resolution* and it applies to both built-in and user-defined function.

A function is invoked by its function name, which is implicitly or explicitly qualified with a schema name, followed by parentheses that enclose the arguments to the function. Within the database, each function is uniquely identified by its *function signature*, which is its schema name, function name, the number of parameters, and the data types of the parameters. Thus, a schema can contain several functions that have the same name but each of which have a different number of parameters or parameters with different data types. Also, a function with the same name, number of parameters, and types of parameters can exist in multiple schemas.

Function resolution has two steps:

1. DB2 determines the set of candidate functions based on the qualification of the name of the invoked function, the unqualified name of the invoked function, and the number of arguments that are specified.
2. DB2 determines the best fit from the set of candidate functions based on the data types of the arguments of the invoked function as compared with the data types of the parameters of the functions in the set of candidate functions.

Function resolution is similar for functions that are invoked with a qualified or unqualified function name with the exception that for an unqualified name, DB2 needs to search more than one schema.

To improve performance of function resolution and to prevent potential issues as new functions are added, consider invoking user-defined functions by using a fully qualified name, including the schema name.

For a function invocation that passes a transition table, the data type, length, precision, and scale of each column in the transition table must exactly match the data type, length, precision, and scale of each column of the table that is named in the function definition.

The timestamp for the creation of a user-defined function must be older than the timestamp that results from an explicit bind for the plan or package that contains the function invocation. During autobind, built-in functions that are introduced in a DB2 release that is later than the DB2 release that is used to explicitly bind the package or plan are not considered for function resolution.

In a CREATE VIEW statement, function resolution occurs at the time the view is created. If another function with the same name is subsequently created, the view is not affected, even if the new function is a better fit than the one that was chosen at the time the view was created.

Qualified function resolution: When a function is invoked with a schema name and a function name, DB2 only searches the specified schema to resolve which function to execute.

DB2 selects candidate functions based on the following criteria:

- The name of the function instance must match the name in the function invocation.
- The number of input parameters in the function instance must match the number of arguments in the function invocation.
- The authorization ID of the statement must have the EXECUTE privilege to the function instance.

If no function meets these criteria, an error is returned. If one or more candidate functions are found in the schema, this set of candidate functions is processed for best fit.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

Unqualified function resolution: When a function is invoked without a qualifier, DB2 searches the list of schemas in the SQL path to resolve which function instance to execute. For each schema in the SQL path, DB2 searches the schema for candidate functions based on the following criteria:

- The name of the function instance must match the name in the function invocation.
- The number of input parameters in the function instance must match the number of function arguments in the function invocation.
- The authorization ID of the statement must have the EXECUTE privilege on the function instance.

If DB2 does not find any candidate functions, an error is returned.

If no function meets these criteria, an error is returned. If one or more candidate functions are found in the schema, this set of candidate functions is processed for best fit.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

Determining the best fit

More than one function with the same name might exist that is a candidate for execution. In that case, DB2 determines which function is the best fit for the invocation by comparing the data types of the parameters of each function in the set of candidate functions to determine which function satisfies the best fit requirements.

DB2 determines the function, or set of functions, that meet the best fit requirements for the invocation by comparing the argument and parameter data types. The data type of the result of the function or the type of function (aggregate, scalar, or table) under consideration does not enter into the determination of best fit.

When determining whether the data types of the parameters are the same as the arguments:

- Synonyms of data types match. For example, DOUBLE and FLOAT are considered to be the same.
- Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
- The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.
- For this argument, if one function has a data type that fits the function invocation better than the data types in the other functions, that function is the best fit. The precedence list for the promotion of data types in shows the data types that fit each data type, in best-to-worst order.
- If the data types of the first parameter for all the candidate functions fit the function invocation equally well, DB2 repeats this process for the next argument of the function invocation. DB2 continues this process for each argument until a best fit is found.

A subset of the candidate functions is obtained by considering only those functions for which the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance. The precedence list for the promotion of data types in Table 14 on page 108 shows the data types that fit (considering promotion) for each data type in

best-to-worst order. If this subset is not empty, the best fit is determined using the promotable process on this subset of candidate functions. If this subset is empty, and the original set of candidate functions consisted of a single function, the best fit is determined using the castable process on the original candidate function. Otherwise, an error is returned.

Promotable process:

The *promotable process* determines the best fit for function resolution by considering only whether input arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition.

For the subset of candidate functions, DB2 compares the parameter lists from left to right, using the following process:

- The data type of the argument in the function invocation is compared to the data type of the corresponding parameter in the definition of each candidate function. (synonyms of data types match and attributes of data type are ignored).
 - Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
 - The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.
- For this argument, if one candidate function has a data type that fits the function invocation better than the data types in the other candidate functions, that function is the best fit. The precedence list for the promotion of data types in Table 14 on page 108 shows the data types that fit each data type, in best-to-worst order.
- If the data types of the first parameter for more than one candidate functions fits the function invocation equally well, DB2 repeats this process for the next argument of the function invocation. DB2 continues this process for each argument until a best fit is found.

If only one candidate function remains after comparing all the arguments, that function is the best fit. If more than one candidate function remains, all the remaining candidate functions are considered to be equally the best fit. In this case, DB2 selects the function whose schema is first in the SQL path.

If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned.

Function resolution and input argument casting:

In considering the best fit of a candidate function, DB2 determines if the input arguments can be implicitly cast to the data type of the corresponding parameter for function resolution.

The *castable process* determines the best fit of a function, first considering if the input arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition, and then if the input arguments can be implicitly cast to the data type of the corresponding

parameter for function resolution. For the set of candidate functions, DB2 compares the parameter lists from left to right, using the following process:

- The data type of the argument in the function invocation is compared to the data type of the corresponding parameter in the definition of the candidate function to ensure that each argument can be promoted or cast to the corresponding parameter. If not, an error is returned.

If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned.

Implicit casting for function resolution: Implicit casting for function resolution is not supported for arguments with a user-defined type, binary, ROWID, or XML data type. It is also not supported for built-in or user-defined cast functions. Implicit casting is supported for the following cases:

- A numeric data type can be cast to a value of another numeric data type that is not in the data type promotion list for the source data type. This includes casting a numeric value to a numeric data type that is lower in the promotion list.
- A numeric data type can be cast to a character or graphic string data type, except for a LOB.
- A character or graphic string data type, except for a LOB, can be cast to a numeric data type.
- A character or graphic string data type, except for a LOB, can be cast to a date, time, or timestamp data type.
- A varying length character string data type, except for a LOB, can be cast to a fixed length character data type.

Best-fit consideration:

After determining the function that is the best fit, use of the function still might not be permitted. Each function is defined to return a result with a specific data type. If this result data type is not compatible with the context in which the function is invoked, an error occurs.

For example, assume functions named STEP are defined with different data types:

```
STEP(SMALLINT) returns CHAR(5)
STEP(DOUBLE) returns INTEGER
```

Assume also that the function is invoked with the following function reference (where S is a SMALLINT column):

```
SELECT ... 3+STEP(S) ...
```

Because there is an exact match on argument type, the first STEP is chosen. An error occurs on the statement because the result type is CHAR(5) instead of a numeric type as required for an argument of the addition operator.

In cases where the arguments of the function invocation are not an exact match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution using the same rules as assignment to columns. See “Assignment and comparison” on page 119. Problems with conversions can also occur when precision, scale, length, or the encoding scheme differs between the argument and the parameter. Conversion might occur for a character string argument when the corresponding parameter of the function

has a different encoding scheme or CCSID. For example, an error occurs on function invocation when mixed data that actually contains DBCS characters is specified as an argument and the corresponding parameter of the function is declared with an SBCS subtype.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

An error also occurs in the following examples:

- The function is referenced in a FROM clause, but the function selected by the function resolution step is a scalar or aggregate function.
- The function calls for a scalar or aggregate function, but the function selected by the resolution step is a table function.

SQL path considerations for built-in functions

Function resolution applies to all functions, including built-in functions and other functions provided by DB2. If a function is invoked without its schema name, the SQL path is searched.

With the exception of the DB2 MQSeries[®] functions, the built-in functions are in schemas SYSIBM or SYSIBMADM.

Additional functions are available in other schemas, but are not considered as built-in functions because they are developed as user-defined functions that have no special processing considerations. User-defined functions cannot be defined in the SYSIBM schema (or any schema where the name begins with "SYS").

If SYSIBM is not first in the path, it is possible that DB2 will select another function instead of the intended built-in function. If schema "SYSIBM", "SYSFUN", "SYSPROC" is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path. DB2 adds implicitly assumed schemas in the order of "SYSIBM", "SYSFUN", "SYSPROC".

"SQL path" on page 65

Version resolution

Normally, the currently active version of an SQL function is used for invocation of the function.

However, if the invocation is a recursive invocation that occurs inside the body of the same function, and the currently active version has changed since the original invocation, the active version is not used. The version that is used in the original invocation is used for any recursive invocation until the entire function completes. This preserves the semantics of the version that is used by the original invocation.

The version used in the original invocation is also used when the recursive invocation is indirect. For example, assume that function FN1 invokes function FN2, which in turn invokes FN1 (indirect, recursive invocation). The invocation of function FN1 in function FN2 uses the version of FN1 that is active at the time of the original invocation of function FN1.

Since the currently active version is used at the next invocation (except in recursive invocations), it is possible that two or more versions of the same function can be

run by a given thread. For example, an invocation of function FN1 in an application causes the currently active version of FN1 to load and execute. During or after execution of the original invocation of FN1, an ALTER FUNCTION statement that specifies ACTIVE VERSION FN1_V2 is run and changes the active version of the function FN1 to version FN1_V2. Subsequent invocations of function FN1 from the same thread will load and execute the currently active version of the function, FN1_V2.

Examples of function resolution

The following examples illustrate function resolution.

Example 1: Assume that MYSCHEMA contains two functions, both named FUNA, that were registered with these partial CREATE FUNCTION statements.

1. CREATE FUNCTION MYSCHEMA.FUNA (VARCHAR(10), INT, DOUBLE) ...
2. CREATE FUNCTION MYSCHEMA.FUNA (VARCHAR(10), REAL, DOUBLE) ...

Also assume that a function with three arguments of data types VARCHAR(10), SMALLINT, and DECIMAL is invoked with a qualified name:

```
MYSCHEMA.FUNA(VARCHARCOL, SMALLINTCOL, DECIMALCOL)
```

Both MYSCHEMA.FUNA functions are candidates for this function invocation because they meet the criteria specified in “Function resolution” on page 221. The data types of the first parameter for the two function instances in the schema, which are both VARCHAR, fit the data type of the first argument of the function invocation, which is VARCHAR, equally well. However, for the second parameter, the data type of the first function (INT) fits the data type of the second argument (SMALLINT) better than the data type of second function (REAL). Therefore, DB2 selects the first MYSCHEMA.FUNA function as the function instance to execute.

Example 2: Assume that these functions were registered with these partial CREATE FUNCTION statements:

1. CREATE FUNCTION SMITH.ADDIT (CHAR(5), INT, DOUBLE) ...
2. CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE) ...
3. CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE, INT) ...
4. CREATE FUNCTION JOHNSON.ADDIT (INT, DOUBLE, DOUBLE) ...
5. CREATE FUNCTION JOHNSON.ADDIT (INT, INT, DOUBLE) ...
6. CREATE FUNCTION TODD.ADDIT (REAL) ...
7. CREATE FUNCTION TAYLOR.SUBIT (INT, INT, DECIMAL) ...

Also assume that the SQL path at the time an application invokes a function is "TAYLOR" "JOHNSON", "SMITH". The function is invoked with three data types (INT, INT, DECIMAL) as follows:

```
SELECT ... ADDIT(INTCOL1, INTCOL2, DECIMALCOL) ...
```

Function 5 is chosen as the function instance to execute based on the following evaluation:

- Function 6 is eliminated as a candidate because schema TODD is not in the SQL path.
- Function 7 in schema TAYLOR is eliminated as a candidate because it does not have the correct function name.
- Function 1 in schema SMITH is eliminated as a candidate because the INT data type is not promotable to the CHAR data type of the first parameter of Function 1.
- Function 3 in schema SMITH is eliminated as a candidate because it has the wrong number of parameters.

- Function 2 is a candidate because the data types of its parameters match or are promotable to the data types of the arguments.
- Both Function 4 and 5 in schema JOHNSON are candidates because the data types of their parameters match or are promotable to the data types of the arguments. However, Function 5 is chosen as the better candidate because although the data types of the first parameter of both functions (INT) match the first argument (INT), the data type of the second parameter of Function 5 (INT) is a better match of the second argument (INT) than Function 4 (DOUBLE).
- Of the remaining candidates, Function 2 and 5, DB2 selects Function 5 because schema JOHNSON comes before schema SMITH in the SQL path.

Expressions

An *expression* specifies a value and can take a number of different forms.

Authorization: The use of some of the expressions, such as a *scalar-fullselect*, *sequence-reference*, or *function-invocation*, requires having the appropriate authorization. For these objects, the privilege set that is defined below must include the following authorization:

- *cast-specification*. The authorization to reference a user-defined type in a cast specification. For information about authorization considerations, see “CAST specification” on page 254.
- *function-invocation*. Authorization to execute the function. For information about how the particular function is chosen and authorization considerations, see “Function resolution” on page 221.
- *scalar-fullselect*. For information about authorization considerations, see “Authorization” on page 1080.
- *sequence-reference*. The USAGE privilege on the specified sequence, ownership of the sequence, DATAACCESS authority, or SYSADM authority. For example, with a sequence reference, USAGE authorization on the sequence is required.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

The form of an expression is as follows:

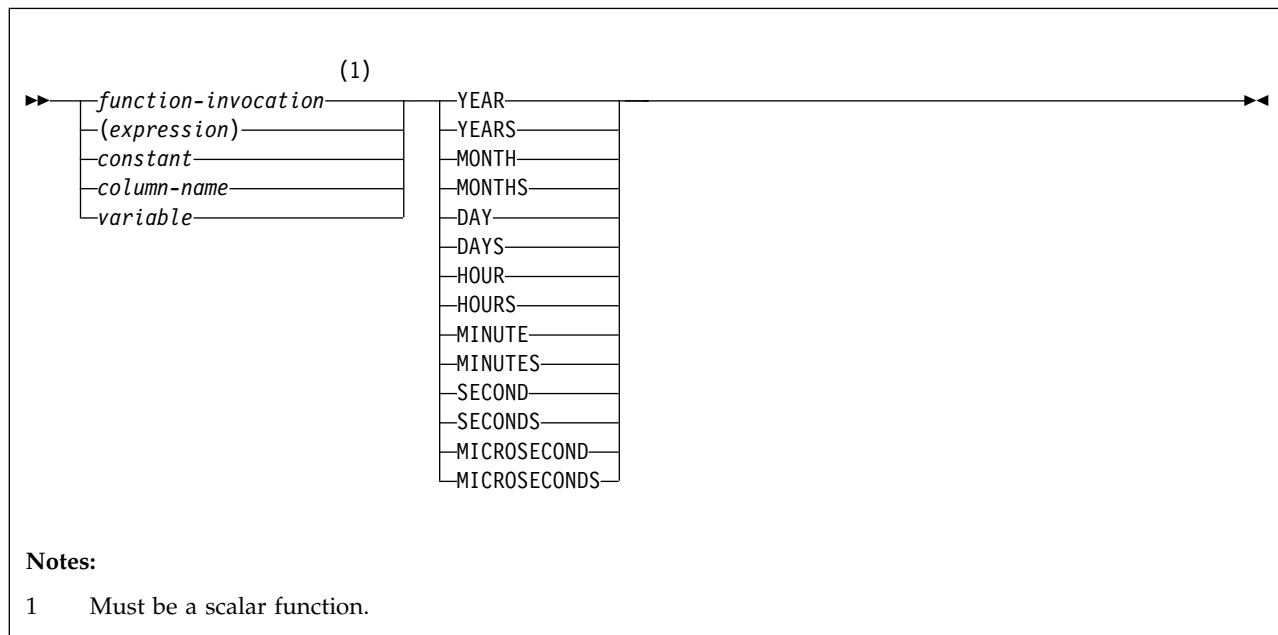

Notes:

- 1 Must be a scalar function. See “Functions” on page 219 for more information.
- 2 See “Scalar-fullselect” on page 240 for more information.
- 3 See Labeled durations for more information.
- 4 See “CASE expressions” on page 250 for more information.
- 5 See “CAST specification” on page 254 for more information.
- 6 See “XMLCAST specification” on page 263 for more information.
- 7 See “OLAP specification” on page 265
- 8 See “ROW CHANGE expression” on page 272
- 9 See “Sequence reference” on page 274

operator:

labeled-duration:

Expressions without operators

If no operators are used, the result of the expression is the specified value.

Examples:

SALARY :SALARY 'SALARY' MAX(SALARY)

Expressions with arithmetic operators

If arithmetic operators are used, the result of the expression is a number derived from the application of the operators to the values of the operands.

The result of the expression can be null. If any operand has the null value, the result of the expression is the null value. Arithmetic operators (except unary plus, which is meaningless) must not be applied to strings. For example, USER+2 is invalid. Multiplication and division operators must not be applied to datetime values, which can only be added and subtracted.

The prefix operator + (*unary plus*) does not change its operand. The prefix operator - (*unary minus*) reverses the sign of a nonzero operand. If the data type of *A* is *small integer*, the data type of *-A* is *large integer*. The first character of the token following a prefix operator must not be a plus or minus sign.

The *infix operators* +, -, *, and / specify addition, subtraction, multiplication, and division, respectively. The value of the second operand of division must not be zero.

Arithmetic with two integer operands

If both operands of an arithmetic operator are integers, the operation is performed in binary. The result is a large integer unless either (or both) operand is a big integer, in which case the result is a big integer.

The result of an integer arithmetic operation (including unary minus) must be within the range of the result type.

Arithmetic with an integer and a decimal operand

If one operand is an integer and the other operand is decimal, the operation is performed in decimal. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal number.

The temporary copy of the integer that has been converted to a decimal number has a precision p and scale 0. p is 19 for a big integer, 11 for a large integer, and 5 for a small integer. In the case of an integer constant, p depends on the number of digits in the integer constant. p is 5 for an integer constant consisting of 5 digits or fewer. Otherwise, p is the same as the number of digits in the integer constant.

Arithmetic with an integer and a decimal floating-point operand

If one operand is a small integer, large integer, or big integer and the other is a decimal floating-point number, the operation is performed in decimal floating point. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal floating-point number.

For small integer or large integer, the temporary copy of the integer is converted to DECFLOAT(16). For big integer, the temporary copy of the big integer is converted to DECFLOAT(34). The rules for two decimal floating point operands are then applied.

Arithmetic with two decimal operands

If both operands are decimal, the operation is performed in decimal.

The result of any decimal arithmetic operation is a decimal number with a precision and scale that depend on two factors:

The precision and scale of the operands

In the discussion of operations with two decimal operands, the precision and scale of the first operand are denoted by p and s , that of the second operand by p' and s' . Thus, for a division, the dividend has precision p and scale s , and the divisor has precision p' and scale s' .

Whether DEC31 or DEC15 is in effect for the operation

DEC31 and DEC15 specify the rules to be used when both operands in a decimal operation have precisions of 15 or less. DEC15 specifies the rules which do not allow a precision greater than 15 digits, and DEC31 specifies the rules which allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15.

For static SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4 or the SQL processing option DEC determines whether DEC15 or DEC31 is used.

For dynamic SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4, the SQL processing option DEC, or the special register CURRENT PRECISION determines whether DEC15 or DEC31 is used according to these rules:

- Field DECIMAL ARITHMETIC applies if either of these conditions is true:
 - DYNAMICRULES run behavior applies and the application has not set CURRENT PRECISION.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.

- DYNAMICRULES bind, define, or invoke behavior applies; the value of installation panel field USE FOR DYNAMICRULES is YES; and the application has not set CURRENT PRECISION.
- SQL processing option DEC applies if DYNAMICRULES bind, define, or invoke behavior is in effect, the value of installation panel field USE FOR DYNAMICRULES is NO, and the application has not set CURRENT PRECISION.
- Special register CURRENT PRECISION applies if the application sets the register.

The value of DECIMAL ARITHMETIC is the default value for the SQL processing option and the special register. SQL statements executed using SPUI use the value in DECIMAL ARITHMETIC.

Decimal addition and subtraction:

For decimal operations, the precision and scale of the result depends on the precision and scale of the operands.

If the operation is addition or subtraction and the operands do not have the same scale, the operation is performed with a temporary copy of one of the operands that has been extended with trailing zeros so that its fractional part has the same number of digits as the other operand.

The precision of the result is the minimum of n and the quantity $\text{MAX}(p-s, p'-s')+1$. The scale is $\text{MAX}(s, s')$. n is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise, n is 15.

In COBOL, blanks must precede and follow a minus sign to avoid any ambiguity with COBOL host variable names (which allow the use of a dash).

Decimal multiplication:

For decimal multiplication, the precision and scale of the result depends on the precision and scale of the operands.

For multiplication, the precision of the result is $\text{MIN}(n, p+p')$, and the scale is $\text{MIN}(n, s+s')$. n is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise, n is 15.

If both operands have a precision greater than 15, the operation is performed using a temporary copy of the operand with the smaller precision. If the operands have the same precision, the second operand is selected. If more than 15 significant digits are needed for the integral part of the copy, the statement's execution is ended and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of $\text{MAX}(0, S-(P-15))$, where P and S are the original precision and scale. If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

When both operands have a precision greater than 15, the foregoing formulas for the precision and scale of the result still apply, with one change: for the operand selected as the copy, use the precision and scale of the truncated copy; that is, use 15 as the precision and $\text{MAX}(0, S-(P-15))$ for the scale.

Let n denote the value of the operand with the greater precision or the first operand in the case of operands with the same precision. The number of leading zeros in a 31-digit representation of n must be greater than the precision of the other operand. This is always the case if the precision of the operand is 15 or less. With greater precisions, overflow can occur even if the precision of the result is less than 31. For example, the expression:

100000000000000000000000000000000. * 1

will cause overflow because the number of leading zeros in the 31-digit representation of the large number and the precision of the small number are both 5 (see "Arithmetic with an integer and a decimal operand" on page 231).

Decimal division:

The rules for a specific decimal division depend on whether the DEC31 option is in effect for the operation, whether p is greater than 15, and whether p' is greater than 15

The following table shows how the precision and scale of the result depend on these factors. In that table, the occurrence of "N/A" in a row implies that the indicated factor is not relevant to the case represented by the row.

Table 45. Precision (p) and scale (s) of the result of a decimal division

| DEC31 | p | p' | P | S |
|---------------|-----------|-----------|-----|---|
| Not in effect | ≤ 15 | ≤ 15 | 15 | $15 - (p - s + s')$ |
| In effect | ≤ 15 | ≤ 15 | 31 | $N - (p - s + s')$, where N is $30 - p'$ if p' is odd. N is $29 - p'$ if p' is even. |
| N/A | > 15 | ≤ 15 | 31 | $N - (p - s + s')$, where N is $30 - p'$ if p' is odd. N is $29 - p'$ if p' is even. |
| N/A | N/A | > 15 | 31 | $15 - (p - s + x)$, where x is $\text{MAX}(0, s' - (p' - 15))$ (See the following note) |

Notes on decimal division: If p' is greater than 15, the division is performed using a temporary copy of the divisor. If more than 15 significant digits are needed for the integral part of the divisor, the statement's execution is ended, and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of $\text{MAX}(0, s' - (p' - 15))$, which is the formula for x . If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

Minimum divide result scale

If the calculated value of 's' is negative, an error occurs. If a minimum divide result scale is specified, this error does not occur.

The minimum scale is determined according to the following precedence:

Static SQL

1. The precompiler DEC option, if it is set with a non-zero scale.
2. The DECIMAL ARITHMETIC field (DECARTH) on installation panel DSNTIP4, if it is set with a non-zero scale.

3. The MINIMUM DIVIDE SCALE opaque subsystem parameter (MINDVSCL), if it is set to a value other than NONE.
4. The MINIMUM DIVIDE SCALE field (DECDIV3) on installation panel DSNTIP4, if it is set to YES.

Dynamic SQL

1. The CURRENT PRECISION special register, if it is set with a non-zero scale.
2. Either of the following cases:
 - For a package that was bound with DYNAMICRULES RUN or if the USE FOR DYNAMICRULES field (DYNRULS) on installation panel DSNTIP4 is set to YES: The DECIMAL ARITHMETIC field (DECARTH) on installation panel DSNTIP4, if it is set with a non-zero scale.
 - For all other cases: The precompiler DEC option, if it is set with a non-zero scale.
3. The MINIMUM DIVIDE SCALE opaque subsystem parameter (MINDVSCL), if it is set to value other than NONE.
4. The MINIMUM DIVIDE SCALE field (DECDIV3) on installation panel DSNTIP4, if it is set to YES

SQL statements that are executed using SPUIFI

The value in DECIMAL ARITHMETIC (DECARTH).

The default value for both the precompiler DEC option and the CURRENT PRECISION special register is DECIMAL ARITHMETIC.

A minimum divide result scale of 3 can be specified using the MINIMUM DIVIDE SCALE field on the installation panel DSNTIP4. A minimum divide scale result between 1 and 9 can be specified using the DECIMAL ARITHMETIC OPTION of the form 'Dpp.s' where 'pp' is 15 or 31 and represents the precision and 's' represents the minimum divide scale, as a number between 1 and 9. Such a specification overrides the MINIMUM DIVIDE SCALE. When a minimum divide result scale is specified, the formula $\text{MAX}(s, s')$, where s represents the scale derived from the above table and s' represents the value specified by the minimum divide result scale, is applied and a new scale is derived. The newly derived scale is the scale of the result and overrides any scale derived using the table above.

Arithmetic with a decimal and a decimal floating-point operand

If one operand is a decimal and the other is a decimal floating point, the operation is performed in decimal floating point. The arithmetic operation uses a temporary copy of the decimal that has been converted to a decimal floating point based on the precision of the decimal number.

If the decimal number has a precision of less than 17, the decimal number is converted to DECFLOAT(16). Otherwise, the decimal number is converted to DECFLOAT(34). The rules for two decimal floating-point operands are then applied.

Arithmetic with floating-point operands

If either operand of an arithmetic operator is floating-point, the operation is performed in floating-point. If necessary, the operands are first converted to double-precision floating-point numbers. Thus, if any element of an expression is a floating-point number, the result of the expression is a double-precision floating-point number.

An operation involving a floating-point number and an integer is performed with a temporary copy of the integer that has been converted to double-precision floating-point. An operation involving a floating-point number and a decimal number is performed with a temporary copy of the decimal number that has been converted to double-precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

The order in which floating-point operands (or arguments to functions) are processed can affect the results slightly because floating-point operands are approximate representations of real numbers. Because the order in which operands are processed might be implicitly modified by DB2 (for example, DB2 might decide what degree of parallelism to use and what access plan to use), an application that uses floating-point operands should not depend on the results being precisely the same each time an SQL statement is executed.

Arithmetic with a floating-point and a decimal floating-point operand

If one operand is a floating-point number (real or double) and the other is a decimal floating-point number, the operation is performed in decimal floating-point. The arithmetic operation uses a temporary copy of the floating-point number that has been converted to a decimal floating-point number.

Arithmetic with two decimal floating-point operands

If both operands are decimal floating point, the operation is performed in decimal floating point. If one operand is `DECFLOAT(n)` and the other is `DECFLOAT(m)`, the operation is performed in `DECFLOAT(max(n,m))`.

General Arithmetic Operation Rules for DECFLOAT:

Certain general rules apply to all arithmetic operations on the `DECFLOAT` data type.

The following general rules apply to all arithmetic operations on the `DECFLOAT` data type:

- Every operation on finite numbers is carried out as though an exact mathematical result is computed, using integer arithmetic on the coefficient where possible.

If the coefficient of the theoretical exact result has no more than the number of digits that reflect its precision (16 or 34), it is used for the result without change (unless there is an underflow or overflow condition). If the coefficient has more than the number of digits that reflect its precision, it is rounded to exactly the number of digits that reflect its precision (16 or 34), and the exponent is increased by the number of digits that are removed.

For static SQL statements other than `CREATE VIEW`, the `ROUNDING` bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static `CREATE VIEW` statements), the special register `CURRENT DECFLOAT ROUNDING MODE` determines the rounding mode.

If the value of the adjusted exponent of the result is less than E_{\min} , an exception condition is returned. In this case, the calculated coefficient and exponent form the result, unless the value of the exponent is less than E_{tiny} , in which case the exponent is set to E_{tiny} , the coefficient is rounded (possibly to zero) to match the adjustment of the exponent, and the sign is unchanged. If this rounding gives an inexact result, an underflow exception condition is returned.

If the value of the adjusted exponent of the result is larger than E_{\max} , an overflow exception condition is returned. In this case, the result is as defined as an overflow exception condition and might be infinite. It will have the same sign as the theoretical result.

- Arithmetic that uses the special value infinity follows the usual rules, where negative infinity is less than every finite number and positive infinity is greater than every finite number.

Under these rules, an infinite result is always exact. Certain uses of infinity return an invalid operation condition. The following list is a list of operations that can cause an invalid operation condition and the result of the operation is NaN when one of the operands is infinity but the other operand is not NaN nor sNaN.

- Add +infinity to -infinity during an addition or subtraction operation
- Multiply 0 by +infinity or -infinity
- Divide either +infinity or -infinity by either +infinity or -infinity
- The dividend for a MOD function is either +infinity or -infinity
- Either argument of the QUANTIZE function is +infinity or -infinity
- The second argument of the POWER[®] function is +infinity or -infinity
- Signaling NaNs when used as an operand to an arithmetic operation

The following arithmetic rules apply to arithmetic operations and the NaN value:

- The result of any arithmetic operation which has an operand which is a NaN (a quiet NaN or signaling NaNs) is NaN. The sign of the result is copied from the first operand which is a signaling NaN, or if neither operand is signaling then the sign is copied from the first operand which is a NaN. Whenever a result is a NaN, the sign of the result depends only on the copied operand.
- The sign of the result of a multiplication or division will be negative only if the operands have different signs and neither is a NaN.
- The sign of the result of an addition or subtraction will be negative only if the result is less than zero and neither operand is a NaN, except for the following cases where the result is a negative 0:
 - A result is rounded to zero, and the value, before rounding, had a negative sign
 - Subtract 0 from -0
 - Addition of operands with opposite signs (or subtraction of operands with the same sign), the result has a coefficient of 0, and the rounding mode is ROUND_FLOOR
 - Multiplication or division and the result has a coefficient of 0 and the signs of the operands are different
 - The first argument of the POWER function is -0, and the second argument is a positive odd number
 - The argument of the CEIL, FLOOR, or SQRT function is -0
 - The first argument of the ROUND or TRUNCATE function is -0

Examples involving special DECFLOAT values:

```

INFINITY + 1           = INFINITY
INFINITY + INFINITY   = INFINITY
INFINITY + -INFINITY  = NAN      -- exception
NAN + 1               = NaN
NAN + INFINITY        = NaN
1 - INFINITY          = -INFINITY
INFINITY - INFINITY   = NAN      -- exception

```

```

-INFINITY - -INFINITY    = NAN          -- exception
-0.0 - 0.0E1           = -0
-1.0 * 0.0E1           = -0
1.0E1 / 0              = INFINITY
-1.0E5 / 0.0           = -INFINITY
1.0E5 / -0              = -INFINITY
INFINITY / -INFINITY    = NAN          -- exception
INFINITY / 0            = INFINITY
-INFINITY / 0           = -INFINITY
-INFINITY / -0          = INFINITY

```

Arithmetic with distinct type operands

A distinct type cannot be used with arithmetic operators even if its source data type is numeric.

To perform an arithmetic operation, create a function with the arithmetic operator as its source. For example, if there were distinct types INCOME and EXPENSES, both of which had DECIMAL(8,2) data types, the following user-defined function, REVENUE, could be used to subtract one from the other.

```

CREATE FUNCTION REVENUE ( INCOME, EXPENSES )
  RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL)

```

Alternately, the - (minus) operator could be overloaded using a function to subtract the new data types.

```

CREATE FUNCTION "-" ( INCOME, EXPENSES )
  RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL)

```

Alternatively, the distinct type can be cast to a built-in data type and the result used as an operand of an arithmetic operator.

Expressions with the concatenation operator

When two strings operands are concatenated, the result of the expression is a string.

Introductory concepts:

String data types (Introduction to DB2 for z/OS)

Concatenation of strings (Introduction to DB2 for z/OS)

The operands of concatenation must be compatible strings. A binary string cannot be concatenated with a character string, including character strings that are defined as FOR BIT DATA (for more information on the compatibility of data types, see the compatibility matrix in Table 23 on page 119). A distinct type that is based on a string type can be concatenated only if an appropriate user-defined function is created.

Both CONCAT and the vertical bars (||) represent the concatenation operator. Vertical bars (or the characters that must be used in place of vertical bars in some countries¹³) can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs¹³. Thus, CONCAT is the preferable concatenation operator.

13. In various EBCDIC code pages, DB2 supports code point combinations X'4F4F', X'BBBB', and X'5A5A' to mean concatenation. X'BBBB' and X'5A5A' are interpreted to mean concatenation only on single byte character set DB2 subsystems.

If either operand can be null, the result can be null, and if either is null, the result is the null value. Otherwise, the result consists of the first operand string followed by the second.

The following table shows how the string operands determine the data type and the length attribute of the result (the order in which the operands are concatenated has no effect on the result).

Table 46. Data type and length of concatenated operands

| If one operand column is | And the other operand is | The data type of the result column is ¹ |
|--------------------------|---|--|
| CHAR(x) | CHAR(y) with a combined length attribute that is less than 256 | CHAR(x+y) ² |
| | CHAR(y) with a combined length attribute that is greater than 255 | VARCHAR(MIN(x'+y',32704)) ³ |
| | VARCHAR(y) | |
| VARCHAR(x) | VARCHAR(y) | VARCHAR(MIN(x'+y',32704)) ³ |
| CLOB(x) | CHAR(y) | CLOB(MIN(x'+y',2G)) |
| | VARCHAR(y) | |
| | CLOB(y) | |
| | GRAPHIC(y) | DBCLOB(MIN(x+y,1G)) |
| | VARGRAPHIC(y) | |
| | DBCLOB(y) | |
| GRAPHIC(x) | CHAR(y) | VARGRAPHIC(MIN(x+y,16352)) ⁴ |
| | VARCHAR(y) | |
| | VARGRAPHIC(y) | |
| VARGRAPHIC(x) | CHAR(y) | VARGRAPHIC(MIN(x+y,16352)) ⁴ |
| | VARCHAR(y) | |
| | GRAPHIC(y) | |
| | GRAPHIC(y) | |
| DBCLOB(x) | CHAR(y) | DBCLOB(MIN(x+y,1G)) |
| | VARCHAR(y) | |
| | CLOB(y) | |
| | GRAPHIC(y) | |
| | VARGRAPHIC(y) | |
| | DBCLOB(y) | |
| BINARY(x) | BINARY(y) with a combined length attribute that is less than 256 | BINARY(x+y) |
| | BINARY(y) with a combined length attribute that is greater than 255 | VARBINARY(MIN(x+y,32704)) |
| VARBINARY(x) | VARBINARY(y) | VARBINARY(MIN(x+y,32704)) |
| | BINARY(y) | |

Table 46. Data type and length of concatenated operands (continued)

| If one operand column is | And the other operand is | The data type of the result column is ¹ |
|--------------------------|--------------------------|--|
| BLOB(<i>x</i>) | BLOB(<i>y</i>) | BLOB(MIN(<i>x+y</i> , 2G)) |

Notes:

- 2G represents 2,147,483,647 bytes
 - 1G represents 1,073,741,823 double-byte characters
- Neither CHAR(*x*) nor CHAR(*y*) can contain mixed data. If either operand contains mixed data, the result is VARCHAR(MIN(*x'+y'*,32704)).
- If conversion of the first operand is required, *x'* = 3*x*; otherwise, it remains *x*. If conversion of the second operand is required, *y'* = 3*y*; otherwise, it remains *y*.
- Both operands are converted to UTF-16, if necessary (that is, the operand is not already UTF-16), and the results are concatenated.

As the previous table shows, the length of the result is the sum of the lengths of the operands. However, the length of the result is two bytes less if redundant shift code characters are eliminated from the result. Redundant shift code characters exist when both character strings are EBCDIC mixed data, and the first string ends with a “shift-in” character (X'0F') and the second operand begins with a “shift-out” character (X'0E'). These two shift code characters are removed from the result.

The CCSID of the result is determined by the rules set forth in “Character conversion in set operations and concatenations” on page 1128. Some consequences of those rules are the following:

- If either operand is BIT data, the result is BIT data.
- The conversion that occurs when SBCS data is compared with mixed data depends on the encoding scheme. If the encoding scheme is Unicode, the SBCS operand is converted to MIXED. Otherwise, the conversion depends on the field MIXED DATA on installation panel DSNTIPF for the DB2 that does the comparison:
 - Mixed data if the MIXED DATA option at the server is YES. The result is not necessarily well-formed mixed data.
 - SBCS data if the MIXED DATA option at the server is NO. If the mixed data cannot be converted to pure SBCS data, an error occurs.

If an operand is a string from a column with a field procedure, the operation applies to the decoded form of the value. The result does not inherit the field procedure.

One operand of concatenation can be a parameter marker. When one operand is a parameter marker, its data type and length attributes are considered to be the same as those for the operand that is not a parameter marker except for a string data type. Refer to Table 46 on page 238 for the formula used to calculate data type length for untyped parameter markers in the CONCAT operator when another operand is a string data type. The order of concatenation operations must be considered to determine these attributes in the case of nested concatenation.

No operand of concatenation can be a distinct type even if the distinct type is based on a character data type. To concatenate a distinct type, create a user-defined function that is sourced on the CONCAT operator. For example, if distinct types

TITLE and TITLE_DESCRIPTION were both sourced on data type VARCHAR(25), the following user-defined function, named ATTACH, could be used to concatenate the two distinct types:

```
CREATE FUNCTION ATTACH (TITLE, TITLE_DESCRIPTION)
  RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Alternatively, the concatenation operator could be overloaded by using a user-defined function to add the distinct types:

```
CREATE FUNCTION "||" (TITLE, TITLE_DESCRIPTION)
  RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

“CONCAT” on page 391

Scalar-fullselect

A *scalar-fullselect* as supported in an expression is a fullselect, enclosed in parentheses, that returns a single row consisting of a single column value. If the fullselect does not return a row, the result of the expression is the null value. If more than one row is to be returned for a scalar fullselect, an error occurs.

►►—(*fullselect*)—◄◄

If a set operator is not specified in the outermost fullselect and the select list element is an expression that is simply a column name, the result column name is based on the name of the column. Otherwise, the result column is unnamed.

If a column mask is used to mask the column values in the final result table, and if a column mask is applied to the column in the select list of a *scalar-fullselect*, the result of the *scalar-fullselect* must not be derived using set operators. See Chapter 6, “Queries,” on page 1079 for more information about how column access controls affect a fullselect.

A scalar fullselect cannot be used in the following instances:

- A CHECK constraint in CREATE TABLE and ALTER TABLE statements
- A CREATE VIEW statement where the view definition includes the WITH CHECK option
- A CREATE FUNCTION (SQL) statement (subselect already restricted from the expression in the RETURN clause)
- An argument in a CALL statement for an input parameter
- An argument to an aggregate function, other than the XML-expression argument of the XMLAGG function
- An ORDER BY clause
- A GROUP BY clause
- A join-condition of the ON clause for INNER and OUTER JOINS

If the scalar fullselect is a subselect, it is also referred to as a scalar subselect. See “subselect” on page 1082 for more information.

The following examples illustrate the use of *scalar-fullselect*. Assume that four tables (PARTS, PRODUCTS, PARTPRICE, and PARTINVENTORY) contain product data.

Example 1 - *scalar-fullselect* in a WHERE clause:

Find which products have the prices in the range of at least twice the lowest price of all the products and at most half the price of all the products.

```
SELECT PRODUCT, PRICE FROM PRODUCTS A
WHERE
  PRICE BETWEEN 2 * (SELECT MIN(PRICE) FROM PRODUCTS)
  AND .5 * (SELECT MAX(PRICE) FROM PRODUCTS);
```

Example 2 - *scalar-fullselect* in a SELECT list:

For each part, find its price and its inventory.

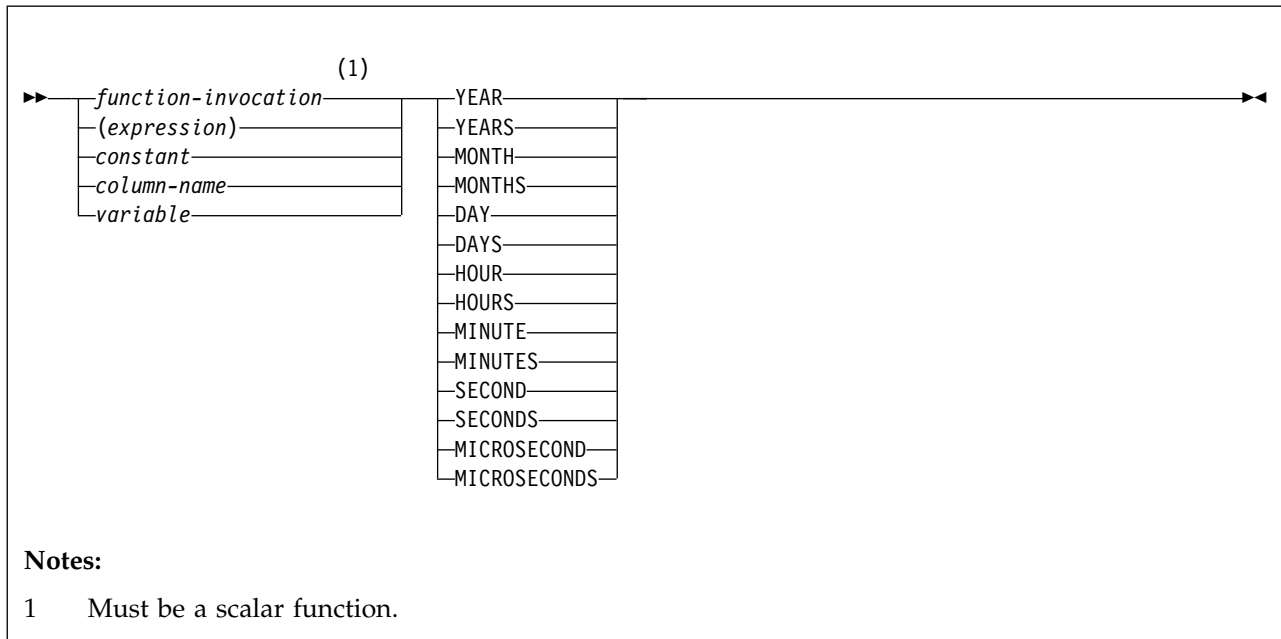

```
SELECT PART,
  (SELECT PRICE FROM PARTPRICE WHERE PART=A.PART),
  (SELECT ONHAND# FROM INVENTORY WHERE PART=A.PART)
FROM PARTS A;
```

Datetime operands and durations

Datetime values can be incremented, decremented, and subtracted. These operations can involve decimal numbers called durations. A *duration* is a positive or negative number representing an interval of time.

Labeled durations

The form a labeled duration is as follows:

A *labeled duration* represents a specific unit of time as expressed by a number (which can be the result of an expression) followed by one of the seven duration keywords.¹⁴ The number specified is converted as if it were assigned to a DECIMAL(15,0) number, except for SECONDS, which uses DECIMAL(27,12) to allow 0 to 12 fractional second digits to be included.

14. The singular form of these keywords is also acceptable: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, and MICROSECOND.

A labeled duration can only be used as an operand of an arithmetic operator in which the other operand is a value of the data type of date, time, or timestamp. Thus, the expression `HIREDATE + 2 MONTHS + 14 DAYS` is valid, whereas the expression `HIREDATE + (2 MONTHS + 14 DAYS)` is not. In both of these expressions, the labeled durations are `2 MONTHS` and `14 DAYS`.

Date duration

A *date duration* represents a number of years, months, and days expressed as a `DECIMAL(8,0)` number. To be properly interpreted, the number must have the format `yyyymmdd`, where `yyyy` represents the number of years, `mm` the number of months, and `dd` the number of days. The result of subtracting one `DATE` value from another, as in the expression `HIREDATE - BIRTHDATE`, is a date duration.

Time duration

A *time duration* represents a number of hours, minutes, and seconds expressed as a `DECIMAL(6,0)` number. To be properly interpreted, the number must have the format `hhmmss`, where `hh` represents the number of hours, `mm` the number of minutes, and `ss` the number of seconds. The result of subtracting one `TIME` value from another is a time duration.

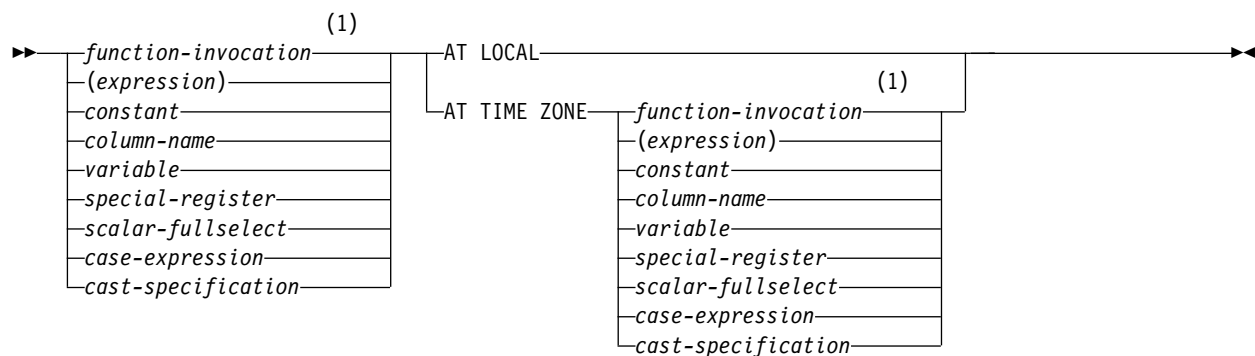

Timestamp duration

A *timestamp duration* represents a number of years, months, days, hours, minutes, seconds, and fractional seconds expressed as a `DECIMAL(14+s,s)` number, where `s` is the number of fractional seconds in the range from 0 to 12. To be interpreted properly, the number must have the format `yyyymmddhhmmss.zzzzzzzzzzzz`, where `yyyy`, `xx`, `dd`, `hh`, `mm`, `ss`, and `zzzzzzzzzzzz` represent, respectively, the number of years, months, days, hours, minutes, seconds, and fractional seconds. The result of subtracting one timestamp value from another is a timestamp duration with a scale that matches the maximum timestamp precision of the timestamp operands.

Time zone specific expressions

Time zone specific expressions can be used to adjust timestamp values and character-string or graphic-string representations of timestamp values to specific time zones.

time-zone-specific-expressions

Notes:

- 1 Must be a scalar function.

The first operand for *time-zone-specific-expression* must be an expression that returns the value of either a built-in timestamp or a built-in character or graphic string data type. If the first operand is a character string or graphic string, it must not be a CLOB or DBCLOB value and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of datetime values, see “String representations of datetime values” on page 101.

If the first operand of *time-zone-specific-expression* returns a `TIMESTAMP WITHOUT TIME ZONE` value, the expression is implicitly cast to `TIMESTAMP WITH TIME ZONE` before being adjusted to the indicated time zone.

AT LOCAL

Specifies that the timestamp value is to be adjusted for the local time zone using the `SESSION TIME ZONE` special register.

AT TIME ZONE

Specifies that the timestamp is to be adjusted for the time zone that is represented by the expression.

expression is a character or graphic string. It must not be a CLOB or DBCLOB value, and its value must be left justified and be of the form ' $\pm th:tm$ ', where *th* represents the time zone hour between -12 and +14, and *tm* represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00. The value must not be the null value.

The expression returns a `TIMESTAMP WITH TIME ZONE` value in the indicated time zone.

Syntax alternatives: `TIMEZONE` can be specified as an alternative to `TIME ZONE`.

Cast a timestamp for April 12, 2010 to the local time zone. Assume that the `IMPLICIT TIME ZONE` system parameter is set to '-8:00'.

```
CAST('2010-04-12-10:30:00.0 -5:00' AT LOCAL AS TIMESTAMP)
```

Returns: 2010-04-12-07:30:00.000000.

Insert a timestamp value with a time zone into a table, tz, and retrieve it as a timestamp with the local time zone, with +08:00, and adjusted for UTC. Assume that table tz exists as follows:

```
CREATE TABLE tz(tstz TIMESTAMP WITH TIME ZONE);
```

```
INSERT INTO tz(tstz) VALUES(TIMESTAMP '2010-01-01-10.23.51-08:00');
```

1. Retrieve the value of the tstz column adjusted for the local time:

```
SELECT tstz AT LOCAL  
FROM SYSIBM.SYSDUMMY1;
```

2. Retrieve the value of the tstz column adjusted for the time zone +08:00:

```
SELECT tstz AT TIME ZONE '+08:00'  
FROM SYSIBM.SYSDUMMY1;
```

3. Retrieve the value of the tstz column adjusted for UTC:

```
SELECT tstz AT TIME ZONE '00:00'  
FROM SYSIBM.SYSDUMMY1;
```

Datetime arithmetic in SQL

The only arithmetic operations that can be performed on datetime values are addition and subtraction.

If a datetime value is the operand of addition, the other operand must be a duration. The specific rules governing the use of the addition operator with datetime values follow.

- If one operand is a date, the other operand must be a date duration or labeled duration of years, months, or days.
- If one operand is a time, the other operand must be a time duration or a labeled duration of hours, minutes, or seconds.
- If one operand is a timestamp, the other operand must be a duration. Any type of duration is valid.
- Neither operand of the addition operator can be a parameter marker. For a discussion of parameter markers, see Parameter markers in “PREPARE” on page 2083.

The rules for the use of the subtraction operator on datetime values are not the same as those for addition because a datetime value cannot be subtracted from a duration, and because the operation of subtracting two datetime values is not the same as the operation of subtracting a duration from a datetime value. The specific rules governing the use of the subtraction operator with datetime values follow.

- If the first operand is a date, the second operand must be a date, a date duration, a string representation of a date, or a labeled duration of years, months, or days.
- If the second operand is a date, the first operand must be a date, or a string representation of a date.
- If the first operand is a time, the second operand must be a time, a time duration, a string representation of a time, or a labeled duration of hours, minutes, or seconds.
- If the second operand is a time, the first operand must be a time, or string representation of a time.
- If the first operand is a timestamp, the second operand must be a timestamp, a string representation of a timestamp, or a duration.
- If the second operand is a timestamp, the first operand must be a timestamp or a string representation of a timestamp.

- Neither operand of the subtraction operator can be a parameter marker.

When an operand in a datetime expression is a string, it might undergo character conversion before it is interpreted and converted to a datetime value. When its CCSID is not that of the default for mixed strings, a mixed string is converted to the default mixed data representation. When its CCSID is not that of the default for SBCS strings, an SBCS string is converted to the default SBCS representation.

Date arithmetic

Date values can be subtracted, incremented, or decremented.

Subtracting dates: The result of subtracting one date (DATE2) from another (DATE1) is a date duration that specifies the number of years, months, and days between the two dates. The data type of the result is DECIMAL(8,0). If DATE1 is greater than or equal to DATE2, DATE2 is subtracted from DATE1. If DATE1 is less than DATE2, however, DATE1 is subtracted from DATE2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation $RESULT = DATE1 - DATE2$.

| Date subtraction: result = date1 - date2 |
|--|
| <ul style="list-style-type: none"> • If $DAY(DATE2) \leq DAY(DATE1)$ then $DAY(RESULT) = DAY(DATE1) - DAY(DATE2)$ • If $DAY(DATE2) > DAY(DATE1)$ then $DAY(RESULT) = N + DAY(DATE1) - DAY(DATE2)$ where N = the last day of $MONTH(DATE2)$. $MONTH(DATE2)$ is then incremented by 1. • If $MONTH(DATE2) \leq MONTH(DATE1)$ then $MONTH(RESULT) = MONTH(DATE1) - MONTH(DATE2)$ • If $MONTH(DATE2) > MONTH(DATE1)$ then $MONTH(RESULT) = 12 + MONTH(DATE1) - MONTH(DATE2)$ and $YEAR(DATE2)$ is incremented by 1. • $YEAR(RESULT) = YEAR(DATE1) - YEAR(DATE2)$ |

For example, the result of $DATE('3/15/2005') - '12/31/2004'$ is 215 (or, a duration of 0 years, 2 months, and 15 days). In this example, notice that the second operand did not need to be converted to a date. According to one of the rules for subtraction, described under “Datetime arithmetic in SQL” on page 244, the second operand can be a string representation of a date if the first operand is a date.

Incrementing and decrementing dates: The result of adding a duration to a date, or of subtracting a duration from a date, is itself a date. (For the purposes of this operation, a month denotes the equivalent of a calendar page. Adding months to a date, then, is like turning the pages of a calendar, starting with the page on which the date appears.) The result must fall between the dates January 1, 0001 and December 31, 9999 inclusive. If a duration of years is added or subtracted, only the year portion of the date is affected. The month is unchanged, as is the day unless the result would be February 29 of a non-leap-year. Here the day portion of the result is set to 28, and the SQLWARN6 field of the SQLCA is set to W, indicating that an end-of-month adjustment was made to correct an invalid date. *DB2 Application Programming and SQL Guide* also describes how SQLWARN6 is set.

Similarly, if a duration of months is added or subtracted, only months and, if necessary, years are affected. The day portion of the date is unchanged unless the result would be invalid (September 31, for example). In this case the day is set to the last day of the month, and the SQLWARN6 field of the SQLCA is set to W to indicate the adjustment.

Adding or subtracting a duration of days will, of course, affect the day portion of the date, and potentially the month and year. Adding or subtracting a duration of days will not cause an end-of-the-month adjustment.

Date durations, whether positive or negative, can also be added to and subtracted from dates. As with labeled durations, the result is a valid date, and SQLWARN6 is set to W to indicate any necessary end-of-month adjustment.

When a positive date duration is added to a date, or a negative date duration is subtracted from a date, the date is incremented by the specified number of years, months, and days, in that order. Thus, DATE1+X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

```
DATE1 + YEAR(X) YEARS + MONTH(X) MONTHS + DAY(X) DAYS
```

When a positive date duration is subtracted from a date, or a negative date duration is added to a date, the date is decremented by the specified number of days, months, and years, in that order. Thus, DATE1-X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

```
DATE1 - DAY(X) DAYS - MONTH(X) MONTHS - YEAR(X) YEARS
```

Adding a month to a date gives the same day one month later unless that day does not exist in the later month. In that case, the day in the result is set to the last day of the later month. For example, January 28 plus one month gives February 28; one month added to January 29, 30, or 31 results in either February 28 or, for a leap year, February 29. If one or more months is added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date.

If one or more months are added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date. In addition, logically equivalent expressions might not produce the same result. For example, the following two expressions do not produce the same result:

```
(DATE('2005 01 31') + 1 MONTH) + 1 MONTH    -- results in 2005-03-28
DATE('2005 01 31') + 2 MONTHS              -- results in 2005-03-31
```

The order in which labeled date durations are added to and subtracted from dates can affect the results. When you add labeled date durations to a date, specify them in the order of YEARS + MONTHS + DAYS. When you subtract labeled date durations from a date, specify them in the order of DAYS - MONTHS - YEARS. For example, to add one year and one day to a date, specify:

```
DATE1 + 1 YEAR + 1 DAY
```

To subtract one year, one month, and one day from a date, specify:

```
DATE1 - 1 DAY - 1 MONTH - 1 YEAR
```

Time arithmetic

Times can be subtracted, incremented, or decremented.

Subtracting times: The result of subtracting one time (*TIME2*) from another (*TIME1*) is a time duration that specifies the number of hours, minutes, and seconds between the two times. The data type of the result is DECIMAL(6,0). If *TIME1* is greater than or equal to *TIME2*, *TIME2* is subtracted from *TIME1*. If *TIME1* is less than *TIME2*, however, *TIME1* is subtracted from *TIME2*, and the sign

of the result is made negative. The following procedural description clarifies the steps involved in the operation $RESULT = TIME1 - TIME2$.

Time subtraction: $result = time1 - time2$

- If $SECOND(TIME2) \leq SECOND(TIME1)$ then $SECOND(RESULT) = SECOND(TIME1) - SECOND(TIME2)$.
- If $SECOND(TIME2) > SECOND(TIME1)$ then $SECOND(RESULT) = 60 + SECOND(TIME1) - SECOND(TIME2)$ and $MINUTE(TIME2)$ is incremented by 1.
- If $MINUTE(TIME2) \leq MINUTE(TIME1)$ then $MINUTE(RESULT) = MINUTE(TIME1) - MINUTE(TIME2)$.
- If $MINUTE(TIME2) > MINUTE(TIME1)$ then $MINUTE(RESULT) = 60 + MINUTE(TIME1) - MINUTE(TIME2)$ and $HOUR(TIME2)$ is incremented by 1.
- $HOUR(RESULT) = HOUR(TIME1) - HOUR(TIME2)$.

For example, the result of $TIME('11:02:26') - '00:32:56'$ is '102930' (a duration of 10 hours, 29 minutes, and 30 seconds). In this example, notice that the second operand did not need to be converted to a time. According to one of the rules for subtraction, described under "Datetime arithmetic in SQL" on page 244, the second operand can be a string representation of a time if the first operand is a time.

Incrementing and decrementing times: The result of adding a duration to a time, or of subtracting a duration from a time, is itself a time. Any overflow or underflow of hours is discarded, thereby ensuring that the result is always a time. If a duration of hours is added or subtracted, only the hours portion of the time is affected. Adding 24 hours to the time '00:00:00' results in the time '24:00:00'. However, adding 24 hours to any other time results in the same time; for example, adding 24 hours to the time '00:00:59' results in the time '00:00:59'. The minutes and seconds are unchanged.

Similarly, if a duration of minutes is added or subtracted, only minutes and, if necessary, hours are affected. The seconds portion of the time is unchanged.

Adding or subtracting a duration of seconds affects the seconds portion of the time and might affect the minutes and hours.

Time durations, whether positive or negative, can also be added to and subtracted from times. The result is a time that has been incremented or decremented by the specified number of hours, minutes, and seconds, in that order. Thus, $TIME1 + X$, where X is a positive $DECIMAL(6,0)$ number, is equivalent to the expression

$TIME1 + HOUR(X) HOURS + MINUTE(X) MINUTES + SECOND(X) SECONDS$

Timestamp arithmetic

Timestamps can be subtracted, incremented, or decremented.

If any of the operands are `TIMESTAMP WITH TIME ZONE`, any `TIMESTAMP WITHOUT TIME ZONE` values are implicitly cast to `TIMESTAMP WITH TIME ZONE`, and the datetime arithmetic operation is performed in UTC time (ignoring the time zone).

Subtracting timestamps: The result of subtracting one timestamp ($TS2$) from another ($TS1$) is a timestamp duration that specifies the number of years, months, days, hours, minutes, seconds, and fractional seconds between the two timestamps.

The data type of the result is $DECIMAL(14+s,s)$, where s is the maximum timestamp precision of $TS1$ and $TS2$. If $TS1$ is greater than or equal to $TS2$, $TS2$ is

subtracted from *TS1*. If *TS1* is less than *TS2*. However, *TS1* is subtracted from *TS2* and the sign of the result is made negative. A subtraction that involves a timestamp with a time zone operand is based on the UTC value of the timestamp with the time zone. The time zone is ignored.

The following procedural description clarifies the steps involved in the operation $RESULT = TS1 - TS2$.

Timestamp subtraction: $result = ts1 - ts2$

- If $MICROSECOND(TS2) \leq MICROSECOND(TS1)$ then $MICROSECOND(RESULT) = MICROSECOND(TS1) - MICROSECOND(TS2)$.
- If $MICROSECOND(TS2) > MICROSECOND(TS1)$ then $MICROSECOND(RESULT) = 1000000 + MICROSECOND(TS1) - MICROSECOND(TS2)$ and $SECOND(TS2)$ is incremented by 1.
- If $SECOND(TS2,s) \leq SECOND(TS1,s)$ then $SECOND(RESULT,s) = SECOND(TS1,s) - SECOND(TS2,s)$.
- If $SECOND(TS2,s) > SECOND(TS1,s)$ then $SECOND(RESULT,s) = 60 + SECOND(TS1,s) - SECOND(TS2,s)$.
 $MINUTE(TS2)$ is incremented by 1.
- If $HOUR(TS2) \leq HOUR(TS1)$ then $HOUR(RESULT) = HOUR(TS1) - HOUR(TS2)$.
- If $HOUR(TS2) > HOUR(TS1)$ then $HOUR(RESULT) = 24 + HOUR(TS1) - HOUR(TS2)$ and $DAY(TS2)$ is incremented by 1.

The minutes part of the timestamps are subtracted as specified in the rules for subtracting times.

The date part of the timestamps is subtracted as specified in the rules for subtracting dates.

Incrementing and decrementing timestamps: The result of adding a duration to a timestamp, or of subtracting a duration from a timestamp, is itself a timestamp. The precision of the result timestamp matches the precision of the timestamp operand. The date and time arithmetic is performed as previously defined, except that an overflow or underflow of hours is carried into the date part of the result, which must be within the range of valid dates. The time arithmetic portion is similar to time arithmetic, except that it also considers the fractional seconds included in the duration. For example, subtracting a duration, *X*, from a timestamp, *TIMESTAMP1*, where *X* is a *DECIMAL(14+s,s)* number, is equivalent to the expression:

```
TIMESTAMP1 - YEAR(X) YEARS - MONTH(X) MONTHS - DAY(X) DAYS
            - HOUR(X) HOURS - MINUTE(X) MINUTES - SECOND(X, s) SECONDS
```

When subtracting a duration with a non-zero scale or a labeled duration of *SECOND* or *SECONDS* with a value that includes fractions of a second, the subtraction is performed as if the timestamp value has up to 12 fractional second digits. The resulting value is assigned to a timestamp value with the timestamp precision of the timestamp operand, which could result in truncation of fractional second digits.

When the result of an operation is midnight, the time portion of the result can be '24.00.00' or '00.00.00'. A comparison of those two values does not result in 'equal'. Microseconds overflow into seconds.

Precedence of operations

Expressions within parentheses are evaluated first. When the order of evaluation is not specified by parentheses, prefix operators are applied before multiplication and

division, and multiplication, division, and concatenation are applied before addition and subtraction. Operators at the same precedence level are applied from left to right.

Example 1: In this example, the first operation is the addition in (SALARY + BONUS) because it is within parenthesis. The second operation is multiplication because it is a higher precedence level than the second addition operator and it is to the left of the division operator. The third operation is division because it is at a higher precedence level than the second addition operator. Finally, the remaining addition is performed.

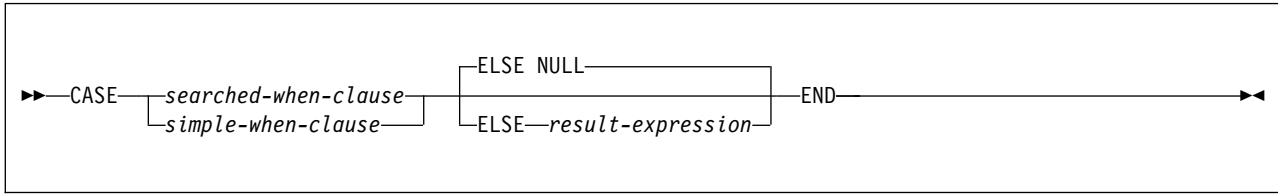

```
1.10 * (SALARY + BONUS) + SALARY / :VAR3
      (2)      (1)      (4)      (3)
```

Example 2: In this example, the first operation (CONCAT) combines the character strings in the variables *YYYYMM* and *DD* into a string representing a date. The second operation (-) then subtracts that date from the date being processed in DATECOL. The result is a date duration that indicates the time elapsed between the two dates.

```
DATECOL - :YYYYMM CONCAT :DD
          (2)      (1)
```

CASE expressions

A CASE expression allows an expression to be selected based on the evaluation of one or more conditions.

searched-when-clause:

simple-when-clause:

In general, the value of the *case-expression* is the value of the *result-expression* following the first (leftmost) *when-clause* that evaluates to true. If no case evaluates to true and the ELSE keyword is present, the result is the value of the *result-expression* or NULL. If no case evaluates to true and the ELSE keyword is not present, the result is NULL. When a case evaluates to unknown (because of NULL values), the case is NOT true and hence is treated the same way as a case that evaluates to false.

searched-when-clause

| Specifies a *search-condition* that is applied to each row or group of table data
| presented for evaluation, and the result when that condition is true.

| Pair-wise comparison is performed. Implicit cast of each pair follows the same
| rule as for a basic predicate. The *searched-when-clause* performs implicit cast on
| string and numeric search conditions.

simple-when-clause

Specifies that the value of the *expression* prior to the first WHEN keyword is tested for equality with the value of each *expression* that follows the WHEN keyword. It also specifies the result for when that condition is true.

The data type of the *expression* prior to the first WHEN keyword must be compatible with the data types of the *expression* that follows each WHEN

keyword. The data type of any of the expressions cannot be a CLOB, DBCLOB or BLOB. In addition, the *expression* prior to the first WHEN keyword cannot include a function that is not deterministic or has an external action.

result-expression or NULL

Specifies the value that follows the THEN and ELSE keywords. It specifies the result of a *searched-when-clause* or a *simple-when-clause* that is true, or the result if no case is true. There must be at least one *result-expression* in the CASE expression with a defined data type. NULL cannot be specified for every case.

All *result-expressions* must have compatible data types. The attributes of the result are determined according to the rules that are described in “Rules for result data types” on page 143. When the result is a string, its attributes include a CCSID. For the rules on how the CCSID is determined, see “Determining the encoding scheme and CCSID of a string” on page 51.

search-condition

Specifies a condition that is true, false, or unknown about a row or group of table data. The *search-condition* can be a predicate, including predicates that contain fullselects (scalar or non-scalar) or row-value expressions.

If *search-condition* in a *searched-when-clause* specifies a quantified predicate or an IN predicate that includes a fullselect, the CASE expression cannot be used in the following contexts:

- select lists
- a VALUES clause of an INSERT or MERGE statement
- a SET or assignment clause of an UPDATE, MERGE, or DELETE statement
- the right side of a SET or assignment statement
- the definition of a column mask or a row permission

If *search-condition* in a *searched-when-clause* specifies an EXISTS predicate, the CASE expression cannot be used in the following contexts:

- a VALUES clause of an INSERT or MERGE statement
- the right side of a SET or assignment statement

END

Ends a *case-expression*.

If a CASE expression is in a select list that derives the final result table, and if the *simple-when-clause* or the *searched-when-clause* references a basic predicate with a fullselect, column masks cannot be applied to the columns in the THEN clauses which derive the result of the CASE expression.

If a CASE expression is in a select list that derives the final result table, and if the *simple-when-clause* or *searched-when-clause* references a column for which column access control is activated, the column mask cannot be applied to the column and an error is returned.

If a CASE expression is in a SET clause of an UPDATE, MERGE, or DELETE statement, a VALUES clause of an INSERT or MERGE statement, or the fullselect of an INSERT from a fullselect, and if the *simple-when-clause* or the *searched-when-clause* references a column for which column access control is activated, the column access control is ignored for the column.

Two scalar functions, NULLIF and COALESCE, are specialized to handle a subset of the functionality provided by CASE. The following table shows the equivalent expressions using CASE or these functions.

Table 47. Equivalent case expressions

| CASE expression | Equivalent expression |
|--|------------------------|
| CASE WHEN e1=e2 THEN NULL ELSE e1 END | NULLIF(e1,e2) |
| CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END | COALESCE(e1,e2) |
| CASE WHEN e1 IS NOT NULL THEN e1 ELSE COALESCE(e2,...,eN) END | COALESCE(e1,e2,...,eN) |

Example 1 (simple-when-clause): Assume that in the EMPLOYEE table the first character of a department number represents the division in the organization. Use a CASE expression to list the full name of the division to which each employee belongs.

```
SELECT EMPNO, LASTNAME,
       CASE SUBSTR(WORKDEPT,1,1)
         WHEN 'A' THEN 'Administration'
         WHEN 'B' THEN 'Human Resources'
         WHEN 'C' THEN 'Design'
         WHEN 'D' THEN 'Operations'
       END
FROM EMPLOYEE;
```

Example 2 (searched-when-clause): You can also use a CASE expression to avoid “division by zero” errors. From the EMPLOYEE table, find all employees who earn more than 25 percent of their income from commission, but who are not fully paid on commission:

```
SELECT EMPNO, WORKDEPT, SALARY+COMM FROM EMPLOYEE
WHERE (CASE WHEN SALARY=0 THEN 0
         ELSE COMM/(SALARY+COMM)
       END) > 0.25;
```

Example 3 (searched-when-clause): You can use a CASE expression to avoid “division by zero” errors in another way. The following queries show an accumulation or summing operation. In the first query, DB2 performs the division before performing the CASE statement and an error occurs along with the results.

```
SELECT REF_ID,PAYMT_PAST_DUE_CT,
       CASE
         WHEN PAYMT_PAST_DUE_CT=0 THEN 0
         WHEN PAYMT_PAST_DUE_CT>0 THEN
           SUM(BAL_AMT/PAYMT_PAST_DUE_CT)
       END
FROM PAY_TABLE
GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

However, if the CASE expression is included in the SUM aggregate function, the CASE expression would prevent the errors. In the following query, the CASE expression screens out the unwanted division because the CASE operation is performed before the division.

```
SELECT REF_ID,PAYMT_PAST_DUE_CT,
       SUM(CASE
         WHEN PAYMT_PAST_DUE_CT=0 THEN 0
         WHEN PAYMT_PAST_DUE_CT>0 THEN
```

```

        BAL_AMT/PAYMT_PAST_DUE_CT
    END)
FROM PAY_TABLE
GROUP BY REF_ID,PAYMT_PAST_DUE_CT;

```

Example 4: This example shows how to group the results of a query by a CASE expression without having to re-type the expression. Using the sample employee table, find the maximum, minimum, and average salary. Instead of finding these values for each department, assume that you want to combine some departments into the same group.

```

SELECT CASE_DEPT,MAX(SALARY),MIN(SALARY),AVG(SALARY)
FROM (SELECT SALARY,CASE WHEN WORKDEPT = 'A00' OR WORKDEPT = 'E21'
                        THEN 'A00_E21'
                        WHEN WORKDEPT = 'D11' OR WORKDEPT = 'E11'
                        THEN 'D11_E11'
                        ELSE WORKDEPT
                        END AS CASE_DEPT
FROM DSN8A10.EMP) X
GROUP BY CASE_DEPT;

```

CAST specification

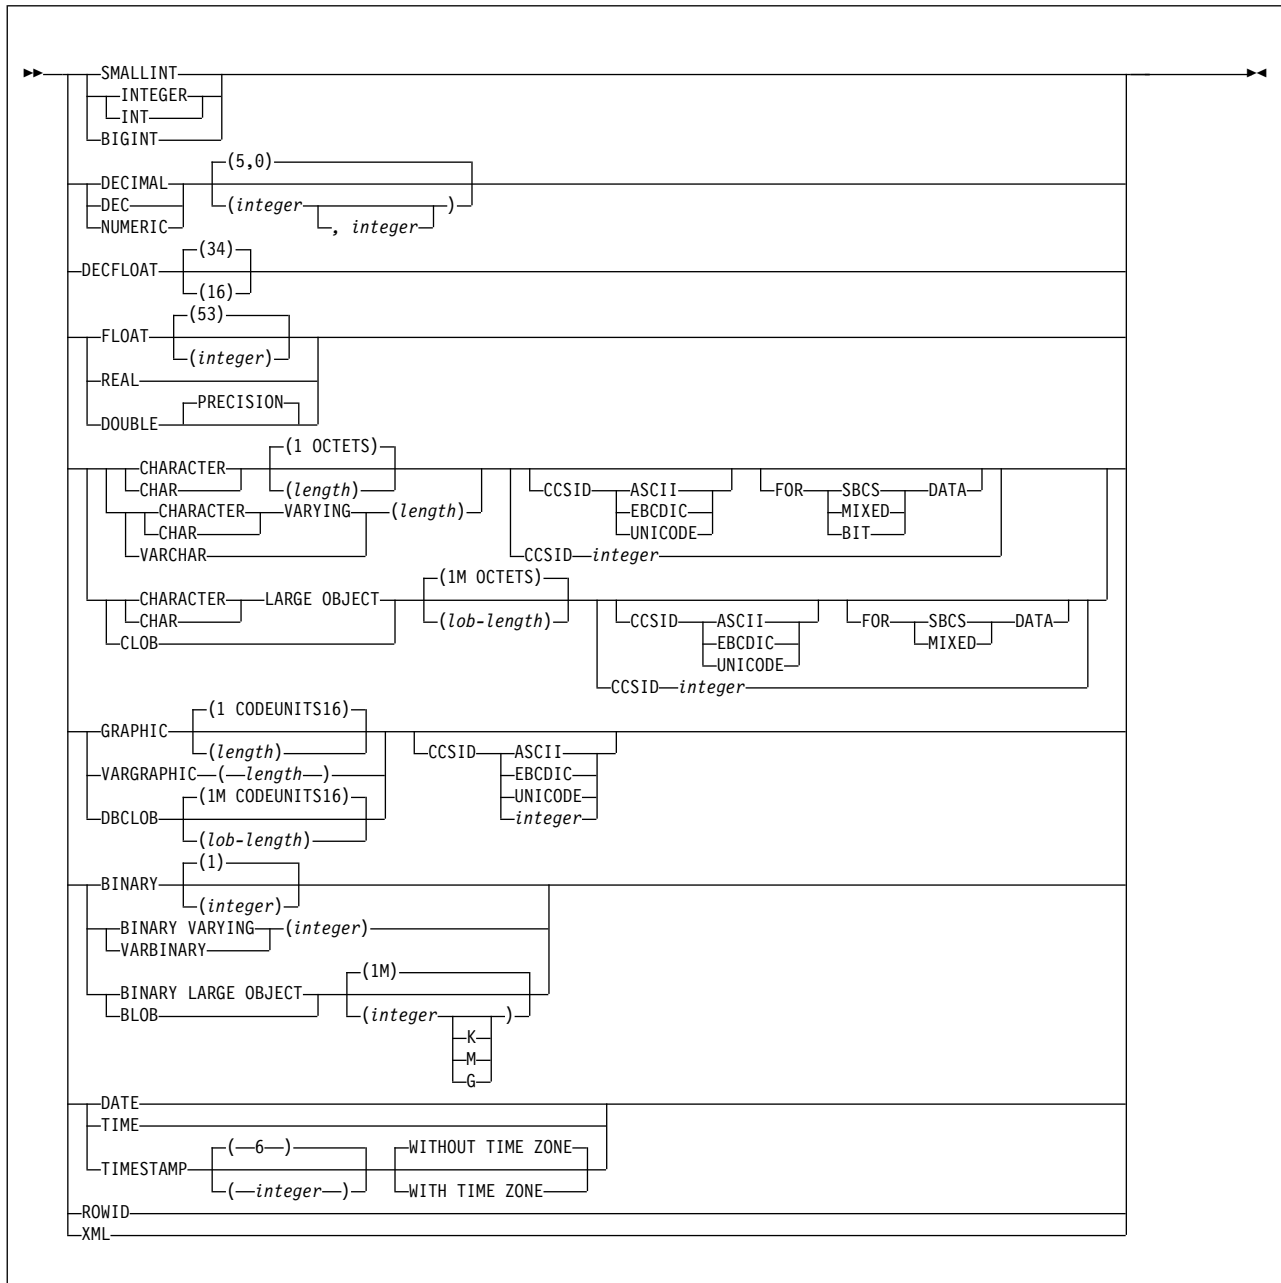

The CAST specification returns the first operand (the cast operand) converted to the data type that is specified by *data-type*.

data-type:

built-in-type:

length:

lob-length:

If the data type of either operand is a distinct type, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type. The CAST specification allows the second operand to be cast to a particular encoding scheme or CCSID if the second operand represents character data. The CCSID clause can be specified following CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, and DBCLOB data types.

expression

Specifies that the cast operand is an expression other than NULL or a parameter marker. The result is the value of the operand value converted to the specified target *data type*.

The supported casts are shown in “Casting between data types” on page 109. If the cast is not supported, an error is returned.

When a character string is cast to a character string with a different length or a graphic string is cast to a graphic string with a different length, a warning occurs if any characters except trailing blanks are truncated. The warning also occurs if any characters are truncated when a BLOB operand is cast, or if the time zone characters are truncated when a TIMESTAMP WITH TIME ZONE operand is cast to a string

NULL

Specifies that the cast operand is null. The result is a null value with the specified target *data type*.

parameter-marker

A parameter marker, which is normally considered an expression, has a special meaning as a cast operand. When the cast operand is a *parameter-marker*, the *data type* that is specified represents the “promise” that the replacement value for the parameter marker will be assignable to the specified data type (using “store assignment” rules). Such a parameter marker is considered a *typed parameter marker*. Typed parameter markers are treated like any other typed value for the purpose of function resolution, a DESCRIBE of a select list, or column assignment.

data-type

Specifies the data type of the result. If the data type is not qualified, the SQL path is used to find the appropriate data type. For more information, see “SQL path” on page 65. For a description of *data-type*, see “CREATE TABLE” on page 1706. (For portability across operating systems, when specifying a floating-point data type, use REAL or DOUBLE instead of FLOAT.)

- If the cast operand is *expression*, see “Casting between data types” on page 109 and use any of the target data types that are supported for the data type of the cast operand.
- If the cast operand is NULL, you can use any data type.
- If the cast operand is a *parameter-marker*:

- If the target data type is a distinct type, the application that uses the parameter marker uses the source data type of the distinct type.
- Otherwise, any data type is valid.

length

Specifies the length of the result.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If *expression* is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If *expression* is a graphic string, OCTETS cannot be specified.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

lob-length

Specifies the length of the result.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If *expression* is a graphic string, OCTETS cannot be specified.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

CCSID *encoding-scheme*

Specifies the encoding scheme for the target data type. The specific CCSIDs for SBCS, BIT, and MIXED data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

CCSID *integer*

Specifies that the target data type be encoded using the CCSID *integer*. The value must be one of the CCSID values in DECP. If the second operand is CHAR, VARCHAR, or CLOB, the CCSID specified must be either a SBCS, or MIXED CCSID, or 65535 for bit data. If the second operand is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID specified must be a DBCS CCSID. See Determining the CCSID of the result if neither CCSID *integer* nor CCSID *encoding-scheme* is specified. See Determining the CCSID of the result for special considerations regarding CCSID 367.

Interaction between length and CCSID clauses: If both the *length* and CCSID clauses are specified, the data is first cast to the specified CCSID, and then the *length* is applied. If either CODEUNITS16 or CODEUNITS32 is specified, the specification of length applies to the units specified. That is, the data is converted to an intermediate form (in Unicode), the length is applied, and the data is converted to the specified CCSID.

Resolution of cast functions: DB2 uses the implicit or explicit schema name and the data type name of *data-type*, and function resolution to determine the specific function to use to convert *expression* to *data-type*. See Qualified function resolution for more information.

Result of the CAST: When numeric data is cast to character data, the data type of the result is a fixed-length character string, which is similar to the result that the CHAR function would give. (For more information, see “CHAR” on page 370.) When character data is cast to numeric data, the data type of the result depends on the data type of the specified number. For example, character data that is cast to an

integer becomes a large integer, which is similar to the result that the INTEGER function would give. (For more information see “INTEGER or INT” on page 468.)

If the data type of the result is character, the subtype of the result is determined as follows:

- If *expression* is graphic, the subtype of the result is mixed.
- If *expression* is a datetime data type, the subtype of the result is mixed. The exception is when the default encoding scheme is EBCDIC and there is no mixed or graphic data on the system for EBCDIC.
- If *expression* is a row ID and *data-type* is not CLOB, the result is bit data.
- If *expression* is character, the subtype of the result is the same as *expression*.
- Otherwise, the subtype depends on the encoding scheme of the result. If the encoding scheme of the result is not Unicode and the field MIXED DATA on installation panel DSNTIPF is NO, the subtype of the result is SBCS. Otherwise, the subtype of the result is mixed.

Casting constant values to DECFLOAT: To cast a constant value, where the value is negative zero, or a floating point constant to DECFLOAT, specify the value as a character string constant rather than a numeric constant. For example:

```
DECFLOAT('-0')           -- causes DB2 to retain the negative sign for a
                        -- value of negative zero
DECFLOAT('1.00E20')    -- causes DB2 to preserve the precision of the
                        -- floating point constant
```

Determining the CCSID and encoding scheme of the result: The CCSID of the result depends on whether the CCSID clause was specified and the context in which the CAST specification was specified.

If the CCSID clause was specified, the CCSID clause is used to determine the CCSID of the result as follows:

- If the CCSID clause was specified with EBCDIC, ASCII, or UNICODE, the clause determines the encoding scheme of the result. The CCSID of the result is the appropriate CCSID (from DECP) for that encoding scheme for the data type of the result.
- If the CCSID clause was specified with a numeric value representing bit data (65535), the CCSID of the result depends on the data type of the source. If the source data is not string data, the CCSID of the result is the appropriate CCSID for the application encoding scheme. See Note 1 in Table 4 on page 52. If the source is string data, the encoding scheme of the result is the same as the encoding scheme of *expression*, but the result is considered bit data.
- If the CCSID clause was specified with a numeric value, that number is the CCSID of the result. The encoding scheme of the result is determined from the numeric CCSID. In a CAST specification, CCSID 367 refers to ASCII data. For example, assume that MYDATA is string data to be cast to CHAR(10). The following CAST specification returns ASCII SBCS data:

```
CAST(MYDATA AS CHAR(10) CCSID 367)
```

To explicitly cast the data to Unicode SBCS, use the following syntax:

```
CAST(MYDATA AS CHAR(10) CCSID UNICODE
     FOR SBCS DATA)
```

If the CCSID clause was not specified, the CCSID of the result is 65535 if the result is bit data. Otherwise, if the data type of the result is a character or graphic string data type, the encoding scheme and CCSID of the result are determined as follows:

- If the *expression* and *data-type* are both character, the encoding scheme of the result is the same as *expression*. For example, assume CHAR_COL is a character column in the following sample:

```
CAST(CHAR_COL AS VARCHAR(25))
```

The result of the CAST is a varying length string with the same encoding scheme as the input. The CCSID of the result is the appropriate CCSID for the encoding scheme and subtype of the result.

- If the *expression* and *data-type* are both graphic, the encoding scheme and CCSID of the result is the same as *expression*.
- If the result is string and the *expression* is datetime, the result CCSID is the appropriate CCSID of the *expression* encoding scheme and the result subtype is the appropriate subtype of the CCSID.
- If the result is character, the encoding scheme and CCSID of the result depends on the context in which the CAST specification is specified:
 - If the statement follows the rules that are described for type 1 statements in “Determining the encoding scheme and CCSID of a string” on page 51, the CCSID is determined as follows:
 - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
 - Otherwise, the default EBCDIC encoding scheme is used for the result.

The CCSID of the result is the appropriate CCSID for the encoding scheme and subtype of the result.

- Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme and subtype of the result.
- If the result is graphic, the encoding scheme and the CCSID of the result depends on the context in which the CAST specification is specified:
 - If the statement follows the rules that are described for type 1 statements in “Determining the encoding scheme and CCSID of a string” on page 51, the CCSID is determined as follows:
 - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
 - Otherwise, the default EBCDIC encoding scheme is used for the result.
 - The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.
 - Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme of the result.
- Otherwise, the CCSID of the result depends on the context in which the CAST specification was specified.
 - If the statement follows the rules that are described for type 1 in statements in “Determining the encoding scheme and CCSID of a string” on page 51, the CCSID is determined as follows:
 - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
 - Otherwise, the default EBCDIC encoding scheme is used for the result.

The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.

Alternative syntax for casting distinct types: There is alternative syntax for casting a distinct type to its source data type and vice versa. Assume that a distinct type D_MONEY was defined with the following statement and column MONEY was defined with that data type.

```
CREATE TYPE D_MONEY AS DECIMAL(9,2);
```

DECIMAL(MONEY) is equivalent syntax to CAST(MONEY AS DECIMAL(9,2)). Both forms of the syntax use the cast function that DB2 generated when the distinct type D_MONEY was created to convert the distinct type to its source type of DECIMAL(9,2).

However, it is possible that different cast functions might be chosen for the equivalent syntax forms because of the difference in function resolution, particularly the treatment on unqualified names. Although the process of function resolution is similar for both, in the CAST specification as described above, DB2 uses the schema name of the target data type to locate the function. Therefore, if an unqualified data type name is specified as the target data type, DB2 uses the SQL path to resolve the schema name of the distinct type and then searches for the function in that schema. In function notation, when an unqualified function name is specified, DB2 searches the schemas in the SQL path to find an appropriate function match, as described under “Function resolution” on page 221. For example, assume that you defined the following distinct types, which implicitly gives you both USAGE authority on the distinct types and EXECUTE authority on the cast functions that are generated for them:

```
CREATE TYPE SCHEMA1.AGE AS DECIMAL(2,0);
  one of the generated cast functions is:
  FUNCTION SCHEMA1.AGE(SYSIBM.DECIMAL(2,0)) RETURNS SCHEMA1.AGE
CREATE TYPE SCHEMA2.AGE AS INTEGER;
  one of the generated cast functions is:
  FUNCTION SCHEMA2.AGE(SYSIBM.INTEGER) RETURNS SCHEMA2.AGE
```

If *STU_AGE*, an INTEGER host variable, is cast to the distinct type with either of the following statements and the SQL path is SYSIBM, SCHEMA1, SCHEMA2:

```
Syntax 1: CAST(:STU_AGE AS AGE);
Syntax 2: AGE(:STU_AGE);
```

different cast functions are chosen. For syntax 1, DB2 first resolves the schema name of distinct type AGE as SCHEMA1 (the first schema in the path that contains a distinct type named AGE for which you have EXECUTE authority for the appropriate generated cast function). Then it looks for a suitable function in that schema and chooses SCHEMA1.AGE because the data type of *STU_AGE*, which is INTEGER, is promotable to the data type of the function argument, which is DECIMAL(2,0). For syntax 2, DB2 searches all the schemas in the path for an appropriate function and chooses SCHEMA2.AGE. DB2 selects SCHEMA2.AGE over SCHEMA1.AGE because the data type of its argument (INTEGER) is an exact match for *STU_AGE* (INTEGER) and, therefore, a better match than the argument for SCHEMA1.AGE, which is DECIMAL(2,0).

Syntax alternatives: TIMEZONE can be specified as an alternative to TIME_ZONE.

Example 1: Assume that an application needs only the integer portion of the SALARY column, which is defined as DECIMAL(9,2) from the EMPLOYEE table. The following query for the employee number and the integer value of SALARY could be prepared.

```
SELECT EMPNO, CAST(SALARY AS INTEGER) FROM EMPLOYEE;
```

Example 2: Assume that two distinct types exist in schema SCHEMAX. Distinct type D_AGE was based on SMALLINT and is the data type for the AGE column in the PERSONNEL table. Distinct type D_YEAR was based on INTEGER and is the data type for the RETIRE_YEAR column in the same table. The following UPDATE statement could be prepared.

```
UPDATE PERSONNEL SET RETIRE_YEAR =?
WHERE AGE = CAST( ? AS SCHEMAX.D_AGE);
```

The first parameter is an untyped parameter marker that has a data type of RETIRE_YEAR. However, the application will use an integer for the parameter marker. The parameter marker does not need to be cast because the SET is an assignment.

The second parameter marker is a typed parameter marker that is cast to the distinct type D_AGE. Casting the parameter marker satisfies the requirement that comparisons must be performed with compatible data types. The application will use the source data type, SMALLINT, to process the parameter marker.

Example 3: A CAST specification can be used to explicitly specify the data type of a parameter in a context where a parameter marker must be typed. In the following example, the CAST specification is used to tell DB2 to assume that the value that will be provided as input to the TIME function will be CHAR(20). See “PREPARE” on page 2083 for a list of contexts when invoking functions where parameter markers can be untyped. For all other contexts when invoking a function, the CAST specification can be used to explicitly specify the type of a parameter marker.

```
INSERT INTO ADMF001.CASTSQLJ VALUES( TIME(CAST(? AS CHAR(20)) ) )
```

Example 4: Assume that an application wants to cast an EBCDIC string to Unicode UTF-8. The string contains the value 'Jürgen', which is 6 bytes in ASCII or EBCDIC and is 7 bytes in Unicode UTF-8. In the following query, the CAST specification is invoked with the *length* clause with CODEUNITS32 specified to ensure that the data is not truncated. (In this case, CODEUNITS16 could also be specified as the string unit.)

```
SELECT CAST('Jürgen' AS VARCHAR(6 CODEUNITS32) CCSID UNICODE)
FROM SYSIBM.SYSDUMMY1;
```

For this query, the data is converted from EBCDIC to Unicode UTF-16, the length clause is applied, and then the UTF-16 result is converted to UTF-8.

Example 5: When a keyword is used for a special value that is expressed as a constant in a context where the keyword could be interpreted as a name, the CAST specification can be used to explicitly cast the special value to decimal-floating point. Assume that MYTAB contains columns named C1 and INFINITY, and that you want to reference the decimal float-point value for infinity in the same SQL statement. Use the CAST specification to explicitly cast INFINITY as a decimal floating-point value to ensure that it is not interpreted as the name of a column, parameter or variable:

```
SELECT INFINITY -- column named INFINITY
FROM MYTAB
WHERE C1 = CAST ('INFINITY' AS DECFLOAT) -- comparison is made with the
-- decimal floating-point
-- infinity value
```

XMLCAST specification

The XMLCAST specification returns the first operand (the cast operand) converted to the type specified by *data-type*.

XMLCAST supports casts involving XML values, including conversions between non-XML data types and the XML data type. Either the type of the cast operand or the specified data type must be XML. If both the type of the cast operand and the target data type are XML, XMLCAST acts as a no-op.

expression

If the cast operand is an expression, the result is the argument value converted to the specified target data type. The expression or the target data type must be the XML data type. *expression* cannot be a host variable or parameter marker.

NULL

If the cast operand is the NULL keyword, the target data type must be the XML data type. The result is a null XML value.

parameter-marker

If the cast operand is a parameter marker, the target data type must be the XML data type. A parameter marker (specified as a question mark character) is normally considered to be an expression, but in this case because it has special meaning. When the cast operand is a *parameter-marker*, the data type that is specified represents the "promise" that the replacement value for the parameter marker will be assignable to the specified data type (using assignment rules). Such a parameter marker is considered to be a typed parameter marker, which is treated like any other typed value for the purpose of function resolution, a describe operation on a select list, or column assignment.

data-type

The name of an SQL data type. If the name is not qualified, the SQL path is used to perform data type resolution. *data-type* must not specify a distinct type. If a data type has associated attributes, such as length or precision and scale, these attributes should be included when specifying a value for *data-type*. CHAR defaults to a length of 1, and DECIMAL defaults to a precision of 5 and a scale of 0 if not specified. CLOB and DBCLOB default to a length of 1M. When the target data type is XML and the source data type is TIMESTAMP, trailing zeroes in the fractional seconds part of the value are not included in the result. Restrictions on the supported data types are based on the specified cast operand. The default encoding scheme for string data types is Unicode. The encoding scheme can be changed by specifying the CCSID clause.

Table 48. Supported conversions from Non-XML values to XML values

| Source data type | Target data type: XML | Resulting XML schema type |
|------------------|-----------------------|---------------------------|
| DATE | Y | xs:date |
| TIME | Y | xs:time |

Table 48. Supported conversions from Non-XML values to XML values (continued)

| Source data type | Target data type: XML | Resulting XML schema type |
|-----------------------------|-----------------------|---------------------------|
| TIMESTAMP(p) WITH TIME ZONE | Y | xs:dateTime |

Examples

Example 1: Create a null XML value.

```
XMLCAST(NULL AS XML)
```

Example 2: Convert a value extracted from an XMLQUERY expression into an INTEGER:

```
XMLCAST(XMLQUERY('/PRODUCT/QUANTITY'  
PASSING xmlcol) AS INTEGER)
```

Example 3: Convert a value extracted from an XMLQUERY expression into a varying-length character string:

```
XMLCAST(XMLQUERY('/PRODUCT/NAME'  
PASSING xmlcol) AS VARCHAR(20))
```

Note that in the above two examples, if the XMLQUERY returns a sequence of more than one node, the XMLCAST specification will return an error.

Example 4: Convert a value extracted from an SQL scalar subquery into an XML value:

```
XMLCAST((SELECT quantity FROM product AS p  
WHERE p.id = 1077) AS XML)
```

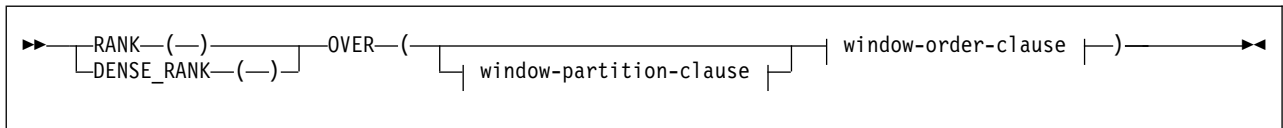

OLAP specification

Online analytical processing (OLAP) specifications provide the ability to return ranking, row numbering, and aggregation information as a scalar value in the result of a query. An OLAP specification can be included in an expression, in a *select-list*, or in the ORDER BY clause of a *select-statement*. The query result to which the OLAP specifications is applied is the result table of the innermost subselect that includes the OLAP specification.

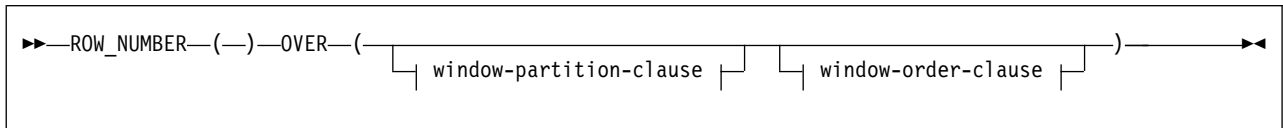

OLAP-specification

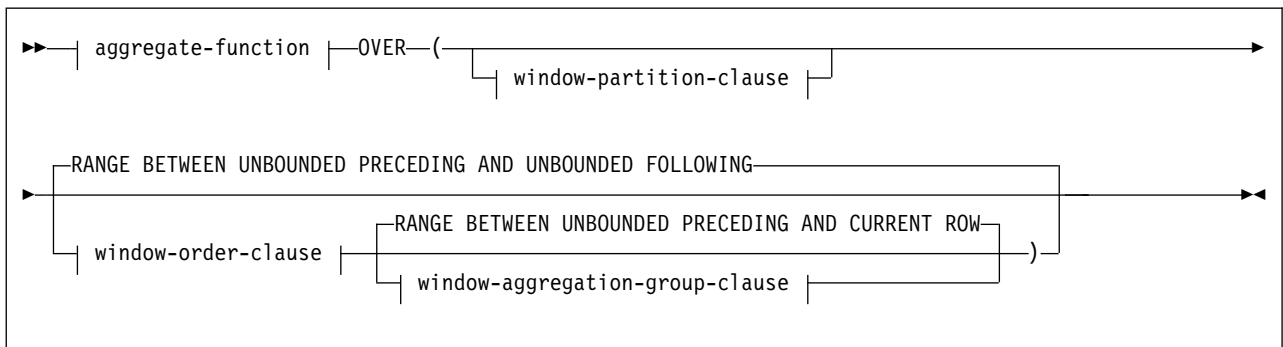

ordered-OLAP-specification

numbering-specification

aggregation-specification

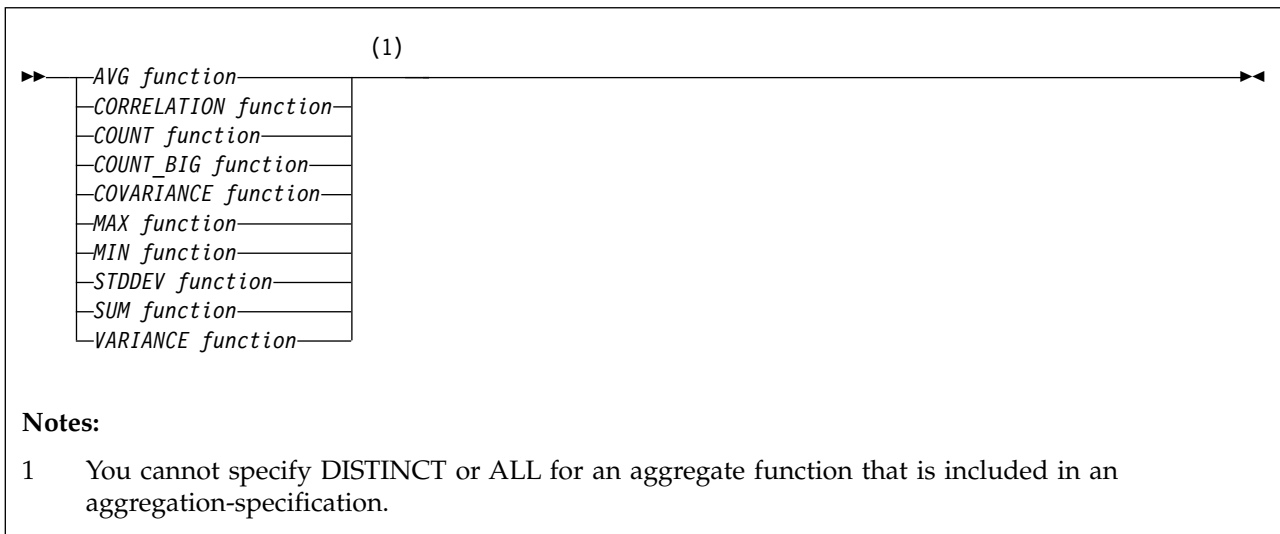

window-partition-clause

window-order-clause

|
| **aggregate-function**

|
| **window-aggregation-group-clause**

|
| **group-start**

|
| **group-between**

RANK, DENSE_RANK, and ROW_NUMBER are sometimes called window functions.

An OLAP specification is not valid in a **WHERE**, **VALUES**, **GROUP BY**, **HAVING**, or **SET** clause. An OLAP specification cannot be used as an argument of an aggregate function.

When invoking an OLAP specification, a window is specified that defines the rows over which the function is applied and in which order.

The result of a RANK, DENSE_RANK, or ROW_NUMBER specification is BIGINT. The result cannot be null.

RANK or DENSE_RANK

Specifies that the ordinal rank of a row within the specified window is computed. Rows that are not distinct with respect to the ordering within the specified window are assigned the same rank. The results of the ranking can be defined with or without gaps in the numbers that result from duplicate values.

RANK

Specifies that the rank of a row is defined as 1 plus the number of rows that strictly precede the row. Thus, if two or more rows are not distinct with respect to the ordering, there will be one or more gaps in the sequential rank numbering.

DENSE_RANK

Specifies that the rank of a row is defined as 1 plus the number of preceding rows that are distinct with respect to the ordering. Therefore, there will be no gaps in the sequential rank numbering.

ROW_NUMBER

Specifies that a sequential row number is computed for the row that is defined by the ordering, starting with 1 for the first row. If the **ORDER BY** clause is not specified in the window, the row numbers are assigned to the rows in an arbitrary order, as the rows are returned (not according to any **ORDER BY** clause in the *select-statement*).

PARTITION BY (*partitioning-expression*,...)

Defines the partition within which the OLAP operation is applied. A *partitioning-expression* is an expression that is used in defining the partitioning of the result table. Each column name that is referenced in a *partitioning-expression* must unambiguously reference a column of the result table of the subselect that contains the OLAP specification. A *partitioning-expression* cannot include a *scalar-fullselect* an XMLQUERY or XMLEXISTS expression or any function that is not deterministic or has an external action.

ORDER BY (*sort-key-expression*,...)

Defines the ordering of rows within a partition that is used to determine the value of the OLAP specification. It does not define the ordering of the result table.

sort-key-expression

Specifies an expression to use in defining the ordering of the rows within a window partition. Each column name that is referenced in a *sort-key-expression* must unambiguously reference a column of the result table of the subselect, including the OLAP specification. A *sort-key-expression* cannot include a scalar fullselect, an XMLQUERY or XMLEXISTS expression, or any function that is not deterministic or that has an external action.

ASC

Specifies that the values of *sort-key-expression* are used in ascending order.

DESC

Specifies that the values of *sort-key-expression* are used in descending order.

NULLS FIRST

Specifies that the window ordering considers null values before all non-null values in the sort order.

NULLS LAST

Specifies that the window ordering considers null values after all non-null values in the sort order.

window-aggregation-group-clause

The aggregation group of a given row is a set of rows that is defined in relation to the given row (in the ordering of the rows in the partition of the given row). *window-aggregation-group-clause* specifies the aggregation group. If this clause is not specified and a *window-order-clause* is also not specified, the aggregation group consists of all rows of the window partition. The aggregation group of all rows of the window partition can be explicitly specified using the RANGE or ROWS clauses.

If *window-order-clause* is specified, but *window-aggregation-group-clause* is not specified, the window aggregation group consists of all rows that precede a

given row of the partition of the given row or all rows that are peers of the given row in the window ordering of the window partition that is defined by the *window-order-clause*

ROW

Specifies that the aggregation group is defined by counting rows.

RANGE

Specifies that the aggregation group is defined by an offset from a sort key.

group-start

Specifies the starting point for the aggregation group. The aggregation group end is the CURRENT ROW. Specifying *group-start* is equivalent to specifying *group-between* as **BETWEEN *group-start* AND CURRENT ROW**.

group-between

Specifies that the aggregation group start and end based on either ROWS or RANGE.

group-end

Specifies the ending point for the aggregation group. The aggregation group start is the CURRENT ROW. Specifying *group-end* is equivalent to specifying *group-between* as **BETWEEN CURRENT ROW AND *group-end***.

UNBOUNDED PRECEDING

Specifies that the entire partition that precedes the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that precedes the current row can also be specified with multiple *sort-key-expressions* in the *window-order-clause*.

UNBOUNDED FOLLOWING

Specifies that the entire partition that follows the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that follows the current row can also be specified with multiple *sort-key-expressions* in the *window-order-clause*.

CURRENT ROW

Specifies that the aggregation group starts or ends based on the current row. If ROWS is specified, the current row is the aggregation group boundary. If RANGE is specified, the aggregation group boundary includes the set of rows with the values specified for the *sort-key-expression* as the current row. This clause cannot be specified in *group-bound-2* if *group-bound-1* specifies *unsigned-constant* **FOLLOWING**.

unsigned-constant **PRECEDING**

Specifies either the range or the number of rows that precede the current row. If ROWS is specified, *unsigned-constant* must be zero or a positive integer that indicates a number of rows. If RANGE is specified, the data type of *unsigned-constant* must be comparable to the data type of the *sort-key-expression* of the *window-order-clause*. Only one *sort-key-expression* is allowed, and the data type of *sort-key-expression* must allow subtraction. This clause cannot be specified in *group-bound-2* if *group-bound-1* is CURRENT ROW or *unsigned-constant* **FOLLOWING**.

unsigned-constant **FOLLOWING**

Specifies either the range or the number of rows that follow the current row. If ROWS is specified, *unsigned-constant* must be zero or a positive integer that indicates a number of rows. If RANGE is specified, the data type of *unsigned-constant* must be comparable to the data type of the

| *sort-key-expression* of the *window-order-clause*. Only one *sort-key-expression* is
| allowed, and the data type of *sort-key-expression* must allow addition.

Notes

| **Using a column mask with an OLAP specification:** If a column mask is used to
| mask the column values in the final result table and an OLAP specification is
| referenced in the select list that is used to derive the final result table, the column
| mask cannot be applied to the column that is specified in the *partitioning-expression*
| or the *sort-key-expression* in the OLAP specification.

| **Syntax alternatives and synonyms:** For compatibility, the keywords **DENSERANK**
| and **ROWNUMBER** can be used as synonyms for **DENSE_RANK** and
| **ROW_NUMBER** respectively.

| **Example 1:** Display the ranking of employees that have a total salary of more than
| \$30,000, in order by last name:

```
SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,  
       RANK() OVER(ORDER BY SALARY+BONUS DESC) AS RANK_SALARY  
FROM EMP WHERE SALARY+BONUS > 30000  
ORDER BY LASTNAME;
```

| If the result is to be ordered by rank, **ORDER BY LASTNAME** would be replaced with
| **ORDER BY RANK_SALARY**.

| **Example 2:** Rank the departments according to their average total salary:

```
SELECT WORKDEPT, AVG(SALARY+BONUS) AS AVG_TOTAL_SALARY,  
       RANK() OVER(ORDER BY AVG(SALARY+BONUS) DESC) AS RANK_AVG_SAL  
FROM EMP  
GROUP BY WORKDEPT  
ORDER BY RANK_AVG_SAL;
```

| **Example 3:** Rank the departments according to their education level. Having
| multiple employees with the same rank in the department should not increase the
| next ranking value:

```
SELECT WORKDEPT, EMPNO, LASTNAME, FIRSTNAME, EDLEVEL,  
       DENSE_RANK() OVER  
       (PARTITION BY WORKDEPT ORDER BY EDLEVEL DESC) AS RANK_EDLEVEL  
FROM EMP  
ORDER BY WORKDEPT, LASTNAME;
```

| **Example 4:** Provide row numbers in the results of a query:

```
SELECT ROW_NUMBER() OVER(ORDER BY WORKDEPT, LASTNAME) AS NUMBER,  
       LASTNAME, SALARY  
FROM EMP  
ORDER BY WORKDEPT, LASTNAME;
```

| **Example 5:** List the top five wage earners:

```
SELECT EMPNO, LASTNAME, FIRSTNAME, TOTAL_SALARY, RANK_SALARY  
FROM (SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,  
          RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY  
FROM EMP) AS RANKED_EMPLOYEE  
WHERE RANK_SALARY < 6  
ORDER BY RANK_SALARY;
```

| A nested table expression is used to first compute the result, including the ranking,
| before the rank can be used in the **WHERE** clause. A common table expression
| could also have been used.

| *Example 6:* The following example is used to calculate the 30 day moving average
| for the stocks 'ABC' and 'XYZ' during 2005:

```
| CREATE VIEW V1 AS  
| SELECT SYMBOL, TRADINGDATE,  
|         AVG(CLOSINGPRICE) OVER (PARTITION BY SYMBOL  
|                               ORDER BY TRADINGDATE  
|                               ROWS BETWEEN 29 PRECEDING AND CURRENT ROW)  
| FROM DAILYSTOCKDATA  
| WHERE SYMBOL IN ('ABC', 'XYZ')  
|        AND TRADINGDATE BETWEEN DATE('2005-01-01') - 2 MONTHS AND '2005-12-31';  
|  
| SELECT SYMBOL, TRADINGDATE, MOVINGAVG30DAY  
| FROM V1  
| WHERE TRADINGDATE BETWEEN '2005-01-01' AND '2005-12-31'  
| ORDER BY SYMBOL, TRADINGDATE;  
|
```

ROW CHANGE expression

A ROW CHANGE expression returns a token or a timestamp that represents the last change to a row.

ROW CHANGE expression

TIMESTAMP

Specifies that a timestamp is returned that represents the last time when a row was changed. If the row has not been changed, the result is the time that the initial value was inserted.

TOKEN

Specifies that a token that is a BIGINT value is returned that represents a relative point in the modification sequence of a row. If the row has not been changed, the result is a token that represents when the initial value was inserted.

FOR *table-designator*

Identifies the table in which the expression is referenced. *table-designator* must uniquely identify a base table, a view, or a nested table expression of a subselect. If *table-designator* identifies a view or a nested table expression, the ROW CHANGE expression returns the TIMESTAMP or TOKEN of the base table of the view or the nested table expression. The view or nested table expression must contain only one base table in its outer subselect. *table-designator* must not identify a materialized view, a nested table expression that is materialized, an alias, or a synonym.

The result can be null. The ROW CHANGE TIMESTAMP and ROW CHANGE TOKEN expressions are not deterministic.

Notes

Tables without a row change timestamp column:

For tables without a row change timestamp column, the ROW CHANGE TIMESTAMP expression returns a timestamp value that reflects changes made to the page instead of to the row. This timestamp value indicates that at least one row in the page has changed, but does not indicate which row, or even how many rows, have changed. The ROW CHANGE TIMESTAMP expression might indicate that a row has changed, however, the change might be for other rows in the same page.

In a data sharing environment, the returned timestamp value is based on the LRSN value of the page and reflects the most recent time the page was modified.

In a non-data sharing environment, the returned timestamp value is based on the RBA value of the page. In a non-data sharing environment, changes made to the same page within a half hour of each other might be indistinguishable. For example, issuing the following SELECT statements in a non-data sharing environment will possibly return the same value, even though the row was changed between the two SELECT statements:

```
CREATE TABLE T1 (C1 INTEGER NOT NULL);
INSERT INTO T1 VALUES (1);
SELECT ROW CHANGE TIMESTAMP FOR T1 FROM T1;
UPDATE T1 SET C1 = 2 WHERE C1 = 1;
SELECT ROW CHANGE TIMESTAMP FOR T1 FROM T1;
```

Example 1:

The following example returns all the rows that have been changed in the last day:

```
SELECT * FROM ORDERS
WHERE ROW CHANGE TIMESTAMP FOR ORDERS >
CURRENT TIMESTAMP - 24 HOURS;
```

Example 2:

The following example returns a timestamp value that corresponds to the most recent change to each row from the EMP table for those employees in department 20:

```
SELECT ROW CHANGE TIMESTAMP FOR EMP
FROM EMP WHERE DEPTNO = 20;
```

Example 3:

The following example returns a BIGINT value that corresponds to a relative point in the modification sequence of EMP with employee number '3500':

```
SELECT ROW CHANGE TOKEN FOR EMP
FROM EMP WHERE EMPNO = '3500';
```

Sequence reference

A sequence is referenced by using the NEXT VALUE and PREVIOUS VALUE expressions specifying the name of the sequence.

sequence-reference

NEXT VALUE FOR*sequence-name*

A NEXT VALUE expression generates and returns the next value for a specified sequence. A new value is generated for a sequence when a NEXT VALUE expression specifies the name of the sequence. However, if there are multiple instances of a NEXT VALUE expression specifying the same sequence name within a query, the sequence value is incremented only once for each row of the result, and all instances of NEXT VALUE return the same value for a row of the result. The NEXT VALUE expression is not deterministic with external actions since it causes the sequence value to be incremented.

When the next value for the sequence is generated, if the maximum value for an ascending sequence or the minimum value for a descending sequence of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, then an error occurs. To avoid this error, either alter the sequence attributes to extend the range of value or to enable cycles for the sequence or drop and re-create the sequence with a different data type that allows a larger range of values.

The data type and length attributes of the result of a NEXT VALUE expression are the same as for the specified sequence. The result cannot be null.

PREVIOUS VALUE FOR*sequence-name*

A PREVIOUS VALUE expression returns the most recently generated value for the specified sequence for a previous statement within the current application process. This value can be repeatedly referenced by using PREVIOUS VALUE expressions to specify the name of the sequence. There can be multiple instances of PREVIOUS VALUE expressions specifying the same sequence name within a single statement and they all return the same value.

A PREVIOUS VALUE expression can be used only if a NEXT VALUE expression specifying the same sequence name has already been referenced in the current application process.

The data type and length attributes of the result of a PREVIOUS VALUE expression are the same as for the specified sequence. The result cannot be null.

sequence-name

Identifies the sequence that is to be referenced. The combination of name and the implicit or explicit schema name must identify an existing sequence at the current server. *sequence-name* must not be the name of an internal sequence object that is generated by DB2 for an identity column. The contents of the SQL PATH are not used to determine the implicit qualifier of a sequence name.

Notes

Authorization:

If a sequence is referenced in a statement, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For the sequence identified in the statement:
 - The USAGE privilege on the sequence
 - Ownership of the sequence
- SYSADM or SYSCTRL authority

Generating values with NEXT VALUE:

When a value is generated for a sequence, that value is consumed, and the next time that a value is requested, a new value will be generated. This is true even when the statement containing the NEXT VALUE expression fails or is rolled back.

Scope of NEXT VALUE and PREVIOUS VALUE:

The value of PREVIOUS VALUE cannot be directly set and is a result of executing the NEXT VALUE expression for the sequence. The value of PREVIOUS VALUE persists until the next value is generated for the sequence in the current session, the sequence is dropped or altered, or the application session ends.

The value for the sequence cannot persist across a COMMIT or ROLLBACK for a local or remote application if, after the COMMIT or ROLLBACK, the DB2 application thread or server thread is assigned to another user or DB2 connection because of some form of thread reuse, re-signon, or connection pooling is in effect. For example, this can occur for CICS-DB2 applications and for client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing because they are not able to restore the NEXT or PREVIOUS VALUES for a sequence. In these situations, the availability of the value for a sequence should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following:

- issue an EXEC CICS SYNCPOINT command
- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value that is associated with NEXT VALUE or PREVIOUS VALUE expressions across transaction boundaries for local or distributed applications that are subject to thread reuse, re-signon, or connection pooling, take one of the following actions to prevent the local or server thread from re-signon, being reused by a different user, or from being pooled:

- Define at least one cursor as WITH HOLD and leave it as OPEN.
- Specify the bind option KEEP DYNAMIC(YES).

Use as a unique key value:

The same sequence number can be used as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row (this generates the sequence value), and a

PREVIOUS VALUE expression for the other rows (the instance of PREVIOUS VALUE refers to the sequence value most recently generated in the current session), as shown in the following example:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
INSERT INTO LINE_ITEM (ORDERNO, PARTNO, QUANTITY)
VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 1);
```

Allowed use of NEXT VALUE and PREVIOUS VALUE:

The NEXT VALUE and PREVIOUS VALUE expressions can be specified in the following places:

- Within the *select-clause* of a SELECT statement or SELECT statement that does not contain a **DISTINCT** keyword, a **GROUP BY** clause, an **ORDER BY** clause, or a set operator.
- Within a **VALUES** clause of an INSERT statement, including a multiple row INSERT statement with multiple **VALUES** clauses and the insert operation of a MERGE statement, which can include a NEXT VALUE expression for a particular sequence name for each **VALUES** clause.
- Within the *select-clause* of the fullselect of an INSERT statement.
- Within the **SET** clause of a searched or positioned UPDATE statement, including the update operation of the MERGE statement, though NEXT VALUE cannot be specified in the *select-clause* of the fullselect of an expression in the **SET** clause.

A PREVIOUS VALUE expression can be specified anywhere with a **SET** clause of an update operation (the UPDATE or MERGE statement), but a NEXT VALUE expression can be specified only in a **SET** clause if it is not within the *select-clause* of the fullselect of an expression. For instance, the following uses of sequence references are supported:

```
UPDATE T SET C1 = (SELECT PREVIOUS VALUE FOR S1 FROM T);
UPDATE T SET C1 = PREVIOUS VALUE FOR S1;
UPDATE T SET C1 = NEXT VALUE FOR S1;
```

The following uses of sequence references are not supported:

```
UPDATE T SET C1 = (SELECT NEXT VALUE FOR S1 FROM T);
SET :C2 = (SELECT NEXT VALUE FOR S1 FROM T);
```

- In a **SET** *host-variable* or *assignment-statement*, except within the *select-clause* of the fullselect of an expression.

The following uses of sequence references are supported:

```
SET ORDERNUM = NEXT VALUE FOR INVOICE;
SET ORDERNUM = PREVIOUS VALUE FOR INVOICE;
```

The following uses of sequence references are not supported:

```
SET X = (SELECT NEXT VALUE FOR S1 FROM T);
SET X = (SELECT PREVIOUS VALUE FOR S1 FROM T);
```

- In a **VALUES** or **VALUES INTO** statement though not within the *select-clause* of the fullselect of an expression.
- Within the *SQL-routine-body* of a CREATE or ALTER PROCEDURE statement for a SQL procedure.
- Within the *RETURN-statement* of a CREATE FUNCTION statement for an SQL function.
- Within the *SQL-trigger-body* of a CREATE TRIGGER statement (PREVIOUS VALUE is not allowed).

Use of PREVIOUS VALUE in a nested application:

PREVIOUS VALUE is defined to have a linear scope within an application

session. Therefore, in a nested application on entry to a nested function, procedure, or trigger, the nested application inherits the most recently generated value for a sequence. That is, an invocation of PREVIOUS VALUE in a nested application reflects sequence activity done in the invoking environment prior to entering the nested application. In addition, on return from a function, procedure, or trigger, the invoking application is affected by any sequence activity in the lower level applications. That is, an invocation of PREVIOUS VALUE in the invoking application after returning from the nested application reflects any sequence activity that occurred in the lower level applications.

Restrictions on the use of NEXT VALUE and PREVIOUS VALUE:

Some of the places where the NEXT VALUE and PREVIOUS VALUE expressions cannot be specified include the following:

- Join condition of a full outer join
- DEFAULT value for a column in a CREATE TABLE or ALTER TABLE statement
- Materialized query table definition in a CREATE TABLE or ALTER TABLE statement
- Condition of a CHECK constraint
- Input value specification for LOAD
- CREATE VIEW statement
- The SELECT list of a subselect that contains a NOT ATOMIC data change statement
- ORDER BY clause when used in an OLAP specification

In addition, the NEXT VALUE expression cannot be specified in the following places:

- A CASE expression
- The parameter list of an aggregate function
- A subquery in a context other than those explicitly allowed
- A SELECT statement for which the outer SELECT contains a DISTINCT operator or a GROUP BY clause
- A SELECT statement for which the outer SELECT is combined with another SELECT statement using a set operator
- A join condition of a join
- A nested table expression
- The parameter list of a table function
- A *select-clause* of the fullselect of an expression in the SET clause of an UPDATE, a DELETE, or a MERGE statement.
- A WHERE clause of the outer-most SELECT statement or a DELETE, an UPDATE, or a MERGE statement
- An ORDER BY clause of the outer-most SELECT statement
- An IF, WHILE, DO UNTIL, or CASE statement in an SQL routine

Using sequence expressions with a cursor:

Normally, a SELECT NEXT VALUE FOR ORDER_SEQ FROM T1 would produce a result table containing as many generated values from the sequence ORDER_SEQ as the number of rows retrieved from T1. A reference to a NEXT VALUE expression in the SELECT statement of a cursor refers to a value that is generated for a row of the result table. A sequence value is generated for a NEXT VALUE expression each time a row is retrieved.

If blocking is done at a client in a DRDA environment, sequence values might get generated at the DB2 server before the processing of an application's FETCH statement. If the client application does not explicitly fetch all the rows that have been retrieved from the database, the application will never see all those values of the sequence that are generated but not fetched (as many values as the rows that are not fetched). These generated but not fetched values might constitute a gap in the sequence. If it is important to prevent such a gap in the sequence, do the following:

- Use NEXT VALUE only where it would function without being controlled by a cursor and where block-fetching by the client will have no effect on it.
- If you must use NEXT VALUE in the SELECT statement of a cursor-definition, weigh the importance of preventing the gap against performance and other implications of taking the following actions:
 - Use FETCH FOR 1 ROW ONLY clause with the SELECT statement.
 - Try preventing block-fetch by other means documented in Block fetch (Introduction to DB2 for z/OS).

Using the PREVIOUS VALUE expression with a cursor:

A reference to the PREVIOUS VALUE expression in a SELECT statement of a cursor is evaluated at OPEN time. In other words, a reference to the PREVIOUS VALUE expression in the SELECT statement of a cursor refers to the last value generated by this application process for the specified sequence prior to the opening of the cursor and, once evaluated at OPEN time, the value returned by PREVIOUS VALUE within the select statement of the cursor will not change from FETCH to FETCH, even if NEXT VALUE is invoked with the select statement of the cursor. After the cursor is closed, the value of PREVIOUS VALUE will be the last NEXT VALUE that is generated by the application process.

IF PREVIOUS VALUE is used in the SELECT statement of a cursor while the cursor is open, the value of PREVIOUS VALUE would be the last NEXT VALUE for the generated sequence before the cursor was opened. After the cursor is closed, the value of PREVIOUS VALUE would be the last NEXT VALUE generated by the application process.

Syntax alternatives and synonyms:

For compatibility, the keywords NEXTVAL and PREVVAL can be used as synonyms for NEXT VALUE and PREVIOUS VALUE respectively.

sequence-name.NEXTVAL can be specified in place of **NEXT VALUE FOR** *sequence-name*, and *sequence-name*.CURRVAL can be specified in place of **PREVIOUS VALUE FOR** *sequence-name*.

Example

Assume that there is a table called ORDER, and that a sequence called ORDER_SEQ is created as follows:

```
CREATE SEQUENCE ORDER_SEQ START WITH 1
      INCREMENT BY 1
      NO MAXVALUE
      NO CYCLE
      CACHE 24
```

The following examples illustrate how to generate an ORDER_SEQ sequence number with a NEXT VALUE expression:

```

INSERT INTO ORDER (ORDERNO, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
UPDATE ORDER SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
WHERE CUSTNO = 123456;
VALUES NEXT VALUE FOR ORDER_SEQ INTO :HV_SEQ;

```

Predicates

A *predicate* specifies a condition that is true, false, or unknown about a given row or group.

The types of predicates are:

The following rules apply to predicates of any type:

- Predicates are evaluated after the expressions that are operands of the predicate.
- All values that are specified in the same predicate must be compatible.
- Except for the EXISTS predicate, a subquery in a predicate must specify a single column unless the operand on the other side of the comparison operator is a fullselect.
- The value of a host variable can be null (that is, the variable can have a negative indicator variable).
- The CCSID conversion of operands of predicates that involve two or more operands is done according to “Conversion rules for comparisons” on page 137.
- Use of an XML value is limited to the NULL or XMLEXISTS predicates.

Row-value-expression: The operand of several predicates (basic, quantified, DISTINCT, and IN) can be a *row-value-expression*:

A *row-value-expression* returns a single row that consists of one or more column values. The values can be specified as a list of expressions. The number of columns that are returned by the *row-value-expression* is equal to the number of expressions that are specified in the list.

Other predicate examples: In addition to the examples of predicates in the following topics, see information on distinct type comparisons in “Assignment and

comparison” on page 119, which contains several examples of predicates that use distinct types. “Distinct type comparisons” on page 141, which contains several examples of predicates that use distinct types.

Basic predicate

A *basic predicate* compares two values or compares a set of values with another set of values.

When *expression* is a fullselect, the fullselect must return a single result column with a single value, whether null or not null. If the value of either operand is null or the result of the fullselect is empty, the result of the predicate is unknown. Otherwise, the result is either true or false.

When a *row-value-expression* is specified on the left side of the operator, another *row-value-expression*, with an identical number of value expressions, must be specified on the right side. The data types of the corresponding expressions or columns of the *row-value-expressions* must be compatible.

The value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the operator, as in the following:

- If the operator is =, the result of the predicate is:
 - True - if all pairs of corresponding value expressions evaluate to true.
 - False - if any one pair of corresponding value expressions evaluates to false.
 - Unknown - if the comparisons is neither true nor false. That is, if at least one comparison of corresponding value expressions is unknown because of a null value and no pair of corresponding value expressions evaluates to false.
- If the operator is <>, the result of the predicate (Rx1,Rx2,...,Rxn) <> (Ry1,Ry2,...,Ryn) is:

15. The following forms of the comparison operators are also supported in basic and quantified predicates in code pages where the exclamation point is X'5A': !=, !<, and !>. In addition, the forms ^=, ^<, and ^> are supported as long as the code point used for the logical not symbol is the correct one for the specified code page. These forms of the operators are intended only to support existing SQL statements that use them and are not recommended for use when writing new SQL statements.

A logical not sign (^) can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs. To avoid this problem, substitute an equivalent operator for any operator that includes a not sign. For example, substitute '<>' for '^<', '<=' for '^>', and '>=' for '^<'.

- True - if, and only if, $R_{xi}=R_{yi}$ evaluates to false for some value of i . That is, there is at least one pair of non-null values, R_{xi} and R_{yi} , that are not equal to each other.
- False - if, and only if, $R_{xi}=R_{yi}$ evaluates to true for every value of i . That is, $(R_{x1},R_{x2},\dots,R_{xn})=(R_{y1},R_{y2},\dots,R_{yn})$ is true.
- Unknown - if the comparison is neither true nor false. That is, R_{xi} or R_{yi} is a null value for some value of i , and there is no value of j such that $R_{xj}=R_{yj}$ evaluates to false.

Table 49. For values x and y

| Predicate | Is true if and only if ... |
|------------|-------------------------------------|
| $x = y$ | x is equal to y |
| $x \neq y$ | x is not equal to y |
| $x < y$ | x is less than y |
| $x > y$ | x is greater than y |
| $x \leq y$ | x is less than or equal to y |
| $x \geq y$ | x is greater than or equal to y |

Examples for values x and y :

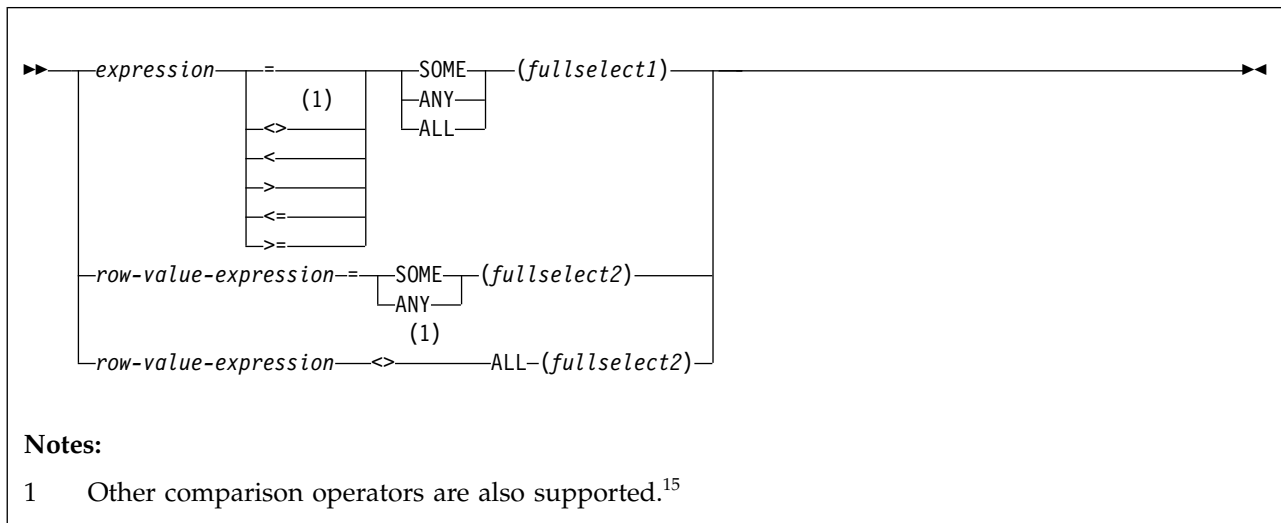

```
EMPNO = '528671'
SALARY < 20000
PRSTAFF <> :VAR1
SALARY >= (SELECT AVG(SALARY) FROM DSN8A10.EMP)
```

Example: List the name, first name, and salary of the employee who is responsible for the 'SECRET' project. This employee might appear in either the PROJA1 or PROJA2 tables. A UNION is used in case the employee appears in both tables to eliminate duplicate RESPEMP values.

```
SELECT LASTNAME, FIRSTNAME, SALARY
FROM DSN8A10.EMP X
WHERE EMPNO = (
SELECT RESPEMP
FROM PROJA1 Y
WHERE MAJPROJ = 'SECRET'
UNION
SELECT RESPEMP
FROM PROJA2 Z
WHERE MAJPROJ = 'SECRET');
```

Quantified predicate

A *quantified predicate* compares a value or values with a collection of values.

When *expression* is specified, *fullselect1* must return a single result column, and can return any number of values, whether null or not null. The result depends on the operator that is specified:

- When the operator is *ALL*, the result of the predicate is:
 - True – if the result of the fullselect is empty or if the specified relationship is true for every value returned by the fullselect.
 - False – if the specified relationship is false for at least one value returned by the fullselect.
 - Unknown – if the specified relationship is not false for any values returned by the fullselect and at least one comparison is unknown because of a null value.
- When the operator is *SOME* or *ANY*, the result of the predicate is:
 - True – if the specified relationship is true for at least one value returned by the fullselect.
 - False – if the result of the fullselect is empty or if the specified relationship is false for every value returned by the fullselect.
 - Unknown – if the specified relationship is not true for any of the values returned by the fullselect and at least one comparison is unknown because of a null value.

When *row-value-expression* is specified, the number of result columns returned by *fullselect2* must be the same as the number of value expressions specified by *row-value-expression*, and *fullselect2* can return any number of rows of values. The data types of the corresponding expressions of the row value expressions must be compatible. The value of each expression from *row-value-expression* is compared with the value of the corresponding result column from *fullselect2*. The value of the predicate depends on the operator that is specified:

- When the operator is *ALL*, the result of the predicate is:
 - True – if the result of *fullselect2* is empty or if the specified relationship is true for every row returned by *fullselect2*.
 - False – if the specified relationship is false for at least one row returned by *fullselect2*.

- Unknown – if the specified relationship is not false for any row returned by *fullselect2* and at least one comparison is unknown because of a null value.
- When the operator is SOME or ANY, the result of the predicate is:
 - True – if the specified relationship is true for at least one row returned by *fullselect2*
 - False – if the result of the fullselect is empty or if the specified relationship is false for every row returned by *fullselect2*.
 - Unknown – if the specified relationship is not true for any of the rows returned by *fullselect2* and at least one comparison is unknown because of a null value.

Quantified predicates are equivalent to IN predicates. See Table 55 on page 292 for some examples of equivalent quantified and IN predicates.

Examples: Use the following tables when referring to the following examples. In all examples, “row *n* of TBLA” refers to the row in TBLA for which COLA has the value *n*.

Table 50. TBLA

| COLA |
|------|
| 1 |
| 2 |
| 3 |
| 4 |

Table 51. TBLB

| COLB | COLC |
|------|------|
| 2 | 2 |
| 3 | -- |

Table 52. TBLC

| COLB | COLC |
|------|------|
| 2 | 2 |

Example 1: In the following predicate, the fullselect returns the values 2 and 3. The predicate is false for rows 1, 2, and 3 of TBLA, and is true for row 4.

```
COLA > ALL(SELECT COLB FROM TBLB
           UNION
           SELECT COLB FROM TBLC)
```

Example 2: In the following predicate, the fullselect returns the values 2 and 3. The predicate is false for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

```
COLA > ANY(SELECT COLB FROM TBLB
           UNION
           SELECT COLB FROM TBLC)
```

Example 3: In the following predicate, the fullselect returns the values 2 and null. The predicate is false for rows 1 and 2 of TBLA, and is unknown for rows 3 and 4. The result is an empty table.

```
COLA > ALL(SELECT COLC FROM TBLB
           UNION
           SELECT COLC FROM TBLC)
```

Example 4: In the following predicate, the fullselect returns the values 2 and null. The predicate is unknown for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

```
COLA > SOME(SELECT COLC FROM TBLB
            UNION
            SELECT COLC FROM TBLC)
```

Example 5: In the following predicate, the fullselect returns an empty result column. Hence, the predicate is true for all rows of TBLA.

```
COLA < ALL(SELECT COLB FROM TBLB WHERE COLB>3
           UNION
           SELECT COLB FROM TBLC WHERE COLB>3)
```

Example 6: In the following predicate, the fullselect returns an empty result column. Hence, the predicate is false for all rows of TBLA.

```
COLA < ANY(SELECT COLB FROM TBLB WHERE COLB>3
           UNION
           SELECT COLB FROM TBLC WHERE COLB>3)
```

If COLA were null in one or more rows of TBLA, the predicate would still be false for all rows of TBLA.

BETWEEN predicate

The BETWEEN predicate determines whether a given value lies between two other given values that are specified in ascending order.

Each of the predicate's two forms has an equivalent search condition, as shown in the following table:

Table 53. BETWEEN predicate and equivalent search conditions

| BETWEEN predicate | Equivalent search condition |
|---|--|
| <i>value1</i> BETWEEN <i>value2</i> AND <i>value3</i> | <i>value1</i> >= <i>value2</i> AND <i>value1</i> <= <i>value3</i> ¹ |
| <i>value1</i> NOT BETWEEN <i>value2</i> AND <i>value3</i> | <i>value1</i> < <i>value2</i> OR <i>value1</i> > <i>value3</i> ¹ |

or, equivalently:
 NOT(*value1* BETWEEN *value2* AND *value3*)

Note: 1. Might not be equivalent if *value1*, *value2*, or *value3* are columns or derived values based on columns that are not the same CCSID set because the clause is evaluated in Unicode.

Search conditions are discussed in “Search conditions” on page 305.

If the operands include a mixture of datetime values and valid string representations of datetime values, all values are converted to the data type of the datetime operand.

Example: Consider the following predicate:

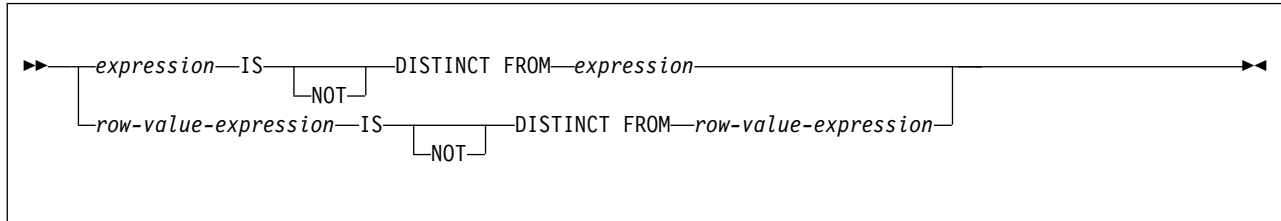

A BETWEEN B AND C

The following table shows the value of the predicate for various values of A, B, and C.

| Value of A | Value of B | Value of C | Value of predicate |
|------------|------------|------------|--------------------|
| 1,2, or 3 | 1 | 3 | true |
| 0 or 4 | 1 | 3 | false |
| 0 | 1 | null | false |
| 4 | null | 3 | false |
| null | any value | any value | unknown |
| 2 | 1 | null | unknown |
| 3 | null | 4 | unknown |

DISTINCT predicate

A distinct predicate compares a value with another value or a set of values with another set of values.

The number of elements that are returned by the *row-value-expression* that specified after the distinct operator must match the number of elements that are returned by the *row-value-expression* that is specified prior to the distinct operator. The data types of the corresponding columns or expressions of the *row-value-expressions* must be compatible. When the predicate is evaluated, the value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the form of the predicate.

When the predicate is **IS DISTINCT**, the result of the predicate is true if at least one comparison of a pair of corresponding value expressions evaluates to false. Otherwise, the result of the predicate is false. The result cannot be unknown.

When the predicate is **IS NOT DISTINCT FROM**, the result of the predicate is true if all pairs of corresponding value expressions evaluate to true (null values are considered equal to null values). Otherwise, the predicate is false. The result cannot be unknown.

The DISTINCT predicate cannot be used in the following contexts:

- The **ON** *join-condition* of a full outer join
- A check constraint
- A quantified predicate

The following DISTINCT predicates are logically equivalent to the corresponding search conditions:

Table 54. DISTINCT predicates and logically equivalent search conditions

| DISTINCT predicate | Search condition |
|-------------------------------------|--|
| value 1 IS NOT DISTINCT FROM value2 | (value1 IS NOT NULL AND value2 IS NOT NULL AND value1 = value 2) OR (value1 IS NULL AND value2 IS NULL) |
| value 1 IS DISTINCT FROM value2 | NOT (value1 IS NOT DISTINCT FROM value2) |

Example 1: Assume that T1 is a single-column table with three rows. Column C1 has the following values: 1, 2, and null. Consider the following query:

```

SELECT * FROM T1
WHERE C1 IS DISTINCT FROM :HV;
  
```

The following table shows the value of the predicate for various values of C1 and the host variable.

| Value of C1 | Value of HV | Result of predicate |
|-------------|-------------|---------------------|
| 1 | 2 | True |
| 2 | 2 | False |
| null | 2 | True |
| 1 | null | True |
| 2 | null | True |
| null | null | False |

Example 2: Assume the same table as in the first example, but now consider the negative form of the predicate in the query:

```
SELECT * FROM T1
WHERE C1 IS NOT DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

| Value of C1 | Value of HV | Result of predicate |
|-------------|-------------|---------------------|
| 1 | 2 | False |
| 2 | 2 | True |
| null | 2 | False |
| 1 | null | False |
| 2 | null | False |
| null | null | True |

EXISTS predicate

The EXISTS predicate tests for the existence of certain rows. The fullselect can specify any number of columns, and can result in true or false.

►►—EXISTS—(fullselect)—◄◄

The result of the EXISTS predicate:

- Is true only if the number of rows that is specified by the fullselect is not zero.
- Is false only if the number of rows specified by the fullselect is zero.
- Cannot be unknown.

The SELECT clause in the fullselect can specify any number of columns because the values returned by the fullselect are ignored. For convenience, use:

```
SELECT *
```

Unlike the NULL, LIKE, and IN predicates, the EXISTS predicate has no form that contains the word NOT. To negate an EXISTS predicate, precede it with the logical operator NOT, as follows:

```
NOT EXISTS (fullselect)
```

The result is then false if the EXISTS predicate is true, and true if the predicate is false. Here, NOT is a logical operator and not a part of the predicate. Logical operators are discussed in “Search conditions” on page 305.

Example 1: The following query lists the employee number of everyone represented in DSN8A10.EMP who works in a department where at least one employee has a salary less than 20000. Like many EXISTS predicates, the one in this query involves a correlated variable.

```
SELECT EMPNO
FROM DSN8A10.EMP X
WHERE EXISTS (SELECT * FROM DSN8A10.EMP
              WHERE X.WORKDEPT=WORKDEPT AND SALARY<20000);
```

Example 2: List the subscribers (SNO) in the state of California who made at least one call during the first quarter of 2009. Order the results according to SNO. Each MONTH nn table has columns for SNO, CHARGES, and DATE. The CUST table has columns for SNO and STATE.

```
SELECT C.SNO
FROM CUST C
WHERE C.STATE = 'CA'
AND EXISTS (
  SELECT *
  FROM MONTH1
  WHERE DATE BETWEEN '01/01/2009 AND '01/31/2009'
  AND C.SNO = SNO
UNION ALL
  SELECT *
  FROM MONTH2
  WHERE DATE BETWEEN '02/01/2009 AND '02/28/2009'
  AND C.SNO = SNO
UNION ALL
  SELECT *
```

```
FROM MONTH3  
WHERE DATE BETWEEN '03/01/2009 AND '03/31/2009'  
AND C.SNO = SNO  
)  
ORDER BY C.SNO;
```

IN predicate

The IN predicate compares a value or values with a set of values.

When *expression1* is specified, the IN predicate compares a value with a set of values. When *fullselect1* is specified, the fullselect must return a single result column, and can return any number of values, whether null or not null. The data type of *expression1* and the data type of the result column of *fullselect1* or *expression2* must be compatible. If *expression* is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

When a *row-value-expression* is specified, the IN predicate compares values with a collection of values. The result table of the *fullselect2* must have the same number of columns as the *row-value-expression*. The data type of each expression in *row-value-expression* and the data type of its the corresponding result column of *fullselect2* must be compatible. The value of each expression in *row-value-expression* is compared with the value of its corresponding result column of *fullselect2*. The value of the predicate depends on the operator that is specified:

- When the operator is IN, the result of the predicate is:
 - True if at least one row returned from *fullselect2* is equal to the *row-value-expression*.
 - False if the result of *fullselect2* is empty or if no row returned from *fullselect2* is equal to the *row-value-expression*.
 - Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and no row returned from *fullselect2* is equal to the *row-value-expression*).
- When the operator is NOT IN, the result of the predicate is:
 - True if the result of *fullselect2* is empty or if the *row-value-expression* is not equal to any of the rows returned by *fullselect2*.
 - False if the *row-value-expression* is equal to at least one row returned by *fullselect2*.
 - Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and the comparison of *row-value-expression* to the row returned from *fullselect2* is not true for any row returned by the *fullselect2*).

The IN predicate is equivalent to the quantified predicate as follows:

Table 55. IN predicate and equivalent quantified predicates

| IN predicate | Equivalent quantified predicate |
|---|--|
| <i>expression1</i> IN (<i>expression2</i>) | <i>expression1</i> = <i>expression2</i> |
| <i>expression</i> IN (<i>fullselect1</i>) | <i>expression</i> = ANY (<i>fullselect1</i>) |
| <i>expression</i> NOT IN (<i>fullselect1</i>) | <i>expression</i> <> ALL (<i>fullselect1</i>) |
| <i>expression1</i> IN (<i>expressiona</i> , <i>expressionb</i> , ...) | <i>expression1</i> IN (SELECT * FROM R) When T is a table with a single row and R is a result table formed by the following fullselect: SELECT value1 FROM T UNION SELECT value2 FROM T UNION . . UNION SELECT valuen FROM T |
| <i>row-value-expression</i> IN (<i>fullselect2</i>) | <i>row-value-expression</i> = SOME (<i>fullselect2</i>) |
| <i>row-value-expression</i> IN (<i>fullselect2</i>) | <i>row-value-expression</i> = ANY (<i>fullselect2</i>) |
| <i>row-value-expression</i> NOT IN (<i>fullselect2</i>) | <i>row-value-expression</i> <> ALL (<i>fullselect2</i>) |

If the operands of the IN predicate have different data types or attributes, the rules that are used to determine the data type for evaluation of the IN predicate are those for UNION, EXCEPT, and INTERSECT. For a description, see “Rules for result data types” on page 143.

If the operands of the IN predicate are strings with different CCSIDs, the rules used to determine which operands are converted are those for operations that combine strings. See “Character and graphic string comparisons” on page 134.

Example 1: The following predicate is true for any row whose employee is in department D11, B01, or C01.

```
WORKDEPT IN ('D11', 'B01', 'C01')
```

Example 2: The following predicate is true for any row whose employee works in department E11.

```
EMPNO IN (SELECT EMPNO FROM DSN8A10.EMP  
WHERE WORKDEPT = 'E11')
```

Example 3: The following predicate is true if the date that a project is estimated to start (PRENDATE) is within the next two years.

```
YEAR(PRENDATE) IN (YEAR(CURRENT DATE),  
YEAR(CURRENT DATE + 1 YEAR),  
YEAR(CURRENT DATE + 2 YEARS))
```

Example 4: The following example obtains the phone number of an employee in DSN8A10.EMP where the employee number (EMPNO) is a value specified within the COBOL structure defined below.

```
77 PHNUM PIC X(6).  
01 EMPNO-STRUCTURE.  
05 CHAR-ELEMENT-1 PIC X(6) VALUE '000140'.  
05 CHAR-ELEMENT-2 PIC X(6) VALUE '000340'.
```

```
05 CHAR-ELEMENT-3 PIC X(6) VALUE '000220'.  
.  
.  
EXEC SQL DECLARE PHCURS CURSOR FOR  
  SELECT PHONENO FROM DSN8A10.EMP  
  WHERE EMPNO IN  
    (:EMPNO-STRUCTURE.CHAR-ELEMENT-1,  
     :EMPNO-STRUCTURE.CHAR-ELEMENT-2,  
     :EMPNO-STRUCTURE.CHAR-ELEMENT-3)  
END-EXEC.  
EXEC SQL OPEN PHCURS  
END-EXEC.  
EXEC SQL FETCH PHCURS INTO :PHNUM  
END-EXEC.
```

LIKE predicate

The LIKE predicate searches for strings that have a certain pattern.

The *match-expression* is the string to be tested for conformity to the pattern specified in *pattern-expression*. Underscore and percent sign characters in the pattern have a special meaning instead of their literal meanings unless *escape-expression* is specified. For more information, see the description of *pattern-expression*.

The following rules summarize how a predicate in the form of *m* LIKE *p* is evaluated:

- If *m* or *p* is null, the result of the predicate is unknown.
- If *m* and *p* are both empty, the result of the predicate is true.
- If *m* is empty and *p* is not, the result of the predicate is unknown unless *p* consists of one or more percent signs.
- If *m* is not empty and *p* is empty, the result of the predicate is false.
- Otherwise, if *m* matches the pattern in *p*, the result of the predicate is true. The description of *pattern-expression* provides a detailed explanation on how the pattern is matched to evaluate the predicate to true or false.

The values for *match-expression*, *pattern-expression*, and *escape-expression* must all be character or graphic strings or a mixture of both or they must all be binary strings (BLOBs). None of the expressions can yield a distinct type; however, an expression can be a function that casts a distinct type to its source type.

There are slight differences in what expressions are supported for each argument. The description of each argument lists the supported expressions.

match-expression

An expression that specifies the string to be tested for conformity to a certain pattern of characters.

LIKE *pattern-expression*

An expression that specifies the pattern of characters to be matched.

The expression can be specified by any one of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

The expression must also meet these restrictions:

- The maximum length of *pattern-expression* must not be larger than 4000 bytes.

- If a host variable is used in *pattern-expression*, the host variable must be defined in accordance with the rules for declaring string host variables and must not be a structure.
- If *escape-expression* is specified, *pattern-expression* must not contain the escape character that is identified by *escape-expression*, except when immediately followed by the escape character, '%', or '_'. For example, if '+' is the escape character, any occurrences of '+' other than '++', '+_', or '+ in the pattern is an error.

When the pattern specified in a LIKE predicate is a parameter marker and a fixed-length character host variable is used to replace the parameter marker, specify a value for the host variable that is the correct length. If you do not specify the correct length, the select does not return the intended results. For example, if the host variable is defined as CHAR(10) and the value WYSE% is assigned to that host variable, the host variable is padded with blanks on assignment. The pattern used is 'WYSE ', which requests DB2 to search for all values that start with WYSE and end with five blank spaces. If you intended to search for only the values that start with 'WYSE ', you should assign the value 'WYSE%%%%%%%%%' to the host variable.

If the pattern is specified in a fixed-length string variable, any trailing blanks are interpreted as part of the pattern. Therefore, it is better to use a varying-length string variable with an actual length that is the same as the length of the pattern. If the host language does not allow varying-length string variables, place the pattern in a fixed-length string variable whose length is the length of the pattern.

For more information about the use of host variables with specific programming languages, see Host variables (DB2 Application programming and SQL).

The pattern is used to specify the conformance criteria for values in the *match-expression* where:

- The underscore character (_) represents any single character.
- The percent sign (%) represents a string of zero or more characters.
- Any other character represents a single occurrence of itself.

If the *pattern-expression* must include either the underscore or the percent character, the *escape-expression* is used to specify a character to precede either the underscore or percent character in the pattern. For character strings, the terms *character*, *percent sign*, and *underscore* refer to SBCS characters. For graphic strings, the terms refer to double-byte or UTF-16 characters.

A rigorous description of the pattern: This more rigorous description of the pattern ignores the use of the *escape-expression*.

Let *m* denote the value of *match-expression* and let *p* denote the value of *pattern-expression*. The string *p* is interpreted as a sequence of the minimum number of substring specifiers so each character of *p* is part of exactly one substring specifier. A substring specifier is an underscore, a percent sign, or any non-empty sequence of characters other than an underscore or a percent sign.

The result of the predicate is unknown if *m* or *p* is the null value. Otherwise, the result is either true or false. The result is true if *m* and *p* are both empty strings or there exists a partitioning of *m* into substrings such that:

- A substring of *m* is a sequence of zero or more contiguous characters and each character of *m* is part of exactly one substring.
- If the *n*th substring specifier is an underscore, the *n*th substring of *m* is any single character.
- If the *n*th substring specifier is a percent sign, the *n*th substring of *m* is any sequence of zero or more characters.
- If the *n*th substring specifier is neither an underscore nor a percent sign, the *n*th substring of *m* is equal to that substring specifier and has the same length as that substring specifier.
- The number of substrings of *m* is the same as the number of substring specifiers.

It follows that if *p* is an empty string and *m* is not an empty string, the result is false. Similarly, if *m* is an empty string and *p* is not an empty string consisting of a value other than percentage signs, the result is false.

The predicate *m* NOT LIKE *p* is equivalent to the search condition NOT (*m* LIKE *p*).

Mixed data patterns: If *match-expression* represents mixed data, the pattern is assumed to be mixed data. For ASCII and EBCDIC, the special characters in the pattern are interpreted as follows:

- An SBCS underscore refers to one SBCS character.
- A DBCS underscore refers to one MBCS character.
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

For EBCDIC, redundant shift bytes in *match-expression* or *pattern-expression* are ignored.

For Unicode, the special characters in the pattern are interpreted as follows:

- An SBCS or DBCS underscore refers to one character (either SBCS or MBCS).
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

When the LIKE predicate is used with Unicode data, the Unicode percent sign and underscore use the code points indicated in the following table:

| Character | UTF-8 | UTF-16 |
|--------------|-----------|---------|
| Half-width % | X'25' | X'0025' |
| Full-width % | X'EFBC85' | X'FF05' |
| Half-width_ | X'5F' | X'005F' |
| Full-width_ | X'EFBCBF' | X'FF3F' |

The full-width or half-width % matches zero or more characters. The full-width or half-width_ character matches exactly one character. (For ASCII or EBCDIC

data, a full-width `_` character matches one DBCS character.)

Binary data patterns: For columns with binary data, the pattern contains bytes. The special bytes in the pattern are interpreted as follows:

- The code point for an SBCS underscore (X'6D') refers to 1 byte.
- The code point for an SBCS percent (X'6C') refers to any number of bytes.

ESCAPE *escape-expression*

An expression that specifies the escape character to be used to modify the special meaning of the underscore (`_`) and percent (`%`) characters in *pattern-expression*. Specifying an expression, which is optional, allows the LIKE predicate to explicitly test that the value contains a `'%'` or `'_'` in the character positions that you want. The escape character consists of a single SBCS (1 byte) or DBCS (2 bytes) character. An escape clause is allowed for Unicode mixed (UTF-8) data, but is restricted for ASCII and EBCDIC mixed data.

The expression can be specified by:

- A constant
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above

The following rules also apply to the use of the **ESCAPE** clause and *escape-expression*:

- The result of *escape-expression* must be one SBCS or DBCS character or a binary string that contains exactly 1 byte.
- The **ESCAPE** clause cannot be used if *match-expression* is mixed data.
- If *escape-expression* is specified by a host variable, the host variable must be defined in accordance with the rules for declaring fixed-length string host variables.¹⁶ If the host variable has a negative indicator variable, the result of the predicate is unknown.
- The pattern must not contain the escape character except when followed by the escape character, `'%'` or `'_'`. For example, if `'+'` is the escape character, any occurrences of `'+'` other than `'++'`, `'+_'`, or `'+%'` in the pattern is an error.

The following table shows the effect of successive occurrences of the escape character, which in this case is the plus sign (`+`).

Table 56. Effect of successive occurrences of the escape character

| When the pattern string is... | The actual pattern is... |
|-------------------------------|---|
| <code>+%</code> | A percent sign |
| <code>++%</code> | A plus sign followed by zero or more arbitrary characters |
| <code>+++%</code> | A plus sign followed by a percent sign |

Examples

Example 1: The following predicate is true when the string to be tested in NAME has the value SMITH, NESMITH, SMITHSON, or NESMITHY. It is not true when the string has the value SMYTHE:

```
NAME LIKE '%SMITH%'
```

16. If it is NUL-terminated, a C character string variable of length 2 can be specified.

Example 2: In the predicate below, a host variable named PATTERN holds the string for the pattern:

```
NAME LIKE :PATTERN ESCAPE '+'
```

Assume that the string in PATTERN has the following value:

```
AB+ _C_%
```

Observe that in this string, the plus sign preceding the first underscore is an escape character. The predicate is true when the string being tested in NAME has the value AB_CD or AB_CDE. It is false when this string has the value AB, AB_, or AB_C.

Example 3: The following two predicates are equivalent; three of the four percent signs in the first predicate are redundant.

```
NAME LIKE 'AB%%CD'
NAME LIKE 'AB%CD'
```

Example 4: Assume that a distinct type named ZIP_TYPE with a source data type of CHAR(5) exists and an ADDRZIP column with data type ZIP_TYPE exists in some table TABLEY. The following statement selects the row if the zip code (ADDRZIP) begins with '9555'.

```
SELECT * FROM TABLEY
WHERE CHAR(ADDRZIP) LIKE '9555%'
```

Example 5: The RESUME column in sample table DSN8A10.EMP_PHOTO_RESUME is defined as a CLOB. The following statement selects the RESUME column when the string JONES appears anywhere in the column.

```
SELECT RESUME FROM DSN8A10.EMP_PHOTO_RESUME
WHERE RESUME LIKE '%JONES%'
```

Example 6: In the following table, assume COL1 is a column that contains mixed EBCDIC data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

| Predicates | COL1 Values | Result |
|-----------------------------|----------------|--------|
| WHERE COL1 LIKE 'aaa AB% C' | 'aaa ABDZC' | True |
| WHERE COL1 LIKE 'aaa AB% C' | 'aaa AB dzx C' | True |
| WHERE COL1 LIKE 'a% C' | 'a C' | True |
| | 'ax C' | True |
| | 'ab DE fg C' | True |
| WHERE COL1 LIKE 'a_ C' | 'a% C' | True |
| | 'a XC' | False |
| WHERE COL1 LIKE 'a__ C' | 'a XC' | True |
| | 'ax C' | False |
| WHERE COL1 LIKE '' | Empty string | True |
| WHERE COL1 LIKE 'ab C_' | 'ab C d' | True |
| | 'ab C d' | True |

Example 7: In the following table, assume COL1 is a column that contains mixed ASCII data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

| Predicates | COL1 Values | Result |
|-----------------------------|----------------|--------|
| WHERE COL1 LIKE 'aaa AB% C' | 'aaa ABDZC' | True |
| WHERE COL1 LIKE 'aaa AB% C' | 'aaa AB dzx C' | True |

Example 8: In the following table, assume COL1 is a column that contains Unicode data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

Table 57. COL1 contain Unicode data

| Predicates | COL1 values | Result |
|----------------------------|--------------|--------|
| WHERE COL1 LIKE 'aaaAB% C' | 'aaaABDZC' | True |
| | 'aaaABdzc' | True |
| | empty string | False |
| WHERE COL1 LIKE 'aaaAB% C' | 'aaaABDZC' | True |
| | 'aaaABdzc' | True |
| | empty string | False |
| WHERE COL1 LIKE '' | 'aaaABDZC' | False |
| | 'aaaABdzc' | False |
| | empty string | True |
| WHERE COL1 LIKE '%' | 'aaaABDZC' | True |
| | 'aaaABdzc' | True |
| | empty string | True |

Table 57. COL1 contain Unicode data (continued)

| Predicates | COL1 values | Result |
|-------------------------|--------------|--------|
| WHERE COL1 LIKE ' %' | 'aaaABDZC' | True |
| | 'aaaABdzc' | True |
| | empty string | False |
| WHERE COL1 LIKE ' ' | 'aaaABDZC' | False |
| | 'aaaABdzc' | False |
| | empty string | False |

NULL predicate

The NULL predicate tests for null values.

The result of a NULL predicate cannot be unknown. If the value of the expression is null, the result is true. If the value is not null, the result is false. If NOT is specified, the result is reversed.

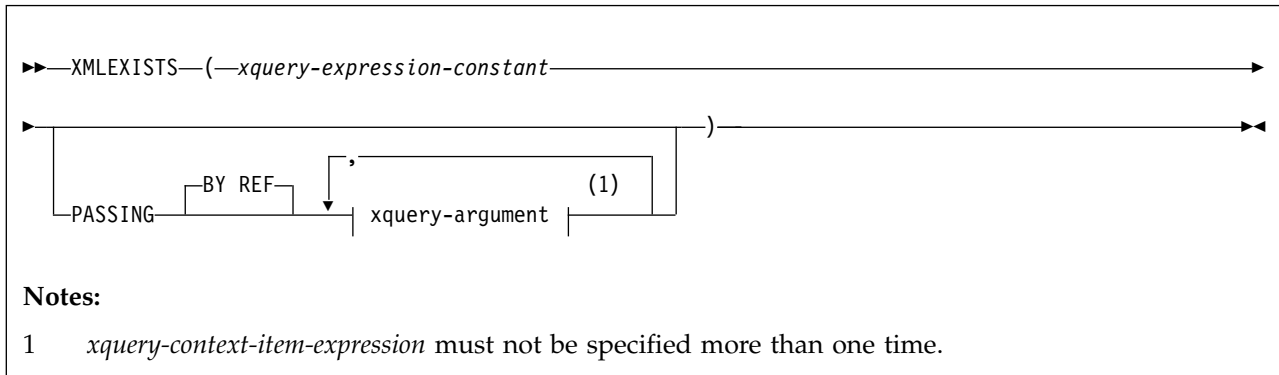

A parameter marker must not be specified for or within the expression.

Example 1: The following predicate is true whenever PHONENO has the null value, and is false otherwise.

```
PHONENO IS NULL
```

XMLEXISTS predicate

The XMLEXISTS predicate tests whether an XQuery expression returns a sequence of one or more items.

xquery-argument

xquery-expression-constant

Specifies a character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. See *DB2 XML Guide* for information about the XQuery language syntax. *xquery-expression-constant* cannot be an XQuery updating expression. The XQuery expression is evaluated with the arguments specified in *xquery-argument*. *xquery-expression-constant* must not be an empty string or a string of all blanks.

PASSING

Specifies input values and the manner in which these values are passed to the XQuery expression specified by *xquery-expression-constant*.

BY REF

Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, preserving all properties including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons that involve some nodes that are contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

xquery-argument

Specifies an argument to use in the evaluation of the XQuery expression specified by *xquery-expression-constant*. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-argument* must not return ROWID, TIMESTAMP,

binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression or a *OLAP-specification*.

An argument specifies a value and the manner in which that value is to be passed. How an argument in the *PASSING* clause is used in the XQuery expression depends on whether the argument is specified as the *xquery-context-item-expression* or an *xquery-variable-expression*. The argument includes an SQL expression that is evaluated before passing the result to the XQuery expression.

- If the resulting value is an XML value, it becomes an *input-xml-value*. It is passed by reference which means that the original values, not copies, are used in the evaluation of the XQuery expression.
- If the resulting value is not an XML value, the result of the expression must be able to be cast to an XML value. The cast value becomes an *input-xml-value*. An empty string is converted to an XML empty string.
- If the resulting value is a null value, it is converted to an XML empty sequence if the argument is *xquery-variable-expression*. If the argument is *xquery-context-expression*, the *XMLEXISTS* predicates returns unknown.

xquery-context-item-expression

xquery-context-item-expression specifies the *initial context item* in the XQuery expression specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-context-item-expression must not be a sequence of more than one item. If the result of *xquery-context-item-expression* is an empty string, the XQuery expression is evaluated with the initial context item set to an XML empty string.

If the *xquery-context-item-expression* is not specified or is an empty string, the initial context item in the XQuery expression is undefined, and the XQuery expression must not reference the initial context item. An XQuery variable is not created for the context item expression.

If the *xquery-context-expression* is not specified or the *input-xml-value* that results from the *xquery-context-expression* is an XML empty sequence, the initial context item is undefined. If the XQuery expression refers to the initial context item, it must be specified with a value that is not an XML empty sequence.

xquery-variable-expression

xquery-variable-expression specifies an argument to the XQuery expression. An XQuery variable is created for each *xquery-variable-expression*, and the XQuery variable is set to the result of *xquery-argument-expression* cast to XML. If the result of *xquery-variable-expression* is an empty string, the XQuery variable is set to an XML empty string. If *xquery-variable-expression* is null, the XQuery variable is set to an XML empty sequence. For example, *PASSING T.A + T.B as "sum"* creates an XQuery variable named *sum*. The scope of the XQuery variables created from the *PASSING* clause is the XQuery expression that is specified by *xquery-expression-constant*.

AS *identifier*

Specifies that the value that is generated by *xquery-variable-expression* will be passed to *xquery-expression-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. The leading dollar sign (\$) that precedes variable names in the XQuery language is not included in

identifier. The name must be an XML NCName that is not the same as *identifier* for another *xquery-variable-expression* in the same PASSING clause.

The result of the predicate is determined as follows:

- The result is unknown if *xquery-context-item-expression* specified in the PASSING clause is a NULL value
- the result is false if the result of the XQuery expression is an empty sequence
- the result is true in all other cases

If the evaluation of the XQuery expression results in an error, XMLEXISTS returns an error. The XMLEXISTS predicate is not supported in ON clause of outer joins.

Example: Find all the purchase orders that buy a baby monitor. This example finds the product number for baby monitors from the product table and joins the result to the PurchaseOrders table. It then evaluates the XQuery expression `//item[@partnum = $n]` for each row and returns those rows that contain an item element node with a partNum attribute that is equal to the product number of 'Baby Monitor'. The context item for the XQuery expression is PO.POrder. An XQuery variable, *\$n*, is created and initialized to the value of S.prodno:

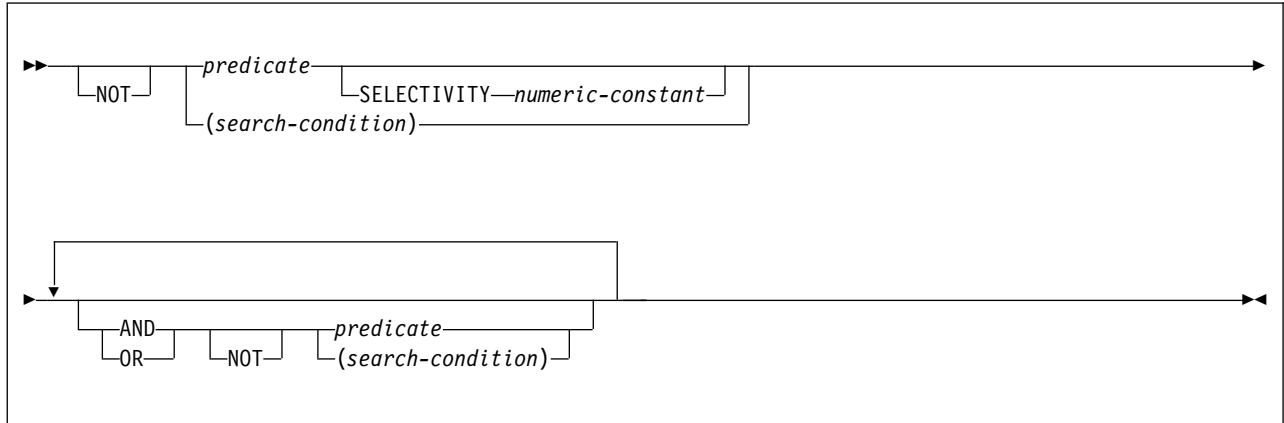

```
SELECT S.prodno, count(*) as result
FROM PurchaseOrders PO, Products S
WHERE XMLEXISTS ('//item[@partNum = $n]'
                PASSING PO.POrder,
                        S.prodno AS "n")
AND S.prod_name = 'Baby Monitor';
```

The results might be similar to the following:

| Prodno | result |
|--------|--------|
| 926-AA | 1 |

Search conditions

A *search condition* specifies a condition that is true, false, or unknown about a given row or group. When the condition is true, the row or group qualifies for the results. When the condition is false or unknown, the row or group does not qualify.

Description

SELECTIVITY *numeric-constant*

Specifies the expected selectivity percentage for the predicate. You can specify the SELECTIVITY clause only when the predicate contains one of the indexable spatial predicate functions and the predicate is in the form of *spatial-predicate-function operator expression*, where *operator* is either = or <. The selectivity value must be an integer or decimal constant value in the range from 0 to 1 (inclusive). For example, if you specify 0.01, the spatial predicate function is expected to filter out all but one percent of all the rows in the table. An error is returned if the SELECTIVITY clause is specified for a non-spatial predicate function.

The result of a search condition is derived by application of the specified *logical operators* (AND, OR, NOT) to the result of each specified predicate. If logical operators are not specified, the result of the search condition is the result of the specified predicate.

AND and OR are defined in the following table, in which *P* and *Q* are any predicates:

Table 58. Truth table for AND and OR

| <i>P</i> | <i>Q</i> | <i>P and Q</i> | <i>P or Q</i> |
|----------|----------|----------------|---------------|
| True | True | True | True |
| True | False | False | True |
| True | Unknown | Unknown | True |
| False | True | False | True |
| False | False | False | False |
| False | Unknown | False | Unknown |
| Unknown | True | Unknown | True |

Table 58. Truth table for AND and OR (continued)

| <i>P</i> | <i>Q</i> | <i>P and Q</i> | <i>P or Q</i> |
|----------|----------|----------------|---------------|
| Unknown | False | False | Unknown |
| Unknown | Unknown | Unknown | Unknown |

NOT(true) is false and NOT(false) is true, but NOT(unknown) is still unknown. The NOT logical operator has no effect on an unknown condition. The result of NOT(unknown) is still unknown.

Search conditions within parentheses are evaluated first. If the order of evaluation is not specified by parentheses, NOT is applied before AND, and AND is applied before OR. The order in which operators at the same precedence level are evaluated is undefined to allow for optimization of search conditions.

Example 1: In the first of the search conditions below, AND is applied before OR. In the second, OR is applied before AND.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB
SALARY>:SS AND (COMM>:CC OR BONUS>:BB)
```

Example 2: In the first of the search conditions below, NOT is applied before AND. In the second, AND is applied before NOT.

```
NOT SALARY>:SS AND COMM>:CC
NOT (SALARY>:SS AND COMM>:CC)
```

Example 3: For the following search condition, AND is applied first. After the application of AND, the OR operators could be applied in either order without changing the result. DB2 can therefore select the order of applying the OR operators.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB OR SEX=:GG
```

Options affecting SQL

Certain DB2 precompiler or coprocessor options (referred to as SQL processing options), DB2 subsystem parameters (set through the installation panels), bind options, options for CREATE PROCEDURE and ALTER PROCEDURE statements for native SQL procedures, and special registers affect how SQL statements can be composed or determine how SQL statements are processed.

The following table summarizes the effect of these options and shows where to find more information. (Some of the items are described in detail following the table, while other items are described elsewhere.)

Table 59. Summary of items affecting composition and processing of SQL statements

| SQL processing option | Other ¹ | Affects |
|-----------------------|--|--|
| | DYNAMICRULES bind option or the native SQL procedures option | <p>The rules that DB2 applies to dynamic SQL statements. For details about authorization, see “Authorization IDs and dynamic SQL” on page 75. The option can also affect decimal point representation, string delimiters, and decimal arithmetic.</p> <p>For details about how DB2 applies the options to dynamic SQL statements when DYNAMICRULES bind, define, or invoke behavior is in effect, see “SQL processing options for dynamic statements” on page 308.</p> |

Table 59. Summary of items affecting composition and processing of SQL statements (continued)

| SQL processing option | Other ¹ | Affects |
|-----------------------|--|---|
| NOFOR or STDSQL | | Whether the FOR UPDATE clause must be specified (in the SELECT statement of the DECLARE CURSOR statement). For details, see "Positioned updates of columns" on page 314. |
| CONNECT | | Whether the rules for the CONNECT(1) or CONNECT(2) SQL processing option apply. For details about the SQL processing option, see <i>DB2 Application Programming and SQL Guide</i> . |
| | SQLRULES bind option | Whether a CONNECT statement is processed with DB2 rules or SQL standard rules. |
| | CURRENT RULES special register | Whether the statements ALTER TABLE, CREATE TABLE, GRANT, and REVOKE are processed with DB2 rules or SQL standard rules. For details, see "CURRENT RULES" on page 187. Whether DB2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for a LOB column in a base table. For details, see <i>Creating a table with LOB columns</i> . Whether DB2 automatically creates an index on a ROWID column that is defined with GENERATED BY DEFAULT. For details, see the description of the clause for "CREATE TABLE" on page 1706. Whether an external stored procedure runs as a main or subprogram. For details, see "CREATE PROCEDURE (external)" on page 1637. |
| | SQLRULES bind option or CURRENT RULES special register | Whether SQLCODE +236 is issued when the SQLDA provided on DESCRIBE or PREPARE INTO is too small and the result columns do not involve LOBs or distinct types. For details, see "DESCRIBE" on page 1899 and "SQL descriptor area (SQLDA)" on page 2366. |
| DEC | DECIMAL ARITHMETIC or CURRENT PRECISION special register | Whether DEC15 or DEC31 rules are used when both operands in a decimal operation have 15 digits or less. For details, see "Arithmetic with two decimal operands" on page 231. |

Note: ¹ The entries in this column are fields on installation panels unless otherwise noted.

For further details on SQL processing options, see *DB2 Application Programming and SQL Guide*. For more details on bind options, see *DB2 Command Reference*.

SQL processing options for dynamic statements

Generally, dynamic statements use the application programming defaults specified on installation panel DSNTIPF. However, if the value of installation panel field USE FOR DYNAMICRULES is NO and DYNAMICRULES bind, define, or invoke behavior is in effect, certain SQL processing options are used instead of the application programming defaults.

The following SQL processing options are used instead of the application programming defaults:

- COMMA or PERIOD
- APOST or QUOTE
- APOSTSQL or QUOTESQL
- DEC(15) or DEC(31)

For some languages, the SQL processing option defaults to a value and no alternative is allowed. If the value of installation panel field USE FOR DYNAMICRULES is YES, dynamic statements use the application programming defaults regardless of the value of DYNAMICRULES option.

For additional information on the effect of SQL processing options and application programming defaults on:

- Decimal point representation, see “Decimal point representation.”
- String delimiters, see “Apostrophes and quotation marks as string delimiters” on page 311.
- Decimal arithmetic, see “Arithmetic with two decimal operands” on page 231.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.

DECFLOAT rounding mode

All views and SQL functions referenced in an SQL statement must either not have rounding mode information stored in the SYSENVIRONMENT catalog, or they must all have the same rounding mode information in the SYSENVIRONMENT catalog.

Decimal point representation

Decimal points in SQL statements are represented with either periods or commas.

Two values control the representation:

- The value of field DECIMAL POINT IS on installation panel DSNTIPE, which can be a comma (,) or period (.)
- COMMA or PERIOD, which are mutually exclusive SQL processing options for COBOL

These values apply to SQL statements as follows:

- For a distributed operation, the decimal point is the first of the following values that applies:
 - The decimal point value specified by the requester
 - The value of field DECIMAL POINT IS on panel DSNTIPF at the DB2 where the package is bound
- Otherwise:
 - For static SQL statements:
 - In a COBOL program, the SQL processing option COMMA or PERIOD determines the decimal point representation for every static SQL statement. If neither SQL processing option is specified, the value of DECIMAL POINT IS at precompilation time determines the representation.
 - In non-COBOL programs, the decimal representation for static SQL statements is always the period.
 - For dynamic SQL statements:

- If DYNAMICRULES run behavior applies, the decimal point is the value of field DECIMAL POINT IS on installation panel DSNTIPF at the local DB2 when the statement is prepared.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.

- If DYNAMICRULES bind, define, or invoke behavior applies, and the value of installation panel field USE FOR DYNAMICRULES is YES, the decimal point is the value of field DECIMAL POINT IS.

If bind, define, or invoke behavior applies, and field USE FOR DYNAMIC RULES is NO, the SQL processing option determines the decimal point representation. For COBOL programs, which supports SQL processing option COMMA or PERIOD, the decimal point representation is determined as described above for static SQL statements in COBOL programs. For programs written in other host languages, the default SQL processing option, which can only be PERIOD, is used.

If the comma is the decimal point, these rules apply:

- In any context, a comma intended as a separator must be followed by a space. Such commas could appear, for example, in a VALUES clause, an IN predicate, or an ORDER BY clause in which numbers are used to identify columns.
- In any context, a comma intended as a decimal point must not be followed by a space.
- If the DECIMAL POINT IS field (and not the SQL processing option) determines the comma as the decimal point, DB2 will recognize either a comma or a period as the decimal point in numbers in dynamic SQL.

 DECIMAL POINT IS field (DECIMAL DECP value) (DB2 Installation and Migration)

 DYNAMICRULES bind option (DB2 Commands)

Apostrophes and quotation marks as string delimiters

SQL processing options and DB2 installation panel fields control the representation of string delimiters in COBOL and SQL statements.

The following SQL processing options control the representation of string delimiters:

- APOST and QUOTE are mutually exclusive SQL processing options for COBOL. Their meanings are exactly what they are for the COBOL compilers:
 - APOST names the apostrophe (') as the string delimiter in COBOL statements.
 - QUOTE names the quotation mark (") as the string delimiter.Neither option applies to SQL syntax. Do not confuse them with the APOSTSQL and QUOTESQL options.
- APOSTSQL and QUOTESQL are mutually exclusive SQL processing options for COBOL. Their meanings are:
 - APOSTSQL names the apostrophe (') as the string delimiter and the quotation mark (") as the escape character in SQL statements.
 - QUOTESQL names the quotation mark (") as the string delimiter and the apostrophe (') as the escape character in SQL statements.

These values apply to SQL statements as follows:

- For a distributed operation, the string delimiter is the first of the following values that applies:
 - The SQL string delimiter value specified by the requester
 - The value of the field SQL STRING DELIMITER on installation panel DSNTIPF at the DB2 where the package is bound
- Otherwise:
 - For static SQL statements:

In a COBOL program, the SQL processing option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither SQL processing option is specified, the value of field SQL STRING DELIMITER on installation panel DSNTIPF determines the string delimiter and escape character.

In a non-COBOL program, the string delimiter is the apostrophe, and the escape character is the quotation mark.
 - For dynamic SQL statements:
 - If DYNAMICRULES run behavior applies, the string delimiter and escape character is the value of field SQL STRING DELIMITER on installation panel DSNTIPF at the local DB2 when the statement is prepared.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.
 - If DYNAMICRULES bind, define, or invoke behavior applies and the value of installation panel field USE FOR DYNAMICRULES is YES, the string delimiter and escape character is the value of field SQL STRING DELIMITER.

If bind, define, or invoke behavior applies and USE FOR DYNAMICRULES is NO, the SQL processing option determines the string delimiter and escape character. For COBOL programs, SQL processing option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither SQL processing option is specified, the value of field SQL STRING DELIMITER determines them. For programs written in other host

languages, the default SQL processing option, which can only be APOSTSQL, determines the string delimiter and escape character.

Katakana characters for EBCDIC

Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the DB2 installation is set to allow it.

The field EBCDIC CCSID on installation panel DSNTIPF determines the system CCSIDs for EBCDIC-encoded data. Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the field contains the value 5026 or 930. There are no corresponding SQL processing options. EBCDIC CCSID applies equally to static and dynamic statements. For dynamically prepared statements, the applicable value is always the one at the local DB2.

Mixed data in character strings

Mixed character data and graphic data are always allowed for Unicode, but for EBCDIC and ASCII, the specific installation of DB2 determines whether mixed data can be used.

The field MIXED DATA on installation panel DSNTIPF can have the value YES or NO for ASCII or EBCDIC character strings. The value YES indicates that character strings can contain a mixture of SBCS and DBCS characters. The value NO indicates that they cannot. Mixed character data and graphic data are always allowed for Unicode; that is the MIXED DATA field does not have an effect on Unicode data.

For static SQL statements, the value of the CCSID SQL processing option or the derived CCSID for the DB2 coprocessor determines whether ASCII or EBCDIC character strings can contain mixed data. If a mixed CCSID is used, mixed strings are allowed. If a single-byte CCSID is used, mixed strings are not allowed.

For dynamic SQL statements, the CCSID that is selected to convert the dynamic statement text to UTF-8 determines whether ASCII or EBCDIC character strings can contain mixed data. The CCSID for a dynamic statement is determined from the SQLDA override (if any) for the host variable on the PREPARE statement, the value of the CURRENT ENCODING SCHEME special register, and the ENCODING bind option.

The value of MIXED DATA affects the parsing of SQL character string constants, the execution of the LIKE predicate, and the assignment of character strings to host variables when truncation is needed. It can also affect concatenation, as explained in “Expressions with the concatenation operator” on page 237. A value that applies to a statement executed at the local DB2 also applies to any statement executed at another server. An exception is the LIKE predicate, for which the applicable value of MIXED DATA is always the one at the statement's server.

The value of MIXED DATA also affects the choice of system CCSIDs for the local DB2 and the choice of data subtypes for character columns. When this value is YES, multiple CCSIDs are available for ASCII and EBCDIC data (SBCS, DBCS, and MIXED). The CCSID specified in the ASCII CCSID or EBCDIC CCSID field is the MIXED CCSID. In this case, DB2 derives the SBCS and MIXED CCSIDs from the DBCS CCSID specified installation panel DSNTIPF. Moreover, a character column can have any one of the allowable data subtypes—BIT, SBCS, or MIXED.

On the other hand, when MIXED DATA is NO, the only ASCII or EBCDIC system CCSIDs are those for SBCS data. Therefore, only BIT and SBCS can be data subtypes for character columns.

Formatting of datetime strings

The format for a datetime string that is in effect for a statement that is executed at the local DB2 is not necessarily in effect for a statement that is executed at a different server.

Fields on installation panel DSNTIP4 (DATE FORMAT, TIME FORMAT, LOCAL DATE LENGTH, and LOCAL TIME LENGTH) and SQL processing options affect the formatting of datetime strings.

The formatting of datetime strings is described in “String representations of datetime values” on page 101. Unlike the subsystem parameters and options previously described, a value in effect for a statement executed at the local DB2 is not necessarily in effect for a statement executed at a different server. See “Restrictions on the use of local datetime formats” on page 105 for more information.

SQL standard language

DB2 SQL and the SQL standard are not identical. The STDSQL SQL processing option addresses some of the differences.

- STDSQL(NO) indicates that conformance with the SQL standard is not intended. The default is the value of field STD SQL LANGUAGE on installation panel DSNTIP4 (which has a default of NO).
- STDSQL(YES)¹⁷ indicates that conformance with the SQL standard is intended.

When a program is precompiled with the STDSQL(YES) option, the following rules apply:

Declaring host variables: All host variable declarations except in Java and REXX must lie between pairs of BEGIN DECLARE SECTION and END DECLARE SECTION statements:

```
BEGIN DECLARE SECTION
  -- one or more host variable declarations
END DECLARE SECTION
```

Separate pairs of these statements can bracket separate sets of host variable declarations.

Declarations for SQLCODE and SQLSTATE: The programmer must declare host variables for either SQLCODE or SQLSTATE, or both. SQLCODE should be defined as a fullword integer and SQLSTATE should be defined as a 5-byte character string. SQLCODE and SQLSTATE cannot be part of any structure. The variables must be declared in the DECLARE SECTION of a program; however, SQLCODE can be declared outside of the DECLARE SECTION when no host variable is defined for SQLSTATE. For PL/I, an acceptable declaration can look like this:

```
DECLARE SQLCODE BIN FIXED(31);
DECLARE SQLSTATE CHAR(5);
```

¹⁷. STDSQL(86) is a synonym, but STDSQL(YES) should be used.

In Fortran programs, the variable `SQLCOD` should be used for `SQLCODE`, and either `SQLSTATE` or `SQLSTA` can be used for `SQLSTATE`.

Definitions for the SQLCA: An SQLCA must not be defined in your program, either by coding its definition manually or by using the `INCLUDE SQLCA` statement. When `STDSQL(YES)` is specified, the DB2 precompiler or coprocessor automatically generates an SQLCA that includes the variable name `SQLCADE` instead of `SQLCODE` and `SQLSTAT` instead of `SQLSTATE`. After each SQL statement executes, DB2 assigns status information to `SQLCODE` and `SQLSTATE`, whose declarations are described above, as follows:

- `SQLCODE`: DB2 assigns the value in `SQLCADE` to `SQLCODE`. In Fortran, `SQLCAD` and `SQLCOD` are used for `SQLCADE` and `SQLCODE`, respectively.
- `SQLSTATE`: DB2 assigns the value in `SQLSTAT` to `SQLSTATE`. (In Fortran, `SQLSTT` and `SQLSTA` are used for `SQLSTAT` and `SQLSTATE`, respectively.)
- No declaration for either `SQLSTATE` or `SQLCODE`: DB2 assigns the value in `SQLCADE` to `SQLCODE`.

If the precompiler or coprocessor encounters an `INCLUDE SQLCA` statement, it ignores the statement and issues a warning message. The precompiler or coprocessor also does not recognize hand-coded definitions, and a hand-coded definition creates a compile-time conflict with the generated definition. A similar conflict arises if definitions of `SQLCADE` or `SQLSTAT`, other than the ones generated by the DB2 precompiler or coprocessor, appear in the program.

Positioned updates of columns

Certain SQL processing options affect the use of the `FOR UPDATE` clause to achieve positioned column updates.

The `NOFOR` SQL processing option affects the use of the `FOR UPDATE` clause. The `NOFOR` option is in effect when either of the following are true:

- The `NOFOR` option is specified.
- The `STDSQL(YES)` option is in effect.

Otherwise, the `NOFOR` option is not in effect. The following table summarizes the differences when the option is in effect and when the option is not in effect:

Table 60. The NOFOR SQL processing option

| When NOFOR is in effect | When NOFOR is not in effect |
|---|---|
| The use of the <code>FOR UPDATE</code> clause in the <code>SELECT</code> statement of the <code>DECLARE CURSOR</code> statement is optional. This clause restricts updates to the specified columns and causes the acquisition of update locks when the cursor is used to fetch a row. If no columns are specified, positioned updates can be made to any updatable columns in the table or view that is identified in the first <code>FROM</code> clause in the <code>SELECT</code> statement. If the <code>FOR UPDATE</code> clause is not specified, positioned updates can be made to any columns that the program has DB2 authority to update. | The <code>FOR UPDATE</code> clause must be specified. |

Table 60. The NOFOR SQL processing option (continued)

| When NOFOR is in effect | When NOFOR is not in effect |
|--|--|
| DBRMs must be built entirely in virtual storage, which might possibly increase the virtual storage requirements of the DB2 precompiler or coprocessor. However, creating DBRMs entirely in virtual storage might cause concurrency problems with DBRM libraries. | DBRMs can be built incrementally using the DB2 precompiler or coprocessor. |

SQL processing options do not affect ODBC behavior.

Mappings from SQL to XML

DB2 maps SQL to XML data according to industry standards and performs several different mappings.

To construct XML data from SQL data, the following mappings are performed:

- SQL character sets to XML character sets
- SQL identifiers to XML names
- SQL data values to XML data values

DB2 maps SQL to XML data according to industry standards. For complete information, see *Information technology - Database languages - SQL- Part 14: XML-Related Specifications (SQL/XML) ISO/IEC 9075-14:2003*.

Mapping SQL character sets to XML character sets

The character set used for XML data is Unicode UTF-8. SQL character data is converted into Unicode when it is used in XML built-in functions.

Mapping SQL identifiers to XML names

Many SQL identifiers that contain certain characters must be escaped when the SQL identifier is converted into an XML name.

Strings that start with 'XML', in any case combination, are reserved for standardization, and characters such as '#', '{', and '}' are not allowed in XML names. Many SQL identifiers containing these characters have to be escaped when converting into XML names.

Full escaping is applied to SQL identifiers that are column names to derive an XML name. The mapping converts a colon (:) to `_x003A_`, `_x` to `_X005F_x`, and other restricted characters to a string of the form `_xUUUU_` where `xUUUU_` is the Unicode value for the character. An identifier with an initial 'xml' (in any case combination) is escaped by mapping the initial 'x' or 'X' to `_x0058_` or `_0078_`, respectively, while the partially escaped variant does not.

Mapping SQL data values to XML data values

SQL data values are mapped to XML values based on SQL data types.

The following data types are not supported and cannot be used as arguments to XML value constructors:

- ROWID
- Character strings that are defined with the FOR BIT DATA attribute

- Binary strings
- A string or a binary string distinct type that is based on a ROWID, FOR BIT DATA character string, or BLOB

For supported data types, the encoding scheme for XML values is Unicode.

Chapter 3. Built-in session variables

DB2 provides several built-in session variables that contain information about the server and application process. The value of a built-in session variable can be obtained by invoking the GETVARIABLE function with the name of the built-in session variable.

DB2 provides the following built-in session variables:

SYSIBM.APPLICATION_ENCODING_SCHEME

Contains a string that corresponds to the value that is specified for the APPLICATION ENCODING field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, UNICODE, or 1-65533, and this session variable can never be null.

SYSIBM.COBOL_STRING_DELIMITER

Contains a string that corresponds to the value that is specified for the STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ", or ', and this session variable can never be null.

SYSIBM.DATA_SHARING_GROUP_NAME

Contains a string that corresponds to the name of the data sharing group for this DB2 subsystem. If the subsystem is not part of data sharing group, the null value is returned.

SYSIBM.DATE_FORMAT

Contains a string that corresponds to the value that is specified for the DATE FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

SYSIBM.DATE_LENGTH

Contains a string that corresponds to the value that is specified for the LOCAL DATE LENGTH field on the DSNTIP4 installation panel. The value will be 10-254, or 0 for no exit, and this session variable can never be null.

SYSIBM.DECIMAL_ARITHMETIC

Contains a string that corresponds to the value that is specified for the DECIMAL ARITHMETIC field on the DSNTIP4 installation panel. The value will be DEC15, DEC31, 15, or 31, and this session variable can never be null.

SYSIBM.DECIMAL_POINT

Contains a string that corresponds to the value that is specified for the DECIMAL POINT IS field on the DSNTIPF installation panel. The value will be '.' or ',' and this session variable can never be null.

SYSIBM.DEFAULT_DECFLOAT_ROUND_MODE

Contains a string that corresponds to the value that is specified for the DECFLOAT ROUNDING MODE field on the DSNTIPF installation panel. This session variable can never be null.

SYSIBM.DEFAULT_SSID

Contains a string that corresponds to the value that is specified for the GROUP ATTACH field on the DSNTIPK installation panel or the SUBSYSTEM NAME field on the DSNTIPM installation panel. This session variable can never be null.

SYSIBM.DEFAULT_LANGUAGE

Contains a string that corresponds to the value that is specified for the LANGUAGE DEFAULT field on the DSNTIPF installation panel. The value will be ASM, C, CPP, IBMCOB, FORTRAN, or PL/I, and this session variable can never be null.

SYSIBM.DEFAULT_LOCALE_LC_CTYPE

Contains a string that corresponds to the value that is specified for the LOCALE LC_CTYPE field on the DSNTIPF installation panel. This session variable can never be null.

SYSIBM.DISTRIBUTED_SQL_STRING_DELIMITER

Contains a string that corresponds to the value that is specified for the DIST SQL STR DELIMTR field on the DSNTIPF installation panel. The value will be ", or ', and this session variable can never be null.

SYSIBM.DSNHDECP_NAME

Contains a string that corresponds to the fully qualified data set name of the data set from which the DSNHDECP or a user-specified application defaults module was loaded. For instance, 'DSN910.SDSNEXIT(DSNHDECP)'. This session variable can never be null.

SYSIBM.DYNAMIC_RULES

Contains a string that corresponds to the value that is specified for the USE FOR DYNAMICRULES field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.ENCODING_SCHEME

Contains a string that corresponds to the value that is specified for the DEF ENCODING SCHEME field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, or UNICODE, and this session variable can never be null.

SYSIBM.MIXED_DATA

Contains a string that corresponds to the value that is specified for the MIXED DATA field on the DSNTIPF installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.NEWFUN

Contains a string that represents the default maximum level of the SQL function syntax that is accepted by the DB2 precompiler or the DB2 coprocessor, regardless of the DB2 function level. For more information about the NEWFUN option, see Descriptions of SQL processing options.

SYSIBM.PACKAGE_NAME

Contains a string that corresponds to the name of the package that is currently being executed. If a package is not currently being executed, the null value is returned. (This situation can occur when the plan that is being executed bound one or more DBRMs directly).

SYSIBM.PACKAGE_SCHEMA

Contains a string that corresponds to the collection id of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

SYSIBM.PACKAGE_VERSION

Contains a string that corresponds to the version of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

SYSIBM.PAD_NUL_TERMINATED

Contains a string that corresponds to the value that is specified for the PAD NUL-TERMINATED field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.PLAN_NAME

Contains a string that corresponds to the name to the plan that is currently being executed. This session variable can never be null.

SYSIBM.SECLABEL

Contains a string that corresponds to the RACF SECLABEL value, if any, that has been defined for the current userid. If a value has not been defined, the null value is returned.

SYSIBM.SQL_STRING_DELIMITER

Contains a string that corresponds to the value that is specified for the SQL STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ", or ', and this session variable can never be null.

SYSIBM.SSID

Contains a string that corresponds to the actual DB2 subsystem identifier for this DB2 subsystem. This session variable can never be null.

SYSIBM.STANDARD_SQL

Contains a string that corresponds to the value that is specified for the STD SQL LANGUAGE field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.SYSTEM_NAME

Contains a string that corresponds to the name of the DB2 for z/OS subsystem, as defined in field SUBSYSTEM NAME on installation panel DSNTIPM. This session variable can never be null.

SYSIBM.SYSTEM_ASCII_CCSID

Contains a value that represents the ASCII CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the ASCII CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for ASCII data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

SYSIBM.SYSTEM_EBCDIC_CCSID

Contains a value that represents the EBCDIC CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the EBCDIC CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for EBCDIC data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

SYSIBM.SYSTEM_UNICODE_CCSID

Contains a value that represents the Unicode CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the UNICODE CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for Unicode data on this system. This session variable can never be null.

SYSIBM.TIME_FORMAT

Contains a string that corresponds to the value that is specified for the TIME FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

SYSIBM.TIME_LENGTH

Contains a string that corresponds to the value that is specified for the LOCAL TIME LENGTH field on the DSNTIP4 installation panel. The value will be 8-254 or 0 for no exit, and this session variable can never be null.

SYSIBM.VERSION

Contains a string that represents the version of DB2.

The format of product identifier values is *pppvrrm*, where *ppp* is a 3-letter product code (such as DSN for DB2), *vv* is the version, *rr* is the release, and *m* is the modification level. For example, DSN10015 identifies DB2 10 in new-function mode, the value is 'DSN10015'. The product code (*ppp*) is one of the following values:

- AQT** for IBM DB2 Analytics Accelerator for z/OS
- ARI** for DB2 Server for VSE & VM
- DSN** for DB2 for z/OS
- JCC** for IBM Data Server Driver for JDBC and SQLJ
- QSQ** for DB2 for i
- SQL** for DB2 for Linux, UNIX, and Windows

Modification (*m*) values have the following meanings:

- Values '0' and '1' identify modification levels in conversion and enabling-new-function mode from Version 8 (CM8, CM8*, ENFM8, and ENFM8*)
- Values '2' and '3' identify modification levels in conversion and enabling-new-function mode from Version 9 (CM9, CM9*, ENFM9, and ENFM9*)
- Value 4 is reserved.
- Values '5', '6', '7', '8', and '9' identify modification levels in new-function mode.

This session variable can never be null.

For example, the following statement sets the value of host variable *hv1* to the name of the plan that is currently being executed:

```
SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

For more information about the GETVARIABLE function, see GETVARIABLE.

Chapter 4. Built-in functions

A *function* is an operation denoted by a function name followed by zero or more input values that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*.

The types of functions are aggregate, scalar, and table. A built-in function is classified as a aggregate function or a scalar function. A user-defined function can be a column, scalar, or table function.

If a column mask is used to mask the column values in the final result table and a column mask is applied to a column that is an argument for a function, the result of the function might be different because the column mask is applied to the column before the function operation can take place. For example, applying a column mask to column SSN can change the result of the aggregate function, COUNT(DISTINCT SSN).

The DISTINCT operation is performed on the masked column values.

OLAP specification and functions

The RANK, DENSE_RANK, and ROW_NUMBER specifications are sometimes referred to as built-in 'functions'. Refer to "OLAP specification" on page 265 for more information on these specifications.

DB2 MQSeries functions

DB2 MQSeries functions integrate MQSeries messaging operations within SQL statements. The functions help you integrate MQSeries messaging with database applications. You can use the functions to access MQSeries messaging from within SQL statements and to combine MQSeries messaging with DB2 database access.

The functions can be scalar or table functions. For more information on using MQSeries functions, see the information on enabling MQSeries functions in *DB2 Installation Guide* and on programming techniques in *DB2 Application Programming and SQL Guide*.

Administrative task scheduler functions

The administrative task scheduler table functions provide information and status about the tasks that are scheduled to run using the administrative task scheduler. The administrative task scheduler provides the ability to run stored procedures, JCL jobs, and other administrative tasks according to a time or an event-based schedule. Refer to *DB2 Administration Guide* for additional information about the administrative task scheduler.

The following table lists the functions that DB2 supports.

Table 61. Supported functions

| Function name | Description |
|---------------|---|
| ABS | Returns the absolute value of its argument |
| ACOS | Returns the arc cosine of an argument as an angle, expressed in radians |
| ADD_MONTHS | Returns a date that represents the date argument plus the number of months argument |

Table 61. Supported functions (continued)

| Function name | Description |
|--|---|
| ADMIN_TASK_LIST | Returns a table with one row for each of the tasks that are defined in the administrative task scheduler task list |
| ADMIN_TASK_OUTPUT | Returns the output parameter values and result sets, if available. If the task that was executed is not a stored procedure or the requested execution status is not available, the function returns an empty table. |
| ADMIN_TASK_STATUS | Returns a table with one row for each task in the administrative task scheduler task list that contains the status for the last time the task was run |
| ASCII | Returns the ASCII code value of the leftmost character of the argument as an integer |
| ASCII_CHR | Returns the character that corresponds to the ASCII code value that is specified by the argument |
| ASCII_STR | Returns an ASCII version of the character or graphic string argument. |
| ASIN | Returns the arc sine of an argument as an angle, expressed in radians |
| ATAN | Returns the arc tangent of an argument as an angle, expressed in radians |
| ATANH | Returns the hyperbolic arc tangent of an argument as an angle, expressed in radians |
| ATAN2 | Returns the arc tangent of x and y coordinates as an angle, expressed in radians |
| AVG | Returns the average of a set of numbers |
| BLOB | Returns a BLOB representation of its argument |
| BIGINT | Returns a big integer representation of its argument |
| BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT | Return a corresponding base 10 integer value in a data type that is based on the data type of the input arguments. |
| BINARY | Returns a fixed-length binary string representation of its argument |
| CCSID_ENCODING | Returns the encoding scheme of a CCSID with a value of ASCII, EBCDIC, UNICODE, or UNKNOWN |
| CEILING | Returns the smallest integer greater than or equal to the argument |
| CHAR | Returns a fixed-length character string representation of its argument |
| CHARACTER_LENGTH | Returns the length of its argument in the number of string units that are specified |
| CLOB | Returns a CLOB representation of its argument |
| COALESCE | Returns the first argument in a set of arguments that is not null |
| COLLATION_KEY | Returns a string that represents the collation key of the argument in the specified collation |
| COMPARE_DECFLOAT | Returns a SMALLINT value that indicates whether two arguments are equal, or unordered, or whether one argument is greater than the other. |
| CONCAT | Returns the concatenation of two strings |
| CONTAINS | Returns a result about whether or not a match was found during a search of a text search index |
| CORRELATION | Returns the coefficient of the correlation of a set of number pairs |
| COS | Returns the cosine of an argument that is expressed as an angle in radians |

Table 61. Supported functions (continued)

| Function name | Description |
|--|---|
| COSH | Returns the hyperbolic cosine of an argument that is expressed as an angle in radians |
| COUNT | Returns the number of rows or values in a set of rows or values |
| COUNT_BIG | Same as COUNT, except the result can be greater than the maximum value of an integer |
| COVARIANCE or COVARIANCE_SAMP | Returns the (population) covariance of a set of number pairs |
| DATE | Returns a date derived from its argument |
| DAY | Returns the day part of its argument |
| DAYOFMONTH | Similar to DAY |
| DAYOFWEEK | Returns an integer in the range of 1 to 7, where 1 represents Sunday |
| DAYOFWEEK_ISO | Returns an integer in the range of 1 to 7, where 1 represents Monday |
| DAYOFYEAR | Returns an integer in the range of 1 to 366, where 1 represents January 1 |
| DAYS | Returns an integer representation of a date |
| DBCLOB | Returns a DBCLOB representation of its argument |
| DECIMAL or DEC | Returns a decimal representation of its argument |
| DECFLOAT | Returns a DECFLOAT representation of its argument |
| DECFLOAT_FORMAT | Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format. |
| DECFLOAT_SORTKEY | Returns a binary value that can be used when sorting DECFLOAT values |
| DECODE | Returns a specified <i>result-expression</i> based on a comparison of input expressions (similar to the CASE expression). |
| DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, or DECRYPT_DB | Returns the decrypted value of an encrypted argument |
| DEGREES | Returns the number of degrees for an argument that is expressed in radians |
| DIFFERENCE | Returns a value that represents the difference between the sounds of two strings based on applying the SOUNDEX function to the strings. |
| DIGITS | Returns a character string representation of a number |
| DOUBLE or DOUBLE_PRECISION | Returns a double precision floating-point representation of its argument |
| DSN_XMLVALIDATE | Returns an XML value that is the result of applying XML schema validation to the first argument. |
| EBCDIC_CHR | Returns the character that corresponds to the EBCDIC code value that is specified by the argument |
| EBCDIC_STR | Returns an EBCDIC version of the string argument |
| ENCRYPT_TDES | Returns the argument as an encrypted value |
| EXP | Returns the exponential function of an argument |
| EXTRACT | Returns a portion of a date or timestamp based on its arguments |
| FLOAT | Same as DOUBLE |
| FLOOR | Returns the largest integer that is less than or equal to the argument |

Table 61. Supported functions (continued)

| Function name | Description |
|--------------------|---|
| GENERATE_UNIQUE | Returns a character string of bit data that is unique compared to any other execution of the function |
| GETHINT | Returns the embedded password hint from encrypted data, if one exists |
| GETVARIABLE | Returns a varying-length character string representation of the value of a session variable |
| GRAPHIC | Returns a fixed-length graphic string representation of its argument |
| HEX | Returns a hexadecimal representation of its argument |
| HOUR | Returns the hour part of its argument |
| IDENTITY_VAL_LOCAL | Returns the most recently assigned value for an identity column |
| IFNULL | Returns the first argument in a set of two arguments that is not null |
| INSERT | Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted |
| INTEGER or INT | Returns an integer representation of its argument |
| JULIAN_DAY | Returns an integer that represents the number of days from January 1, 4712 B.C. |
| LAST_DAY | Returns a date that represents the last day of the month of the date argument |
| LCASE | Returns a string with the characters converted to lowercase |
| LEFT | Returns a string that consists of the specified number of leftmost bytes or the specified string units |
| LENGTH | Returns the length of its argument |
| LN | Returns the natural logarithm of an argument |
| LOCATE | Returns the starting position of one string within another string |
| LOCATE_IN_STRING | Returns the starting position of the first occurrence of one string within another string |
| LOG10 | Returns the base 10 logarithm of an argument |
| LOWER | Returns a string with the characters converted to lowercase |
| LPAD | Returns a string that is padded on the left with blanks or a specified string |
| LTRIM | Returns the characters of a string with the leading blanks or hexadecimal zeros removed |
| MAX (aggregate) | Returns the maximum value in a set of column values |
| MAX (scalar) | Returns the maximum value in a set of values |
| MICROSECOND | Returns the microsecond part of its argument |
| MIDNIGHT_SECONDS | Returns an integer in the range of 0 to 86400 that represents the number of seconds between midnight and the argument |
| MIN (aggregate) | Returns the minimum value in a set of column values |
| MIN (scalar) | Returns the minimum value in a set of values |
| MINUTE | Returns the minute part of its argument |
| MOD | Returns the remainder of one argument divided by a second argument |
| MONTH | Returns the month part of its argument |

Table 61. Supported functions (continued)

| Function name | Description |
|--------------------|--|
| MONTHS_BETWEEN | Returns an estimate of the number of months between two arguments |
| MQREAD | Returns a message from a specified MQSeries location (return value of VARCHAR) without removing the message from the queue |
| MQREADALL | Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and without removing the messages from the queue |
| MQREADALLCLOB | Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and without removing the messages from the queue |
| MQREADCLOB | Returns a message from a specified MQSeries location (return value of CLOB) without removing the message from the queue |
| MQRECEIVE | Returns a message from a specified MQSeries location (return value of VARCHAR) with removal of message from the queue |
| MQRECEIVEALL | Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and with removal of messages from the queue |
| MQRECEIVEALLCLOB | Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and with removal of messages from the queue |
| MQRECEIVECLOB | Returns a message from a specified MQSeries location (return value of CLOB) with removal of message from the queue |
| MQSEND | Sends data to a specified MQSeries location, and returns a varying-length character string that indicates whether the function was successful or unsuccessful |
| MULTIPLY_ALT | Returns the product of the two arguments as a decimal value, used when the sum of the argument precisions exceeds 31 |
| NEXT_DAY | Returns a timestamp that represents the first weekday, specified by the second argument, after the date argument |
| NORMALIZE_DECFLOAT | Returns a DECFLOAT value that is the result of normalizing the input argument |
| NORMALIZE_STRING | Returns a string value that is the result of normalizing the input Unicode value |
| NULLIF | Returns NULL if the arguments are equal; else the first argument |
| NVL | Returns the first argument that is not null. |
| OVERLAY | Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted |
| PACK | Returns a binary string value that contains a data type array and a packed representation of each non-null argument. |
| POSITION | Returns the position of the first occurrence of an argument within another argument where the position is expressed in terms of the string units that are specified |
| POSSTR | Returns the position of the first occurrence of an argument within another argument |
| POWER | Returns the value of one argument raised to the power of a second argument |

Table 61. Supported functions (continued)

| Function name | Description |
|--------------------------|---|
| QUANTIZE | Returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and which has an exponent set to be equal to the exponent of the second argument |
| QUARTER | Returns an integer in the range of 1 to 4 that represents the quarter of the year for the date specified in the argument |
| RADIANS | Returns the number of radians for an argument that is expressed in degrees |
| RAISE_ERROR | Raises an error in the SQLCA with the specified SQLSTATE and error description |
| RAND | Returns a double precision floating-point random number |
| REAL | Returns a single precision floating-point representation of its argument |
| REPEAT | Returns a character string composed of an argument repeated a specified number of times |
| REPLACE | Returns a string in which all occurrences of an argument within a second argument are replaced with a third argument |
| RID | Returns the RID of a row |
| RIGHT | Returns a string that consists of the specified number of rightmost bytes or specified string unit |
| ROUND | Returns a number rounded to the specified number of places to the right or left of the decimal place |
| ROUND_TIMESTAMP | Returns a timestamp rounded to the unit specified by the timestamp format string |
| ROWID | Returns a row ID representation of its argument |
| RPAD | Returns a string that is padded on the right with blanks or a specified string |
| RTRIM | Returns the characters of an argument with the trailing blanks or hexadecimal zeros removed |
| SCORE | Returns a relevance score that measures how well a document matches the query used to search a text search index |
| SECOND | Returns the second part of its argument |
| SIGN | Returns the sign of an argument |
| SIN | Returns the sine of an argument that is expressed as an angle in radians |
| SINH | Returns the hyperbolic sine of an argument that is expressed as an angle in radians |
| SMALLINT | Returns a small integer representation of its argument |
| SOAPHTTPC or SOAPHTTPV | Returns a CLOB or VARCHAR representation of XML data from a request to a web service |
| SOAPHTTPNC or SOAPHTTPNV | Returns a complete CLOB or VARCHAR representation of XML data from a complete request to a web service |
| SOUNDEX | Returns a value that represents the sound of the words in the argument. |
| SPACE | Returns a string that consists of the number of blanks the argument specifies |
| SQRT | Returns the square root of its argument |

Table 61. Supported functions (continued)

| Function name | Description |
|-----------------------|---|
| STDDEV or STDDEV_SAMP | Returns the standard deviation (/n), or the sample standard deviation (/n-1), of a set of numbers |
| STRIP | Returns the characters of a string with the blanks (or specified character) at the beginning, end, or both beginning and end of the string removed |
| SUBSTR | Returns a substring of a string |
| SUBSTRING | Returns a substring of a string using the specified string units |
| SUM | Returns the sum of a set of numbers |
| TAN | Returns the tangent of an argument that is expressed as an angle in radians |
| TANH | Returns the hyperbolic tangent of an argument that is expressed as an angle in radians |
| TIME | Returns a time derived from its argument |
| TIMESTAMP | Returns a timestamp derived from its arguments |
| TIMESTAMPADD | Returns a timestamp derived from adding the specified interval to a timestamp |
| TIMESTAMP_FORMAT | Returns a timestamp for a character string expression, using a specified format to interpret the string |
| TIMESTAMP_ISO | Returns a timestamp derived from its arguments |
| TIMESTAMPDIFF | Returns an estimated number of the specified intervals based on the difference between two timestamps |
| TIMESTAMP_TZ | Returns a timestamp with a time zone derived from its arguments |
| TO_CHAR | Returns a character string representation of a timestamp value that has been formatted using a specified character template. |
| TO_DATE | Returns a timestamp value that is based on the interpretation of the input string using the specified format. |
| TO_NUMBER | Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format. |
| TOTALORDER | Returns a SMALLINT value that indicates the comparison order of two arguments |
| TRANSLATE | Returns a string with one or more characters translated |
| TRIM | Removes bytes from the beginning, from the end, or from both the beginning and end of a string expression. |
| TRUNCATE | Returns a number truncated to the specified number of places to the right or left of the decimal point |
| TRUNC_TIMESTAMP | Returns a timestamp truncated to the unit specified by the timestamp format string |
| UCASE | Returns a string with the characters converted to uppercase |
| UNICODE | Returns the Unicode (UTF-16) code value of the leftmost character of the argument as an integer |
| UNICODE_STR | Returns a string in Unicode (UTF-8 or UTF-16) that represents a Unicode encoding of the argument |
| UNPACK | Returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function. |
| UPPER | Returns a string with the characters converted to uppercase |

Table 61. Supported functions (continued)

| Function name | Description |
|---------------------------------|--|
| VALUE | Same as COALESCE |
| VARBINARY | Returns a varying-length binary string representation of its argument |
| VARCHAR | Returns the varying-length character string representation of its argument |
| VARCHAR_FORMAT | Returns a varying-length character string representation of a timestamp, with the string in a specified format |
| VARGRAPHIC | Returns a varying-length graphic string representation of its argument |
| VARIANCE or VARIANCE_SAMP | Returns the variance, or sample variance, of a set of numbers |
| VERIFY_GROUP_FOR_USER | Returns a value that indicates whether the primary authorization ID and the group authorization IDs that are associated with the first argument are included in the authorization names that are specified in the list of the second argument. |
| VERIFY_ROLE_FOR_USER | Returns a value that indicates whether the roles that are associated with the first argument are included in the role names that are specified in the list of the second argument. |
| VERIFY_TRUSTED_CONTEXT_FOR_USER | Returns a value that indicates whether the authorization ID that is associated with first argument has acquired a role in a trusted connection and whether that acquired role is included in the role names that are specified in the list of the second argument. |
| WEEK | Returns an integer that represents the week of the year with Sunday as the first day of the week |
| WEEK_ISO | Returns an integer that represents the week of the year with Monday as first day of a week |
| XMLAGG | Returns an XML type that represents a concatenation of XML elements from a collection of XML elements |
| XMLATTRIBUTES | Returns an XML sequence that contains an XQuery attribute node for each non-null argument |
| XMLCOMMENT | Returns an XML value with a single comment node from a string expression |
| XMLCONCAT | Returns an XML value that represents a forest of XML elements generated by concatenating a variable number of arguments |
| XMLDOCUMENT | Returns an XML value with a single document node and zero or more nodes as its children |
| XMLELEMENT | Returns an XML value that represents an XML element |
| XMLFOREST | Returns an XML value that represents a forest of XML elements that all share a specific pattern |
| XMLMODIFY | Returns an XML value that might have been modified by the evaluation of an XQuery updating expression and XQuery variables that are specified as input arguments. |
| XMLNAMESPACES | Returns the declaration of one or more XML namespaces |
| XMLPARSE | Returns an XML value from parsing the argument as an XML document |
| XMLPI | Returns an XML value with a single processing instruction node |
| XMLQUERY | Returns an XML value from the evaluation of an XPath expression against a set of arguments |
| XMLSERIALIZE | Returns an SQL character string or a BLOB value from an XML value |

Table 61. Supported functions (continued)

| Function name | Description |
|----------------|--|
| XMLTABLE | Returns a result table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables |
| XMLTEXT | Returns an XML value with a single text node that contains the value of the argument |
| XMLXSROBJECTID | Returns the XSR object identifier of the XML schema that is used to validate the XML document specified in the argument. |
| XSLTRANSFORM | The XSLTRANSFORM function transforms an XML document into a different data format. The output can be any form possible for the XSLT processor, including but not limited to XML, HTML, and plain text. Note: This is a DB2-supplied user-defined function. |
| YEAR | Returns the year part of its argument |

Aggregate functions

An aggregate function receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Certain rules apply to all aggregate functions.

The following information applies to all aggregate functions, except for the COUNT(*) and COUNT_BIG(*), variations of the COUNT and COUNT_BIG functions, and the XMLAGG function.

The argument of an aggregate function is a set of values derived from an expression. The expression must not include another aggregate function or a scalar fullselect. The scope of the set is a group or an intermediate result table, as explained in the information on the GROUP BY clause.

If a GROUP BY clause is specified in a query and the intermediate result from the FROM, WHERE, GROUP BY, and HAVING clauses is the empty set, then the aggregate functions are not applied and the result of the query is the empty set.

If the GROUP BY clause is not specified in a query and the intermediate result table of the FROM, WHERE, and HAVING clauses is the empty set, then the aggregate functions are applied to the empty set.

For example, the result of the following SELECT statement is the number of distinct values of JOB for employees in department D11:

```
SELECT COUNT(DISTINCT JOB)
FROM DSN8A10.EMP
WHERE WORKDEPT = 'D11';
```

The keyword DISTINCT is not an argument of the function but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated. If ALL is implicitly or explicitly specified, redundant duplicate values are not eliminated.

DISTINCT must not be specified preceding an XML value.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT in aggregate functions.

When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

An aggregate function can be used in a WHERE clause only if that clause is part of a subquery of a HAVING clause and the column name specified in the expression is a correlated reference to a group. If the expression includes more than one column name, each column name must be a correlated reference to the same group.

The result of the COUNT and COUNT_BIG functions cannot be the null value. As specified in the description of AVG, MAX, MIN, STDDEV, SUM, and VARIANCE, the result is the null value when the function is applied to an empty set. However, the result is also the null value when the function is specified in an outer select list, the argument is given by an arithmetic expression, and any evaluation of the expression causes an arithmetic exception (such as division by zero).

If the argument values of an aggregate function are strings from a column with a field procedure, the function is applied to the encoded form of the values and the result of the function inherits the field procedure.

Related reference:

“group-by-clause” on page 1108

AVG

The AVG function returns the average of a set of numbers.

The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The data type of the result is determined as follows:

- DECFLOAT(34) if the argument is DECFLOAT(*n*).
- Large integer is the argument is small integer.
- Double precision floating-point is the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal with precision *p* and scale *s*, the precision (P) and scale (S) of the result depend on *p* and the decimal precision option:

- If *p* is greater than 15 or the DEC31 option is in effect, P is 31 and S is $\max(0, 28-p+s)$.
- Otherwise, P is 15 and S is $15-p+s$.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the average value of the set. The order in which the summation part of the operation is performed is undefined but every intermediate result must be within the range of the result data type.

If the type of the result is integer, the fractional part of the average is lost.

Example: Assuming DEC15, set the DECIMAL(15,2) variable AVERAGE to the average salary in department D11 of the employees in the sample table DSN8A10.EMP.

```
EXEC SQL SELECT AVG(SALARY)
        INTO :AVERAGE
        FROM DSN8A10.EMP
        WHERE WORKDEPT = 'D11';
```

CORRELATION

The CORRELATION function returns the coefficient of the correlation of a set of number pairs.

►►CORRELATION(*expression-1*,*expression-2*)◄◄

The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result is between -1 and 1. The result can be null.

The function is applied to the set of (*expression-1*, *expression-2*) pairs derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, or if either STDDEV(*expression-1*) or STDDEV(*expression-2*) is equal to zero, the result is a null value. Otherwise, the result is the correlation coefficient for the value pairs in the set. The result is equivalent to the following expression:

$$\frac{\text{COVARIANCE}(\textit{expression-1}, \textit{expression-2})}{(\text{STDDEV}(\textit{expression-1}) * \text{STDDEV}(\textit{expression-2}))}$$

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

CORR can be specified as a synonym for CORRELATION.

Example: Using sample table DSN8A10.EMP, set the host variable :corrln (double-precision floating point) to the correlation between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT CORRELATION(SALARY, BONUS) INTO :corrln
FROM DSN8A10.EMP WHERE WORKDEPT = 'A00';
```

:corrln is set to approximately 9.99853953399538E-001.

COUNT

The COUNT function returns the number of rows or values in a set of rows or values.

The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result is a large integer. The result cannot be null.

The argument of COUNT(*) is a set of rows. The result is the number of rows in the set. Any row that includes only null values is included in the count.

The argument of COUNT(expression) or COUNT(ALL expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT(DISTINCT expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values and redundant duplicate values. The result is the number of different nonnull values in the set.

Example 1: Set the integer host variable FEMALE to the number of females represented in the sample table DSN8A10.EMP.

```
EXEC SQL SELECT COUNT(*)
        INTO :FEMALE
        FROM DSN8A10.EMP
        WHERE SEX = 'F';
```

Example 2: Set the integer host variable FEMALE_IN_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT(DISTINCT WORKDEPT)
        INTO :FEMALE_IN_DEPT
        FROM DSN8A10.EMP
        WHERE SEX = 'F';
```

COUNT_BIG

The COUNT_BIG function returns the number of rows or values in a set of rows or values. It is similar to COUNT except that the result can be greater than the maximum value of an integer.

The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result of the function is a decimal number with precision 31 and scale 0. The result cannot be null.

The argument of COUNT_BIG(*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT_BIG(expression) or COUNT_BIG(ALL expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT_BIG(DISTINCT expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null and redundant duplicate values. The result is the number of different nonnull values in the set.

Example 1: Set the integer host variable FEMALE to the number of females represented in the sample table DSN8A10.EMP.

```
EXEC SQL SELECT COUNT_BIG(*)  
        INTO :FEMALE  
        FROM DSN8A10.EMP  
        WHERE SEX = 'F';
```

Example 2: Set the integer host variable FEMALE_IN_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT_BIG(DISTINCT WORKDEPT)  
        INTO :FEMALE_IN_DEPT  
        FROM DSN8A10.EMP  
        WHERE SEX = 'F';
```

Example 3: To create a sourced function that is similar to the built-in COUNT_BIG function, the definition of the sourced function must include the type of the column that can be specified when the new function is invoked. In this example, the CREATE FUNCTION statement creates a sourced function that takes a CHAR column as input and uses COUNT_BIG to perform the counting. The result is

returned as a double precision floating-point number. The query shown counts the number of unique departments in the sample employee table.

```
CREATE FUNCTION RICK.COUNT(CHAR()) RETURNS DOUBLE
SOURCE SYSIBM.COUNT_BIG(CHAR());
SET CURRENT PATH RICK, SYSTEM PATH;
SELECT COUNT(DISTINCT WORKDEPT) FROM DSN8A10.EMP;
```

The empty parenthesis in the parameter list for the new function (RICK.COUNT) means that the input parameter for the new function is the same type as the input parameter for the function named in the SOURCE clause. The empty parenthesis in the parameter list in the SOURCE clause (SYSIBM.COUNT_BIG) means that the length attribute of the CHAR parameter of the COUNT_BIG function is ignored when DB2 locates the COUNT_BIG function.

COVARIANCE or COVARIANCE_SAMP

The COVARIANCE and COVARIANCE_SAMP functions return the covariance (population) of a set of number pairs.

The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

The function is applied to the set of (*expression-1*, *expression-2*) pairs that are derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the covariance of the value pairs in the set. The result is equivalent to the following outputs:

For COVARIANCE:

1. Let *avgexp1* be the result of AVG(*expression-1*) and let *avgexp2* be the result of AVG(*expression-2*).
2. The result of COVARIANCE(*expression-1*,*expression-2*) is AVG((*expression-1* - *avgexp1*) * (*expression-2* - *avgexp2*))

For COVARIANCE_SAMP:

1. Let *samp_avgexp1* be the result of SUM(*expression-1*)/*n*-1 and let *samp_avgexp2* be the result of SUM(*expression-2*)/*n*-1.
2. The result of COVARIANCE_SAMP(*expression-1*, *expression-2*) is AVG((*expression-1* - *samp_avgexp1*) * (*expression-2* - *samp_avgexp2*))

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

COVAR can be specified as a synonym for COVARIANCE.

COVAR_SAMP can be specified as a synonym for COVARIANCE_SAMP.

Example: Using sample table DSN8A10.EMP, set the host variable *covarnce* (double-precision floating point) to the covariance between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT COVARIANCE(SALARY, BONUS) INTO :covarnce
FROM EMPLOYEE WHERE WORKDEPT = 'A00';
```

covarnce is set to approximately 1.68888888888889E+006.

MAX

The MAX function returns the maximum value in a set of values.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrices in “Assignment and comparison” on page 119. All arguments except the first argument can be parameter markers.

This function cannot be used as a source function when creating a user-defined function.

expression

An expression that returns the value of a built-in data type. Each expression must return a value that is not a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The result of the function is the largest argument value. The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the maximum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

Example 1: Set the DECIMAL(8,2) variable MAX_SALARY to the maximum monthly salary of the employees represented in the sample table DSN8A10.EMP.

```
EXEC SQL SELECT MAX(SALARY) / 12
        INTO :MAX_SALARY
        FROM DSN8A10.EMP;
```

Example 2: Find the surname that comes last in the collating sequence for the employees represented in the sample table DSN8A10.EMP. Set the VARCHAR(15) variable LAST_NAME to that surname.

```
EXEC SQL SELECT MAX(LASTNAME)
        INTO :LAST_NAME
        FROM DSN8A10.EMP;
```

MEDIAN

The MEDIAN function returns the median of a set of numbers. The MEDIAN function can run only on an accelerator server.

```
▶—MEDIAN(numeric-expression)—▶
```

The schema is SYSIBM.

numeric-expression

An expression that returns a built-in numeric data type. *numeric-expression* must not include a scalar fullselect, or invoke a function that is non-deterministic or has an external action.

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double precision floating-point number.

The function is applied to the set of values that are derived from the argument values by the elimination of null values.

The result can be null. If *numeric-expression* is null or if the function is applied to the empty set, the result is the null value.

Example 1: Calculate the median salary of the employees in department D11 from the EMPLOYEE table.

```
SELECT MEDIAN(SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'D11';
```

The result is 24680.00. Department D11 has 11 employees. The middle row of a group of 11 values is the sixth row. The result of MEDIAN over that group is the value of the sixth row, which is 24680.00.

Example 2: Calculate the median salary of the employees in department E21 from the EMPLOYEE table.

```
SELECT MEDIAN(SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'E21';
```

The result is 24605.00. Department E21 has six employees. Because there are an even number of rows, the MEDIAN is computed by interpolating a value between the middle two rows. The middle two rows are the third row with the value 23840.00 and the fourth row with the value 25370.00. MEDIAN is computed by averaging those two values, which is 24605.00.

Note: Consider the following additional notes:

When EXPLAIN is issued against an SQL statement that references the MEDIAN function, but the statement cannot be run on the accelerator server for any reason, the following values are populated in the PLAN_TABLE table:

- For a SELECT statement, column QBLOCK_TYPE would have the value 'PRUNED', and column ACESSTYPE would have the value ' ' (blank).

- For an INSERT statement with a subselect, the PLAN_TABLE rows for the subselect would have column QBLOCK_TYPE with the value 'NCOSUB', and column ACESSTYPE with the value ' ' (blank).

Also, when a view is referenced in an SQL statement that uses the MEDIAN function, the tables referred to in the view must be enabled for acceleration. Those tables referred to in the view do not need to be enabled for acceleration when the view is created.

MIN

The MIN function returns the minimum value in a set of values.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrices in “Assignment and comparison” on page 119. All arguments except the first argument can be parameter markers.

This function cannot be used as a source function when creating a user-defined function.

expression

An expression that returns the value of a built-in data type. Each expression must return a value that is not a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The result of the function is the smallest argument value. The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the minimum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

Example 1: Set the DECIMAL(15,2) variable *MIN_SALARY* to the minimum monthly salary of the employees represented in the sample table DSN8A10.EMP.

```
EXEC SQL SELECT MIN(SALARY) / 12
        INTO :MIN_SALARY
        FROM DSN8A10.EMP;
```

Example 2: Find the surname that comes first in the collating sequence for the employees represented in the sample table DSN8A10.EMP. Set the VARCHAR(15) variable *LAST_NAME* to that surname.

```
EXEC SQL SELECT MIN(LASTNAME)
        INTO :LAST_NAME
        FROM DSN8A10.EMP;
```

STDDEV or STDDEV_SAMP

The STDDEV or STDDEV_SAMP function returns the standard deviation ($/n$), or the sample standard deviation ($/n-1$), of a set of numbers.

The schema is SYSIBM.

The function returns the biased standard deviation ($/n$) or the sample standard deviation ($/n-1$) of a set of numbers, depending on which keyword is specified:

STDDEV

The formula that is used to calculate the biased standard deviation is logically equivalent to:

$$\text{STDDEV} = \text{SQRT}(\text{VAR})$$

STDDEV_SAMP

The formula that is used to calculate the sample standard deviation is logically equivalent to:

$$\text{STDDEV} = \text{SQRT}(\text{VARIANCE_SAMP})$$

The argument values must each be the value of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the standard deviation of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

STDDEV_POP can be specified as a synonym for STDDEV.

Example: Using sample table DSN8A10.EMP, set the host variable *DEV*, which is defined as double precision floating-point, to the standard deviation of the salaries for the employees in department 'A00' (WORKDEPT='A00').

```
SELECT STDDEV(SALARY)
       INTO :DEV
       FROM DSN8A10.EMP
       WHERE WORKDEPT = 'A00';
```

For this example, host variable *DEV* is set to a double precision float-pointing number with an approximate value of '9742.43'.

SUM

The SUM function returns the sum of a set of numbers.

The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The data type of the result is determined as follows:

- DECFLOAT(34) if the argument is DECFLOAT(*n*).
- Large integer if the argument is small integer.
- Double precision floating-point if the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal, the scale of the result is the same as the scale of the argument values, and the precision of the result depends on the precision of the argument values and the decimal precision option:

- If the precision of the argument values is greater than 15 or the DEC31 option is in effect, the precision of the result is $\min(31, P+10)$, where *P* is the precision of the argument values.
- Otherwise, the precision of the result is 15.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the sum of the values in the set. The order in which the summation is performed is undefined but every intermediate result must be within the range of the result data type.

Example: Set the large integer host variable *INCOME* to the total income from all sources (salaries, commissions, and bonuses) of the employees represented in the sample table DSN8A10.EMP. If DEC31 is not in effect, the resultant sum is DECIMAL(15,2) because all three columns are DECIMAL(9,2).

```
EXEC SQL SELECT SUM(SALARY+COMM+BONUS)
           INTO :INCOME
           FROM DSN8A10.EMP;
```

VARIANCE or VARIANCE_SAMP

The VARIANCE function returns the biased variance ($/n$) of a set of numbers. The VARIANCE_SAMP function returns the sample variance ($/n-1$) of a set of numbers.

The schema is SYSIBM.

The function returns the biased variance ($/n$) or the sample variance ($/n-1$) of a set of numbers, depending on which keyword is specified.

VARIANCE

The formula that is used to calculate the biased variance is logically equivalent to:

$$\text{VARIANCE} = \text{SUM}(X**2) / \text{COUNT}(X) - (\text{SUM}(X) / \text{COUNT}(X))**2$$

VARIANCE_SAMP

The formula that is used to calculate the sample variance is logically equivalent to:

$$\text{VARIANCE_SAMP} = (\text{SUM}(X**2) - ((\text{SUM}(X)**2) / (\text{COUNT}(*)))) / (\text{COUNT}(*) - 1)$$

The argument values can be of any built-in numeric type, and their sum must be within the range of the data type of the result. Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point.

The result can be null; if any argument is null, the result is the null value.

Otherwise, the result is the variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Alternative syntax and synonyms:

- VAR or VAR_POP can be specified as synonym for VARIANCE
- VAR_SAMP can be specified as a synonym for VARIANCE_SAMP

Example 1: Using sample table DSN8A10.EMP, set host variable VARNCE, which is defined as double precision floating-point, to the variance of the salaries (SALARY) for those employees in department (WORKDEPT) 'A00'.

```
SELECT VARIANCE(SALARY)
       INTO :VARNCE
       FROM DSN8A10.EMP
       WHERE WORKDEPT = 'A00';
```

The result in *VARNCE* is set to a double precision-floating point number with an approximate value of '94915000.00'.

If *VARIANCE_SAMP* had been specified to find the sample variance of the salaries, the result in *VARNCE* would be set to a double precision-floating point number with an approximate value of '94915000.00'.

XMLAGG

The XMLAGG function returns an XML sequence that contains an item for each non-null value in a set of XML values.

sort-key

The schema is SYSIBM.

XML-expression

An expression that returns an XML value.

Unlike the arguments for other aggregate functions, a scalar fullselect is allowed in *XML-expression*.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a LOB or an XML value. A character string expression cannot have a length greater than 4000 bytes. If the sort key value is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but is simply a constant, which implies no sort key.

The ordering is based on the values of the sort keys, which might or might not be used in *XML-expression*.

If the sort key value is a character string that uses an encoding scheme other than Unicode, the ordering might be different. For example, a column PRODCODE uses EBCDIC. For two values, ('P001' and 'PA01'), relationship 'P001' > 'PA01' is true in EBCDIC, whereas 'P001' < 'PA01' is true in UTF-8. If the same sort key values are used in *XML-expression*, use the CAST specification to convert the sort key to Unicode to keep the ordering of XML values consistent with that of the sort key.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null; if all *XML-expression* arguments are null. If the function is applied to an empty set, the result is the null value. Otherwise, the result is an XML sequence that contains an item for each value in the set.

Example: Group employees by their department, generate a 'Department' element for each department with its name as the attribute, nest all the 'emp' elements for employees in each department, and order the 'emp' elements by 'lname.'

```
SELECT XMLSERIALIZE(XMLDOCUMENT
  ( XMLELEMENT
    ( NAME "Department",
      XMLATTRIBUTES ( e.dept AS "name" ),
      XMLAGG ( XMLELEMENT ( NAME "emp", e.lname)
        ORDER BY e.lname)
      ) ) AS "dept_list"
    AS CLOB(1M))
  FROM employees e
  GROUP BY dept;
```

The result of the query would look similar to the following result:

```
dept_list
-----
<Department name="Accounting">
  <emp>SMITH</emp>
  <emp>Yates</emp>
</Department>
<Department name="Shipping">
  <emp>Martin</emp>
  <emp>Oppenheimer</emp>
</Department>
-----
```

Scalar functions

A scalar function can be used wherever an expression can be used. The restrictions on the use of aggregate functions do not apply to scalar functions, because a scalar function is applied to single set of parameter values rather than to sets of values. The argument of a scalar function can be a function. However, the restrictions that apply to the use of expressions and aggregate functions also apply when an expression or aggregate function is used within a scalar function. For example, the argument of a scalar function can be an aggregate function only if an aggregate function is allowed in the context in which the scalar function is used.

If the argument of a scalar function is a string from a column with a field procedure, the function applies to the decoded form of the value and the result of the function does not inherit the field procedure.

Example: The following SELECT statement calls for the employee number, last name, and age of each employee in department D11 in the sample table DSN8A10.EMP. To obtain the ages, the scalar function YEAR is applied to the expression:

```
CURRENT DATE - BIRTHDATE
```

in each row of DSN8A10.EMP for which the employee represented is in department D11:

```
SELECT EMPNO, LASTNAME, YEAR(CURRENT DATE - BIRTHDATE)
FROM DSN8A10.EMP
WHERE WORKDEPT = 'D11';
```

ABS

The ABS function returns the absolute value of a number.

▶—ABS(*numeric-expression*)—▶

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument.

The result can be null; if the argument is null, the result is the null value.

ABSVAL can be specified as a synonym for ABS. DB2 supports this keyword to provide compatibility with previous releases.

Example: Assume that host variable PROFIT is a large integer with a value of -50000. The following statement returns a large integer with a value of 50000.

```
SELECT ABS(:PROFIT)
FROM SYSIBM.SYSDUMMY1;
```

ACOS

The ACOS function returns the arc cosine of the argument as an angle, expressed in radians. The ACOS and COS functions are inverse operations.

▶▶—ACOS(*numeric-expression*)—◀◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable ACOSINE is DECIMAL(10,9) with a value of 0.070737202. The following statement:

```
SELECT ACOS(:ACOSINE)
FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.49.

ADD_MONTHS

The ADD_MONTHS function returns a date that represents *expression* plus a specified number of months.

►—ADD_MONTHS(*expression*,*numeric-expression*)—►

The schema is SYSIBM.

expression

An expression that specifies the starting date. *expression* must return a value that is a date, timestamp, or a valid string representation of a date or timestamp. A string representation is a value that is a built-in character string data type or graphic string data type, that is not a LOB, and that has an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is first cast to a TIMESTAMP WITHOUT TIME ZONE value with the same precision as *expression*. If *expression* is a string, *expression* is first cast to DATE.

numeric-expression

An expression that returns a value of any built-in numeric data type. The integer portion of *numeric-expression* specifies the number of months to add to the starting date specified by *expression*. A negative numeric value is allowed.

numeric-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone value, the result is determined from the UTC representation of the datetime value.

If *expression* is a timestamp value the result is a TIMESTAMP WITHOUT TIME ZONE with the same precision as *expression*. Otherwise, the result is a DATE value.

The result can be null; if any argument is null, the result is the null value.

If *expression* is the last day of the month or if the resulting month has fewer days than the day component of *expression*, the result is the last day of the resulting month. Otherwise, the result has the same day component as *expression*. Any hours, minutes, seconds, or fractional seconds information included in *expression* is not changed by the function.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Assume today is January 31, 2007. Set the host variable ADD_MONTH with the last day of January plus 1 month.

```
SET :ADD_MONTH = ADD_MONTHS(LAST_DAY(CURRENT_DATE), 1);
```

The host variable `ADD_MONTH` is set with the value representing the end of February, 2007-02-28.

Example 2: Assume `DATE` is a host variable with the value July 27, 1965. Set the host variable `ADD_MONTH` with the value of that day plus 3 months.

```
SET :ADD_MONTH = ADD_MONTHS(:DATE,3);
```

The host variable `ADD_MONTH` is set with the value representing the day plus 3 months, 1965-10-27.

Example 3: It is possible to achieve similar results with the `ADD_MONTHS` function and date arithmetic. The following examples demonstrate the similarities and contrasts.

```
SET :DATEHV = DATE('2008-2-28') + 4 MONTHS;  
SET :DATEHV = ADD_MONTHS('2008-2-28', 4);
```

In both cases, the host variable `DATEHV` is set with the value '2008-06-29'.

Now consider the same examples but with the date '2008-2-29' as the argument.

```
SET :DATEHV = DATE('2008-2-29') + 4 MONTHS;
```

The host variable `DATEHV` is set with the value '2008-06-29'.

```
SET :DATEHV = ADD_MONTHS('2008-2-29', 4);
```

The host variable `DATEHV` is set with the value '2008-06-30'.

In this case, the `ADD_MONTHS` function returns the last day of the month, which is June 30, 2008, instead of June 29, 2008. The reason is that February 29 is the last day of the month. So, the `ADD_MONTHS` function returns the last day of June.

Example 4: Assume `TSZ` is an SQL variable with the `TIMESTAMP WITH TIME ZONE` value 2008-02-29.20.00.00.000000-08.00. Set `TIMESZ` to the value of that `TIMESTAMP WITH TIME ZONE` plus 4 months. The string representation of the timestamp is first implicitly cast to `TIMESTAMP WITHOUT TIME ZONE` for the `ADD_MONTHS` function. The result of the `ADD_MONTHS` function does not contain a time zone.

```
SET TIMESZ: = ADD_MONTHS(TIMESTAMP_TZ(TSZ), 4);
```

With the string representation of a timestamp as input, the function returns a `DATE` value that represents the timestamp plus 4 months: 2008-06-30.

Example 5: Assume `TSZ` is a host variable with the value 2008-02-29.20.00.000000-08.00 which is a string representation of a timestamp with a time zone. Set `TIMESZ` to the value of that timestamp with a time zone plus 4 months.

```
SET TIMESZ: = ADD_MONTHS(:TSZ, 4);
```

The host variable `TIMESZ` is set with the value that represents the timestamp with time zone plus 4 months, 2008-06-30-20.00.00.000000 -8.00.

ASCII

The ASCII function returns the leftmost character of the argument as an integer.

►►—ASCII(*string-expression*)—◄◄

The schema is SYSIBM.

The argument can be any built-in character or graphic string data type, except for CLOB or DBCLOB. If the argument is an EBCDIC, Unicode, or graphic string, it is first converted to an SBCS ASCII character string (CCSID 367)¹⁸ before the function is executed.

| The argument can also be a numeric data type. The numeric argument is implicitly
| cast to a VARCHAR data type.

| The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example: The following statement returns the ASCII value for the character 'A':

```
SET :hv = ASCII('A');
```

The host variable, :hv, is set to an integer with the value 65.

18. If the conversion does not exist, the ASCII function will return an error, or a substitution character might be returned.

ASCII CHR

The ASCII CHR function returns the character that has the ASCII code value that is specified by the argument.

►► ASCII CHR(*expression*) ◄◄

The schema is SYSIBM.

expression

An expression that returns a built-in data type of BIGINT, INTEGER, or SMALLINT.

expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a fixed length character string encoded in the SBCS ASCII CCSID (regardless of the setting of the MIXED option in DSNHDECP). The length of the result is 1. If the value of *expression* is not in the range of 0 to 255, (0 to 127 if the SBCS ASCII CCSID for this system is CCSID 367) the null value is returned.

The result can be null; if the argument is null, the result is the null value.

CHR can be specified as a synonym for ASCII CHR.

Example: Set :hv with the Euro symbol "€" in CCSID 923:

```
SET :hv = ASCII CHR(164); -- x'A4'
```

Set :hv with the Euro symbol "€" in CCSID 1252:

```
SET :hv = ASCII CHR(128); -- x'80'
```

In both cases, the "€" is assigned to :hv, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

ASCII_STR

The ASCII_STR function returns an ASCII version of the string in the system ASCII CCSID. The system ASCII CCSID is the SBCS ASCII CCSID on a MIXED=NO system or the MIXED ASCII CCSID on a MIXED=YES system.

►—ASCII_STR(*string-expression*)—◄

The schema is SYSIBM.

string-expression

| An expression that returns a value of a built-in character or graphic string. A
| character string must not be bit data. *string-expression* must be an ASCII,
| EBCDIC, or Unicode string.

| The argument can also be a numeric data type. The numeric argument is
| implicitly cast to a VARCHAR data type.

| ASCII_STR returns an ASCII version of the string. Non-ASCII characters are
| converted to UTF-16 characters and appear in the result in the form \xxxx (or
| \xxxx\yyyy for surrogate characters), where xxxx and yyyy represent a UTF-16
| code unit.

The length attribute of the result will be $\text{MIN}(\text{length} * 5, 32704)$. Where *n* is the result of applying the formulas in Table 33 on page 141 based on input and output data types.

The result of the function is a varying-length character string in the system ASCII CCSID. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

ASCIISTR can be specified as a synonym for ASCII_STR.

| *Example:* The following example returns the ASCII string equivalent of the Unicode
| (UTF-8) string,

| '4869206D616D6520697320D090D0BDD0B4D180D0B5D0B92020F0908080':

| SET :HV1 =

| ASCII_STR(X'4869206D616D6520697320D090D0BDD0B4D180D0B5D0B92020F0908080');

| :HV1 is assigned the value 'Hi, my name is \0410\043D\0434\0440\0435\0439
| \D800\DC00'. In this example, the UTF-8 characters D090, D0BD, D0B4, D180,
| D0B5, and D0B9 are converted to \0410\043D\0434\0440\0435\0439 and the
| non-ASCII character F0908080 is converted to \D800\DC00.

SET :HV1 = ASCII_STR('Hi, my name is Андрей (Andrei)');

:HV1 is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439
(Andrei)"

ASIN

The ASIN function returns the arc sine of the argument as an angle, expressed in radians. The ASIN and SIN functions are inverse operations.

▶▶—ASIN(*numeric-expression*)—◀◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to $-\pi/2$ and less than or equal to $\pi/2$.

Example: Assume that host variable ASINE is DECIMAL(10,9) with a value of 0.997494987. The following statement:

```
SELECT ASIN(:ASINE)
FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.50.

ATAN

The ATAN function returns the arc tangent of the argument as an angle, expressed in radians. The ATAN and TAN functions are inverse operations.

```
▶▶—ATAN(numeric-expression)—▶▶
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to $-\pi/2$ and less than or equal to $\pi/2$.

Example: Assume that host variable ATANGENT is DECIMAL(10,9) with a value of 14.10141995. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATAN(:ATANGENT)
FROM SYSIBM.SYSDUMMY1;
```

ATANH

The ATANH function returns the hyperbolic arc tangent of a number, expressed in radians. The ATANH and TANH functions are inverse operations.

▶▶—ATANH(*numeric-expression*)—◀◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. The value must be greater than -1 and less than 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HATAN is DECIMAL(10,9) with a value of 0.905148254. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATANH(:HATAN)
FROM SYSIBM.SYSDUMMY1;
```

ATAN2

The ATAN2 function returns the arc tangent of x and y coordinates as an angle, expressed in radians.

```
▶▶—ATAN2(numeric-expression-1,numeric-expression-2)—▶▶
```

The schema is SYSIBM.

The first and second arguments specify the x and y coordinates, respectively.

Each argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. Both arguments must not be 0. Any argument that is not a double precision floating-point number is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if any argument is null, the result is the null value.

Example: Assume that host variables HATAN2A and HATAN2B are DOUBLE host variables with values of 1 and 2, respectively. The following statement returns a double precision floating-point number with an approximate value of 1.1071487:

```
SELECT ATAN2 (:HATAN2A, :HATAN2B)
FROM SYSIBM.SYSDUMMY1;
```

BIGINT

The BIGINT function returns a big integer representation of either a number or a character or graphic string representation of a number.

Numeric to Big Integer:

►►—BIGINT(*numeric-expression*)—◄◄

String to Big Integer:

►►—BIGINT(*string-expression*)—◄◄

The schema is SYSIBM.

Numeric to Big Integer

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a big integer column or variable. If the whole part of the argument is not within the range of big integers, an error is returned. The fractional part of the argument is truncated.

String to Big Integer

string-expression

An expression that returns a value of a character or graphic string (except a CLOB and DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS BIGINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of big integers, an error is returned. Any fractional part of the argument is truncated.

The result of the function is a big integer.

The result can be null; if the argument is null, the result is the null value.

To increase the portability of applications, use the CAST specification.

Example 1: The following function returns the number 12345 (a BIGINT) for the number 12345.6:

```
SELECT BIGINT(12345.6)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a BIGINT value of 123456789012 for the number 00123456789012.

```
SELECT BIGINT('00123456789012')  
FROM SYSIBM.SYSDUMMY1;
```

Related reference:

“CAST specification” on page 254

BINARY

The BINARY function returns a BINARY (fixed-length binary string) representation of a string of any type or of a row ID type.

The schema is SYSIBM.

string-expression

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

integer

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 255 inclusive.

If *integer* is not specified:

- If the *string-expression* is the empty string constant, an error occurs
- Otherwise, the length attribute of the result is the same as the length attribute of *string-expression*, except when the input is graphic data. In this case, the length attribute of the result is twice the length of *string-expression*.

The result of the function is a fixed-length binary string.

The result can be null; if the first argument is null, the result is the null value.

The actual length is the same as the length attribute of the result. If the length of the *string-expression* is less than the length of the result, the result is padded with hexadecimal zeroes up to the length of the result. If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

Following examples assume EBCDIC encoding of the input string constants.

Example 1: The following function returns a fixed-length binary string with a length attribute 1 and a value BX'00'.

```
SELECT BINARY(' ',1)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a fixed-length binary string with a length attribute 5 and a value BX'D2C2C80000'.

```
SELECT BINARY('KBH',5)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'.

```
SELECT BINARY('KBH')
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'

```
SELECT BINARY('KBH ',3)
FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8', a warning is also returned.

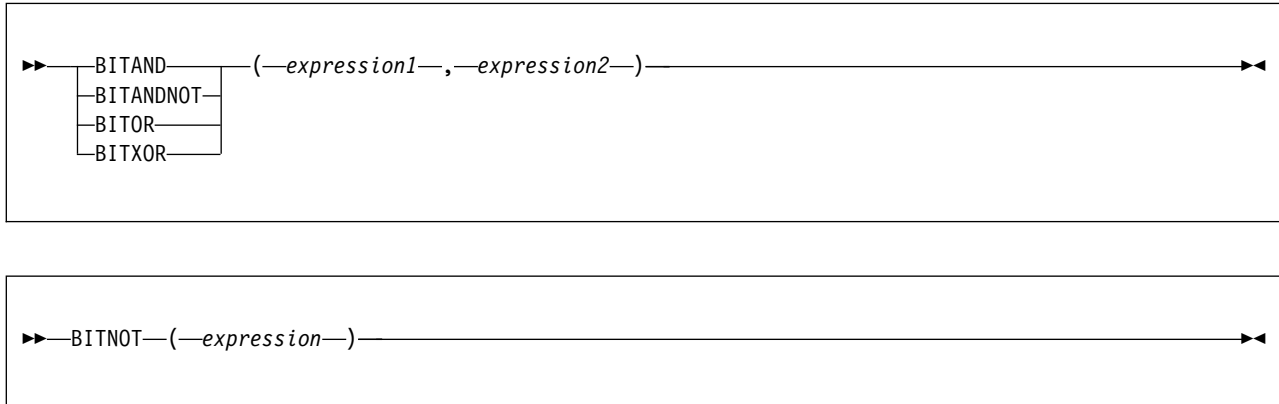

```
SELECT BINARY('KBH 93',3)
FROM SYSIBM.SYSDUMMY1;
```

Example 6: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'C1C2C3', a warning is also returned.

```
SELECT BINARY(BINARY('ABC',5),3)
FROM SYSIBM.SYSDUMMY1;
```

BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT

The bit manipulation functions operate on the *twos complement* representation of the integer value of the input arguments. The functions return the result as a corresponding base 10 integer value in a data type that is based on the data type of the input arguments.

The schema is SYSIBM.

Table 62. The bit manipulation functions

| Function | Description | The bit in the <i>twos complement</i> representation of the result |
|-----------|--|---|
| BITAND | Performs a bitwise AND operation. | 1 - only if the corresponding bits in both arguments are 1. |
| BITANDNOT | Clears any bit in the first argument that is in the second argument. | 0 - if the corresponding bit in the second argument is 1. copied from the corresponding bit in the first argument - if the corresponding bit in the first argument is not 1. |
| BITOR | Performs a bitwise OR operation. | 1 - unless the corresponding bits in both arguments are 0. |
| BITXOR | Performs a bitwise exclusive OR operation. | 1 - unless the corresponding bits in both arguments are the same. |
| BITNOT | Performs a bitwise NOT operation. | Opposite of the corresponding bit in the argument. |

expression, expression1, or expression2

expression, expression1, or expression2 must be integer values represented by the data types SMALLINT, INTEGER, BIGINT, or DECFLOAT. Arguments that are of type DECIMAL, REAL, or DOUBLE are cast to DECFLOAT. The value is truncated to a whole number.

The bit manipulation functions can operate on up to 16 bits for SMALLINT, 32 bits for INTEGER, 64 bits for BIGINT, and 113 bits for DECFLOAT. The range of supported DECFLOAT values includes integers from -2_{122} to $2^{122} - 1$. Special values such as NaN or INFINITY are not supported.

If the two arguments have different data types, the argument that supports fewer bits is cast to a value with the data type of the argument that supports more bits. This cast impacts the bits that are set for negative values. For example, -1 as a SMALLINT value has 16 bits set to 1. When -1 is cast to an INTEGER value, it has 32 bits set to 1.

The result of the functions with two arguments has the data type of the argument that is highest in the data type precedence list for promotion. If either argument is DECFLOAT, the data type of the result is DECFLOAT(34).

The result of the BITNOT function has the same data type as the input argument, except that DECIMAL, REAL, DOUBLE, or DECFLOAT(16) returns DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

Due to differences in internal representation between data types and on different hardware platforms, using functions (such as HEX) or host language constructs to view or compare internal representations of BIT function results and arguments is data type-dependent and not portable. The data type- and platform-independent way to view or compare BIT function results and arguments is to use the actual integer values.

The BITXOR function is can be used to toggle bits in a value.

The BITANDNOT function can be used to clear bits.

`BITANDNOT(val, pattern)` operates more efficiently than `BITAND(val, BITNOT(pattern))`.

The following examples are based on an ITEM table with a PROPERTIES column of type INTEGER.

Return all items for which the third property bit is set.

```
SELECT ITEMID FROM ITEM
WHERE BITAND(PROPERTIES, 4) = 4;
```

Return all items for which the fourth or the sixth property bit is set.

```
SELECT ITEMID FROM ITEM
WHERE BITAND(PROPERTIES, 40) <> 0;
```

Clear the twelfth property of the item whose ID is 3412.

```
UPDATE ITEM
SET PROPERTIES = BITANDNOT(PROPERTIES, 2048)
WHERE ITEMID = 3412;
```

Set the fifth property of the item whose ID is 3412.

```
UPDATE ITEM
SET PROPERTIES = BITOR(PROPERTIES, 16)
WHERE ITEMID = 3412;
```

Toggle the eleventh property of the item whose ID is 3412.

```
UPDATE ITEM
SET PROPERTIES = BITXOR(PROPERTIES, 1024)
WHERE ITEMID = 3412;
```

Switch all the bits in a 16-bit value that has only the second bit on.

```
SELECT BITNOT(CAST(2 AS SMALLINT))
FROM SYSIBM.SYSDUMMY1;
```

This example returns -3 (with a data type of SMALLINT).

BLOB

The BLOB function returns a BLOB representation of a string of any type or of a row ID type.

► BLOB(*string-expression* [, *-integer*]) ◄

The schema is SYSIBM.

string-expression

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

integer

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and the maximum length of a BLOB.

Do not specify *integer* if *string-expression* is a row ID type.

If you do not specify *integer* and *string-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *string-expression*, except when the input is graphic data. In this case, the length attribute of the result is twice the length of *expression*.

The result of the function is a BLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression* (or twice the length of *string-expression* when the input is graphic data). If the length of *string-expression* is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks.

Example 1: The following function returns a BLOB for the string 'This is a BLOB'.

```
SELECT BLOB('This is a BLOB')
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a BLOB for the large object that is identified by locator `myclob_locator`.

```
SELECT BLOB(:myclob_locator)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: Assume that a table has a BLOB column named `TOPOGRAPHIC_MAP` and a VARCHAR column named `MAP_NAME`. Locate any maps that contain the string 'Engles Island' and return a single binary string with the map name concatenated in front of the actual map.

```
SELECT BLOB(MAP_NAME || ': ' || TOPOGRAPHIC_MAP
FROM ONTARIO_SERIES_4
WHERE TOPOGRAPHIC_MAP LIKE BLOB('%Engles Island%'))
```

CCSID_ENCODING

The `CCSID_ENCODING` function returns a string value that indicates the encoding scheme of a CCSID that is specified by the argument.

```
▶▶—CCSID_ENCODING(expression)————▶▶
```

The schema is SYSIBM.

expression

expression must be an expression that returns a value of a built-in numeric, character, or graphic string data type that is not a LOB. A character string must not have a length attribute greater than 255, and a graphic string must not have a length attribute greater than 127. If *expression* is a character or graphic string, the string must contain a valid string representation of a number. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a numeric constant.

The function returns a value of ASCII, EBCDIC, UNICODE, or UNKNOWN depending on the CCSID specified by *expression*.

The result of the function is a fixed-length character string of length 8, which is padded on the right if necessary.

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function was invoked. For more information, refer to “Determining the encoding scheme and CCSID of a string” on page 51.

Example 1: The following function returns a CCSID with a value for EBCDIC data.

```
SELECT CCSID_ENCODING(37) AS CCSID
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a CCSID with a value for ASCII data.

```
SELECT CCSID_ENCODING(850) AS CCSID
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a CCSID with a value for Unicode data.

```
SELECT CCSID_ENCODING(1208) AS CCSID
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a CCSID with a value of UNKNOWN.

```
SELECT CCSID_ENCODING(1) AS CCSID
FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a CCSID with a value for EBCDIC data. The input data is a character string.

```
SELECT CCSID_ENCODING('37') AS CCSID
FROM SYSIBM.SYSDUMMY1;
```

CEILING

The CEILING function returns the smallest integer value that is greater than or equal to the argument.

►►—CEILING—(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is DECIMAL. For example, an argument with a data type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null; if the argument is null, the result is the null value.

CEIL can be specified as a synonym for CEILING.

Example 1: The following statement shows the use of CEILING on positive and negative values:

```
SELECT CEILING(3.5), CEILING(3.1), CEILING(-3.1), CEILING(-3.5)
FROM SYSIBM.SYSDUMMY1;
```

This example returns: 04., 04., -03., -03.

Example 2: Using sample table DSN8A10.EMP, find the highest monthly salary for all the employees. Round the result up to the next integer. The SALARY column has a decimal data type.

```
SELECT CEILING(MAX(SALARY)/12)
FROM DSN8A10.EMP;
```

This example returns 04396. because the highest paid employee is Christine Haas who earns \$52750.00 per year. Her average monthly salary before applying the CEILING function is 4395.83.

CHAR

The CHAR function returns a fixed-length character string representation of the argument.

The syntax of the CHAR function depends on the data type of the input argument. The following types of input arguments are accepted.

Integer to Character:

►► CHAR(*integer-expression*) ◄◄

Decimal to Character:

►► CHAR(*decimal-expression* [, *decimal-character*]) ◄◄

Floating-Point to Character:

►► CHAR(*floating-point-expression*) ◄◄

Decimal floating-point to Character:

►► CHAR(*decimal-floating-point-expression*) ◄◄

Character to Character:

►► CHAR(*character-expression* [, *integer* [, *CODEUNITS16* | *CODEUNITS32* | *OCTETS*]]) ◄◄

Graphic to Character:

Datetime to Character:

Row ID to Character:

The schema is SYSIBM.

The CHAR function returns a fixed-length character string representation of one of the following values:

- An integer number if the first argument is a small, large, or big integer
- A decimal number if the first argument is a decimal number
- A floating-point number if the first argument is a single or double precision floating-point number
- A decimal floating-point number if the first argument is a decimal floating-point number
- A character string value if the first argument is any type of string
- A datetime value if the first argument is a date, time, or timestamp
- A row ID value if the first argument is a row ID

The result of the function is a fixed-length character string (CHAR).

The result can be null; if the first argument is null, the result is the null value.

Integer to Character

integer-expression

An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, or BIGINT).

The result is the fixed-length character string representation of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument. If the argument is negative, the result has a preceding minus sign. The result is left justified, and its length depends on whether the argument is a small or large integer:

- For a small integer, the length of the result is 6. If the number of characters in the result is less than 6, the result is padded on the right with blanks to a length of 6.
- For a large integer, the length of the result is 11; if the number of characters in the result is less than 11, the result is padded on the right with blanks to a length of 11.

A positive value always includes one trailing blank.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Decimal to Character

decimal-expression

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the CHAR function.

decimal-character

Specifies the single-byte character constant (CHAR or VARCHAR) that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see “Decimal point representation” on page 309.

The result is the fixed-length character string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with the preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.¹⁹

The leading blank is not returned for `CAST(decimal-expression AS CHAR(n))`.

The length of the result is $2 + p$, where p is the precision of the *decimal-expression*.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Floating-Point to Character

19. If the function is invoked as CHAR and the BIF_COMPATIBILITY subsystem parameter is set to V9_DECIMAL_VARCHAR, or if the function is invoked as SYSCOMPAT_V9.CHAR, the result is formatted the same as the result of the function.

floating-point-expression

An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

The result is the fixed-length character string representation of the argument in the form of an SQL floating-point constant. The length of the result is 24 bytes.

If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit. If the value of the argument is zero, the result is 0E0. Otherwise, the result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits.

If the number of characters in the result is less than 24, the result is padded on the right with blanks to length of 24.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Decimal floating-point to Character

decimal-floating-point-expression

An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is the fixed-length character string representation of the argument in the form of an SQL decimal floating-point constant. The length of the result is 42 bytes. If the number of characters in the result is less than 42, the result is padded on the right with blanks to length of 42.

If the DECFLOAT value is one of the special values Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', or 'NAN', respectively, are returned. If the special value is negative, a minus sign is the first character in the returned string. The DECFLOAT special value sNaN does not result in an exception when it is converted to a string.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Character to Character

character-expression

An expression that returns a value of a built-in character string.

integer

The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of *character-expression*. If *character-expression* is an empty string constant, an error occurs.

If **CODEUNITS16** or **CODEUNITS32** is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *character-expression* is

a character string that is defined as bit data, **CODEUNITS16** and **CODEUNITS32** cannot be specified.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *integer* is expressed in terms of bytes.

For more information about **CODEUNITS16**, **CODEUNITS32**, and **OCTETS**, see “String unit specifications” on page 87.

The actual length is the same as the length attribute of the result. If the length of *character-expression* is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

If *character-expression* is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

Graphic to Character

graphic-expression

An expression that returns a value of a built-in graphic string.

integer

The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of *graphic-expression*. The length attribute of *graphic-expression* is $(3 * \text{length}(\text{graphic-expression}))$. If *graphic-expression* is an empty string constant, an error occurs.

If **CODEUNITS16** or **CODEUNITS32** is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about **CODEUNITS16** and **CODEUNITS32**, see “String unit specifications” on page 87.

The actual length is the same as the length attribute of the result. If the length of *graphic-expression* is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of

graphic-expression is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

Datetime to Character

datetime-expression

An expression that is one of the following built-in data types:

date The result is the character string representation of the date in the format that is specified by the second argument. If the second argument is omitted, the DATE precompiler option, if one is provided, otherwise field DATE FORMAT on installation panel DSNTIP4 specifies the format. If the format is **LOCAL**, field LOCAL DATE LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 10.

LOCAL denotes the local format at the DB2 subsystem that executes the SQL statement. If **LOCAL** is used for the format, a date exit routine must be installed at that DB2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

time The result is the character string representation of the time in the format that is specified by the second argument. If the second argument is omitted, the TIME precompiler option, if one is provided, otherwise field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is **LOCAL**, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 8.

LOCAL denotes the local format at the DB2 subsystem that executes the SQL statement. If **LOCAL** is used for the format, a time exit routine must be installed at that DB2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

timestamp without time zone

The result is the character string representation of the timestamp. If *datetime-expression* is a **TIMESTAMP(0)** value, the length of the result is 19. If *datetime-expression* is a **TIMESTAMP(integer)** value, the length of the result is 20+*integer*. Otherwise, the length of the result is 26. The second argument must not be specified.

timestamp with time zone

The result is the character string representation of the timestamp with time zone, formatted as *yyyy-mm-dd-hh.mm.ss.nnnnnn±th:tm* with the appropriate number of 'n' characters for the precision of the timestamp. If *datetime-expression* is a **TIMESTAMP(0) WITH TIME ZONE**, the length of the result is 147. If *datetime-expression* is a

TIMESTAMP(*integer*) WITH TIME ZONE, the length of the result is 148+*integer*. The second argument must not be specified.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

ISO, EUR, USA, JIS, or LOCAL

Specifies the date or time format of the resulting character string. For more information, see “String representations of datetime values” on page 101.

Row ID to Character

row-ID-expression

An expression that returns a value that is a built-in row ID data type.

The result is the fixed-length character string representation of the argument. The result is bit data.

The length of the result is 40. If the length of *row-ID-expression* is less than 40, the result is padded on the right with hexadecimal zeros to a length of 40.

Recommendation: To increase the portability of applications, use the CAST specification when the first argument is numeric, or the first argument is a string and the length argument is specified. For more information, see “CAST specification” on page 254.

Example 1: HIREDATE is a DATE column in sample table DSN8A10.EMP. When it represents the date 15 December 1976 (as it does for employee 140), the following example returns the string value '12/15/1976' in character string variable DATESTRING:

```
EXEC SQL SELECT CHAR(HIREDATE, USA)
          INTO :DATESTRING
          FROM DSN8A10.EMP
          WHERE EMPNO = '000140';
```

Example 2: Host variable HOUR has a data type of DECIMAL(6,0) and contains a value of 50000. Interpreted as a time duration, this value is 5 hours. Assume that STARTING is a TIME column in some table. Then, when STARTING represents 17 hours, 30 minutes, and 12 seconds after midnight, the following example returns the value '10:30 PM':

```
CHAR(STARTING+:HOURS, USA)
```

Example 3: Assume that RECEIVED is defined as a TIMESTAMP column in table TABLEY. When the value of the date portion of RECEIVED represents the date 10 March 1997 and the time portion represents 6 hours and 15 seconds after midnight, the following example returns the string value '1997-03-10-06.00.15.000000':

```
SELECT CHAR(RECEIVED)
       FROM TABLEY
       WHERE INTCOL = 1234;
```

Example 4: For sample table DSN8A10.EMP, the following SQL statement sets the host variable AVERAGE, which is defined as CHAR(33), to the character string representation of the average employee salary.

```
EXEC SQL SELECT CHAR(AVG(SALARY))
INTO :AVERAGE
FROM DSN8A10.EMP;
```

With DEC31, the result of AVG applied to a decimal number is a decimal number with a precision of 31 digits. The only host languages in which such a large decimal variable can be defined are Assembler and C. For host languages that do not support such large decimal numbers, use the method shown in this example.

Example 5: For the rows in sample table DSN8A10.EMP, return the values in column LASTNAME, which is defined as VARCHAR(15), as a fixed-length character string and limit the length of the results to 10 characters.

```
SELECT CHAR(LASTNAME,10)
FROM DSN8A10.EMP;
```

For rows that have a LASTNAME with a length greater than 10 characters (excluding trailing blanks), a warning that the value is truncated is returned.

Example 6: FIRSTNAME is a VARCHAR(12) column in a Unicode table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the values shown under 'Function', the results are shown under 'Returns':

| Function ... | Returns ... |
|-------------------------------|-------------------------------------|
| CHAR(FIRSTNAME,3,CODEUNITS32) | 'Jür ' -- x'4AC3BC7220202020202020' |
| CHAR(FIRSTNAME,3,CODEUNITS16) | 'Jür ' -- x'4AC3BC722020202020' |
| CHAR(FIRSTNAME,3,OCETS) | 'Jü' -- x'4AC3BC' |

Example 7: For the rows in sample table DSN8A10.EMP, return the values in column EDLEVEL, which is defined as SMALLINT, as a fixed-length character string.

```
SELECT CHAR(EDLEVEL)
FROM DSN8A10.EMP;
```

An EDLEVEL of 18 is returned as CHAR(6) value '18 ' (18 followed by four blanks).

Example 8: In sample table DSN8A10.EMP, the SALARY column is defined as DECIMAL(9,2). For those employees who have a salary of 52750.00, return the hire date and the salary, using a comma as the decimal character in the salary (52750,00).

```
SELECT HIREDATE, CHAR(SALARY, ',')
FROM DSN8A10.EMP
WHERE SALARY = 52750.00;
```

The salary is returned as the string value '52750,00'.

Example 9: Repeat the scenario in Example 8 except subtract the SALARY column from 60000.00 and return the salary with the default decimal character.

```
SELECT HIREDATE, CHAR (60000.00 - SALARY)
FROM DSN8A10.EMP
WHERE SALARY = 52750.00;
```

The salary is returned as the string value '7250.00'.

Example 10: Assume that host variable SEASONS_TICKETS is defined as INTEGER and has a value of 10000. Use the DECIMAL and CHAR functions to change the value into the character string '10000.00'.

```
SELECT CHAR(DECIMAL(:SEASONS_TICKETS,7,2))
FROM SYSIBM.SYSDUMMY1;
```

Example 11: Assume that columns COL1 and COL2 in table T1 are both defined as REAL and that T1 contains a single row with the values 7.1E+1 and 7.2E+2 for the two columns. Add the two columns and represent the result as a character string.

```
SELECT CHAR(COL1 + COL2)
FROM T1;
```

The result is the character value '1.43E2'.

CHARACTER_LENGTH

The CHARACTER_LENGTH function returns the length of the first argument in the specified string unit.

Character string:

Graphic string:

The schema is SYSIBM.

Character string:

character-expression

An expression that returns a value of a built-in character string. *character-expression* cannot be bit data.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express the length of the result.

CODEUNITS16

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of *character-expression* expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

Graphic string:

graphic-expression

An expression that returns a value of a built-in graphic string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express the length of the result.

CODEUNITS16

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32 see “String unit specifications” on page 87.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of *graphic-expression* expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

Example: Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The following two queries return the value 6:

```
SELECT CHARACTER_LENGTH(NAME, CODEUNITS32)
FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME, CODEUNITS16)
FROM T1 WHERE NAME = 'Jürgen';
```

The following two queries return the value 7:

```
SELECT CHARACTER_LENGTH(NAME, OCTETS)
FROM T1 WHERE NAME = 'Jürgen';
SELECT LENGTH(NAME)
FROM T1 WHERE NAME = 'Jürgen';
```

CLOB

The CLOB function returns a CLOB representation of a string.

Character to CLOB:

Graphic to CLOB:

The schema is SYSIBM.

Character to CLOB

character-expression

An expression that returns a value of a character string. If *character-expression* is bit data, an error occurs.

integer

An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify *integer* and *character-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *character-expression*.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information on how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The result of the function is a CLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *character-expression*.

Graphic to CLOB

graphic-expression

An expression that returns a value of a graphic string.

integer

An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify *integer* and *graphic-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is $(3 * \text{length}(\text{graphic-expression}))$.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information on how to calculate the length attribute of the result string.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

The result of the function is a CLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

Example 1: The following function returns a CLOB for the string 'This is a CLOB'.

```
SELECT CLOB('This is a CLOB')
FROM SYSIBM.SYSDUMMY1;
```

Example 2: FIRSTNME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNME has this value:

| Function ... | Returns ... |
|------------------------------|----------------------|
| CLOB(FIRSTNME,3,CODEUNITS32) | 'Jür' -- x'4AC3BC72' |
| CLOB(FIRSTNME,3,CODEUNITS16) | 'Jür' -- x'4AC3BC72' |
| CLOB(FIRSTNME,3,OCTETS) | 'Jü' -- x'4AC3BC' |

COALESCE

The COALESCE function returns the value of the first nonnull expression.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 23 on page 119. The arguments can be of either a built-in or distinct type.

The COALESCE function cannot be used as a source function when creating a user-defined function.

The arguments are evaluated in the order in which they are specified, and the result of the function is the first argument that is not null. The result can be null only if all arguments can be null. The result is null only if all arguments are null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the “Rules for result data types” on page 143. If the COALESCE function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type is determined.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The COALESCE function can also handle a subset of the functions provided by CASE expressions. The result of using COALESCE(e1,e2) is the same as using the expression:

```
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END
```

VALUE can be specified as a synonym for COALESCE.

Example 1: Assume that SCORE1 and SCORE2 are SMALLINT columns in table GRADES, and that nulls are allowed in SCORE1 but not in SCORE2. Select all the rows in GRADES for which SCORE1 + SCORE2 > 100, assuming a value of 0 for SCORE1 when SCORE1 is null.

```
SELECT * FROM GRADES  
WHERE COALESCE(SCORE1,0) + SCORE2 > 100;
```

Example 2: Assume that a table named DSN8A10.EMP contains a DATE column named HIREDATE, and that nulls are allowed for this column. The following query selects all rows in DSN8A10.EMP for which the date in HIREDATE is either unknown (null) or earlier than 1 January 1960.

```
SELECT * FROM DSN8A10.EMP  
WHERE COALESCE(HIREDATE,DATE('1959-12-31')) < '1960-01-01';
```

The predicate could also be coded as `COALESCE(HIREDATE, '1959-12-31')` because, for comparison purposes, a string representation of a date can be compared to a date.

Example 3: Assume that for the years 1993 and 1994 there is a table that records the sales results of each department. Each table, `S1993` and `S1994`, consists of a `DEPTNO` column and a `SALES` column, neither of which can be null. The following query provides the sales information for both years.

```
SELECT COALESCE(S1993.DEPTNO,S1994.DEPTNO) AS DEPT, S1993.SALES, S1994.SALES
FROM S1993 FULL JOIN S1994 ON S1993.DEPTNO = S1994.DEPTNO
ORDER BY DEPT;
```

The full outer join ensures that the results include all departments, regardless of whether they had sales or existed in both years. The `COALESCE` function allows the two join columns to be combined into a single column, which enables the results to be ordered.

COLLATION_KEY

The COLLATION_KEY function returns a varying-length binary string that represents the collation key of the argument in the specified collation.

```
►►—COLLATION_KEY(string-expression,collation-name[, -integer])—►►
```

The schema is SYSIBM.

The result of COLLATION_KEY on one string can be compared in binary form with the result of COLLATION_KEY on another string to determine their order within the specified *collation-name*. For the comparison to be meaningful, the results of the COLLATION_KEY must be from the same *collation-name*.

string-expression

An expression that returns a character or graphic string that is not a LOB for which the collation key is to be determined. If *string-expression* is a character string, it must not be FOR BIT DATA. If *string-expression* is not in Unicode UTF-16 (CCSID 1200), it is converted to Unicode UTF-16 before the corresponding collation key is obtained. The length of *string-expression* must not exceed 32704 bytes of the UTF-16 representation.

collation-name

A string constant or a string host variable that is not a binary string, CLOB, or DBCLOB. *collation-name* specifies the collation to use when determining the collation key. If *collation-name* is not an EBCDIC value, it is converted to EBCDIC. The length of *collation-name* must be between 1 and 255 bytes of the EBCDIC representation. The value of *collation-name* is not case sensitive and must be a left justified, valid "short path" collation setting for the parameter CUNBOPRM_Collation_Keyword in area CUN4BOPR. For detailed information about the "short path" setting in the parameter CUNBOPRM_Collation_Keyword, see *z/OS Support for Unicode: Using Conversion Services*.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. *collation-name* must be left justified within the host variable. It must also be padded on the right with blanks if the length is less than that of the host variable and the host variable is a fixed length CHAR or GRAPHIC data type.

collation-name is in the form of CUN4BOPR_Collation_Keyword specification. You must specify a value that is acceptable for the z/OS CUNBOPR_Collation_Keyword parameter.

The following table lists some supported values:

Table 63. Collation Keywords Reference

| Attribute name | Key | Possible values |
|----------------|-------|------------------|
| Locale | L.R.V | <locale> |
| Strength | S | 1, 2, 3, 4, I, D |
| Case_Level | K | X, O, D |

Table 63. Collation Keywords Reference (continued)

| Attribute name | Key | Possible values |
|----------------|-----|-----------------|
| Case_First | C | X, L, U, D |
| Alternate | A | N, S, D |
| Variable_Top | T | <hex digits> |
| Normalization | N | X, O, D |
| French | F | X, O, D |
| Hinayana | H | X, O, D |

The following table describes the abbreviations for the collation keywords:

| Abbreviation | Definition |
|--------------|---------------|
| D | default |
| O | on |
| X | off |
| 1 | primary |
| 2 | secondary |
| 3 | tertiary |
| 4 | quaternary |
| I | identical |
| S | shifted |
| N | non-ignorable |
| L | lower-first |
| U | upper-first |

The following examples show keywords using the above specifications:

'UCA400R1_AS_LSV_S3_CU'

UCA version 4.0.1; ignore spaces, punctuation and symbols; use Swedish linguistic conventions; use case-first upper; compare case-sensitive.

'UCA400R1_AN_LSV_S3_CL_NO'

UCA version 4.0.1; do not ignore spaces, punctuation and symbols; use Swedish linguistic conventions; use case-first lower (or does not set it to mean the same, since lower is used in most locales as the default); normalization ON; compare case-sensitive.

integer

An integer value that specifies the length attribute of the result. If specified, the value must be an integer constant between 1 and 32704.

If the length is not specified, the length attribute of the result is determined as follows:

| <i>string-expression</i> | Result length attribute |
|---|--------------------------------------|
| CHAR(<i>n</i>) or VARCHAR(<i>n</i>) | MIN (VARBINARY(12 <i>n</i>), 32704) |
| GRAPHIC(<i>n</i>) or VARGRAPHIC(<i>n</i>) | MIN (VARBINARY(12 <i>n</i>), 32704) |

Regardless of whether the length is specified, the length of the collation key must be less than or equal to the length attribute of the result. The actual result length of the collation key is approximately six times of the length of *string-expression* where the length of *string-expression* is in Unicode byte

representation. For certain *collation-name* such as UCA410_LKO_RKR (for Korean collation) the default length attribute of the result, *12n*, might not be large enough and an error will be returned. To avoid such an error, the length attribute of the result must be explicitly specified to a larger constant. For the proper length attribute of the result, see *z/OS Support for Unicode: Using Conversion Services* for information about target buffer length considerations for Collation Services.

The result can be null; if the first argument is null, the result is the null value.

The COLLATION_KEY function uses Unicode Collation Services in z/OS to return the collation key. Unicode Collation Services support two collation versions:

- UCA400R1. This Collation version support Unicode standard character suite 4.0.0 and use Normalization Service under 4.0.1 Unicode character suite.
- UCA410. This Collation version support Unicode standard character suite 4.1.0 and use Normalization Service under 4.1.0 Unicode character suite.

If Unicode Collation Services are not available when the COLLATION_KEY function is run, an error is returned.

Example 1: The following query orders the employees by their surnames using the default Unicode Collation Algorithm V4.0.1(UCA), ignoring spaces, punctuation, and symbols, using Swedish linguistic conventions, and not comparing case:

```
SELECT FIRSTNAME, LASTNAME
   FROM DSN8A10.EMP
   ORDER BY COLLATION_KEY(LASTNAME, 'UCA400R1_AS_LSV_S2');
```

Example 2: The following query uses the COLLATION_KEY function on the LASTNAME column and the SALES_PERSON column to obtain the sort keys from the same collation name in order to do a culturally correct comparison. It finds the departments of employees in Quebec:

```
SELECT E.WORKDEPT
   FROM EMPLOYEE AS E INNER JOIN SALES AS S
   ON COLLATION_KEY(E.LASTNAME, 'UCA400R1_LFR') =
      COLLATION_KEY(S.SALES_PERSON, 'UCA400R1_LFR')
   WHERE S.REGION = 'Quebec';
```

Example 3: Create an index EMPLOYEE_NAME_SORT_KEY for table EMPLOYEE based on built-in function COLLATION_KEY with collation name 'UCA410_LDE' tailored for German.

```
CREATE INDEX EMPLOYEE_NAME_SORT_KEY
   ON EMPLOYEE (COLLATION_KEY(LASTNAME, 'UCA410_LDE', 600),
      COLLATION_KEY(FIRSTNAME, 'UCA410_LDE', 600),
      ID);
```

COMPARE_DECFLOAT

The COMPARE_DECFLOAT function returns a SMALLINT value that indicates whether the two arguments are equal or unordered, or whether one argument is greater than the other.

►►—COMPARE_DECFLOAT(*decfloat-expression1*,*decfloat-expression2*)—◄◄

The schema is SYSIBM.

decfloat-expression1

An expression that returns a DECFLOAT value.

decfloat-expression2

An expression that returns a DECFLOAT value.

decfloat-expression1 is compared with *decfloat-expression2* and the result is returned according to the following rules:

- If both arguments are finite, the comparison is algebraic and follows the procedure for DECFLOAT subtraction. If the difference is exactly zero with either sign, the arguments are equal. If a nonzero difference is positive, the first argument is greater than the second argument. If a nonzero difference is negative, the first argument is less than the second.
- Positive zero and negative zero compare as equal.
- Positive infinity compares equal to positive infinity.
- Positive infinity compares greater than any finite number.
- Negative infinity compares equal to negative infinity.
- Negative infinity compares less than any finite number.
- Numeric comparison is exact and the result is determined for finite operands as if range and precision were unlimited. Overflow or underflow cannot occur.
- If either argument is NaN or sNaN (positive or negative), the result is unordered.

Numeric comparison is exact, and the result is determined for finite operands as if the range and precision were unlimited. An overflow or underflow condition cannot occur.

If one argument is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

One of the following values will be the result:

- 0** The arguments are exactly equal
- 1** *decfloat-expression1* is less than *decfloat-expression2*
- 2** *decfloat-expression1* is greater than *decfloat-expression2*
- 3** The arguments are unordered

The result of the function is a SMALLINT value.

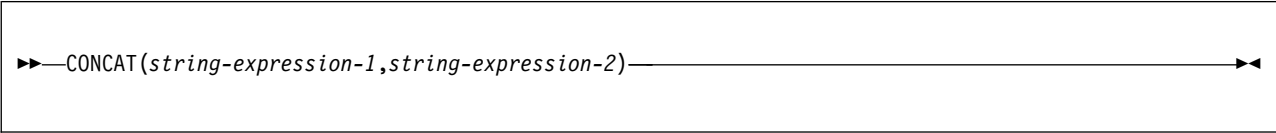

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples demonstrate the values that will be returned when the function is used:

```
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.17))           = 0
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.170))          = 2
COMPARE_DECFLOAT(DECFLOAT(2.170), DECFLOAT(2.17))          = 1
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(0.0))            = 2
COMPARE_DECFLOAT(INFINITY, INFINITY)                        = 0
COMPARE_DECFLOAT(INFINITY, -INFINITY)                      = 2
COMPARE_DECFLOAT(DECFLOAT(-2), INFINITY)                   = 1
COMPARE_DECFLOAT(NAN, NAN)                                  = 3
COMPARE_DECFLOAT(DECFLOAT(-0.1), SNAN)                     = 3
```

CONCAT

The CONCAT function combines two compatible string arguments.

```
▶▶—CONCAT(string-expression-1,string-expression-2)—◀◀
```

The schema is SYSIBM.

The arguments must be compatible strings. For more information on compatibility, refer to the compatibility matrix in Table 23 on page 119.

Either argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The result of the function is a string that consists of the first string followed by the second string.

The result can be null; if any argument is null, the result is the null value.

The CONCAT function is identical to the CONCAT operator. For more information, see “Expressions with the concatenation operator” on page 237.

Example: Using sample table DSN8A10.EMP, concatenate column FIRSTNME with column LASTNAME. Both columns are defined as varying-length character strings.

```
SELECT CONCAT(FIRSTNME, LASTNAME)
FROM DSN8A10.EMP;
```

CONTAINS

The CONTAINS function searches a text search index using criteria that are specified in a search argument and returns a result about whether or not a match was found.

```
CONTAINS ( (1) -column-name-, -search-argument-, (2) -string-constant- )
```

Notes:

- 1 The SQL statement that invokes the CONTAINS function can be dynamically prepared by using a typed parameter marker for the *search-argument*, as in the following example: `CONTAINS(C1,CAST(? AS CHAR(10)))`.
- 2 *string-constant* must conform to the rules for the *search-argument-options*.

search-argument-options:

```
(1) QUERYLANGUAGE = value  
RESULTLIMIT = value  
SYNONYM = OFF/ON
```

Notes:

- 1 The same clause must not be specified more than once.

The schema is SYSIBM.

column-name

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, directly or through another nested view.

search-argument

Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

string-constant

Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

QUERYLANGUAGE = *value*

Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US.

RESULTLIMIT = *value*

Specifies the maximum number of results to be returned from the underlying search engine. The *value* can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect. Also, the RESULTLIMIT option has no effect when the CONTAINS function is used along with the comparison operators (<, >, <=, and >=) or the equality operator (=) and a value of 0 (zero).

SYNONYM = OFF or SYNONYM = ON

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

OFF Do not use a synonym dictionary.

ON Use the synonym dictionary that is associated with the text search index.

The result of the function is a large integer. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is 1 if the document contains a match for the search criteria that are specified in the search argument. Otherwise, the result is 0.

CONTAINS is a non-deterministic function.

Examples

Example 1: The following statement finds all of the employees who have "COBOL" in their resume. The text search argument is not case-sensitive.

```

SELECT EMPNO
FROM EMP_RESUME
WHERE RESUME_FORMAT = 'ascii'
AND CONTAINS(RESUME, 'coba1') = 1

```

Example 2: The search argument does not need to be a string constant. The search argument can be any SQL string expression, including a string contained in a host variable.

The following statement searches for the exact term "ate" in the COMMENT column:

```

char search_arg[100]; /* input host variable */
...
EXEC SQL DECLARE C3 CURSOR FOR
SELECT CUSTKEY
FROM K55ADMIN.CUSTOMERS
WHERE CONTAINS(COMMENT, :search_arg)= 1
ORDER BY CUSTKEY;
strcpy(search_arg, "ate");
EXEC SQL OPEN C3;
...

```

Example 3: The following statement finds 10 students at random who wrote online essays that contain the phrase "fossil fuel" in Spanish, which is "combustible fósil." These students will be invited for a radio interview.

Use the synonym dictionary that was created for the associated text search index. Because only 10 students are needed, you can optimize the query by using the RESULTLIMIT option to limit the number of results from the underlying text search server.

```

SELECT FIRSTNAME, LASTNAME
FROM STUDENT_ESSAYS
WHERE CONTAINS(TERM_PAPER, 'combustible fósil',
'QUERYLANGUAGE= es_ES RESULTLIMIT = 10 SYNONYM=ON') = 1

```

COS

The COS function returns the cosine of the argument, where the argument is an angle, expressed in radians. The COS and ACOS functions are inverse operations.

►►—COS(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable COSINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.07:

```
SELECT COS(:COSINE)
FROM SYSIBM.SYSDUMMY1;
```

COSH

The COSH function returns the hyperbolic cosine of the argument, where the argument is an angle, expressed in radians.

►►—COSH(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HCOS is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.35:

```
SELECT COSH(:HCOS)
FROM SYSIBM.SYSDUMMY1;
```

DATE

The DATE function returns a date that is derived from a value.

►►—DATE(*expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and it must have one of the following values:
 - A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.
 - A character or graphic string with an actual length of 7 that represents a valid date in the form *yyyymmm*, where *yyyy* are digits denoting a year and *mmm* are digits between 001 and 366 denoting a day of that year.
- If *expression* is a number, it must be greater than or equal to one and less than or equal to 3652059.

If *expression* is not a DATE value, *expression* is cast as follows:

- If *expression* is a `TIMESTAMP WITH TIME ZONE` value, *expression* is cast to `TIMESTAMP WITHOUT TIME ZONE`, with the same precision as *expression*.
- If *expression* is a string, *expression* is cast to DATE.

The result of the function is a date.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a timestamp, the result is the date part of the timestamp.

If the argument is a date, the result is that date.

If the argument is a number, the result is the date that is *n*-1 days after January 1, 0001, where *n* is the integral part of the number.

If the argument is a string, the result is the date that is represented by the string. If the string contains a time zone, the time zone is ignored. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Assume that RECEIVED is a `TIMESTAMP` column in some table, and that one of its values is equivalent to the timestamp '1988-12-25-17.12.30.000000'. For this value, the following statement returns the internal representation of 25 December 1988.

DATE(RECEIVED)

Example 2: Assume that DATCOL is a CHAR(7) column in some table, and that one of its values is the character string '1989061'. For this value, the following statement returns the internal representation of 2 March 1989.

DATE(DATCOL)

Example 3: DB2 recognizes '1989-03-02' as the ISO representation of 2 March 1989. So, the following statement returns the internal representation of 2 March 1989.

DATE('1989-03-02')

DAY

The DAY function returns the day part of a value.

►►—DAY(*expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a date duration or a timestamp duration. For the valid formats of datetime durations, see “Datetime operands” on page 145.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules for the function depend on the data type of the argument:

If the argument is a date, timestamp, or string representation of either, the result is the day part of the value, which is an integer between 1 and 31.

If the argument is a date duration or timestamp duration, the result is the day part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: Set the INTEGER host variable DAYVAR to the day of the month on which employee 140 in the sample table DSN8A10.EMP was hired.

```
EXEC SQL SELECT DAY(HIREDATE)
          INTO :DAYVAR
          FROM DSN8A10.EMP
          WHERE EMPNO = '000140';
```

Example 2: Assume that DATE1 and DATE2 are DATE columns in the same table. Assume also that for a given row in this table, DATE1 and DATE2 represent the dates 15 January 2000 and 31 December 1999, respectively. Then, for the given row:

```
DAY(DATE1 - DATE2)
```

returns the value 15.

| *Example 3:* The following invocations of the *DAY* function all return the same
| result:

```
| SELECT DAY('2003-01-02-20.00.00'),  
|         DAY('2003-01-02-12.00.00-08:00'),  
|         DAY('2003-01-03-05.00.00+09:00')  
| FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the *DAY* function in this *SELECT* statement, the result is 2.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the *SELECT* statement all have the same UTC representation:
| 2003-01-02-20.00.00. The day portion of the UTC representation is 2.

DAYOFMONTH

The DAYOFMONTH function returns the day part of a value. The function is similar to the DAY function, except DAYOFMONTH does not support a date or timestamp duration as an argument.

►—DAYOFMONTH(*expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns a value of a date, a timestamp, a character string, or a graphic string built-in data type.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer between 1 and 31, which represents the day part of the value.

The result can be null; if the argument is null, the result is the null value.

Example 1: Set the INTEGER variable DAYVAR to the day of the month on which employee 140 in sample table DSN8A10.EMP was hired.

```
SELECT DAYOFMONTH(HIREDATE)
       INTO :DAYVAR
       FROM DSN8A10.EMP
       WHERE EMPNO = '000140';
```

Example 2: The following invocations of the DAYOFMONTH function returns the same result:

```
SELECT DAYOFMONTH('2003-01-02-20.00.00'),
       DAYOFMONTH('2003-01-02-12.00.00-08:00'),
       DAYOFMONTH('2003-01-03-05.00.00+09:00')
       FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYOFMONTH function in this SELECT statement, the result is 2.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00. The day portion of the UTC representation is 2.

DAYOFWEEK

The DAYOFWEEK function returns an integer, in the range of 1 to 7, that represents the day of the week, where 1 is Sunday and 7 is Saturday. The DAYOFWEEK function is similar to the DAYOFWEEK_ISO function.

►—DAYOFWEEK(*expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.EMP, set the integer host variable DAY_OF_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE).

```
SELECT DAYOFWEEK(HIREDATE)
       INTO :DAY_OF_WEEK
       FROM DSN8A10.EMP
       WHERE EMPNO = '000010';
```

The result is that DAY_OF_WEEK is set to 6, which represents Friday.

Example 2: The following query returns four values: 1, 2, 1, and 2.

```
SELECT DAYOFWEEK(CAST('10/11/1998' AS DATE)),
       DAYOFWEEK(TIMESTAMP('10/12/1998', '01.02')),
       DAYOFWEEK(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
       DAYOFWEEK(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following invocations of the DAYOFWEEK function returns the same result:

```
SELECT DAYOFWEEK('2003-01-02-20.00.00'),
       DAYOFWEEK('2003-01-02-12.00.00-08:00'),
       DAYOFWEEK('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYOFWEEK function in this SELECT statement, the result is 5 (Sunday is considered the first day of the week).

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.00.00.

DAYOFWEEK_ISO

The DAYOFWEEK_ISO function returns an integer, in the range of 1 to 7, that represents the day of the week, where 1 is Monday and 7 is Sunday. The DAYOFWEEK_ISO function is similar to the DAYOFWEEK function.

►—DAYOFWEEK_ISO(*expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.EMP, set the integer host variable DAY_OF_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE).

```
SELECT DAYOFWEEK_ISO(HIREDATE)
       INTO :DAY_OF_WEEK
       FROM DSN8A10.EMP
       WHERE EMPNO = '000010';
```

The result is that DAY_OF_WEEK is set to 5, which represents Friday.

Example 2: The following query returns four values: 7, 1, 7, and 1.

```
SELECT DAYOFWEEK_ISO(CAST('10/11/1998' AS DATE)),
       DAYOFWEEK_ISO(TIMESTAMP('10/12/1998', '01.02')),
       DAYOFWEEK_ISO(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
       DAYOFWEEK_ISO(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
       FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following list shows what is returned by the DAYOFWEEK_ISO function for various dates.

| DATE: | DAYOFWEEK_ISO returns: |
|------------|------------------------|
| 2003-12-28 | '7' |
| 2003-12-31 | '3' |
| 2004-01-01 | '4' |
| 2004-01-10 | '6' |

| | |
|------------|-----|
| 2005-01-04 | '2' |
| 2005-12-31 | '7' |
| 2006-01-01 | '7' |
| 2006-01-03 | '2' |

| *Example 4:* The following invocations of the DAYOFWEEK_ISO function returns the
| same result:

```
| SELECT DAYOFWEEK_ISO('2003-01-02-20.00.00'),  
|        DAYOFWEEK_ISO('2003-01-02-12.00.00-08:00'),  
|        DAYOFWEEK_ISO('2003-01-03-05.00.00+09:00')  
| FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the DAYOFWEEK_ISO function in this SELECT statement,
| the result is 4 (Monday is considered the first day of the week).

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.00.00.

DAYOFYEAR

The DAYOFYEAR function returns an integer, in the range of 1 to 366, that represents the day of the year, where 1 is January 1.

►—DAYOFYEAR(*expression*)—◄

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.EMP, set the integer host variable AVG_DAY_OF_YEAR to the average of the day of the year on which employees were hired (HIREDATE):

```
SELECT AVG(DAYOFYEAR(HIREDATE))
       INTO :AVG_DAY_OF_YEAR
       FROM DSN8A10.EMP;
```

The result is that AVG_DAY_OF_YEAR is set to 202.

Example 2: The following invocations of the DAYOFYEAR function returns the same result:

```
SELECT DAYOFYEAR('2003-01-02-20.00.00'),
       DAYOFYEAR('2003-01-02-12.00.00-08:00'),
       DAYOFYEAR('2003-01-03-05.00.00+09:00')
       FROM SYSIBM.SYSDUMMY1;
```

The results for this SELECT statement are 2,2,3.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

DAYS

The DAYS function returns an integer representation of a date.

►►—DAYS(*expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is 1 more than the number of days from January 1, 0001 to *D*, where *D* is the date that would occur if the DATE function were applied to the argument.

Example 1: Set the INTEGER host variable DAYSVAR to the number of days that employee 140 had been with the company on the last day of 1997.

```
EXEC SQL SELECT DAYS('1997-12-31') - DAYS(HIREDATE) + 1
        INTO :DAYSVAR
        FROM DSN8A10.EMP
        WHERE EMPNO = '000140';
```

Example 2: The following invocations of the DAYS function returns the same result:

```
SELECT DAYS('2003-01-02-20.00.00'),
        DAYS('2003-01-02-12.00.00-08:00'),
        DAYS('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYS function in this SELECT statement, the result is 731217.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

DBCLOB

The DBCLOB function returns a DBCLOB representation of a character string value (with the single-byte characters converted to double-byte characters) or a graphic string value.

Character to DBCLOB:

Graphic to DBCLOB:

The schema is SYSIBM.

Character to DBCLOB

character-expression

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 84 for these rules.)

integer

The length attribute of the resulting DBCLOB. The value of *integer* must be between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 90 for information about how to calculate the length attribute of the result string. If CODEUNITS32 is specified, the value of *integer* must be between 1 and the maximum length of a DBCLOB divided by two (to allow for an intermediate result string that is long enough to evaluate the function).

If *integer* is not specified and *character-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *character-expression*.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression*, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*.

For EBCDIC input data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*.

The result is derived from *S* using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

Graphic to DBCLOB

graphic-expression

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded graphic string.

integer

The length attribute for the resulting varying-length graphic string. The value must be an integer between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and *graphic-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *graphic-expression*.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length attribute of the result, truncation is performed. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

The result of the function is a DBCLOB.

The result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

Example 1: Assume that the application encoding scheme is Unicode. The following statement returns a graphic (UTF-16) host variable.

```
VALUES DBCLOB('123')
      INTO :GHV1;
```

Example 2: FIRSTNAME is a VARCHAR(12) column (Unicode UTF-8 data) in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

| Function ... | Returns ... |
|---------------------------------|--------------------------|
| DBCLOB(FIRSTNAME,3,CODEUNITS32) | 'Jür' -- x'004A00FC0072' |
| DBCLOB(FIRSTNAME,3,CODEUNITS16) | 'Jür' -- x'004A00FC0072' |

DECFLOAT

The DECFLOAT function returns a decimal floating-point representation of either a number or a character string representation of a number, a decimal number, an integer, a floating-point number, or a decimal floating-point number.

Numeric to DECFLOAT:

String to DECFLOAT:

The schema is SYSIBM.

Numeric to DECFLOAT

numeric-expression

An expression that returns a value of any built-in numeric data type.

34 or 16

Specifies the number of digits of precision for the result. The default is 34.

String to DECFLOAT

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. Leading and trailing blanks are eliminated, and the resulting string is folded to uppercase. The expression must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

Use the *string-expression* syntax variation to specify a negative zero as a constant, or to preserve the precision of a floating point constant.

34 or 16

Specifies the number of digits of precision for the result. The default is 34.

The result is the same number that would result from CAST(*string-expression* AS DECFLOAT(*n*)) or CAST(*numeric-expression* AS DECFLOAT(*n*)). Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a string representation of an SQL decimal-floating point constant.

If necessary, the source is rounded to the precision of the target.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

The result of the function is a DECFLOAT with the implicitly or explicitly specified number of digits of precision.

The result can be null; if the first argument is null, the result is the null value.

Note: To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 254.

Example: When a keyword is used for a special value that is expressed as a constant in a context where the keyword could be interpreted as a name, the DECFLOAT function can be used to explicitly cast the value to decimal-floating point. Assume that MYTAB contains columns C1 and SNAN, and that you want to reference the decimal floating-point value for infinity in the same SQL statement. Use the DECFLOAT function to explicitly cast SNAN as a decimal floating-point value to ensure that it is not interpreted as the name of a column, parameter or variable:

```
SELECT INFINITY                -- column named SNAN
   FROM MYTAB
  WHERE C1 = DECFLOAT ('sNaN' ) -- comparison is made with the
                               -- decimal floating-point sNaN value
```

DECFLOAT_FORMAT

The DECFLOAT_FORMAT function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

The diagram shows the function signature: DECFLOAT_FORMAT(*string-expression* [, *format-string*]). The function name is on the left, followed by an opening parenthesis. The first argument is *string-expression*. A bracketed optional argument *format-string* follows, with a comma before it. The signature ends with a closing parenthesis. Arrows point from the left and right towards the opening and closing parentheses respectively.

The schema is SYSIBM.

string-expression

An expression that returns a value that is a CHAR and VARCHAR data type. If a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. Leading and trailing blanks are removed from the string. If *format-string* is not specified, the resulting substring must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and not be greater than 42 bytes. Otherwise, the resulting substring must contain the components of a number that corresponds to the format specified by *format-string*.

format-string

An expression that returns a value that is a built-in character string data type. If a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is evaluated. The actual length must not be greater than 254 bytes.

The value is a template for how *string-expression* is to be interpreted for conversion to a DECFLOAT value. *format-string* must contain a valid combination of the listed format elements according to the following rules:

- At least one '0' or '9' format element must be specified.
- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
- Alphabetic format elements must be specified in upper case.
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements.
- A comma format element can be the first format element that is not a prefix format element. There can be any number of comma format elements.
- Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored.

Table 64. Format elements for the DECFLOAT_FORMAT function

| Format element | Description |
|----------------|---|
| 0 | Represents a digit. A digit is expected if the '0' format element is to the left of the decimal point. Leading zeros must be specified if there are fewer digits to the left of the decimal point in the <i>string-expression</i> than in the <i>format-string</i> . A digit can be included if the '0' format element is to the right of the decimal point. |
| 9 | Represents a digit that can be included at the specified location. |
| S | Prefix If <i>string-expression</i> represents a negative number, a leading minus sign (-) is expected at the specified location. If <i>string-expression</i> represents a positive number, a leading plus sign (+) or leading blank can be included at the specified location. |
| \$ | Prefix A leading dollar sign ('\$') is expected at the specified location. |
| MI | Suffix If <i>string-expression</i> represents a negative number, a trailing minus sign (-) is expected at the specified location. If <i>string-expression</i> represents a positive number, a trailing blank can be included at the specified location. |
| PR | Suffix If <i>string-expression</i> represents a negative number, a leading less than character (<) and a trailing greater than character (>) are expected. If <i>string-expression</i> represents a positive number, a leading blank and a trailing blank can be included. |
| ' | Represents a group separator. A group separator is expected at the specified location if there is a character to the left of it that is not a prefix character. |
| . | A period represents a decimal point that is expected at the specified location. |

If *format-string* is not specified, *string-expression* must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and have a length not greater than 42 bytes.

The result is a DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

Syntax alternatives: TO_NUMBER is a synonym for DECFLOAT_FORMAT.

Table 65. Examples of DECFLOAT_FORMAT

| Example | Result |
|--|------------|
| DECFLOAT_FORMAT('123.45') | 123.45 |
| DECFLOAT_FORMAT('-123456.78') | -123456.78 |
| DECFLOAT_FORMAT('+123456.78') | 123456.78 |
| DECFLOAT_FORMAT('1.23E4') | 12300 |
| DECFLOAT_FORMAT('123.4', '9999.99') | 123.40 |
| DECFLOAT_FORMAT('001,234', '000,000') | 1234 |
| DECFLOAT_FORMAT('1234 ', '9999MI') | 1234 |
| DECFLOAT_FORMAT('1234-', '9999MI') | -1234 |
| DECFLOAT_FORMAT('+1234', 'S9999') | 1234 |
| DECFLOAT_FORMAT('-1234', 'S9999') | -1234 |
| DECFLOAT_FORMAT(' 1234 ', '9999PR') | 1234 |
| DECFLOAT_FORMAT('<1234>', '9999PR') | -1234 |
| DECFLOAT_FORMAT('\$123,456.78', '\$999,999.99') | 123456.78 |

DECFLOAT_SORTKEY

The DECFLOAT_SORTKEY function returns a binary value that can be used when sorting DECFLOAT values. The sorting occurs in a manner that is consistent with the IEEE 754R specification on total ordering.

►—DECFLOAT_SORTKEY(*decfloat-expression*)—◄

The schema is SYSIBM.

decfloat-expression

An expression that returns a DECFLOAT value.

decfloat-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result is a fixed length binary string with a length attribute of 9 if *decfloat-expression* is a DECFLOAT(16) value or 17 if *decfloat-expression* is a DECFLOAT(34) value.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that the following CREATE TABLE statement is used to create a table with a column that contains DECFLOAT values and the INSERT statements are used to populate the table:

```
CREATE TABLE T1(D1 DECFLOAT(16));
INSERT INTO T1 VALUES (2.100);
INSERT INTO T1 VALUES (2.10);
INSERT INTO T1 VALUES (2.1000);
INSERT INTO T1 VALUES (2.1);
```

Then the following SELECT statement is used to return the values from D1:

```
SELECT D1 FROM T1 ORDER BY D1;
```

The SELECT statement returns the following values, but because all numbers in the column have the same value, the ORDER BY clause has no effect and the values are returned in an arbitrary order:

```
D1
-----
2.1
2.1000
2.10
2.100
```

The following SELECT statement, which includes the DECFLOAT_SORTKEY function in the ORDER BY clause, returns the properly ordered values:

```
SELECT D1
FROM T1
ORDER BY (DECFLOAT_SORTKEY(D1));

D1
-----
```

2.1000
2.100
2.10
2.1

DECIMAL or DEC

The DECIMAL function returns a decimal representation of either a number or a character-string or graphic-string representation of a number, an integer, or a decimal number.

Numeric to Decimal:

String to Decimal:

The schema is SYSIBM.

Numeric to decimal

numeric-expression

An expression that returns a value of any built-in numeric data type.

precision

An integer constant with a value in the range of 1 to 31. The value of this second argument specifies the precision of the result.

The default value depends on the data type of the first argument as follows:

- 5 if the first argument is a small integer
- 11 if the first argument is a large integer
- 19 if the first argument is a big integer
- 31 if the first argument is a DECFLOAT value
- 15 in all other cases

scale

An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

The result of the function is the same number that would occur if the argument were assigned to a decimal column or variable with precision *p* and scale *s*, where *p* and *s* are specified by the second and third arguments. An error occurs if the number of significant digits required to represent the whole part of the number is greater than *p-s*.

String to decimal

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes.

The string must contain a valid string representation of a number. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL integer or decimal constant.

precision

An integer constant with a value in the range of 1 to 31. The value of this second argument specifies the precision of the result.

The default value depends on the data type of the first argument as follows:

- 5 if the first argument is a small integer
- 11 if the first argument is a large integer
- 15 in all other cases

scale

An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

decimal-character

A single-byte character constant used to delimit the decimal digits in *string-expression* from the whole part of the number. The character cannot be a digit, plus (+), minus (-), or blank. The default value is period (.) or comma (,); the default value cannot be used in *string-expression* if a different value for *decimal-character* is specified.

The result is the same number that would result from `CAST(string-expression AS DECIMAL(p,s))`. Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *s*. An error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) in *string-expression* is greater than *p-s*.

The result of the function is a decimal number with precision of *p* and scale of *s*, where *p* and *s* are the second and third arguments. If the first argument can be null, the result can be null; if the first argument is null, the result is null.

Note: To increase the portability of applications when the precision is specified, use the CAST specification. For more information, see “CAST specification” on page 254.

Example 1: Represent the average salary of the employees in DSN8A10.EMP as an 8-digit decimal number with two of these digits to the right of the decimal point.

```
SELECT DECIMAL(AVG(SALARY),8,2)
FROM DSN8A10.EMP;
```

Example 2: Assume that updates to the SALARY column are input as a character string that uses comma as the decimal character. For example, the user inputs 21400,50. The input value is assigned to the host variable NEWSALARY that is defined as CHAR(10), and the host variable is used in the following UPDATE statement:

```
UPDATE DSN8A10.EMP
SET SALARY = DECIMAL (:NEWSALARY,9,2,',')
WHERE EMPNO = :EMPID;
```

DECODE

The DECODE function compares each *expression2* to *expression1*. If *expression1* is equal to *expression2*, or both *expression1* and *expression2* are null, the value of the *result-expression* is returned. If no *expression2* matches *expression1*, the value of *else-expression* is returned. Otherwise a null value is returned.

The schema is SYSIBM.

The DECODE function is similar to the CASE expression, with the exception of how DECODE handles null values:

- A null value in *expression1* will match a corresponding null value in *expression2*.
- If the NULL keyword is used as an argument in the DECODE function, it must be cast to a data type that is appropriate for comparison.

The rules for determining the result type of the result of the DECODE function are based on the corresponding CASE expression.

The following table shows equivalent DECODE functions and CASE expressions. Both the DECODE function and the corresponding CASE expression achieve the same result.

Table 66. Equivalent DECODE functions and CASE expressions (each returns the same results)

| DECODE function | CASE expression | Notes |
|-------------------------------------|--|--|
| DECODE(c1, 7, 'a', 6, 'b', 'c') | CASE c1 WHEN 7 THEN 'a' WHEN 6 THEN 'b' ELSE 'c' END | |
| DECODE(c1, var1, 'a', var2, 'b') | CASE WHEN c1 = var1 OR (c1 IS NULL AND var1 ISNULL) THEN 'a' WHEN c1 = var2 OR (c1 IS NULL AND var2 ISNULL) THEN 'b' ELSE NULL END | The values of c1, var1, and var2 can be null values. |

Table 66. Equivalent DECODE functions and CASE expressions (each returns the same results) (continued)

| DECODE function | CASE expression | Notes |
|---|---|-------|
| <pre>SELECT ID, DECODE(STATUS, 'A', 'Accepted', 'D', 'Denied', CAST(NULL AS VARCHAR(1)), 'Unknown', 'Other') FROM CONTRACTS</pre> | <pre>SELECT ID, CASE WHEN STATUS = 'A' THEN 'Accepted' WHEN STATUS = 'D' THEN 'Denied' WHEN STATUS IS NULL THEN 'Unknown' ELSE 'Other' END FROM CONTRACTS</pre> | |

DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB

The decryption functions return a value that is the result of decrypting encrypted data. The decryption functions can decrypt only values that are encrypted by using the ENCRYPT_TDES function.

The schema is SYSIBM.

The password used for decryption is either the *password-string* value or the ENCRYPTION PASSWORD value, which is assigned by the SET ENCRYPTION PASSWORD statement.

encrypted-data

An expression that returns a complete, encrypted data value of a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY data type. The data string must have been encrypted using the ENCRYPT_TDES function. The length attribute must be greater than or equal to 0 (zero) and less than or equal to 32672.

password-string

An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes. This expression must be the same password that was used to encrypt the data or decryption will result in a different value than was originally encrypted. For enhanced security, *password-string* should be specified using a host variable rather than a string constant. If the value of the password argument is null or not provided, the data will be decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

For a static SQL statement, it is recommended that the password be specified with a host variable rather than with a string constant.

DEFAULT

The data is decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

ccsid-constant

A integer constant that specifies the CCSID in which the data should be returned by the decryption function. If DECRYPT_BIT or DECRYPT_BINARY is specified, *ccsid-constant* must not be specified. The default is

- The ENCODING bind option of the plan or package or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures that contain the static SQL statements
- The value of the APPLICATION ENCODING special register for dynamic SQL statements

The data type of the result of the function is determined by the function that is specified and the data type of the first argument, as shown in the following table. If the cast from the actual type of the encrypted data to the result of the function is not supported, a warning or error is returned.

Table 67. Result of the decryption function

| Function | Type of first argument | Actual type of encrypted data | Result |
|-----------------|---|--|---|
| DECRYPT_BINARY | FOR BIT DATA ¹ , BINARY, VARBINARY | Any string (except for LOBs) | VARBINARY |
| DECRYPT_BIT | FOR BIT DATA, BINARY, VARBINARY | CHAR, VARCHAR | VARCHAR FOR BIT DATA |
| DECRYPT_BIT | FOR BIT DATA, BINARY, VARBINARY | GRAPHIC, VARGRAPHIC (UTF16) | Warning or error If a warning is returned, the result is VARCHAR FOR BIT DATA |
| DECRYPT_BIT | FOR BIT DATA, BINARY, VARBINARY | GRAPHIC, VARGRAPHIC (not UTF16) | Warning or error If a warning is returned, the result is VARCHAR FOR BIT DATA |
| DECRYPT_BIT | FOR BIT DATA, BINARY, VARBINARY | BINARY, VARBINARY | Warning or error If a warning is returned, the result is VARCHAR FOR BIT DATA |
| DECRYPT_CHAR | FOR BIT DATA, BINARY, VARBINARY | CHAR, VARCHAR | VARCHAR(3) |
| DECRYPT_CHAR | FOR BIT DATA, BINARY, VARBINARY | GRAPHIC, VARGRAPHIC (UTF16) | VARCHAR(3) |
| DECRYPT_CHAR | FOR BIT DATA, BINARY, VARBINARY | GRAPHIC, VARGRAPHIC (not UTF16) | Warning or error If a warning is returned, the result is VARCHAR(3) |
| DECRYPT_CHAR | FOR BIT DATA, BINARY, VARBINARY | BINARY, VARBINARY | Warning or error If a warning is returned, the result is VARCHAR(3) |
| DECRYPT_DB | FOR BIT DATA, BINARY, VARBINARY | CHAR, VARCHAR, GRAPHIC, VARGRAPHIC | VARGRAPHIC |
| DECRYPT_DB | FOR BIT DATA, BINARY, VARBINARY | BINARY, VARBINARY | Warning or error If a warning is returned, the result is VARGRAPHIC |

Table 67. Result of the decryption function (continued)

| Function | Type of first argument | Actual type of encrypted data | Result |
|---|------------------------|-------------------------------|--------|
| Note: ¹ FOR BIT DATA means CHAR or VARCHAR FOR BIT DATA | | | |

If *encrypted-data* included a hint, the hint is not returned by the function. The length attribute of the result is the length attribute of *encrypted-data* minus 8 bytes. The actual length of the value that is returned by the function will match the length of the original string that was encrypted. If *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

Administration of encrypted data: The decryption functions can only decrypt data that was encrypted using the Triple DES encryption algorithm. Therefore, columns with encrypted data can only be used after replication if they were encrypted using the Triple DES encryption algorithm.

If the data is decrypted using a different CCSID than the originally encrypted value, it is possible that expansion might occur when converting the decrypted value to this CCSID. In such situations, the *encrypted-data* value must first be cast to a VARCHAR string with a larger number of bytes before performing the decryption functions.

The result can be null; if the first argument is null, the result is the null value.

For additional information about using the decryption functions, see “ENCRYPT_TDES” on page 436 and “GETHINT” on page 448.

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source statement. Instead, use the ENCRYPTION PASSWORD special register or specify the password using a host variable.

Example 1: Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password to insert a decrypted social security number into the table. Decrypt the value of the added social security number, using the ENCRYPTION PASSWORD value.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

This example returns the value '289-46-8832'.

Example 2: Decrypt the social security number that is inserted into the table. Instead of using the ENCRYPTION PASSWORD value, explicitly specify 'Ben123' as the encryption password.

```
SELECT DECRYPT_CHAR(SSN,'Ben123') FROM EMP;
```

This example returns the value '289-46-8832'.

Example 3: Insert a decrypted social security number into the table, explicitly specifying 'Ben123' as the password. Decrypt the data and have it converted to CCSID 1208.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

When a CCSID is specified, it might be necessary to explicitly cast the data to a longer value to ensure that there is room for expansion when the data is decrypted. The following example illustrates the technique:

```
SELECT DECRYPT_CHAR(CAST(SSN AS VARCHAR(57)),
                   'Ben123',1208)
FROM EMP;
```

In the first case, where the data is not cast to a longer value, the result is a VARCHAR(11) value. In the second case, to allow for expansion, SSN is cast as VARCHAR(57) (11 * 3 + 24). Casting the data to a longer value allows for three times expansion in the normal VARCHAR(11) result. Three times expansion is often associated with a worst case of ASCII or EBCDIC to Unicode UTF-8 conversion. In both cases in this example, the result is the VARCHAR(11) value '289-46-8832'.

DEGREES

The DEGREES function returns the number of degrees of the argument, which is an angle, expressed in radians.

```
▶▶—DEGREES(numeric-expression)—▶▶
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HRAD is a DOUBLE with a value of 3.1415926536. The following statement returns a double precision floating-point number with an approximate value of 180.0.

```
SELECT DEGREES(:HRAD)
FROM SYSIBM.SYSDUMMY1;
```

DIFFERENCE

The DIFFERENCE function returns a value, from 0 to 4, that represents the difference between the sounds of two strings, based on applying the SOUNDEX function to the strings. A value of 4 is the best possible sound match.

►—DIFFERENCE(*expression-1*,*expression-2*)—►

The schema is SYSIBM.

expression-1 or *expression-2*

Each expression must return a value that is a built-in numeric, character string, or graphic string data type that is not a LOB. A numeric argument is cast to a character string before the function is evaluated. For more information on converting a numeric string to a character string, see “VARCHAR” on page 641.

The data type of the result is INTEGER.

The result can be null; if any argument is null, the result is the null value.

Example 1: Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONSTANT':

```
SELECT DIFFERENCE('CONSTRAINT', 'CONSTANT'),
       SOUNDEX('CONSTRAINT'),
       SOUNDEX('CONSTANT')
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 4, C523, and C523. Since the two strings return the same SOUNDEX value, the difference is 4 (the highest value possible).

Example 2: Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONTRITE':

```
SELECT DIFFERENCE('CONSTRAINT', 'CONTRITE'),
       SOUNDEX('CONSTRAINT'),
       SOUNDEX('CONTRITE')
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 2, C523, and C536. In this case, the two strings return different SOUNDEX values, and hence, a lower difference value.

DIGITS

The DIGITS function returns a character string representation of the absolute value of a number.

►►—DIGITS(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns a value that is a SMALLINT, INTEGER, BIGINT, or DECIMAL built-in numeric data type.

The result of the function is a fixed-length character string representing the absolute value of the argument without regard to its scale. The result does not include a sign or a decimal point. Instead, it consists exclusively of digits, including, if necessary, leading zeros to fill out the string. The length of the string is:

- 5 if the argument is a small integer
- 10 if the argument is a large integer
- 19 if the argument is a big integer
- p if the argument is a decimal number with a precision of p

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Example 1: Assume that an INTEGER column called INTCOL containing a 10-digit number is in a table called TABLEX. INTCOL has the data type INTEGER instead of CHAR(10) to save space. the following query lists all combinations of the first four digits in column INTCOL.

```
SELECT DISTINCT SUBSTR(DIGITS(INTCOL),1,4)
FROM TABLEX;
```

Example 2: Assume that COLUMNX has the data type DECIMAL(6,2), and that one of its values is -6.28. For this value, the following statement returns the value '000628'.

```
DIGITS(COLUMNX)
```

The result is a string of length six (the precision of the column) with leading zeros padding the string out to this length. Neither sign nor decimal point appear in the result.

DOUBLE_PRECISION or DOUBLE

The DOUBLE_PRECISION and DOUBLE functions returns a floating-point representation of either a number or a character-string or graphic-string representation of a number, an integer, a decimal number, or a floating-point number.

Numeric to Double:

String to Double:

The schema is SYSIBM.

Numeric to Double

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the expression were assigned to a double precision floating-point column or variable.

String to Double

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS DOUBLE PRECISION)`. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL floating-point, integer, or decimal constant.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Note: To increase the portability of applications, use the CAST specification. For more information, see "CAST specification" on page 254.

FLOAT can be specified as a synonym for DOUBLE or DOUBLE_PRECISION.

Example: Using sample table DSN8A10.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved in the

calculation, SALARY and COMM, have decimal data types. To eliminate the possibility of out-of-range results, apply the DOUBLE function to SALARY so that the division is carried out in floating-point.

```
SELECT EMPNO, DOUBLE(SALARY)/COMM
FROM DSN8A10.EMP
WHERE COMM > 0;
```

DSN_XMLVALIDATE

The DSN_XMLVALIDATE function returns an XML value that is the result of applying XML schema validation to the first argument of the function. DSN_XMLVALIDATE can validate XML data that has a maximum length of 2 GB - 1 byte.

```
DSN_XMLVALIDATE(  
  string-expression | xml-expression ,  
  schema-name-string | target-namespace-uri-string, schema-location-string )
```

The schema is SYSIBM.

string-expression

An expression that returns a built-in character, graphic, or binary string. The value must be a well-formed XML document that conforms to the XML Version 1.0 standard.

xml-expression

An expression that returns an XML value in the XML data type. The value must be a well-formed XML document that conforms to XML Version 1.0 standard.

schema-name-string

An expression that returns a built-in varying length character string that is not a CLOB. The value specifies the name of the XML schema object that is used for validation. The value must not be an empty string or the null value, and the actual length must be less than or equal to 257. If the XML schema name is qualified, the qualifier must be SYSXSR (SYSXSR is the default qualifier). The value must identify a registered XML schema in the DB2 XML schema repository.

target-namespace-uri-string

An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the target namespace name or universal resource identifier (URI) of the XML schema that is to be used for validation. If the value is an empty string or the null value, no namespace is used to locate the XML schema.

schema-location-string

An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the XML schema location hint URI of the XML schema that is to be used for validation. If the value is an empty string or the null value, no schema location is used to locate the XML schema.

If *target-namespace-uri-string* and *schema-location-string* are specified, the combination must identify a registered XML schema in the DB2 XML schema repository, and there must be only one such registered XML schema.

A schema must be registered successfully in the DB2 XML schema repository before it can be used for DSN_XMLVALIDATE. If the validation fails, DB2 returns an error.

The result of the function is an XML value.

The result can be null; if the first argument is null, the result is the null value.

Example 1: The following example shows how the DSN_XMLVALIDATE function validates the XML data that is contained in the *value_host_var* host variable. The XML schema, SYSXSR.ORDERSCHEMA, was registered prior to this statement:

```
INSERT INTO T1(C1) VALUES(  
    DSN_XMLVALIDATE(:value_host_var, 'SYSXSR.MYXMLSCHEMA'));
```

Example 2: The following example is similar to the previous example but references the namespace and schema location:

```
INSERT INTO T1(C1) VALUES(  
    DSN_XMLVALIDATE(:value_host_var,  
                    'http://www.n1.com',  
                    'http://www.n1.com/report.xsd'));
```

EBCDIC_CHR

The EBCDIC_CHR function returns the character that has the EBCDIC code value that is specified by the argument.

►—EBCDIC_CHR(*expression*)—◄

The schema is SYSIBM.

expression

An expression that returns a BIGINT, INTEGER, or SMALLINT built-in data type value.

expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a CHAR(1) string encoded in the SBCS EBCDIC CCSID (regardless of the setting of the MIXED option in DSNHDECP). If the value of *expression* is not in the range of 0 to 255, the null value is returned.

The result can be null; if the argument is null, the result is the null value.

Example: Set *hv* with the Euro symbol "€" in CCSID 1140:

```
SET :hv = EBCDIC_CHR(159); -- x'9F'
```

Set *hv* with the Euro symbol "€" in CCSID 1142:

```
SET :hv = EBCDIC_CHR(90); -- x'5A'
```

In both cases, the "€" is assigned to *hv*, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

EBCDIC_STR

The EBCDIC_STR function returns a string, in the system EBCDIC CCSID, that is an EBCDIC version of the string.

►►—EBCDIC_STR(*string-expression*)—◄◄

The schema is SYSIBM.

The system EBCDIC CCSID is defined as the SBCS EBCDIC CCSID on a MIXED=NO system or the MIXED EBCDIC CCSID on a MIXED=YES system.

string-expression

An expression that returns a value of a built-in character or graphic string. If the string is a character string, it cannot be bit data. *string-expression* must be an ASCII, EBCDIC, or Unicode string. EBCDIC_STR returns an EBCDIC version of the string. Non-EBCDIC characters are converted to the form `\xxxx`, where `xxxx` represents a UTF-16 code unit.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The length attribute of the result is calculated using the formulas in Table 33 on page 141. The length attribute of the result will be $\text{MIN}(\text{5} * n, 32704)$. Where n is the result of applying the formulas in Table 33 on page 141 based on input and output data types.

The result of the function is an EBCDIC character string (in the system EBCDIC CCSID). If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

Example: The following example returns the EBCDIC string equivalent of the text string "Hi my name is А н д р е й (Andrei)"

```
SET :HV1 = EBCDIC_STR('Hi, my name is А н д р е й (Andrei)');
```

HV1 is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439 (Andrei)"

ENCRYPT_TDES

The ENCRYPT_TDES function returns a value that is the result of encrypting the first argument by using the Triple DES encryption algorithm. The function can also set the password that is used for encryption.

The encryption password can also be set by using the ENCRYPTION PASSWORD value, which is assigned by using the SET ENCRYPTION PASSWORD statement.

The schema is SYSIBM.

data-string

An expression that returns the string value to be encrypted. The string expression must return a built-in string data type that is not a LOB. The length attribute must be greater than or equal to 0 (zero). The length attribute is limited to 32640 if *hint-string* is specified and 32672 if *hint-string* is not specified.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

password-string

An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The value represents the password that is used to encrypt *data-string*. If the value of the password argument is null or not specified, the data is encrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

hint-string

An expression that returns a CHAR or VARCHAR value up to 32 bytes that is to help data owners remember passwords (for example, 'Ocean' as a hint to remember 'Pacific').

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If this argument is null or not specified and no hint was specified when the ENCRYPTION PASSWORD was set, no hint is embedded in the result. If *password-string* is not specified, the hint can be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

Table 68. Data type of the results of the ENCRYPT_TDES function

| Data type of the first argument | Data type of the result |
|------------------------------------|-------------------------|
| BINARY, VARBINARY | VARBINARY |
| CHAR, VARCHAR, GRAPHIC, VARGRAPHIC | VARCHAR FOR BIT DATA |

The encoding scheme of the result is the same as the encoding scheme of *data-string*. If the result is character data, the result is bit data.

The length attribute of the result is different depending of whether *hint-string* is specified:

- If *hint-string* is specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
- If *hint-string* is not specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + the number of bytes to the next 8 byte boundary.

The result can be null; if the first argument is null, the result is the null value.

The encrypted result is longer than the *data-string* value. Therefore, when assigning encrypted values, ensure that the target is declared with a length that can contain the entire encrypted value.

When encrypting data, be aware of the following points:

- **Password protection:** To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a variable.
- **Encryption algorithm:** The internal encryption algorithm used is Triple DES cipher block chaining (CBC) with padding. The 128-bit secret key is derived from the password using an MD5 hash.
- **Encryption passwords and data:** It is your responsibility to perform password management. After data is encrypted, only the password that is used to encrypt it can be used to decrypt it. If a different password is used to decrypt the data than was used to encrypt the data, the results of decryption will not match the original string. No error or warning is returned. CHAR variables might be padded with blanks if they are used to set password values. The encrypted result might contain null terminator and other non-printable characters.
- **Table column definitions:** When defining columns and types to contain encrypted data, always calculate the length attribute as follows:
 - For encrypted data with an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
 - For encrypted data without an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary.

Here are some sample column length calculations, which assume that a hint is not embedded:

| | |
|---|----------|
| Maximum length of non-encrypted data | 6 bytes |
| 24 bytes for encryption key | 24 bytes |
| Number of bytes to the next 8 byte boundary | 2 bytes |

```

-----
Encrypted data column length          32 bytes
Maximum length of non-encrypted data  32 bytes
24 bytes for encryption key           24 bytes
Number of bytes to the next 8 byte boundary  0 bytes
-----

```

```

Encrypted data column length          56 bytes

```

- **Administration of encrypted data:** Encrypted data can be decrypted only on servers that support the decryption of data that was encrypted using the Triple DES encryption algorithm. Hence, replication of columns with encrypted data should only be done to servers that support the decryption functions and the same encryption algorithms.

ENCRYPT can be specified as a synonym for ENCRYPT_TDES. DB2 supports this keyword to provide compatibility with other products in the DB2 family.

Example 1: Encrypt the social security number that is inserted into the table. Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password.

```

SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832');

```

Example 2: Encrypt the social security number that is inserted into the table. Explicitly specify 'Ben123' as the encryption password.

```

INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832','Ben123');

```

Example 3: Encrypt the social security number that is inserted into the table. Specify 'Pacific' as the encryption password, and provide 'Ocean' as a hint to help the user remember the password of 'Pacific'.

```

INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832','Pacific','Ocean');

```

The preceding statement returns a double precision floating-point number with an approximate value of 31.62.

EXP

The EXP function returns a value that is the base of the natural logarithm (e), raised to a power that is specified by the argument. The EXP and LN functions are inverse operations.

►►—EXP(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable E is DECIMAL(10,9) with a value of 3.453789832. The following statement returns a double precision floating-point number with an approximate value of 31.62.

```
SELECT EXP(:E)
FROM SYSIBM.SYSDUMMY1;
```

EXTRACT

The EXTRACT function returns a portion of a date or timestamp, based on its arguments.

Extract date values:

Extract time values:

Extract time zone values:

The schema is SYSIBM.

The result can be null; if the argument is null, the result is the null value.

Extract date values

YEAR

Specifies that the year portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the YEAR scalar function. For more information, see “YEAR” on page 702.

MONTH

Specifies that the month portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the MONTH scalar function. For more information, see “MONTH” on page 506.

DAY

Specifies that the day portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the DAY scalar function. For more information, see “DAY” on page 399.

date-expression

An expression that returns the value of either a built-in date or built-in character string data type.

If *date-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a date. For the valid formats of string representations of dates, see “String representations of datetime values” on page 101.

timestamp-expression

An expression that returns the value of either a built-in timestamp or built-in character string data type.

If *timestamp-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 101.

Extract time values

HOUR

Specifies that the hour portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the HOUR scalar function. For more information, see “HOUR” on page 456.

MINUTE

Specifies that the minute portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the MINUTE scalar function. For more information, see “MINUTE” on page 502.

SECOND

Specifies that the second portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the SECOND scalar function where the precision and scale of the result depend on the type of *time-expression* or *timestamp-expression*. For more information, see “SECOND” on page 572.

time-expression

An expression that returns the value of either a built-in time or built-in character string data type.

If *time-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a time. For the valid formats of string representations of times, see “String representations of datetime values” on page 101.

timestamp-expression

An expression that returns the value of either a built-in timestamp or built-in character string data type.

If *timestamp-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a timestamp. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 101.

Extract time zone values

TIMEZONE_HOUR

Specifies that the hour component of the time zone of the timestamp

value is returned. `TIMEZONE_HOUR` can only be specified if the second argument is a *timestamp-expression* and the *timestamp-expression* contains a time zone.

TIMEZONE_MINUTE

Specifies that the minute component of the time zone of the timestamp value is returned. `TIMEZONE_MINUTE` can only be specified if the second argument is a *timestamp-expression* and the *timestamp-expression* contains a time zone.

The values of `TIMEZONE_HOUR` and `TIMEZONE_MINUTE` shall either both be non-negative or both be non-positive.

If the *timestamp-expression* argument includes a time zone, the result is determined from the UTC representation of the datetime value.

The data type of the result of the function depends on the part of the datetime value that is specified:

- The result is `INTEGER`, if one of the following is specified:
 - `YEAR`
 - `MONTH`
 - `DAY`
 - `HOUR`
 - `MINUTE`
 - `TIMEZONE_HOUR`
 - `TIMEZONE_MINUTE`
- The result is `DECIMAL(2+p, p)` where *p* is the fractional second precision, if `SECOND` is specified with a `TIMESTAMP(p)` value.
- The result is `DECIMAL(8,6)`, if `SECOND` is specified with a `TIME` value or a string representation of a `TIME` or timestamp. The fractional digits contains fractional seconds.

Example 1:

Assume that the column `PRSTDATE` has an internal value that is equivalent to 2010-12-25. The following statement returns the value 12:

```
SELECT EXTRACT(MONTH FROM PRSTDATE)
FROM PROJECT;
```

Example 2:

Assume that host variable `PRSTSZ` contains the value 2008-02-29.20.00.000000 -08.30:

```
SELECT EXTRACT(HOUR FROM :PRSTSZ) FROM PROJECT;
```

The `SELECT` statement returns the value 4, which is the hour of the input datetime value expressed in UTC.

To return the same hour value as expressed in the input, cast the value to `TIMESTAMP WITHOUT TIME ZONE` before using the `EXTRACT` function:

```
SELECT EXTRACT(HOUR FROM CAST (:PRSTSZ AS TIMESTAMP ) ) FROM PROJECT;
```

The `SELECT` statement returns the value 20, which is the hour as it was originally expressed as a string in the host variable.

```
SELECT EXTRACT(TIMEZONE_HOUR FROM :PRSTSZ) FROM PROJECT;
```

| This SELECT statement returns the value -8.
| SELECT EXTRACT(TIMEZONE_MINUTE FROM :PRSTSZ) FROM PROJECT;
| This SELECT statement returns the value -30.

FLOAT

The FLOAT function returns a floating-point representation of either a number or a string representation of a number. FLOAT is a synonym for the DOUBLE function.

▶—FLOAT(*numeric-expression*)—▶

The schema is SYSIBM.

FLOAT is a synonym for the DOUBLE function. See “DOUBLE_PRECISION or DOUBLE” on page 430 for details.

FLOOR

The FLOOR function returns the largest integer value that is less than or equal to the argument.

►►—FLOOR(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument. When the argument is DECIMAL, the scale of the result is 0 and not the scale of the input argument. For example, an argument with a date type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.EMP, find the highest monthly salary, rounding the result down to the next integer. The SALARY column has a decimal data type.

```
SELECT FLOOR(MAX(SALARY)/12)
FROM DSN8A10.EMP;
```

This example returns 04395 because the highest paid employee is Christine Haas who earns \$52750.00 per year. Her average monthly salary before applying the FLOOR function is 4395.83.

Example 2: This example demonstrates using FLOOR with both positive and negative numbers.

```
SELECT FLOOR( 3.5),
       FLOOR( 3.1),
       FLOOR(-3.1),
       FLOOR(-3.5)
FROM SYSIBM.SYSDUMMY1;
```

This example returns (leading zeros are shown to demonstrate the precision and scale of the result):

03. 03. -04. -04.

GENERATE_UNIQUE

The `GENERATE_UNIQUE` function returns a bit data character string that is unique, compared to any other execution of the same function.

►►—GENERATE_UNIQUE()—►►

The schema is `SYSIBM`.

The `GENERATE_UNIQUE` function returns a bit data character string 13 bytes long (`CHAR(13) FOR BIT DATA`) that is unique compared to any other execution of the same function. The function is defined as not deterministic. Although the function has no arguments, the empty parentheses must be specified when the function is invoked.

The result of the function is a unique value that includes the internal form of the Universal Time, Coordinated (UTC) and, if in a sysplex environment, the sysplex member where the function was processed.

The result cannot be null.

The result of this function can be used to provide unique values in a table. The sequence is based on the time when the function was executed.

This function differs from using the special register `CURRENT_TIMESTAMP` in that a unique value is generated for each row of a multiple row insert statement, an insert statement with a `fullselect`, or an insert operation in a `MERGE` statement.

The timestamp value that is part of the result of this function can be determined using the `TIMESTAMP` function with the result of `GENERATE_UNIQUE` as an argument.

Example: Create a table that includes a column that is unique for each row. Populate this column using the `GENERATE_UNIQUE` function. Notice that the `UNIQUE_ID` column is defined as `FOR BIT DATA` to identify the column as a bit data character string.

```
CREATE TABLE EMP_UPDATE
  (UNIQUE_ID VARCHAR(13)FOR BIT DATA,
  EMPNO CHAR(6),
  TEXT VARCHAR(100));
INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),'000020','Update entry 1...');
INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),'000050','Update entry 2...');
```

This table will have a unique identifier for each row if `GENERATE_UNIQUE` is always used to set the value the `UNIQUE_ID` column. You can create an insert trigger on the table to ensure that `GENERATE_UNIQUE` is used to set the value:

```
CREATE TRIGGER EMP_UPDATE_UNIQUE
  NO CASCADE BEFORE INSERT ON EMP_UPDATE
  REFERENCING NEW AS NEW_UPD
  FOR EACH ROW MODE DB2SQL
  SET NEW_UPD.UNIQUE_ID = GENERATE_UNIQUE();
```

With this trigger, the previous INSERT statements that were used to populate the table could be issued without specifying a value for the UNIQUE_ID column:

```
INSERT INTO EMP_UPDATE (EMPNO,TEXT) VALUES ('000020','Update entry 1...');
INSERT INTO EMP_UPDATE (EMPNO,TEXT) VALUES ('000050','Update entry 2...');
```

The timestamp (in UTC) for when a row was added to EMP_UPDATE can be returned using:

```
SELECT TIMESTAMP(UNIQUE_ID), EMPNO, TEXT FROM EMP_UPDATE;
```

Therefore, the table does not need a timestamp column to record when a row is inserted.

GETHINT

The GETHINT function returns a hint for the password if a hint was embedded in the encrypted data. A password hint is a phrase that helps you remember the password with which the data was encrypted. For example, 'Ocean' might be used as a hint to help remember the password 'Pacific'.

►—GETHINT(*encrypted-data*)—◄

The schema is SYSIBM.

encrypted-data

An expression that returns a string that contains a complete, encrypted data string. *encrypted-data* must return a value that is a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY built-in data type. The string must have been encrypted using ENCRYPT_TDES function.

The result of the function is VARCHAR(32). The actual length of the result is the actual length of the hint that was provided when the data was encrypted.

The result can be null; if the argument is null, the result is the null value.

If no hint was specified when the ENCRYPT_TDES function was used to encrypt the data, the result is the null value.

The encoding scheme of the result is the same as the encoding scheme of *encrypted-data*. If *encrypted-data* is bit data, the CCSID of the result is the default character CCSID for that encoding scheme. Otherwise, the CCSID of the result is the same as the CCSID of *encrypted-data*.

For additional information about this function, see “DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB” on page 423 and “ENCRYPT_TDES” on page 436.

Example: This example shows how to embed a hint for the password when encrypting data and how to later use the GETHINT function to retrieve the embedded hint. In this example, the hint 'Ocean' is used to help remember the encryption password 'Pacific'.

```
INSERT INTO EMP (SSN) VALUES ENCRYPT_TDES ('289-46-8832','Pacific','Ocean');
SELECT GETHINT (SSN) FROM EMP;
```

The value that is returned is 'Ocean'.

GETVARIABLE

The GETVARIABLE function returns a varying-length character-string representation of the current value of the session variable that is identified by the argument.

The schema is SYSIBM.

string-constant

Specifies a string constant that contains the name of the session variable whose value is to be returned. The string constant:

- Must have a length that does not exceed 142 bytes.
- Must contain the fully qualified name of the variable, with no embedded blanks. Delimited identifiers must not be specified.
- Must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.

The schema qualifier for the variable must be:

- SYSIBM for built-in session variables. For a list of the built-in session variables, see Chapter 3, “Built-in session variables,” on page 317.
- SESSION for user-defined session variables. User-defined session variables are established via the connection or signon exit routines.

default-value

Specifies a string constant that contains the value to be returned if the specified variable does not exist or is not supported by DB2. *default-value* must be a string constant that does not exceed 255 bytes.

If *default-value* is not specified and the specified user-defined session variable does not exist or the built-in session variable is not supported by DB2, an error is returned.

CAST(NULL AS VARCHAR(1))

Specifies that a null value is to be returned if the specified variable does not exist or is not supported by DB2.

The data type of the result is VARCHAR(255). The result can be null.

The CCSID of the result is the CCSID for Unicode mixed data.

Example 1: Use the GETVARIABLE function to set the value of host variable :hv1 to the name of the plan that is currently being executed. The name of the built-in session variable that contains the name of the plan is SYSIBM.PLAN_NAME.

```
SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

If DB2 does not support the name of the session variable, an error is returned. For example, the following statement returns an error because DB2 does not support a built-in session variable that is named SYSIBM.XYZ.

```
SET :hv1 = GETVARIABLE('SYSIBM.XYZ');
```

Example 2: Use the GETVARIABLE function to set the value of host variable :hv2 to the value for the user that is defined in user-defined session variable TEST. If the session variable has not been set or cannot be found, have the function return the value 'TEST FAILED'.

```
SET :hv2 = GETVARIABLE('SESSION.TEST', 'TEST FAILED');
```

Example 3: Use the GETVARIABLE function to set the value of host variable :hv3 to a string representation of the SYSTEM EBCDIC CCSIDs. The name of the built-in session variable that contains the system EBCDIC CCSIDs is SYSIBM.SYSTEM_EBCDIC_CCSID.

```
SET :hv3 = GETVARIABLE('SYSIBM.SYSTEM_EBCDIC_CCSID');
```

Regardless of the setting of the field MIXED DATA on the installation panel (YES or NO), the function returns three comma-delimited values that correspond to the SBCS, MIXED, and GRAPHIC CCSIDs for the encoding scheme.

For example, if the statement were issued on a system with the field MIXED DATA on the installation panel equal to NO and the default system CCSID of 37, this string would be returned:

```
'37,65534,65534'
```

If the statement were issued on a system with the field MIXED DATA on the installation panel equal to YES and a default system CCSID of 930 (the mixed CCSID for the system), this string would be returned:

```
'290,930,300'
```

GRAPHIC

The GRAPHIC function returns a fixed-length graphic-string representation of a character string or a graphic string value, depending on the type of the first argument.

Character to Graphic:

Graphic to Graphic:

The schema is SYSIBM.

The result of the function is a fixed-length graphic string (GRAPHIC).

The result can be null; if the argument is null, the result is the null value.

The length attribute of the result is measured in double-byte characters because it is a graphic string.

Character to Graphic

character-expression

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 84 for these rules.)

The value of the expression must not be an empty string if *integer* is not specified or have the value X'0E0F' if the string is an EBCDIC string.

integer

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of *character-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 90 for information about how to calculate the length attribute of the result string.

If *integer* is not specified, the length of the result for an EBCDIC string is the minimum of 127 and the length attribute of *character-expression*, excluding shift characters. For a Unicode (UTF-8) string, the length is data dependent, but does not exceed 127.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFE'.

For EBCDIC data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for EBCDIC mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for an SBCS character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xxxx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.

- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*.

The result is derived from *S* by using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FEFE'.

Graphic to Graphic

graphic-expression

An expression that returns a value that is a graphic string. The graphic string must not be an empty string if *integer* is not specified.

integer

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of *graphic-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

If *integer* is not specified, the length of the result is the minimum of 127 and the length attribute of *graphic-expression*.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

If the length of the *graphic-expression* is greater than the specified length of the result, the result is truncated. Unless all the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

Example: Assume that MYCOL is a VARCHAR column in TABLEY. The following function returns the string in MYCOL as a fixed-length graphic string.

```
SELECT GRAPHIC(MYCOL)
FROM TABLEY;
```

HEX

The HEX function returns a hexadecimal representation of a value.

►—HEX(*expression*)—◄

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in data type that is not XML. A character or binary string must not have a maximum length greater than 16352. A graphic string must not have a maximum length greater than 8176.

The result of the function is a character string.

The result can be null; if the argument is null, the result is the null value.

The result is a string of hexadecimal digits. The first two represent the first byte of the argument, the next two represent the second byte of the argument, and so forth. If the argument is a datetime value, the result is the hexadecimal representation of the internal form of the argument.

If the argument is a fixed-length string and the length of the result is less than 255, the result is a fixed-length string. Otherwise, the result is a varying-length string with a length attribute that depends on the following considerations:

If the argument is not a varying-length string, the length attribute of the result string is the same as the length of the result.

If the argument is a varying-length character or binary string, the length attribute of the result string is twice the length attribute of the argument.

If the argument is a varying-length graphic string, the length attribute of the result string is four times the length attribute of the argument.

If *expression* returns string data, the CCSID of the result is the SBCS CCSID that corresponds to the CCSID of *expression*. Otherwise, the CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

If the argument is a graphic string, the length of the result is four times the maximum length of the argument. Otherwise, the length of the result is twice the (maximum) length of the argument.

Example: Return the hexadecimal representation of START_RBA in the SYSIBM.SYSCOPY catalog table.

```
SELECT HEX(START_RBA) FROM SYSIBM.SYSCOPY;
```

HOUR

The HOUR function returns the hour part of a value.

►►—HOUR(*expression*)—►►

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 145.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of either, the result is the hour part of the value, which is an integer between 1 and 24.

If the argument is a time duration or timestamp duration, the result is the hour part of the value, which is an integer between -99 and +99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: Assume that a table named CLASSES contains a row for each scheduled class. Also assume that the class starting times are in a TIME column named STARTTM. Select those rows in CLASSES that represent classes that start after the noon hour.

```
SELECT *
  FROM CLASSES
 WHERE HOUR(STARTTM) > 12;
```

Example 2: The following invocations of the HOUR function returns the same result:

```
SELECT HOUR('2003-01-02-20.00.00'),
       HOUR('2003-01-02-12.00.00-08:00'),
       HOUR('2003-01-03-05.00.00+09:00')
  FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the HOUR function in this SELECT statement, the result is
| 20.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.00.00.

IDENTITY_VAL_LOCAL

The IDENTITY_VAL_LOCAL function returns the most recently assigned value for an identity column.

```
▶—IDENTITY_VAL_LOCAL()—▶
```

The schema is SYSIBM.

The IDENTITY_VAL_LOCAL function is not deterministic.²⁰ Although the function has no input parameters, the empty parentheses must be specified when the function is invoked.

The result is DECIMAL(31,0), regardless of the actual data type of the identity column to which the result value corresponds.

A *qualifying data change statement* refers to an insert operation (specified in either an INSERT statement or a MERGE statement).

The value that is returned is the value that was assigned to the identity column of the table identified in the most recent qualifying data change statement or LOAD utility operation for a table with an identity column. The insert operation has to be issued at the same level; that is, the value has to be available locally within the level at which it was assigned until replaced by the next assigned value. A new level is initiated when a trigger, function, or stored procedure is invoked. A trigger condition is at the same level as the associated triggered action.

The assigned value can be a value supplied by the user (if the identity column is defined as GENERATED BY DEFAULT) or an identity value that was generated by DB2.

Note: Use a SELECT FROM data change statement to obtain the assigned value for an identity column. See [data-change-table-reference](#) for more information.

The result can be null. The result is null in the following situations:

- When a qualifying data change statement has not been issued for a table containing an identity column at the current processing level
- When a COMMIT or ROLLBACK of a unit of work occurred since the most recent qualifying data change statement that assigned a value

The result of the function is not affected by a ROLLBACK TO SAVEPOINT statement.

Invoking the function within a qualifying data change statement: Expressions in a qualifying data change statement are evaluated before values are assigned to the target columns of the qualifying data change statement. Thus, when you invoke IDENTITY_VAL_LOCAL in a qualifying data change statement, the value that is

20. Being not deterministic affects what optimization (such as view processing and parallel processing) can be done when this function is used and in what contexts the function can be invoked. For example, the RAND function is another built-in scalar function that is not deterministic. Using functions that are not deterministic within a predicate can cause unpredictable results.

used is the most recently assigned value for an identity column from a previous qualifying data change statement. The function returns the null value if no such qualifying data change statement had been executed within the same level as the invocation of the `IDENTITY_VAL_LOCAL` function. Each qualifying data change statement that involves an `IDENTITY` column causes the identity value to be copied into connection-specific storage in DB2. Thus, the most recent identity value is used for a connection, regardless of what is happening with other concurrent user connections.

Invoking the function following a failed insert operation: The function returns an unpredictable result when it is invoked after the unsuccessful execution of a qualifying data change statement for a table with an identity column. The value might be the value that would have been returned from the function had it been invoked before the failed qualifying data change statement or the value that would have been assigned had the qualifying data change statement succeeded. The actual value returned depends on the point of failure and is therefore unpredictable.

Invoking the function within the SELECT statement of a cursor: Because the results of the `IDENTITY_VAL_LOCAL` function are not deterministic, the result of an invocation of the `IDENTITY_VAL_LOCAL` function from within the `SELECT` statement of a cursor can vary for each `FETCH` statement.

Invoking the function within the trigger condition of an insert trigger: The result of invoking the `IDENTITY_VAL_LOCAL` function from within the condition of an insert trigger is the null value.

Invoking the function within a triggered action of an insert trigger: Multiple before or after insert triggers can exist for a table. In such cases, each trigger is processed separately, and identity values generated by SQL statements issued within a triggered action are not available to other triggered actions using the `IDENTITY_VAL_LOCAL` function. This is the case even though the multiple triggered actions are conceptually defined at the same level.

Do not use the `IDENTITY_VAL_LOCAL` function in the triggered action of a before insert trigger. The result of invoking the `IDENTITY_VAL_LOCAL` function from within the triggered action of a before insert trigger is the null value.

The value for the identity column of the table for which the trigger is defined cannot be obtained by invoking the `IDENTITY_VAL_LOCAL` function within the triggered action of a before insert trigger. However, the value for the identity column can be obtained in the triggered action by referencing the trigger transition variable for the identity column.

The result of invoking the `IDENTITY_VAL_LOCAL` function in the triggered action of an after insert trigger is the value assigned to an identity column of the table identified in the most recent qualifying data change statement. That statement is the one invoked in the same triggered action that had a qualifying data change statement for a table containing an identity column. If a qualifying data change statement for a table containing an identity column was not executed within the same triggered action before invoking the `IDENTITY_VAL_LOCAL` function, then the function returns a null value.

Invoking the function following an insert operation with triggered actions: The result of invoking the function after an insert that activates triggers is the value actually assigned to the identity column (that is, the value that would be returned

on a subsequent SELECT statement). This value is not necessarily the value provided in the qualifying data change statement or a value generated by DB2. The assigned value could be a value that was specified in a SET transition variable statement within the triggered action of a before insert trigger for a trigger transition variable associated with the identity column.

Scope of IDENTITY_VAL_LOCAL: The IDENTITY_VAL_LOCAL value persists until the next insert in the current session into a table that has an identity column defined on it, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements for local applications. The IDENTITY_VAL_LOCAL value cannot be directly set and is a result of inserting a row into a table. Client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing are not able to restore the IDENTITY_VAL_LOCAL value. In these situations, the availability of the IDENTITY_VAL_LOCAL value should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following actions:

- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value associated with IDENTITY_VAL_LOCAL across transaction boundaries for distributed applications, define the cursors as WITH HOLD, or specify the bind option KEEP DYNAMIC(YES) to prevent the server thread from being pooled.

Example 1: Set the variable IVAR to the value assigned to the identity column in the EMPLOYEE table. The value returned from the function in the VALUES statement should be 1.

```
CREATE TABLE EMPLOYEE
(EMPNO      INTEGER GENERATED ALWAYS AS IDENTITY,
 NAME       CHAR(30),
 SALARY     DECIMAL(5,2),
 DEPTNO     SMALLINT);
INSERT INTO EMPLOYEE
(NAME, SALARY, DEPTNO)
VALUES ('Rupert', 989.99, 50);
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;
```

Example 2: Assume two tables, T1 and T2, have an identity column named C1. DB2 generates values 1, 2, 3, . . . for the C1 column in table T1, and values 10, 11, 12, . . . for the C1 column in table T2.

```
CREATE TABLE T1 (C1 SMALLINT GENERATED ALWAYS AS IDENTITY,
                  C2 SMALLINT );
CREATE TABLE T2 (C1 DECIMAL(15,0) GENERATED BY DEFAULT AS IDENTITY
                  (START WITH 10),
                  C2 SMALLINT );
INSERT INTO T1 (C2) VALUES (5);
INSERT INTO T1 (C2) VALUES (5);
SELECT * FROM T1;
   C1          C2
-----
      1          5
      2          5
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;
```

At this point, the `IDENTITY_VAL_LOCAL` function would return a value of 2 in `IVAR`. The following `INSERT` statement inserts a single row into `T2` where column `C2` gets a value of 2 from the `IDENTITY_VAL_LOCAL` function

```
INSERT INTO T2 (C2) VALUES (IDENTITY_VAL_LOCAL());
SELECT * FROM T2
WHERE C1 = DECIMAL(IDENTITY_VAL_LOCAL(),15,0);
      C1                      C2
```

```
-----
                                10          2
```

Invoking the `IDENTITY_VAL_LOCAL` function after this insert would result in a value of 10, which is the value generated by `DB2` for column `C1` of `T2`. Assume another single row is inserted into `T2`. For the following `INSERT` statement, `DB2` assigns a value of 13 to identity column `C1` and gives `C2` a value of 10 from `IDENTITY_VAL_LOCAL`. Thus, `C2` is given the last identity value that was inserted into `T2`.

```
INSERT INTO T2 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 13);
```

Example 3: The `IDENTITY_VAL_LOCAL` function can also be invoked in an `INSERT` statement that both invokes the `IDENTITY_VAL_LOCAL` function and causes a new value for an identity column to be assigned. The next value to be returned is thus established when the `IDENTITY_VAL_LOCAL` function is invoked after the `INSERT` statement completes. For example, consider the following table definition:

```
CREATE TABLE T1 (C1 SMALLINT GENERATED BY DEFAULT AS IDENTITY,
                  C2 SMALLINT);
```

For the following `INSERT` statement, specify a value of 25 for the `C2` column, and `DB2` generates a value of 1 for `C1`, the identity column. This establishes 1 as the value that will be returned on the next invocation of the `IDENTITY_VAL_LOCAL` function.

```
INSERT INTO T1 (C2) VALUES (25);
```

In the following `INSERT` statement, the `IDENTITY_VAL_LOCAL` function is invoked to provide a value for the `C2` column. A value of 1 (the identity value assigned to the `C1` column of the first row) is assigned to the `C2` column, and `DB2` generates a value of 2 for `C1`, the identity column. This establishes 2 as the value that will be returned on the next invocation of the `IDENTITY_VAL_LOCAL` function.

```
INSERT INTO T1 (C2) VALUES (IDENTITY_VAL_LOCAL());
```

In the following `INSERT` statement, the `IDENTITY_VAL_LOCAL` function is again invoked to provide a value for the `C2` column, and the user provides a value of 11 for `C1`, the identity column. A value of 2 (the identity value assigned to the `C1` column of the second row) is assigned to the `C2` column. The assignment of 11 to `C1` establishes 11 as the value that will be returned on the next invocation of the `IDENTITY_VAL_LOCAL` function.

```
INSERT INTO T1 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 11);
```

After the 3 `INSERT` statements have been processed, table `T1` contains the following actions:

```
SELECT * FROM T1;
C1      C2
-----
```

| | |
|----|----|
| 1 | 25 |
| 2 | 1 |
| 11 | 2 |

The contents of T1 illustrate that the expressions in the VALUES clause are evaluated before the assignments for the columns of the INSERT statement. Thus, an invocation of an IDENTITY_VAL_LOCAL function invoked from a VALUES clause of an INSERT statement uses the most recently assigned value for an identity column in a previous INSERT statement.

IFNULL

The IFNULL function returns the first nonnull expression.

▶▶—IFNULL(*expression,expression*)—◀◀

The schema is SYSIBM.

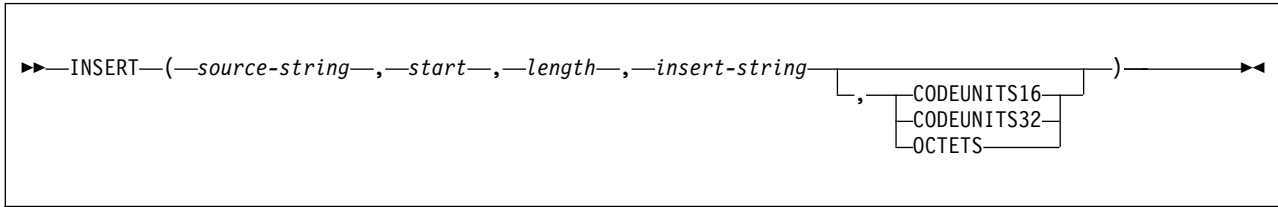

IFNULL is identical to the COALESCE scalar function except that IFNULL is limited to two arguments instead of multiple arguments. For a description, see “COALESCE” on page 384.

Example: For all the rows in sample table DSN8A10.EMP, select the employee number and salary. If the salary is missing (is null), have the value 0 returned.

```
SELECT EMPNO, IFNULL(SALARY,0)
FROM DSN8A10.EMP;
```

INSERT

The INSERT function returns a string where, beginning at *start* in *source-string*, *length* characters have been deleted and *insert-string* has been inserted.

The schema is SYSIBM.

The INSERT function returns a string where *length* characters have been deleted from *source-string*, beginning at *start*, and where *insert-string* has been inserted into *source-string*, beginning at *start*.

source-string

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. The actual length of the string must be greater than or equal to 1 and less than or equal to 32704 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start

An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of *source-string* plus one.

The argument can also be a character string or graphic string data type. The string argument is implicitly cast to a DECFLOAT(34) data type which is then assigned to an INTEGER.

length

An expression that specifies the length of the string to replace in *source-string* starting at *start*. *length* must be an expression that returns a value of the built-in INTEGER data type. *length* is expressed in the string unit specified, and the value must be in the range of 0 to the length of *source-string*. If OCTETS is specified and the result is graphic data, *length* must be even and be between 0 and twice the length of *source-string*. Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

The argument can also be a character string or graphic string data type. The string argument is implicitly cast to a DECFLOAT(34) data type which is then assigned to an INTEGER.

insert-string

An expression that specifies the string to be inserted into the source string,

starting at the position identified by *start*. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

source-string and *insert-string* must have compatible data types.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the units that are used to express *start* and *length*. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used:

- If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point.
- Otherwise, a string unit is a byte.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

If *source-string* and *insert-string* have different CCSID sets, *insert-string* (the string to be inserted) is converted to the CCSID of *source-string* (the source string).

The encoding scheme of the result is the same as *source-string*. The data type of the result of the function depends on the data type of *source-string* and *insert-string*:

- VARCHAR if *source-string* is a character string. The CCSID of the result depends on the arguments:
 - If either *source-string* or *insert-string* is character bit data, the result is bit data.
 - If *source-string* is SBCS Unicode data and *insert-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
 - If both *source-string* and *insert-string* are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
 - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string* and *insert-string* are both binary strings.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

$$L1 - \text{MIN}((L1 - V2 + 1), V3) + L4$$

where:

L1 is the length attribute of *source-string*

V2 is the value of *start*

V3 is the value of *length*

L4 is the length attribute of *insert-string*

- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*. In this case, the length attribute of *source-string* plus the length attribute of *insert-string* must not exceed 32704 for a VARCHAR result or 16352 for a VARCHARIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (*source-string* and *insert-string*), and the representation of that data in Unicode. See “Determining the length attribute of the final result” on page 90 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

$$A1 - \text{MIN}((A1 - V2 + 1), V3) + A4$$

where:

A1 is the actual length of *source-string*

V2 is the value of *start*

V3 is the value of *length*

A4 is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Example 1: The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```
SELECT CHAR(INSERT('INSERTING',4,2,'IS'),10),
       CHAR(INSERT('INSERTING',4,0,'IS'),10),
       CHAR(INSERT('INSERTING',4,2,''),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING '.

Example 2: The previous example demonstrated how to insert text into the middle of some text. This example shows how to insert text before some text by using 1 as the starting point (*start*).

```
SELECT CHAR(INSERT('INSERTING',1,0,'XX'),10),
       CHAR(INSERT('INSERTING',1,1,'XX'),10),
       CHAR(INSERT('INSERTING',1,2,'XX'),10),
       CHAR(INSERT('INSERTING',1,3,'XX'),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'XXINSERTIN', 'XXNSERTING', 'XXSERTING ', and 'XXERTING '.

Example 3: The following example shows how to insert text after some text. Add 'XX' at the end of string 'ABCABC'. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
SELECT CHAR(INSERT('ABCABC',7,0,'XX'),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'ABCABCXX '.

Example 4: The following example shows how the string 'Hegelstraße' can be changed to 'Hegelstrasse'.

```
SELECT VARCHAR(INSERT('Hegelstraße',10,1,'ss'),15)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'Hegelstrasse'.

INTEGER or INT

The INTEGER function returns an integer representation of either a number or a character string or graphic string representation of an integer.

Numeric to Integer:

String to Integer:

The schema is SYSIBM.

Numeric to Integer

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a large integer column or variable. If the whole part of the argument is not within the range of large integers, an error occurs. The fractional part of the argument is truncated.

String to Integer

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS INTEGER)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of large integers, an error is returned.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Recommendation: To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 254.

Example 1: Using sample table DSN8A10.EMP, find the average salary of the employees in department A00, rounding the result to the nearest dollar.

```
SELECT INTEGER(AVG(SALARY)+.5)
FROM DSN8A10.EMP
WHERE WORKDEPT = 'A00';
```

Example 2: Using sample table DSN8A10.EMP, select the EMPNO column, which is defined as CHAR(6), in integer form.

```
SELECT INTEGER(EMPNO)
FROM DSN8A10.EMP;
```

JULIAN_DAY

The JULIAN_DAY function returns an integer value that represents a number of days from January 1, 4713 B.C. (the start of the Julian date calendar) to the date that is specified in the argument.

►—JULIAN_DAY(*expression*)—◄

The schema is SYSIBM.

The argument must be an expression that returns one of the following data types: a date, a timestamp, or a valid string representation of a date or timestamp. An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.EMP, set the integer host variable JDAY to the Julian day of the day that Christine Haas (EMPNO = '000010') was employed (HIREDATE = '1965-01-01').

```
SELECT JULIAN_DAY(HIREDATE)
       INTO :JDAY
FROM DSN8A10.EMP
WHERE EMPNO = '000010';
```

The result is that JDAY is set to 2438762.

Example 2: Set integer host variable JDAY to the Julian day for January 1, 1998.

```
SELECT JULIAN_DAY('1998-01-01')
       INTO :JDAY
FROM SYSIBM.SYSDUMMY1;
```

The result is that JDAY is set to 2450815.

Example 3: The following invocations of the JULIAN_DAY function returns the same result:

```
SELECT JULIAN_DAY('2003-01-02-20.00.00'),
       JULIAN_DAY('2003-01-02-12.00.00-08:00'),
       JULIAN_DAY('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the JULIAN_DAY function in this SELECT statement, the result is 2452642.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.00.00.

LAST_DAY

The LAST_DAY scalar function returns a date that represents the last day of the month of the date argument.

►►—LAST_DAY(*expression*)—◄◄

The schema is SYSIBM.

expression

An expression that specifies the starting date. The expression must return a value of one of the following data types:

- a date
- a timestamp
- a valid string representation of a date or timestamp

An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is first cast to a TIMESTAMP WITHOUT TIME ZONE value with the same precision as *expression*.

The result of the function has the same data type as *expression*, unless *expression* is a string, in which case the result data type is DATE.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

The result can be null; if the argument is null, the result is the null value.

Any hours, minutes, seconds, or fractional seconds information that is included in *expression* is not changed by the function.

Example 1: Set the host variable *END_OF_MONTH* with the last day of the current month.

```
SET :END_OF_MONTH = LAST_DAY(CURRENT_DATE);
```

The host variable *END_OF_MONTH* is set with the value representing the end of the current month. If the current day is 2000-02-10, *END_OF_MONTH* is set to 2000-02-29.

Example 2: Set the host variable *END_OF_MONTH* with the last day of the month in EUR format for the given date.

```
SET :END_OF_MONTH = CHAR(LAST_DAY('1965-07-07'), EUR);
```

The host variable *END_OF_MONTH* is set with the value '31.07.1965'.

| *Example 3:* Assume that host variable *PRSTSZ* contains '2008-02-29.20.00.000000
| -08.30'. The `TIMESTAMP WITH TIME ZONE` value is implicitly cast to
| `TIMESTAMP WITHOUT TIME ZONE` before the `LAST_DAY` function is evaluated.

```
| SELECT LAST_DAY(:PRSTSZ)  
| FROM PROJECT;
```

| The `LAST_DAY` function returns the value '31' (month in UTC is March).

| *Example 4:* Assume *PRSTSZ* is a host variable with the string value
| '2008-04-15.20.00.000000-08.30'. The string value, which is a string representation of
| a timestamp with a time zone, is implicitly cast to a `DATE` before the `LAST_DAY`
| function is evaluated. The `LAST_DAY` function returns the last day of the month as
| a `DATE` value.

```
| SELECT LAST_DAY(:PRSTSZ)  
| FROM PROJECT;
```

| The `LAST_DAY` function returns the value '2008-04-30', the last day of the month
| of April, as a `DATE` value.

| *Example 5:* Assuming that the default date format is `ISO`, the following select
| statement returns '2000-04-30', which is the last day of April in 2000:

```
| SELECT LAST_DAY('2000-04-24')  
| FROM SYSIBM.SYSDUMMY1;
```

LCASE

The LCASE function returns a string in which all the characters are converted to lowercase characters.

The schema is SYSIBM.

The LCASE function is identical to the LOWER function. For more information, see “LOWER” on page 489.

LEFT

The LEFT function returns a string that consists of the specified number of leftmost bytes of the specified string units.

Character string:

Graphic string:

Binary string:

The schema is SYSIBM.

The LEFT function returns the leftmost string of *character-expression*, *graphic-expression*, or *binary-expression* consisting of length of the string units that are specified implicitly or explicitly.

Character string:

character-expression

An expression that specifies the string from which the result is derived. The string must be a character string. A substring of *character-expression* is zero or more contiguous code points of *character-expression*.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

length

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *character-expression*, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *length*. If *character-expression* is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16

Specifies that *length* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *length* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *length* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

Graphic string:

graphic-expression

An expression that specifies the string from which the result is derived. The string must be a graphic string. A substring of *graphic-expression* is zero or more contiguous code points of *graphic-expression*. A partial surrogate character in the expression is replaced with a blank.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

length

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *graphic-expression*, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *length*.

CODEUNITS16

Specifies that *length* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *length* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

Binary string:

binary-expression

An expression that specifies the string from which the result is derived. The string must be a binary string. A substring of *binary-expression* is zero or more contiguous code points of *binary-expression*.

length

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *binary-expression*, expressed in the units that are either implicitly or explicitly specified.

The *character-expression*, *graphic-expression*, or *binary-expression* is effectively padded on the right with the necessary number of padding characters so that the specified substring of the expression always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.
- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 (Unicode mixed data), the padding character is X'20'.
- For UTF-16 (Unicode DBCS) data, the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of the first expression and a data type that depends on the data type of the expression:

- VARCHAR if *character-expression* is CHAR or VARCHAR
- CLOB if *character-expression* is CLOB
- VARGRAPHIC if *graphic-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *graphic-expression* is DBCLOB
- VARBINARY if *binary-expression* is BINARY or VARBINARY
- BLOB if *binary-expression* is BLOB

The actual length of the result is determined from *length*.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of the first expression.

Example 1: Assume that host variable *ALPHA* has a value of 'ABCDEF'. The following statement returns 'ABC', which are the three leftmost characters in *ALPHA*:

```
SELECT LEFT(:ALPHA,3)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: Assume that host variable *NAME*, which is defined as VARCHAR(50), has a value of 'KATIE AUSTIN' and the integer host variable *FIRSTNAME_LEN* has a value of 5. The following statement returns the value 'KATIE':

```
SELECT LEFT(:NAME, :FIRSTNAME_LEN)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following statement returns a zero length string.

```
SELECT LEFT('ABCABC',0)
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The FIRSTNAME column in sample EMP table is defined as VARCHAR(12). Find the first name for an employee whose last name is 'BROWN' and return the first name in a 10-byte string.

```
SELECT LEFT(FIRSTNAME,10)
FROM DSN8A10.EMP
WHERE LASTNAME='BROWN';
```

This function returns a VARCHAR(10) string that has the value of 'DAVID' followed by 5 blank characters.

Example 5: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

| Function ... | Returns ... |
|-------------------------------|------------------------------------|
| LEFT(FIRSTNAME,2,CODEUNITS32) | 'Jü' -- x'4AC3BC' |
| LEFT(FIRSTNAME,2,CODEUNITS16) | 'Jü' -- x'4AC3BC' |
| LEFT(FIRSTNAME,2,OCTETS) | 'J ' -- x'4A20' a truncated string |

LENGTH

The LENGTH function returns the length of a value.

►—LENGTH(*expression*)—◄

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in data type that is not XML.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of the argument. The length does not include the null indicator byte of column arguments that allow null values. The length of strings includes blanks. The length of a varying-length string is the actual length, not the maximum length.

The length of a graphic string is the number of double-byte characters. Unicode UTF-16 data is treated as graphic data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The length of all other values is the number of bytes used to represent the value:

- 2 for small integer
- 4 for large integer
- 8 for big integer
- The integer part of $(p/2)+1$ for decimal numbers with precision p
- 16 for DECFLOAT(34)
- 8 for DECFLOAT(16)
- 4 for single precision floating-point
- 8 for double precision floating-point
- The length of the string for strings
- 4 for DATE
- 3 for TIME
- 10 for TIMESTAMP
- 12 for TIMESTAMP WITH TIME ZONE
- $7+((p+1)/2)$ for TIMESTAMP(p)
- $9+((p+1)/2)$ for TIMESTAMP(p) WITH TIME ZONE
- The length of the row ID

Example 1: Assume that FIRSTNAME is a VARCHAR(12) column that contains 'ETHEL' for employee 280. The following query returns the value 5:

```
SELECT LENGTH(FIRSTNAME)
FROM DSN8A10.EMP
WHERE EMPNO = '000280';
```

Example 2: Assume that HIREDATE is a column of data type DATE. Then, regardless of value the following statement returns the value 4:

```
LENGTH(HIREDATE)
```

And the following function returns the value 10:

```
LENGTH(CHAR(HIREDATE, EUR))
```

LN

The LN function returns the natural logarithm of the argument. The LN and EXP functions are inverse operations.

►►—LN(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

LOG is a synonym for LN.

Example: Assume that host variable NATLOG is DECIMAL(4,2) with a value of 31.62. The following statement returns a double precision floating-point number with an approximate value of 3.45:

```
SELECT LN(:NATLOG)
FROM SYSIBM.SYSDUMMY1;
```

LOCATE

The LOCATE function returns the position at which the first occurrence of an argument starts within another argument.

The schema is SYSIBM.

The LOCATE function returns the starting position of *search-string* within *source-string*. If *search-string* is not found and neither argument is null, the result is zero. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*. If *search-string* has a length of zero, the result returned by the function is 1. If the optional *start* is specified, it indicates the character position in *source-string* at which the search is to begin. An optional string unit can be specified to indicate in what units the start and result of the function are expressed.

search-string

An expression that specifies the string that is to be searched for. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)

- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

start

An expression that specifies the position within *search-string* where the search is to start.

start is expressed in the specified string unit and must return an integer value that is greater than or equal to zero.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If *start* is specified, the LOCATE function is similar to the following POSITION function, where *string-units* is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string,
        SUBSTRING(source-string, start, string-units)) + start - 1
```

If *start* is not specified, the search begins at the first position of *source-string* and the LOCATE function is similar to the following POSITION function, where *string-units* is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string, source-string, string-units)
```

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express *start* and the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *start* and the result are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and the result are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, *start* and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for comparisons” on page 137.

The result of the function is a large integer.

The result can be null; if any argument is null, the result is the null value.

For more information about LOCATE, see the description of “POSITION” on page 536.

Example 1: Find the location of the first occurrence of the character 'N' in the string 'DINING'.

```
SELECT LOCATE('N', 'DINING')
FROM SYSIBM.SYSDUMMY1;
```

The result is the value 3.

Example 2: For all the rows in the table named IN_TRAY, select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD' within the NOTE_TEXT column.

```
SELECT RECEIVED, SUBJECT, LOCATE('GOOD', NOTE_TEXT)
FROM IN_TRAY
WHERE LOCATE('GOOD', NOTE_TEXT) <> 0;
```

Example 3: Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS32);
```

The value of host variable LOCATION is set to 26.

Example 4: Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS16 units, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS16);
```

The value of host variable LOCATION is set to 26.

Example 5: Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,OCTETS);
```

The value of host variable LOCATION is set to 27.

“POSSTR” on page 539

LOCATE_IN_STRING

The LOCATE_IN_STRING function returns the position at which an argument starts within a specified string.

The schema is SYSIBM.

The LOCATE_IN_STRING function returns the starting position of a string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*.

If the optional *start* is specified, an optional instance number can also be specified. The instance argument is used to determine the specific occurrence of *search-string* within *source-string*. Each unique instance can include any of the characters in a previous instance, but not all characters in a previous instance. An optional string unit can be specified to indicate in what units the *start* and result of the function are expressed.

If the *search-string* has a length of zero, the result returned by the function is 1. If the *source-string* has a length of zero, the result returned by the function is 0. If neither condition exists, and if the value of *search-string* is equal to an identical length of a substring of contiguous positions within the value of *source-string*, the result returned by the function is the starting position of that substring within the *source-string* value; otherwise, the result returned by the function is 0.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

search-string

An expression that specifies the string that is the object of the search. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value that is a built-in INTEGER or SMALLINT data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If the value of the integer is greater than zero, the search begins at *start* and continues for each position to the end of the string. If the value of the integer is less than zero, the search begins at the $\text{LENGTH}(\text{source-string}) + \text{start} + 1$ and continues for each position to the beginning of the string.

If *start* is not specified, the default is 1. If the value of the integer is zero, an error is returned.

instance

An expression that specifies which instance of *search-string* to search for within *source-string*. The expression must return a value that is a built-in INTEGER or SMALLINT data type. If *instance* is not specified, the default is 1. The value of the integer must be greater than or equal to one.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express *start* and the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *start* and the result are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and the result are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, *start* and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for comparisons” on page 137.

| At each search position, a match is found when the substring at that position and
| LENGTH(*search-string*) - 1 values to the right of the search position in *source-string*,
| is equal to *search-string*.

The result of the function is a large integer. The result is the starting position of the instance of *search-string* within *source-string*. The value is relative to the beginning of the string (regardless of the specification of *start*).

The result can be null; if any argument is null, the result is the null value.

INSTR can be used as a synonym for LOCATE_IN_STRING.

Example 1: Find the position of an occurrence of the character 'N' in the string 'WINNING' by searching from the start of the string as measured in bytes, within the string.

```
SELECT LOCATE_IN_STRING('WINNING','N',1,3,OCTETS),  
       LOCATE_IN_STRING('WINNING','N',3,2,OCTETS),  
       LOCATE_IN_STRING('WINNING','N',3,3,OCTETS),  
       LOCATE_IN_STRING('WINNING','N',-1,3,OCTETS),  
       LOCATE_IN_STRING('WINNING','N',-3,2,OCTETS),  
       LOCATE_IN_STRING('WINNING','N',-3,3,OCTETS)  
FROM SYSIBM.SYSDUMMY1;
```

Returns the values:

```
6 4 6 3 3 0
```

“LOCATE” on page 482

“POSITION” on page 536

“POSSTR” on page 539

LOG10

The LOG10 function returns the common logarithm (base 10) of a number.

►►—LOG10(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument is an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HLOG is an INTEGER with a value of 100. The following statement returns a double precision floating-point number with an approximate value of 2:

```
SELECT LOG10(:HLOG)
FROM SYSIBM.SYSDUMMY1;
```

LOWER

The LOWER function returns a string in which all the characters are converted to lowercase characters.

```
▶▶—LOWER(string-expression [ ,—locale-name-string ] [ ,—integer ] )—▶▶
```

The schema is SYSIBM.

string-expression

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB. If *string-expression* is an EBCDIC graphic string, a blank string must not be specified for *locale-name-string*. If *string-expression* is bit data, *locale-name-string* must not be specified.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

locale-name-string

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name-string* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name-string* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name-string* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see *z/OS C/C++ Programming Guide*. Some examples of locales include:

```
Fr_BE
Fr_FR@EURO
En_US
Ja_JP
```

The conversion process is determined by the value that is specified for the locale name, as follows:

- blank — SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z. For optimal performance, specify a blank string unless your data must be processed by using the rules that are defined by a specific locale.
- UNI — The conversion uses both the NORMAL and SPECIAL casing capabilities as described in *Select the conversions (z/OS: Unicode Services User's Guide and Reference)*. You must not specify UNI when *string-expression* is EBCDIC data.
- locale name — The locale defines the rules for conversion to lowercase characters.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

- left justified within the host variable

- padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length character or graphic data type

If *locale-name-string* is not specified, the locale is determined by special register CURRENT LOCALE LC_CTYPE. For information about the special register, see “CURRENT LOCALE LC_CTYPE” on page 174. However, if an index references the LOWER function, the local is determined as follows (in order) to determine if the index can be used:

- At prepare time — using the value in the CURRENT LOCALE LC_CTYPE special register
- At bind time — using the value in the LOCALE LC_CTYPE field on installation panel DSNTIPF

If the index is chosen in the access path, the locale in the CURRENT LOCALE LC_CTYPE special register must remain the same at run time, and prepare or bind time. To avoid this dependency, do not omit *locale-name-string*.

If the LOWER function is referenced in an expression-based index, *locale-name-string* must be specified. See the examples section for an example of how the index can be used in a query.

integer

An integer value that specifies the length attribute of the result. If specified, *integer* must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of *string-expression*.

If *integer* is not specified, the length attribute of the result is the same as the length of *string-expression*.

For Unicode data, usage of the LOWER function can result in expansion if certain characters are processed. For example, LOWER('İ') —UX'00CC'— will result in UX'006903070300' (if the LT_LT locale is in effect at the time). You should ensure that the result length is large enough to contain the result of the expression.

The result can be null; if the argument is null, the result is the null value.

LCASE is a synonym for LOWER.

Example 1: Return the characters in the value of host variable NAME in lowercase. NAME has a data type of VARCHAR(30) and a value of 'Christine Smith'. Assume that the locale in effect is blank.

```
SELECT LCASE(:NAME)
FROM SYSIBM.SYSDUMMY1;
```

The result is the value 'christine smith'.

Example 2: Return the lowercase of 'İ'. Assume that the locale in effect is LT_LT.

```
SELECT LOWER('İ')
FROM SYSIBM.SYSDUMMYU;
```

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

```
SELECT LOWER(VARCHAR('İ', 3))
FROM SYSIBM.SYSDUMMYU;
```

The result of the preceding statement is the value UX'006903070300'.

Example 3: Create an index EMPLOYEE_NAME_LOWER for table EMPLOYEE based on built-in function LOWER with locale name 'LT_LT'.

```
CREATE INDEX EMPLOYEE_NAME_LOWER
ON EMPLOYEE (LOWER(LASTNAME, 'LT_LT', 60),
             LOWER(FIRSTNAME, 'LT_LT', 60),
             ID);
```

Example 4: Create an index LNAME for table T1 based on the LOWER function with the default local value, ''. Then specify the same expression in a query.

```
CREATE INDEX LNAME
ON T1 (LOWER(LASTNAME, ''));

SELECT LOWER(LASTNAME, '')
FROM T1
WHERE LOWER(LASTNAME, '') = 'smith';
```

Example 5: Create an index LNAME that is based on the LOWER function with a locale name 'FR_CA' for the table T1. Then specify the same expression in a query except *locale-name-string* is omitted.

```
CREATE INDEX LNAME
ON T1 (LOWER(LASTNAME, 'FR_CA'));
```

If the query is a dynamic statement and the CURRENT LOCALE LC_CTYPE special register contains 'FR_CA':

```
SELECT LASTNAME
FROM T1
WHERE LOWER(LASTNAME)='smith';
```

At prepare time, locale 'FR_CA' in CURRENT LOCALE LC_CTYPE is used for LOWER(LASTNAME) in the predicate to determine whether index LNAME can be used for index access. If index LNAME is used in access path selection, at run time, the locale in CURRENT LOCALE LC_CTYPE must remain the same.

If the query is a static statement and locale 'FR_CA' has been set on the LOCALE LC_CTYPE field of installation panel DSNTIPF:

```
SELECT LASTNAME
FROM T1
WHERE LOWER(LASTNAME)='smith';
```

At bind time, local 'FR_CA' in the LOCALE LC_CTYPE file of installation panel DSNTIPF is used for LOWER(LASTNAME) in the predicate to determine whether index LNAME is used for index access. If index LNAME is chosen in access path selection, the locale in the CURRENT LOCALE LC_CTYPE special register must contain 'FR_CA'.

 [z/OS XL C/C++ Programming Guide](#)

LPAD

The LPAD function returns a string that is composed of *string-expression* that is padded on the left, with *pad* or blanks. The LPAD function treats leading or trailing blanks in *string-expression* as significant.

A diagram showing the LPAD function syntax: LPAD(string-expression, integer [, pad]). The function name and arguments are enclosed in a box with arrows pointing outwards. A bracket underlines the optional 'pad' argument.

Padding occurs only if the actual length of *string-expression* is less than *integer*, and if *pad* is not an empty string.

The schema is SYSIBM.

string-expression

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

integer

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is 32704 if *string-expression* is a character or binary string, or where *n* is 16352 if *string-expression* is a graphic string.

pad

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- DBCS blank character if *string-expression* is a graphic string.
- Hexadecimal zero (X'00'), if *string-expression* is a binary string.

The result of the function is a varying length string that has the same CCSID of *string-expression*. *string-expression* and *pad* must have compatible data types. If the string expressions have different CCSID sets, then *pad* is converted to the CCSID set of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA, no character conversion occurs.

The length attribute of the result depends on *integer*. If *integer* is greater than 0, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1.

The actual length of the result is determined from *integer*. If *integer* is 0, the actual length is 0, and the result is the empty result string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

The result can be null; if any argument is null, the result is the null value.

Example 1: Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will pad a value on the left with periods.

```
SELECT LPAD(NAME,15,'.' ) AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
.....Chris
.....Meg
.....Jeff
```

Example 2: Similar to Example 1, the following query will only pad each value to a length of 5:

```
SELECT LPAD(NAME,5,'.' ) AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
Chris
.Meg
.Jeff
```

Example 3: Assume that NAME is a CHAR(15) column containing the values 'Chris', 'Meg', and 'Jeff'. Note that the LPAD function does not pad because NAME is a fixed length character field and is blank padded already. However, since the length of the result is 5, the columns are truncated:

```
SELECT LPAD(NAME,5,'.' ) AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
Chris
Meg
Jeff
```

Example 4: Assume that NAME is a VARCHAR(15) column containing the values 'Chris', 'Meg', and 'Jeff'. Note that in some cases, a partial instance of the pad specification is returned.

```
SELECT LPAD(NAME,15,'123') AS NAME
FROM T1
```

The results are similar to the following output:

```
NAME
-----
1231231231Chris
123123123123Meg
12312312312Jeff
```

LTRIM

The LTRIM function removes bytes from the beginning of a string expression based on the content of a trim expression.

The diagram shows the function signature: LTRIM(—string-expression— [, —trim-expression—]). The arguments are enclosed in a box with arrows pointing outwards.

The schema is SYSIBM.

The LTRIM function removes all of the characters that are contained in *trim-expression* from the beginning of *string-expression*. The search is done by comparing the binary representation of each character (which consists of one or more bytes) in *trim-expression* to the bytes at the beginning of *string-expression*. If the *string-expression* is defined as FOR BIT DATA, the search is done by comparing each byte in *trim-expression* to the byte at the beginning of *string-expression*.

string-expression

An expression that specifies the source string. The argument must be an expression that returns a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated. If *string-expression* is not FOR BIT DATA, *trim-expression* must not be FOR BIT DATA.

trim-expression

An expression that specifies the characters to remove from the beginning of *string-expression*. The expression must return a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated.

The default for *trim-expression* depends on the data type of *string-expression*:

- A DBCS blank if *string-expression* is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if *string-expression* is a Unicode graphic string.
- A value of X'00' if *string-expression* is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. If not EBCDIC, X'20' represents a blank.

string-expression and *trim-expression* must have compatible data types. If *string-expression* and *trim-expression* have different CCSID sets, *trim-expression* is converted to the CCSID of *string-expression*.

The result of the function depends on the data type of *string-expression*:

- VARCHAR if *string-expression* is a character string. If *string-expression* is defined as FOR BIT DATA the result is FOR BIT DATA.
- VARGRAPHIC if *string-expression* is a graphic string.

- VARBINARY if *string-expression* is a binary string.

The length attribute of the result is the same as the length attribute of *string-expression*.

The actual length of the result for a character or binary string is the length of *string-expression* minus the number of bytes that are removed. The actual length of the result for a graphic string is the length (in the number of double byte characters) of *string-expression* minus the number of double byte characters removed. If all of the characters bytes are removed, the result is an empty string (the length is zero).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Example: Use the LTRIM function to remove individual numbers in the second argument from the beginning (left side) of the first argument:

```
SELECT LTRIM ('123DEFG123', '321'),
       LTRIM ('12DEFG123', '321'),
       LTRIM ('123123222XYZ22', '123'),
       LTRIM ('12321', '213'),
       LTRIM ('XYX123 ', '321')
FROM SYSIBM.SYSDUMMY1
```

The result is 'DEFG123', 'DEFG123', 'XYZ22', '' (an empty string - all characters removed), and 'XYX123' (no characters removed).

The LTRIM function does not remove instances of '1', '2', and '3' on the right side of the string, following characters that are not '1', '2', or '3'.

Example: Use the LTRIM function to remove individual special characters in the second argument from the beginning (left side) of the first argument:

```
SELECT LTRIM ('[[ -78]]', '- []')
FROM SYSIBM.SYSDUMMY1
```

The result is '78]]'.

Example: Use the LTRIM function to remove dollar signs and periods in the second argument from the beginning (left side) of the first argument:

```
SELECT LTRIM ('...$V..$AR', '$.')
```

The result is 'V..\$AR'.

Example: Use the LTRIM function to trim full multi-byte X'D090' characters:

Assume that these strings are encoded in UTF-8.

```
SELECT LTRIM (X'D090D091D092', X'D090')
```

The result is X'D091D092'.

Note that the function does not remove individual bytes x'D0' and x'90'.

MAX

The MAX scalar function returns the maximum value in a set of values.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 23 on page 119. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML.

Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

The arguments are evaluated in the order in which they are specified. The result of the function is the maximum argument value.

The result can be null; if any argument is null, the result is the null value.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 143. If the MAX function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

GREATEST can be specified as a synonym for MAX.

Example 1: Assume the host variable *M1* is a DECIMAL(2,1) host variable with a value of 5.5, host variable *M2* is a DECIMAL(3,1) host variable with a value of 4.5, and host variable *M3* is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 6.25.

```
MAX(:M1, :M2, :M3)
```

Example 2: Assume the host variable *M1* is a CHAR(2) host variable with a value of 'AA', host variable *M2* is a CHAR(3) host variable with a value of 'AA ', and host variable *M3* is a CHAR(4) host variable with a value of 'AA A'. The following function returns the value 'AA A'.

```
MAX(:M1, :M2, :M3)
```

MICROSECOND

The MICROSECOND function returns the microsecond part of a value.

►—MICROSECOND(*expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a timestamp duration. For the valid formats of timestamp durations, see “Datetime operands” on page 145.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a timestamp or string representation of a timestamp, the result is the microsecond part of the value, which is an integer between 0 and 999999. If the precision of the timestamp exceeds 6, the value is truncated.

If the argument is a duration, the result is the microsecond part of the value, which is an integer between -999999 and 999999. A nonzero result has the same sign as the argument.

Example 1: Assume that table TABLEX contains a TIMESTAMP column named TSTMPCOL and a SMALLINT column named INTCOL. Select the microseconds part of the TSTMPCOL column of the rows where the INTCOL value is 1234:

```
SELECT MICROSECOND(TSTMPCOL) FROM TABLEX
WHERE INTCOL = 1234;
```

Example 2: The following invocations of the MICROSECOND function returns the same result:

```
SELECT MICROSECOND('2003-01-02-20.00.00.123456'),
       MICROSECOND('2003-01-02-12.00.00.123456-08:00'),
       MICROSECOND('2003-01-03-05.00.00.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MICROSECOND function in this SELECT statement, the result is 123456.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.00.00.123456.

MIDNIGHT_SECONDS

The MIDNIGHT_SECONDS function returns an integer, in the range of 0 to 86400, that represents the number of seconds between midnight and the time that is specified in the argument.

►—MIDNIGHT_SECONDS(*expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Find the number of seconds between midnight and 00:01:00, and midnight and 13:10:10. Assume that host variable *XTIME1* has a value of '00:01:00', and that *XTIME2* has a value of '13:10:10'.

```
SELECT MIDNIGHT_SECONDS(:XTIME1), MIDNIGHT_SECONDS(:XTIME2)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 60 and 47410. Because there are 60 seconds in a minute and 3600 seconds in an hour, 00:01:00 is 60 seconds after midnight ((60 * 1) + 0), and 13:10:10 is 47410 seconds ((3600 * 13) + (60 * 10) + 10).

Example 2: Find the number of seconds between midnight and 24:00:00, and midnight and 00:00:00.

```
SELECT MIDNIGHT_SECONDS('24:00:00'), MIDNIGHT_SECONDS('00:00:00')
FROM SYSIBM.SYSDUMMY1;
```

This example returns 86400 and 0. Although these two values represent the same point in time, different values are returned.

Example 3: The following invocations of the MIDNIGHT_SECONDS function returns the same result:

```
SELECT MIDNIGHT_SECONDS('2003-01-02-20.10.05.123456'),
MIDNIGHT_SECONDS('2003-01-02-12.10.05.123456-08:00'),
MIDNIGHT_SECONDS('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the MIDNIGHT_SECONDS function in this SELECT
| statement, the result is 72605.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.10.05.123456.

MIN

The MIN scalar function returns the minimum value in a set of values.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 23 on page 119. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML.

| Character string arguments and binary string arguments cannot have a length
| attribute greater than 32704, and graphic string arguments cannot have a length
| attribute greater than 16352.

The arguments are evaluated in the order in which they are specified. The result of the function is the minimum argument value.

The result can be null; if any argument is null, the result is the null value.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the “Rules for result data types” on page 143. If the MIN function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

LEAST can be specified as a synonym for MIN.

Example 1: Assume the host variable *M1* is a DECIMAL(2,1) host variable with a value of 5.5, host variable *M2* is a DECIMAL(3,1) host variable with a value of 4.5, and host variable *M3* is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 4.5.

```
MIN(:M1, :M2, :M3)
```

Example 2: Assume the host variable *M1* is a CHAR(2) host variable with a value of 'AA', host variable *M2* is a CHAR(3) host variable with a value of 'AAA', and host variable *M3* is a CHAR(4) host variable with a value of 'AAAA'. The following function returns the value 'AA'.

```
MIN(:M1, :M2, :M3)
```

MINUTE

The MINUTE function returns the minute part of a value.

►►—MINUTE(*expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 145.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of either, the result is the minute part of the value, which is an integer between 0 and 59.

If the argument is a time duration or timestamp duration, the result is the minute part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start on the hour.

```
SELECT * FROM CLASSES
WHERE MINUTE(STARTTM) = 0;
```

Example 2: The following invocations of the MINUTE function returns the same result:

```
SELECT MINUTE('2003-01-02-20.10.05.123456'),
MINUTE('2003-01-02-12.10.05.123456-08:00'),
MINUTE('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the MINUTE function in this SELECT statement, the result
| is 2.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.10.05.123456. The minute portion of the UTC representation is 10.

MOD

The MOD function divides the first argument by the second argument and returns the remainder.

►►—MOD(*numeric-expression-1*,*numeric-expression-2*)—◄◄

The schema is SYSIBM.

The formula used to calculate the remainder is:

$$\text{MOD}(x,y) = x - \text{FLOOR}(x/y) * y$$

Where x/y is the truncated integer result of the division. The result is negative only if the first argument is negative.

Each argument must be an expression that returns a value of any built-in numeric data type.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

The attributes of the result are based on the arguments as follows:

- If both arguments are large or small integers, the data type of the result is large integer.
- If both arguments are integers and at least one argument is a big integer, the data type of the result is big integer.
- If one argument is an integer and the other is a decimal, the data type of the result is decimal with the same precision and scale as the decimal argument.
- If both arguments are decimal, the data type of the result is decimal. The precision of the result is $\min(p-s, p'-s') + \max(s, s')$, and the scale of the result is $\max(s, s')$, where the symbols p and s denote the precision and scale of the first argument, and the symbols p' and s' denote the precision and scale of the second argument.
- If one argument is a floating-point number, and the other is not a DECFLOAT, or both argument is a floating-point number, the data type of the result is double precision floating-point.

The operation is performed in floating-point. If necessary, the operands are first converted to double precision floating-point numbers. For example, an operation that involves a floating-point number and either an integer or a decimal number is performed with a temporary copy of the integer or decimal number that has been converted to double precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34).

If either argument is a special decimal floating point value, the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 235 for more information.

If one argument is a DECFLOAT and the second argument is zero, the result is NaN and an invalid operation condition is returned.

Example: Assume that *M1* and *M2* are two host variables. Find the remainder of dividing *M1* by *M2*.

```
SELECT MOD(:M1,:M2)
FROM SYSIBM.SYSDUMMY1;
```

The following table shows the result for this function for various values of *M1* and *M2*.

| <i>M1</i> data type | <i>M1</i> value | <i>M2</i> data type | <i>M2</i> value | Result of MOD(:M1,:M2) |
|---------------------|-----------------|---------------------|-----------------|---------------------------|
| INTEGER | 5 | INTEGER | 2 | 1 |
| INTEGER | 5 | DECIMAL(3,1) | 2.2 | 0.6 |
| INTEGER | 5 | DECIMAL(3,2) | 2.20 | 0.60 |
| DECIMAL(4,2) | 5.50 | DECIMAL(4,1) | 2.0 | 1.50 |
| DECFLOAT | 1 | DECFLOAT | -INFINITY | 1 |
| DECFLOAT | -0 | DECFLOAT | INFINITY | -0 |
| DECFLOAT | -0 | DECFLOAT | -INFINITY | -0 |

MONTH

The MONTH function returns the month part of a value.

►►—MONTH(*expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see “Datetime operands” on page 145.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a date, timestamp, or string representation of either, the result is the month part of the value, which is an integer between 1 and 12.

If the argument is a date duration or timestamp duration, the result is the month part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: Select all rows in the sample table DSN8A10.EMP for employees who were born in May:

```
SELECT * FROM DSN8A10.EMP
WHERE MONTH(BIRTHDATE) = 5;
```

Example 2: The following invocations of the MONTH function returns the same result:

```
SELECT MONTH('2003-01-02-20.10.05.123456'),
       MONTH('2003-01-02-12.10.05.123456-08:00'),
       MONTH('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MONTH function in this SELECT statement, the result is 1.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.10.05.123456. The month portion of the UTC representation is 1.

MONTHS_BETWEEN

The MONTHS_BETWEEN function returns an estimate of the number of months between two arguments.

```
▶▶—MONTHS_BETWEEN(expression1,expression2)————▶▶
```

The schema is SYSIBM.

expression1 or *expression2*

Expressions that return a value of any of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If either expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression1* is a `TIMESTAMP WITH TIME ZONE` value, *expression1* is first cast to `TIMESTAMP WITHOUT TIME ZONE` with the same precision as *expression1*. If *expression2* is a `TIMESTAMP WITH TIME ZONE` value, *expression2* is first cast to `TIMESTAMP WITHOUT TIME ZONE` with the same precision as *expression2*.

If *expression1* represents a date that is later than *expression2*, the result is positive. If *expression1* represents a date that is earlier than *expression2*, the result is negative.

- If *expression1* and *expression2* represent dates or timestamps with the same day of the month, or both arguments represent the last day of their respective months, the result is a the whole number difference based on the year and month values, ignoring any time portions of timestamp arguments.
- Otherwise, the whole number part of the result is the difference based on the year and month values. The fractional part of the result is calculated from the remainder based on an assumption that every month has 31 days. If either argument represents a timestamp, the arguments are effectively processed as timestamps with maximum precision, and the time portions of these values are also considered when determining the result.

The result of the function is a `DECIMAL(31,15)`.

The result can be null; if any argument is null, the result is the null value.

Examples 1: The following example calculates the months between two dates:

```
SELECT MONTHS_BETWEEN ('2008-01-17', '2008-02-17')
       AS MONTHS_BETWEEN
FROM SYSIBM.SYSDUMMY1;
```

The results of this statement are similar to the following results:

```
MONTHS_BETWEEN
-----
-1.000000000000000
```

Examples 2: The following example calculates the months between two dates:

```
SELECT MONTHS_BETWEEN ('2008-02-20', '2008-01-17')
       AS MONTHS_BETWEEN
FROM SYSIBM.SYSDUMMY1;
```

The results of this statement are similar to the following results:

```
MONTHS_BETWEEN
-----
1.096774193548387
```

Example 3: Calculate the number of months that project AD3100 will take. Assume that the start date is 1982-01-01 and the end date is 1983-02-01:

```
SELECT MONTHS_BETWEEN (PRENDATE, PRSDATE)
       FROM PROJECT
       WHERE PROJNO='AD3100';
```

The result is 13.000000000000000.

Example 4: The following table illustrates the use of the MONTHS_BETWEEN function in certain situations:

Table 69. Additional examples using MONTHS_BETWEEN

| Value for <i>expression1</i> | Value for <i>expression2</i> | Value returned by MONTHS_BETWEEN (<i>expression1,expression2</i>) | Value returned by ROUND (MONTHS_BETWEEN (<i>expression1,expression2</i>)*31,2) |
|------------------------------|------------------------------|---|--|
| 2005-02-02 | 2005-01-01 | 1.032258064516129 | 32.00 |
| 2007-11-01-09.00.00.00000 | 2007-12-07-14.30.12.12345 | -1.200945386592741 | -37.23 |
| 2007-12-13-09.40.30.00000 | 2007-11-13-08.40.30.00000 | 1.000000000000000 ¹ | 31.00 ¹ |
| 2007-03-15 | 2007-02-20 | 0.838709677419354 ² | 26.00 ² |
| 2008-02-29 | 2008-02-28-12.00.00 | 0.016129032258064 | 0.50 |
| 2008-03-29 | 2008-02-29 | 1.000000000000000 | 31.00 |
| 2008-03-30 | 2008-02-29 | 1.032258064516129 | 32.00 |
| 2008-03-31 | 2008-02-29 | 1.000000000000000 ³ | 31.00 ³ |

Notes:

1. The time difference is ignored because the day of the month is the same for both values.
2. The result is not 23 because, even though February has 28 days, the assumption is that all months have 31 days.
3. The result is not 33 because both dates are the last day of their respective month, and so the result is only based on the year and month portions.

MQREAD

The MQREAD function returns a message from a specified MQSeries location without removing the message from the queue.

The schema is DB2MQ.

The MQREAD function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

The result of the function is a varying-length string with a length attribute of 4000. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Retrieve the message at the beginning of the queue that is specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREAD()  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by the default server and using the default policy is returned as VARCHAR(4000).

| *Example 2:* Read the message from the beginning of the queue specified by the
| service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
| SELECT MQREAD('MYSERVICE')  
| FROM SYSIBM.SYSDUMMY1;
```

| The message at the beginning of the queue specified by MYSERVICE and using
| DB2.DEFAULT.POLICY is returned as VARCHAR(4000).

| *Example 3:* Read the message from the beginning of the queue specified by the
| service MYSERVICE, using the policy MYPOLICY.

```
| SELECT MQREAD('MYSERVICE', 'MYPOLICY')  
| FROM SYSIBM.SYSDUMMY1;
```

| The message at the beginning of the queue specified by MYSERVICE and using the
| policy MYPOLICY is returned as VARCHAR(4000).

MQREADCLOB

The MQREADCLOB function returns a message from a specified MQSeries location without removing the message from the queue.

The schema is DB2MQ.

The MQREADCLOB function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Read the message from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADCLOB()  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as a CLOB.

Example 2: Read the message from the beginning of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADCLOB('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the default policy is returned as a CLOB.

Example 3: Read the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY:

```
SELECT MQREADCLOB('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the policy MYPOLICY is returned as a CLOB.

MQRECEIVE

The MQRECEIVE function returns a message from a specified MQSeries location and removes the message from the queue.

The schema is DB2MQ.

The MQRECEIVE function returns a message from the MQSeries location specified by *receive-service*, using the quality-of-service policy defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a varying-length string of length attribute of 4000. The result can be null. The result is null if no messages are available to return.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Retrieve the message from beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVE()  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by the default service and using the default policy.

Example 2: Retrieve the first message from the beginning of the queue specified by the service MYSERVICE, using the default policy, DB2.DEFAULT.POLICY.

```
SELECT MQRECEIVE('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by the service MYSERVICE using the default policy, DB2.DEFAULT.POLICY.

Example 3: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVE('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and the message is deleted from the queue. The queue is specified by the service MYSERVICE using the policy MYPOLICY.

Example 4: Retrieve the first message with a correlation identifier that matches '1234' from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVE('MYSERVICE', 'MYPOLICY', '1234')  
FROM SYSIBM.SYSDUMMY1;
```

The first message with CORRELID of '1234' from the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by MYSERVICE and using MYPOLICY.

MQRECEIVECLOB

The MQRECEIVECLOB function returns a message from a specified MQSeries location and removes the message from the queue.

The schema is DB2MQ.

The MQRECEIVECLOB function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Retrieve the message from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRERECEIVECLOB()  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by the default service and using the default policy.

Example 2: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVECLOB('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the default policy.

Example 3: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVECLOB('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the policy MYPOLICY.

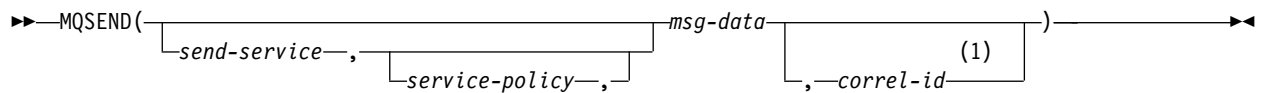

Example 4: Retrieve the first message from the beginning of the queue with a correlation identifier that matches '1234' from the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVECLOB('MYSERVICE', 'MYPOLICY', '1234')  
FROM SYSIBM.SYSDUMMY1;
```

The first message at the beginning of the queue with a correlation identifier with '1234' is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the policy MYPOLICY.

MQSEND

The MQSEND function sends data to a specified MQSeries location, and returns a varying-length character string that indicates whether the function was successful or unsuccessful.

The diagram shows the function signature: MQSEND(send-service, service-policy, msg-data, correl-id(1)). Brackets indicate that 'send-service' and 'service-policy' are optional arguments, while 'msg-data' and 'correl-id' are required. A '(1)' is placed next to 'correl-id'.

Notes:

- 1 *correl-id* cannot be specified unless a send service and a service policy are also specified.

The schema is DB2MQ.

The MQSEND function sends the data that is contained in *msg-data* to the MQSeries location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*. The returned value is '1' if the function was successful or '0' if unsuccessful.

send-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *send-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

msg-data

An expression that returns a value that is a built-in character string data type. If the expression is a CLOB, the value must not be longer than 1 MB. Otherwise, the value must not be longer than 4000 bytes. The value of the

expression is the message data that is to be sent via MQSeries. A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values.

| *correl-id*

| An expression that returns a value that is a built-in character string or graphic
| string data type that is not a LOB. The expression must have an actual length
| that is no greater than 24 bytes. The value of the expression specifies the
| correlation identifier that is associated with this message. A correlation
| identifier is often specified in request-and-reply scenarios to associate requests
| with replies. *correl-id* must not be specified unless *send-service* and *service-policy*
| are also specified.

| A fixed length string with trailing blanks is considered a valid value. However,
| when the *correl-id* is specified on another request such as MQRECEIVE, the
| *correl-id* must be specified the same to be recognized as a match. For example,
| specifying a value of 'test' for *correl-id* on MQSEND does not match a *correl-id*
| value of 'test ' (with trailing blanks) specified subsequently on an
| MQRECEIVE request.

| If *correl-id* is not specified, is an empty string, or is the null value, a correlation
| identifier is not sent.

| The result of the function is a varying-length string with a length attribute of 1.
| The result is nullable, even though a null value is never returned. The result is '1' if
| the function is successful or '0' if unsuccessful.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Send the string "Testing msg" to the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY) and no correlation identifier.

```
SELECT MQSEND('Testing msg')  
FROM SYSIBM.SYSDUMMY1;
```

The message is sent to the default service, using the default policy.

| *Example 2:* Send the message 'Testing 345' to the service MYSERVICE, using the
| policy MYPOLICY, with no correlation identifier.

```
SELECT MQSEND('MYSERVICE', 'MYPOLICY', 'Testing 345')  
FROM SYSIBM.SYSDUMMY1;
```

| The message 'Testing 345' is sent to the MYSERVICE service, using the policy
| MYPOLICY.

| *Example 3:* Send the message 'Testing 123' to the service MYSERVICE, using the
| policy MYPOLICY and the correlation identifier 'TEST3'.

```
SELECT MQSEND('MYSERVICE', 'MYPOLICY', 'Testing 123', 'TEST3')  
FROM SYSIBM.SYSDUMMY1;
```

The message 'Testing 123' is sent to the service MYSERVICE, using the policy MYPOLICY and the correlation identifier "TEST3".

| *Example 4:* Send the message 'Testing 901' to the service "MYSERVICE", using the
| default policy (DB2.DEFAULT.POLICY), and no correlation identifier.

```
|          SELECT MQSEND('MYSERVICE','Testing 901')  
|          FROM SYSIBM.SYSDUMMY1;
```

```
|          The message 'Testing 901' is sent to the service MYSERVICE, using the default  
|          policy (DB2.DEFAULT.POLICY).
```

MULTIPLY_ALT

The MULTIPLY_ALT scalar function returns the product of the two arguments. This function is an alternative to the multiplication operator and is especially useful when the sum of the precisions of the arguments exceeds 31.

►—MULTIPLY_ALT(*exact-numeric-expression-1*,*exact-numeric-expression-2*)—►

The schema is SYSIBM.

Each argument must be an expression that returns the value of one of the following built-in numeric data types: DECIMAL, BIGINT, INTEGER, or SMALLINT.

The result of the function is a DECIMAL. The precision and scale of the result are determined as follows, using the symbols p and s to denote the precision and scale of the first argument, and the symbols p' and s' to denote the precision and scale of the second argument.

- The precision is $\text{MIN}(31, p+p')$
- The scale is:
 - 0 if the scale of both arguments is 0
 - $\text{MIN}(31, s+s')$ if $p+p'$ is less than or equal to 31
 - $\text{MAX}(\text{MIN}(3, s+s'), 31-(p-s+p'-s'))$ if $p+p'$ is greater than 31.

The result can be null; if any argument is null, the result is the null value.

The MULTIPLY_ALT function is a better choice than the multiplication operator when performing decimal arithmetic where you want a scale of at least 3 and the sum of the precisions exceeds 31. In these cases, the internal computation is performed so that overflows are avoided and then assigned to the result type value using truncation for any loss of scale in the final result. Note that the possibility of overflow of the final result is still possible when the scale is 3.

The following table compares the result data types from the MULTIPLY_ALT function with the result data type of the multiplication operator when decimal data is used:

| Type of Argument1 | Type of Argument2 | Result using MULTIPLY_ALT | Result using multiplication operator |
|-------------------|-------------------|---------------------------|--------------------------------------|
| DECIMAL(31,3) | DECIMAL(15,8) | DECIMAL(31,3) | DECIMAL(31,11) |
| DECIMAL(26,23) | DECIMAL(10,1) | DECIMAL(31,19) | DECIMAL(31,24) |
| DECIMAL(18,17) | DECIMAL(20,19) | DECIMAL(31,29) | DECIMAL(31,31) |
| DECIMAL(16,3) | DECIMAL(17,8) | DECIMAL(31,9) | DECIMAL(31,11) |
| DECIMAL(26,5) | DECIMAL(11,0) | DECIMAL(31,3) | DECIMAL(31,5) |
| DECIMAL(21,1) | DECIMAL(15,1) | DECIMAL(31,2) | DECIMAL(31,2) |

NEXT_DAY

The NEXT_DAY function returns a datetime value that represents the first weekday, named by *string-expression*, that is later than the date in *expression*.

►►—NEXT_DAY(*expression*,*string-expression*)—◄◄

The schema is SYSIBM.

If *expression* is a timestamp or valid string representation of a timestamp, the timestamp value has the same hours, minutes, seconds, and partial seconds as *expression*. If *expression* is a date, or a valid string representation of a date, then the hours, minutes, seconds, and partial seconds value of the result is 0.

expression

An expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* does not have data type TIMESTAMP WITHOUT TIME ZONE, *expression* is cast as follows:

- If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as *expression*.
- Otherwise, *expression* is cast to TIMESTAMP(6) WITHOUT TIME ZONE.

string-expression

An expression that returns a built-in character or graphic string data type that is not a LOB. For portability across the platforms, the value should compare equal to the full name of a day of the week or should compare equal to the abbreviation of a day of the week. For example:

| Day of week | Abbreviation |
|-------------|--------------|
| MONDAY | MON |
| TUESDAY | TUE |
| WEDNESDAY | WED |
| THURSDAY | THU |
| FRIDAY | FRI |
| SATURDAY | SAT |
| SUNDAY | SUN |

The minimum length of the input value is the length of the abbreviation. Leading blanks must not be specified in *string-expression*. Trailing blanks are trimmed from *string-expression*. The resulting value is folded to uppercase. Any characters other than blank that immediately follow a valid abbreviation are ignored.

If *expression* is a timestamp, the result is a `TIMESTAMP WITHOUT TIME ZONE` value with the same precision as *expression*. If *expression* is `DATE`, the result is a `DATE` value. Otherwise, the result is a `TIMESTAMP(6) WITHOUT TIME ZONE` value.

Any hours, minutes, seconds, or fractional seconds information that is included in *expression* is not changed by the function. If *expression* is a string that represents a date, the time information in the resulting timestamp value is all set to zero.

The result can be null; if any argument is null, the result is the null value.

The result `CCSID` is the appropriate `CCSID` of the argument encoding scheme and the result subtype is the appropriate subtype of the `CCSID`.

Example 1: Set the host variable `NEXTDAY` with a timestamp for the date of the Tuesday that follows April 24, 2007.

```
SET :NEXTDAY = NEXT_DAY(TIMESTAMP '2007-04-24-00.00.00.000000', 'TUESDAY');
```

The host variable `NEXTDAY` is set with the value of `'2007-05-01-00.00.00.000000'`, since April, 24, 200 is itself a Tuesday'.

Example 2: Set the host variable `vNEXTDAY` with the date of the first Monday in May, 2007. Assume the host variable `vDAYOFWEEK = 'MON'`:

```
SET :vNEXTDAY = NEXT_DAY(LAST_DAY(CURRENT_DATE), :vDAYOFWEEK);
```

The host variable `vNEXTDAY` is set with the value of `'2007-05-07'`, assuming that the value of the `CURRENT_DATE` special register is `'2007-04-24'`.

NORMALIZE_DECFLOAT

The NORMALIZE_DECFLOAT function returns a DECFLOAT value that is the result of the argument, set to its simplest form. That is, a non-zero number that has any trailing zeros in the coefficient has those zeros removed by dividing the coefficient by the appropriate power of ten and adjusting the exponent accordingly. A zero has its exponent set to 0.

►—NORMALIZE_DECFLOAT(*decfloat-expression*)—◄

The schema is SYSIBM.

decfloat-expression

The argument must be an expression that returns a DECFLOAT value.

decfloat-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is a special decimal floating point value then the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 235 for more information.

The result of the function is a DECFLOAT(16) value if the data type of *decfloat-expression* is DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value.

The result can be null; if the argument is null, the result is the null value.

Examples: The following examples show the result of using the NORMALIZE_DECFLOAT function on various DECFLOAT values:

| | |
|--------------------------------------|-------------|
| NORMALIZE_DECFLOAT(DECFLOAT(2.1)) | = 2.1 |
| NORMALIZE_DECFLOAT(DECFLOAT(-2.0)) | = -2 |
| NORMALIZE_DECFLOAT(DECFLOAT(1.200)) | = 1.2 |
| NORMALIZE_DECFLOAT(DECFLOAT(-120)) | = -1.2E+2 |
| NORMALIZE_DECFLOAT(DECFLOAT(120.00)) | = 1.2E+2 |
| NORMALIZE_DECFLOAT(DECFLOAT(0.00)) | = 0 |
| NORMALIZE_DECFLOAT(-NAN) | = -NAN |
| NORMALIZE_DECFLOAT(-INFINITY) | = -INFINITY |

NORMALIZE_STRING

The NORMALIZE_STRING function takes a Unicode string argument and returns a normalized string that can be used for comparison.

The NORMALIZE_STRING function can convert two strings that look the same (such as Å, which can be encoded in UTF-16 as X'00C5' and as X'0041030a') but might not be encoded using the same Unicode code point, to a normalized form that can be compared.

The schema is SYSIBM.

unicode_string

An expression that returns a value of a built-in character string or graphic string data type that is either Unicode UTF-8 or Unicode UTF-16, and is not a LOB. The CAST specification can be used to convert ASCII or EBCDIC data to Unicode for use with this function.

NFC, NFD, NFKC, or NFKD

Specifies the normalized form:

NFC Canonical Decomposition followed by Canonical Composition

NFD Canonical Decomposition

NFKC Compatibility Decomposition followed by Canonical Composition

NFKD Compatibility Decomposition

integer

The length attribute, in bytes if the string is a character string, or in double byte code points if the string is a graphic string, for the resulting variable length string. The value must be an integer between 1 and 32704 if the source string is character, or 16352 if the source string is graphic.

The result of the function is a varying length string with a data type that depends on the data type of *unicode-string*:

- VARCHAR if *unicode-string* is CHAR or VARCHAR
- VARGRAPHIC if *unicode-string* is GRAPHIC or VARGRAPHIC

The CCSID of the result is the same as the CCSID of *unicode-string*.

The length attribute of the result depends on whether *integer* is specified. If *integer* is specified, the length attribute of the result is *integer* bytes or double byte code points. If *integer* is not specified, the length attribute of the result is MIN(3*n, 32704) for character strings, or MIN(3*n, 16352) for graphic strings, where *n* is the length attribute of the source.

The result can be null; if the first argument is null, the result is the null value.

Example 1: In the following example, "åbc" is normalized to normalization form NFC:

```
SET :hv1 = NORMALIZE_STRING('âbc',NFC) -- x'0061030100620063'
```

hv1 is set to 'âbc' -- X'00E100620063'. Using normalization form NFC, the two code-point sequence X'00610301', which represents the character 'á', is normalized to X'00E1' which is also the pre-composed equivalent of X'00610301'.

Example 2: In the following example, "âbc" is normalized to normalization form NFD.

```
SET :hv1 = NORMALIZE_STRING('âbc',NFD) -- x'00E100620063'
```

hv1 is set to 'âbc' -- X'0061030100620063'. Using normalization form NFD, the code point X'00E1' is decomposed into the two code-point sequence X'00610301', which consists of the Latin lower case letter A and the combining acute accent character.

NULLIF

The NULLIF function returns the null value if the two arguments are equal; otherwise, it returns the value of the first argument.

►►—NULLIF(*expression,expression*)—◄◄

The schema is SYSIBM.

The two arguments must be compatible. The arguments can be of either a built-in or user-defined data type. Neither argument can be a BLOB, CLOB, DBCLOB, or XML. Character-string and graphic-string arguments are compatible with datetime values. For more information on compatibility, refer to the compatibility matrices in “Assignment and comparison” on page 119.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The attributes of the result are the attributes of the first argument.

The result of using NULLIF(*e1,e2*) is the same as using the CASE expression:

```
CASE WHEN e1=e2 THEN NULL ELSE e1 END
```

When *e1=e2* evaluates to unknown because one or both arguments is null, CASE expressions consider the evaluation not true. In this case, NULLIF returns the value of the first argument.

Example: Assume that host variables *PROFIT*, *CASH*, and *LOSSES* have decimal data types with the values of 4500.00, 500.00, and 5000.00 respectively. The following function returns a null value:

```
NULLIF (:PROFIT + :CASH , :LOSSES)
```

NVL

The NVL function returns the first argument that is not null.

► NVL (*expression* , *expression*) ◀

The schema is SYSIBM.

The NVL function is a synonym for the COALESCE function.

OVERLAY

The OVERLAY function returns a string that is composed of one argument that is inserted into another argument at the same position where some number of bytes have been deleted.

The schema is SYSIBM.

The OVERLAY function returns a string where a substring of *length*, beginning at *start* has been deleted from *source-string*, and where *insert-string* has been inserted into *source-string* beginning at *start*. If the value of *start* plus *length* is greater than the length of *source-string*, the substring that is deleted is from *start* to the end of *source-string*.

If the length of the result string exceeds the maximum for the return type, an error is returned.

The OVERLAY function is identical to the INSERT function, except that the length argument is optional.

source-string

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The actual length of the string must be greater than or equal to 1 byte and less than or equal to 32704 bytes.

insert-string

An expression that specifies the string that is inserted into *source-string*, starting at the position that is identified by *start*. *insert-string* must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. *source-string* and *insert-string* must have compatible data types.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start

An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of *source-string* plus one.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length

An expression that specifies the length of the string to replace in *source-string*

starting at *start*. *length* must be an expression that returns a value of the built-in INTEGER data type. *length* is expressed in the string unit specified, and the value must be in the range of 0 to the length of *source-string*. If OCTETS is specified and the result is graphic data, *length* must be even and be between 0 and twice the length of *source-string*. Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the units that are used to express *start* and *length* in the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used. If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point. Otherwise, a string unit is a byte.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87. *length* must be an even number if *source-string* is graphic data and OCTETS is specified

If *source-string* and *insert-string* have different CCSID sets, *insert-string* (the string to be inserted) is converted to the CCSID of *source-string* (the source string).

The encoding scheme of the result is the same as *source-string*. The data type of the result of the function depends on the data type of *source-string* and *insert-string*:

- VARCHAR if *source-string* is a character string. The CCSID of the result depends on the arguments:
 - If either *source-string* or *insert-string* is character bit data, the result is bit data.
 - If both *source-string* and *insert-string* are SBCS:
 - If both *source-string* and *insert-string* are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
 - If *source-string* is SBCS Unicode data and *insert-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
 - Otherwise, the CCSID of the result is the same as the CCSID of *source-string*.

- Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string* and *insert-string* are both binary strings.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

$$L1 - \text{MIN}((L1 - V2 + 1), V3) + L4$$

where:

L1 is the length attribute of *source-string*

V2 is the value of *start*

V3 is the value of *length*

L4 is the length attribute of *insert-string*

- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*. In this case, the length attribute of *source-string* plus the length attribute of *insert-string* must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (*source-string* and *insert-string*), and the representation of that data in Unicode. See “Determining the length attribute of the final result” on page 90 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

$$A1 - \text{MIN}((A1 - V2 + 1), V3) + A4$$

where:

A1 is the actual length of *source-string*

V2 is the value of *start*

V3 is the value of *length*

A4 is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Example 1: The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```
SELECT CHAR(OVERLAY('INSERTING','IS',4,2,OCTETS),10),
       CHAR(OVERLAY('INSERTING','IS',4,0,OCTETS),10),
       CHAR(OVERLAY('INSERTING','',4,2,OCTETS),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING '.

Example 2: Use the `OVERLAY` function to insert the character 'C' into the Unicode string '&N~AB', where '&' is the character for the musical symbol, G CLEF, and '~' is the character for combining tilde. The following table shows the Unicode string in different Unicode encoding forms:

| Unicode format | & | N | ~ | A | B |
|----------------|-------------|---------|---------|---------|---------|
| UTF-8 | X'F09D849E' | X'4E' | X'CC83' | X'41' | X'42' |
| UTF-16 | X'D834DD1E' | X'004E' | X'0303' | X'0041' | X'0042' |

Assume the host variable `UTF8_VAR` contains the UTF-8 representation of '&N~AB', and `UTF16_VAR` contains the UTF-16 representation of '&N~AB'. Then the following `SELECT` statement is run:

```
SELECT OVERLAY (:UTF8_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF8_VAR, 'C', 1, CODEUNITS32),
       OVERLAY (:UTF8_VAR, 'C', 1, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

This statement returns the following values:

```
C N~AB
CN~AB
C?N~AB -- ? is the invalid UTF-8 sequence X'9D849E'
```

Assume that the previous `SELECT` statement was not run, but the following `SELECT` statement is run:

```
SELECT OVERLAY (:UTF8_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF8_VAR, 'C', 5, CODEUNITS32),
       OVERLAY (:UTF8_VAR, 'C', 5, OCTETS)
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
&N~CB
&N~AC
&C~AB
```

Assume that the previous `SELECT` statement was not run, but the following `SELECT` statement is run:

```
SELECT OVERLAY (:UTF16_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF16_VAR, 'C', 1, CODEUNITS32)
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
C?N~AB
CN~AB
```

Assume that the previous `SELECT` statement was not run, but the following `SELECT` statement is run:

```
SELECT OVERLAY (:UTF16_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF16_VAR, 'C', 5, CODEUNITS32),
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
&N~CB
&N~AC
```

PACK

The PACK function returns a binary string value that contains a data type array and a packed representation of each non-null *expression* argument.

The schema is SYSIBM.

CCSID 1208

Specifies that CCSID 1208 is used to encode character string values.

expression

An expression that returns a value to be encoded in the result string. The *expression* must be a built-in data type that is not DECFLOAT, GRAPHIC, VARGRAPHIC, ROWID, a LOB, XML, or a character string defined as FOR BIT DATA.

The result of the PACK function is a binary string that is constructed from the following items:

- A flag byte that is reserved for future use
- A 2-byte integer value that indicates the number of arguments encoded in the resulting string
- The data type array that contains an element with data type information for each of the encoded arguments
- The encoded values for the *expression* arguments in the order as specified in the function invocation.

The resulting binary string is formatted as follows:

| 2-byte length | Flag byte | Number of items | Data type array | Encoded data values |
|------------------|----------------|-----------------|-----------------|---------------------|
| VARBINARY length | VARBINARY data | | | |

The data type array includes an element for each *expression* argument in the same order as specified in the function invocation. Each array element contains a 2-byte SQLTYPE value that indicates the data type of the corresponding expression. When the SQLTYPE value is an odd number, the corresponding expression represents a null value and the value is not encoded in the resulting string. When the SQLTYPE value is an even number, the resulting string contains an encoded representation of the value depending on the data type. The following table describes the data types:

Table 70. Data types for the *expression* of the PACK function

| Data type of expression | Description of the encoded representation of the value in the resulting string |
|------------------------------|---|
| SMALLINT, INTEGER, or BIGINT | The value of expression as a 16-bit signed binary integer, 32-bit signed binary integer, or 64-bit signed binary integer depending on the data type |

Table 70. Data types for the expression of the PACK function (continued)

| Data type of expression | Description of the encoded representation of the value in the resulting string |
|---|--|
| decimal(<i>p,s</i>) ¹ | A sequence of 1-byte precision <i>p</i> , 1-byte scale <i>s</i> , and (<i>p</i> +2)/2 bytes of the signed packed-decimal number |
| real ² or double ³ | The value of <i>expression</i> as a 64-bit IEEE floating-point format |
| CHAR or VARCHAR | A sequence of the 2-byte CCSID of the string encoding, followed by the 2-byte length of the string and then the argument data in the specified CCSID encoding |
| BINARY or VARBINARY | A sequence of: 2-byte length of the string, followed by the argument data |
| DATE | A 4-byte unsigned packed-decimal number representation of the date in the form of YYYYMMDD |
| TIME | A 3-byte unsigned packed-decimal number representation of the time in the form of HHMMSS |
| TIMESTAMP(<i>p</i>) WITHOUT TIME ZONE | A sequence of a 2-byte unsigned binary integer value of the precision <i>p</i> , followed by 7+ (<i>p</i> +1)/2 bytes of an unsigned packed-decimal number representation of the timestamp in the form of YYYYMMDDHHMMSSNN, where NN is zero to six bytes of the fractional seconds, depending on the precision <i>p</i> |
| TIMESTAMP(<i>p</i>) WITH TIME ZONE | A sequence of a 2-byte unsigned binary integer value of the precision <i>p</i> , followed by 7+ (<i>p</i> +1)/2 bytes of an unsigned packed-decimal number representation of the timestamp in the form of YYYYMMDDHHMMSSNN, where NN is zero to six bytes of the fractional seconds, depending on the precision <i>p</i> , and then followed by 2 bytes of an unsigned packed-decimal number representation of the time zone (with high order bit set for negative time zone value) |
| <p>Note: The data types in lower case are defined as follows:</p> <ol style="list-style-type: none"> decimal = DECIMAL(<i>p,s</i>) or NUMERIC(<i>p,s</i>) real = REAL or FLOAT(<i>n</i>) where <i>n</i> is the specification for a single precision floating point double = DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(<i>n</i>) where <i>n</i> is the specification for a double precision floating point <p>The synonyms for the data types, in either long or short form, are considered the same as those that are listed.</p> | |

All numeric data is represented in big endian format.

The result of the function is VARBINARY. The length attribute of the result is MIN (32704, the length of the header + length of data type array + SUM(maximum lengths of encoded expression values)). The result cannot be null.

Example 1: The following statement shows that the VARCHAR, DATE, and DOUBLE values are packed into a binary string, and the string is then returned to the application:

```
SELECT PACK(CCSID 1208, 'Alina', DATE'1977-08-01', DOUBLE(0.5))
FROM SYSIBM.SYSDUMMYU;
```

The statement returns a VARBINARY string with the following content (The result is displayed in hexadecimal format and includes space separators for readability. The actual result is not in hexadecimal format and does not include any space separators):

```
00 0003 01C4 0180 01E0 04B80005416C696E61 19770801 3FE0000000000000
```

The resulting string is VARBINARY(30). The length attribute of 30 is determined by the following elements:

- 1 (flag byte)
- +2 (size of number of items)
- +2*3 (2-byte data type times number of items)
- +2 (CCSID) + 2 (length) + 5 (VARCHAR(5) data length)
- +4 (DATE data length)
- +8 (DOUBLE length)

The actual length of the result is also 30.

Example 2: The following statement shows that when NULL values are packed into a binary string, they do not occupy any space in the encoded values portion of the result:

```
SELECT PACK(CCSID 1208, '', CAST(NULL AS TIME),
           CAST('Bridget' AS VARCHAR(20)))
FROM SYSIBM.SYSDUMMYU;
```

The statement returns a VARBINARY string with the following content. (The result is displayed in hexadecimal format and includes space separators for readability. The actual result is not in hexadecimal format and does not include any space separators.)

```
00 0003 01C4 0185 01C4 04B80000 04B8000742726964676574
```

The resulting string is VARBINARY(40). The length attribute of 40 is determined by the following elements:

- 1 (flag byte)
- +2 (size of number of items)
- +2*3 (2-byte data type times number of items)
- +2 (CCSID) + 2 (length) + 0 (empty string data length)
- +3 (TIME data length)
- +2 (CCSID) + 2 (length) + 20 (VARCHAR(20) max length)

The actual length of the resulting string is 24, which is determined by the following elements

- 1 (flag byte)
- +2 (size of number of items)
- +2*3 (2-byte data type times number of items)
- +2 (CCSID) + 2 (length) + 0 (empty string data length)
- +0 (NULL)
- +2 (CCSID) + 2 (length) + 7 (VARCHAR(20) actual length)

“UNPACK” on page 730

POSITION

The POSITION function returns the position of the first occurrence of an argument within another argument, where the position is expressed in terms of the string units that are specified.

The schema is SYSIBM.

If *search-string* is not found and neither argument is null, the result is 0. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*, expressed in the units that are explicitly specified.

search-string

An expression that specifies the string for which to search. *search-string* must return a value that is any built-in string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (although nested function invocations cannot be used)
- An expression that concatenates (using CONCAT or ||) any of the above
- A CAST specification whose arguments are any of the above
- A column name

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is any built-in string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A column name
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express the result. If *source-string* is a

character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified.

CODEUNITS16

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings”.

If the search string and source string have different CCSID sets, then the *search-string* is converted to the CCSID set of the source string. If either CODEUNITS16 or CODEUNITS32 is specified, the function might be evaluated on a temporary copy of the data in Unicode.

The strings can contain mixed data. If OCTETS is specified:

- For ASCII data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and double-byte characters are found in the source string in exactly the same positions.
- For EBCDIC data, if the search string or source string contains mixed data, the search string is found only if any shift-in or shift-out characters are found in the source string in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and multi-byte characters are found in the source string in exactly the same position.

The result of the function is a large integer. The POSITION function accepts mixed data strings.

The result can be null; if any argument is null, the result is the null value.

When the POSITION function is invoked with OCTETS, the function operates on a strict byte-count basis without regard to single-byte or double-byte characters.

If the CCSID of the search string is different than the CCSID of the source string, it is converted to the CCSID of the source string.

The value of the result is determined by applying these rules in the order in which they appear:

- If *search-string* has a length of zero, the result is 1.
- If *source-string* has a length of zero, the result is 0.
- If the value of *search-string* is equal to an identical length of substring of contiguous positions within the value of *source-string*, the result is the starting position of the first such substring within the source string value.

- Otherwise, the result is 0. This includes the case where *search-string* is longer than *source-string*.

Example 1: Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSITION('GOOD BEER', NOTE_TEXT, OCTETS)
FROM IN_TRAY
WHERE POSITION('GOOD BEER', NOTE_TEXT, OCTETS) <> 0;
```

Example 2: Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable *LOCATION* with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',CODEUNITS32);
```

The value of host variable *LOCATION* is set to 27.

Example 3: Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable *LOCATION* with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',OCTETS);
```

The value of host variable *LOCATION* is set to 28.

“LOCATE” on page 482

“LOCATE_IN_STRING” on page 485

“POSSTR” on page 539

POSSTR

The POSSTR function returns the position of the first occurrence of an argument within another argument.

►►—POSSTR(*source-string*,*search-string*)—◄◄

The schema is SYSIBM.

If *search-string* is not found and neither argument is null, the result is 0. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A column name
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

search-string

An expression that specifies the string for which to search. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

A column name cannot be specified for *search-string*, except in some cases where the database manager rewrites the SQL and replaces the column name with a literal value or a variable.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for comparisons” on page 137.

If the *search-string* and *source-string* have different CCSID sets, then the *search-string* is converted to the CCSID set of the *source-string*.

Both *search-string* and *source-string* have zero or more contiguous positions. For character strings and binary strings, a position is a byte. For graphic strings, a position is a DBCS character. Graphic Unicode data is treated as UTF-16 data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The strings can contain mixed data.

- For ASCII data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if the same combination of single-byte and double-byte characters are found in *source-string* in exactly the same positions.
- For EBCDIC data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if any shift-in or shift-out characters are found in *source-string* in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if the same combination of single-byte and multi-byte characters are found in *source-string* in exactly the same position.

POSSTR operates on a strict byte-count basis without regard to single-byte or double-byte characters. It is recommended that if either the *search-string* or *source-string* contains mixed data, POSITION should be used instead of POSSTR. The POSITION function operates on a character basis. In an EBCDIC encoding scheme, any shift-in and shift-out characters are not required to be in exactly the same position and their only significance is to indicate which characters are SBCS and which characters are DBCS.

The result of the function is a large integer. The value of the result is determined by applying these rules in the order in which they appear:

- If the length of *search-string* is zero, the result is 1.
- If the length of *source-string* is zero, the result is 0.
- If the value of *search-string* is equal to an identical length substring of contiguous positions from the value of *source-string*, the result is the starting position of the first such substring within the value of *source-string*.
- If none of the above conditions are met, the result is 0.

The result can be null; if any argument is null, the result is the null value.

Example: Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSSTR(NOTE_TEXT, 'GOOD BEER')
FROM IN_TRAY
WHERE POSSTR(NOTE_TEXT, 'GOOD BEER') <> 0;
```

“LOCATE” on page 482

“LOCATE_IN_STRING” on page 485

“POSITION” on page 536

POWER

The POWER function returns the value of the first argument to the power of the second argument.

►►—POWER(*numeric-expression-1*,*numeric-expression-2*)—◄◄

The schema is SYSIBM.

Each argument must be an expression that returns the value of any built-in numeric data type. If either argument includes a DECIMAL or REAL data type, but not a DECFLOAT data type, the arguments are converted to a double precision floating-point number for processing by the function. If either argument includes a DECFLOAT data type, the arguments are converted to DECFLOAT for processing by the function.

The result of the function depends on the data type of the arguments:

- If both arguments are SMALLINT or INTEGER, the result is INTEGER.
- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34).
If either argument is a DECFLOAT and one of the following statements is true, the result is NaN and an invalid operation condition:
 - both arguments are zero
 - the second argument has a non-zero fractional part
 - the second argument has more than 9 digits
 - the second argument is Infinite
- Otherwise, the result is DOUBLE.

The result can be null; if any argument is null, the result is the null value.

Example 1: Assume that host variable *HPOWER* is INTEGER with a value of 3. The following statement returns the value 8.

```
SELECT POWER(2, :HPOWER)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following statement returns the value 1.

```
SELECT POWER(0,0)
FROM SYSIBM.SYSDUMMY1;
```

QUANTIZE

The QUANTIZE function returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and that has an exponent that is set to equal the exponent of the second argument.

►—QUANTIZE(*expression-1*,*expression-2*)—►

The schema is SYSIBM.

The number of digits that is returned (16 or 34) is the same as the number of digits in *expression-1*.

expression-1

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

expression-2

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing. *expression-2* is an expression that is used as an example pattern that will be used to rescale *expression-1*. The sign and coefficient of the second argument are ignored.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If one argument (after conversion) is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) argument is converted to DECFLOAT(34) before the function is processed.

The coefficient of the result is derived from that of *expression-1*. It is rounded, if necessary (if the exponent is being increased), multiplied by a power of ten (if the exponent is being decreased), or remains unchanged (if the exponent is already equal to that of *expression-2*).

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Unlike other arithmetic operations on the DECFLOAT data type, if the length of the coefficient after the quantize operation is greater than the precision specified by *expression-2*, a warning occurs. This ensures that, unless there is an error condition, the exponent of the result of QUANTIZE is always equal to that of *expression-2*. Furthermore:

- If either argument is NaN, NaN is returned

- If either argument is sNaN, NaN is returned and an exception occurs
- If both arguments are infinity (positive or negative), infinity (positive or negative) is returned.
- If one argument is infinity (positive or negative) and the other argument is not infinity (positive or negative), NaN is returned and an exception occurs

The result of the function is a DECFloat(16) value if both arguments are DECFloat(16). Otherwise, the result of the function is a DECFloat(34) value.

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples illustrate the value that is returned for the QUANTIZE function given the input DECFloat values:

```

QUANTIZE(2.17, DECFloat(0.001)) = 2.170
QUANTIZE(2.17, DECFloat(0.01)) = 2.17
QUANTIZE(2.17, DECFloat(0.1)) = 2.2
QUANTIZE(2.17, DECFloat('1E+0')) = 2
QUANTIZE(2.17, DECFloat('1E+1')) = 0E+1
QUANTIZE(2, DECFloat(INFINITY)) = NAN -- exception
QUANTIZE(-0.1, DECFloat(1) ) = 0
QUANTIZE(0, DECFloat('1E+5')) = 0E+5
QUANTIZE(217, DECFloat('1E-1')) = 217.0
QUANTIZE(217, DECFloat('1E+0')) = 217
QUANTIZE(217, DECFloat('1E+1')) = 2.2E+2
QUANTIZE(217, DECFloat('1E+2')) = 2E+2

```

QUARTER

The `QUARTER` function returns an integer between 1 and 4 that represents the quarter of the year in which the date resides. For example, any dates in January, February, or March return the integer 1.

►—`QUARTER(expression)`—►

The schema is `SYSIBM`.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string data type, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: The following function returns 3 because August is in the third quarter of the year.

```
SELECT QUARTER('2008-08-25')
FROM SYSIBM.SYSDUMMY1
```

Example 2: Using sample table `DSN8A10.PROJ`, set the integer host variable `QUART` to the quarter of the year in which activity number 70 for project 'AD3111' occurred. Activity completion dates are recorded in column `ACENDATE`.

```
SELECT QUARTER(ACENDATE)
INTO :QUART
FROM DSN8A10.PROJ
WHERE PROJNO = 'AD3111' AND ACTNO = 70;
```

`QUART` is set to 4.

Example 3: The following invocations of the `QUARTER` function returns the same result:

```
SELECT QUARTER('2003-01-02-20.10.05.123456'),
QUARTER('2003-01-02-12.10.05.123456-08:00'),
QUARTER('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the `QUARTER` function in this `SELECT` statement, the result is 1.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| 2003-01-02-20.10.05.123456. The month portion of the UTC representation is 1 for
| January, which is in the first quarter.

RADIANS

The RADIANS function returns the number of radians for an argument that is expressed in degrees.

►—RADIANS(*numeric-expression*)—◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *HDEG* is an INTEGER with a value of 180. The following statement returns a double precision floating-point number with an approximate value of 3.1415926536.

```
SELECT RADIANS(:HDEG)
FROM SYSIBM.SYSDUMMY1;
```

RAISE_ERROR

The RAISE_ERROR function causes the statement that invokes the function to return an error with the specified SQLSTATE (along with SQLCODE -438) and error condition. The RAISE_ERROR function always returns the null value with an undefined data type.

►—RAISE_ERROR(*sqlstate*,*diagnostic-string*)—►

The schema is SYSIBM.

sqlstate

An expression that returns a character string (CHAR or VARCHAR) of exactly 5 characters.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR(5) data type. The *sqlstate* value must follow these rules for application-defined SQLSTATES:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00', '01', or '02' because these are not error classes.
- If the SQLSTATE class (first two characters) starts with the character '0' through '6' or 'A' through 'H', the subclass (last three characters) must start with a letter in the range 'I' through 'Z'.
- If the SQLSTATE class (first two characters) starts with the character '7', '8', '9', or 'I' through 'Z', the subclass (last three characters) can be any of '0' through '9' or 'A' through 'Z'.

diagnostic-string

An expression that returns a character string with a data type of CHAR or VARCHAR and a length of up to 70 bytes. The string contains EBCDIC data that describes the error condition. If the string is longer than 70 bytes, it is truncated.

Since the data type of the result of RAISE_ERROR is undefined, it can only be used in a SET *host-variable* or SQL procedure language *assignment-statement*. To use this function in another context, such as alone in a select list, you must use a cast specification to give a data type to the null value that is returned. The RAISE_ERROR function is most useful with CASE expressions.

Example: For each employee in sample table DSN8A10.EMP, list the employee number and education level. List the education level as 'Post Graduate', 'Graduate' and 'Diploma' instead of the integer that it is stored as in the table. If an education level is greater than '20', raise an error ('70001') with a description.

```
SELECT EMPNO,  
       CASE WHEN EDLEVEL < 16 THEN 'Diploma'  
            WHEN EDLEVEL < 18 THEN 'Graduate'  
            WHEN EDLEVEL < 21 THEN 'Post Graduate'  
            ELSE RAISE_ERROR('70001',  
                            'EDUCLVL has a value greater than 20')  
       END  
FROM DSN8A10.EMP;
```

RAND

The RAND function returns a random floating-point value between 0 and 1. An argument can be specified as an optional seed value.

The schema is SYSIBM.

numeric-expression

If *numeric-expression* is specified, it is used as the seed value. The argument must be an expression that returns a value of a built-in integer data type (SMALLINT or INTEGER). The value must be between 0 and 2,147,483,646.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) and then assigned to an INTEGER value.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

A specific seed value, other than zero, will produce the same sequence of random numbers for a specific instance of a RAND function in a query each time the query is executed. The seed value is used only for the first invocation of an instance of the RAND function within a statement. RAND(0) is processed the same as RAND().

The RAND function is a not deterministic.

Example: Assume that host variable *HRAND* is an INTEGER with a value of 100. The following statement returns a random floating-point number between 0 and 1, such as the approximate value .0121398:

```
SELECT RAND(:HRAND)
FROM SYSIBM.SYSDUMMY1;
```

To generate values in a numeric interval other than 0 to 1, multiply the RAND function by the size of the interval that you want. For example, to get a random number between 0 and 10, such as the approximate value 5.8731398, multiply the function by 10:

```
SELECT (RAND(:HRAND) * 10)
FROM SYSIBM.SYSDUMMY1;
```

REAL

The REAL function returns a single-precision floating-point representation of either a number or a string representation of a number.

Numeric to Real:

►►—REAL(*numeric-expression*)—◄◄

String to Real:

►►—REAL(*string-expression*)—◄◄

The schema is SYSIBM.

Numeric to Real

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a single precision floating-point column or variable. If the numeric value of the argument is not within the range of single precision floating-point, an error occurs.

String to Real

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS REAL)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL floating-point, integer, or decimal constant.

The result of the function is a single precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Recommendation: To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 254.

Example: Using sample table DSN8A10.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved, SALARY and COMM, have decimal data types. To express the result in single precision floating-point, apply REAL to SALARY so that the division is carried out in floating-point (actually double precision) and then apply REAL to the complete expression so that the results are returned in single precision floating-point.

```
SELECT EMPNO, REAL (REAL (SALARY) / COMM)
FROM DSN8A10.EMP
WHERE COMM > 0;
```

REPEAT

The REPEAT function returns a character string that is composed of an argument that is repeated a specified number of times.

►►—REPEAT(*expression*,*integer*)—◄◄

The schema is SYSIBM.

expression

An expression that specifies the string to be repeated. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The actual length of the string must be greater or equal to 1 and less than or equal to 32704 bytes.

integer

integer must be a positive large integer value that specifies the number of times to repeat the string.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The result can be null; if any argument is null, the result is the null value.

The encoding scheme of the result is the same as *expression*. The data type of the result of the function depends on the data type of *expression*:

- VARBINARY if *expression* is a binary string
- VARCHAR if *expression* is a character string
- VARGRAPHIC if *expression* is graphic string

The CCSID of the result is the same as the CCSID of *expression*.

If *integer* is a constant, the length attribute of the result is the length attribute of *expression* times *integer*. Otherwise, the length attribute depends on the data type of the result:

- 4000 for VARBINARY and VARCHAR
- 2000 for VARGRAPHIC

The actual length of the result is the actual length of *expression* times *integer*. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

Example 1: Repeat 'abc' two times to create 'abcabc'.

```
SELECT REPEAT('abc',2)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: List the phrase 'REPEAT THIS' five times. Use the CHAR function to limit the output to 60 bytes.

```
SELECT CHAR(REPEAT('REPEAT THIS',5), 60)
FROM SYSIBM.SYSDUMMY1;
```

This example results in 'REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS '.

Example 3: For the following query, the LENGTH function returns a value of 0 because the result of repeating a string zero times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('REPEAT THIS',0))
FROM SYSIBM.SYSDUMMY1;
```

Example 4: For the following query, the LENGTH function returns a value of 0 because the result of repeating an empty string any number of times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('', 5))
FROM SYSIBM.SYSDUMMY1;
```

REPLACE

The REPLACE function replaces all occurrences of *search-string* in *source-string* with *replace-string*. If *search-string* is not found in *source-string*, *source-string* is returned unchanged.

```
►► REPLACE (—source-string—, —search-string—, —replace-string—) ►►
```

The schema is SYSIBM.

source-string

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB and it cannot be an empty string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

search-string

An expression that specifies the string to be removed from the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB; the value cannot be an empty string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

replace-string

An expression that specifies the replacement string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. If *replace-string* is not specified or is an empty string, nothing replaces the string that is removed from the source string.

The actual length of each string must be 32704 bytes or less for character and binary strings or 16352 or less for graphic strings.

All three arguments must have compatible data types. If the expressions have different CCSID sets, then the expressions are converted to the CCSID set of *source-string*.

The data type of the result of the function depends on the data type of *source-string*, *search-string*, and *replace-string*:

- VARCHAR if *source-string* is a character string. The encoding scheme of the result is the same as *source-string*. The CCSID of the result depends on the arguments:
 - If *source-string*, *search-string*, or *replace-string* is bit data, the result is bit data.
 - If *source-string*, *search-string*, and *replace-string* are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.

- If *source-string* is SBCS Unicode data, and *search-string* or *replace-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
- Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The encoding scheme of the result is the same as *source-string*. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string*, *search-string*, and *replace-string* are binary strings.

The length attribute of the result depends on the arguments:

- If the length attribute of *replace-string* is less than or equal to the length attribute of *search-string*, the length attribute of the result is the length attribute of *source-string*.
- If the length attribute of *replace-string* is greater than the length attribute of *search-string*, the length attribute of the result is determined as follows depending on the data type of the result:
 - For VARCHAR or VARBINARY:
 - If $L1 \leq 4000$, the length attribute of the result is $\text{MIN}(4000, (L3 * (L1/L2)) + \text{MOD}(L1, L2))$
 - Otherwise, the length attribute of the result is $\text{MIN}(32704, (L3 * (L1/L2)) + \text{MOD}(L1, L2))$
 - For VARGRAPHIC:
 - If $L1 \leq 2000$, the length attribute of the result is $\text{MIN}(2000, (L3 * (L1/L2)) + \text{MOD}(L1, L2))$
 - Otherwise, the length attribute of the result is $\text{MIN}(16352, (L3 * (L1/L2)) + \text{MOD}(L1, L2))$

where:

L1 is the length attribute of *source-string*
L2 is the length attribute of *search-string* if the search string is a string constant. Otherwise, *L2* is 1.
L3 is the length attribute of *replace-string*

If the result is a character string or binary string, the length attribute of the result must not exceed 32704. If the result is a graphic string, the length attribute of the result must not exceed 16352.

The actual length of the result is the actual length of *source-string* plus the number of occurrences of *search-string* that exist in *source-string* multiplied by the actual length of *replace-string* minus the actual length of *search-string*. If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Example 1: Replace all occurrences of the character 'N' in the string 'DINING' with 'VID'. Use the CHAR function to limit the output to 10 bytes.

```
SELECT CHAR(REPLACE('DINING', 'N', 'VID'), 10)
FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'DIVIDIVIDG'.

Example 2: Replace string 'ABC' in the string 'ABCXYZ' with nothing, which is the same as removing 'ABC' from the string.

```
SELECT REPLACE('ABCXYZ', 'ABC', '')
FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'XYZ'.

Example 3: Replace string 'ABC' in the string 'ABCCABCC' with 'AB'. This example illustrates that the result can still contain the string that is to be replaced (in this case, 'ABC') because all occurrences of the string to be replaced are identified prior to any replacement.

```
SELECT REPLACE('ABCCABCC', 'ABC', 'AB')
FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'ABCABC'.

Related concepts:

“Character strings” on page 84

“Binary strings” on page 95

“Graphic strings” on page 94

RID

The RID function returns the record ID (RID) of a row. The RID is used to uniquely identify a row.

```
►►—RID(table-designator)—◄◄
```

The schema is SYSIBM.

The function might return a different value when it is invoked multiple times for a row. For example, after the REORG utility is run, the RID function might return a different value for a row than would have been returned prior to the REORG utility being run. The RID function is not deterministic.

table-designator

table-designator must uniquely identify a base table, a view, or a nested table expression of a subselect in which the function is referenced.

If *table-designator* specifies a view or a nested table expression, the RID function returns the RID of the base table of the view or nested table expression. The specified view or nested table expression must contain only one base table in its outer subselect.

table-designator must not specify a table function, a materialized view, a nested table expression that is materialized, an alias, or a synonym.

The result of the function is BIGINT. The result can be null.

Considerations for RID values: DB2 might reuse RID numbers when a REORG operation is performed. If the RID function is used to obtain a value for a row and an application depends on that value remaining the same as long as the row exists, consider the following alternatives:

- Add a ROWID column to the table to provide a value that can be associated with each row, rather than invoking the RID function to generate a value for a row.
- Define a primary key for the table, using the columns of the primary key to ensure uniqueness, rather than invoking the RID function to generate a value for a row.

Example 1: Return the RID and last name of employees who are in department '20':

```
SELECT RID(EMP), LASTNAME
FROM EMP
WHERE DEPTNO = '20';
```

Example 2: Set the host variable *HV_EMP_RID* as the value of the RID for the employee with the employee number of '3500':

```
SELECT RID(EMP) INTO :HV_EMP_RID
FROM EMP
WHERE EMPNO = '3500';
```

RIGHT

The RIGHT function returns a string that consists of the specified number of rightmost bytes or specified string unit from a string.

The schema is SYSIBM.

string-expression

An expression that specifies the string from which the result is derived. The string must be any built-in string data type. A substring of *string-expression* is zero or more contiguous code points of *string-expression*. A partial surrogate character in the expression is replaced with a blank.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

integer

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *string-expression*, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *string-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *string-expression* is a graphic string, OCTETS cannot be specified. If *string-expression* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The *string-expression* is effectively padded on the right with the necessary number of padding characters so that the specified substring of *string-expression* always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.
- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 data (Unicode mixed data), the padding character is X'20'.
- For UTF-16 data (Unicode DBCS data), the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of *string-expression* and a data type that depends on the data type of *string-expression*:

- VARBINARY if *string-expression* is BINARY or VARBINARY
- VARCHAR if *string-expression* is CHAR or VARCHAR
- CLOB if *string-expression* is CLOB
- VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *string-expression* is DBCLOB
- BLOB if *string-expression* is BLOB

The actual length of the result is determined from *integer*.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Example 1: Assume that host variable *ALPHA* has a value of 'ABCDEF'. The following statement returns the value 'DEF', which are the three rightmost characters in *ALPHA*.

```
SELECT RIGHT(ALPHA,3)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following statement returns a zero length string.

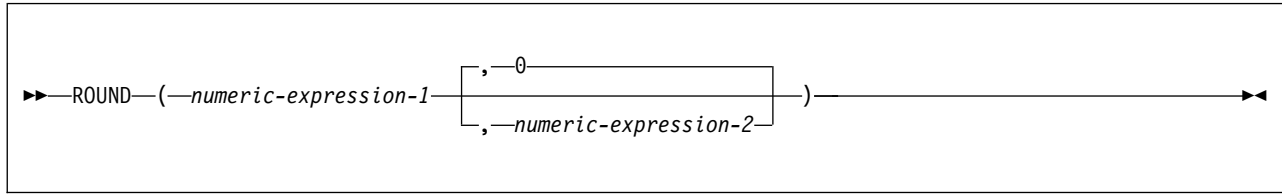

```
SELECT RIGHT('ABCABC',0)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: *FIRSTNME* is a VARCHAR(12) column in table T1. When *FIRSTNME* has the 6-character string 'Jürgen' as a value:

| Function ... | Returns ... |
|-------------------------------|---|
| RIGHT(FIRSTNME,5,CODEUNITS32) | 'ürgen' -- x'C3BC7267656E' |
| RIGHT(FIRSTNME,5,CODEUNITS16) | 'ürgen' -- x'C3BC7267656E' |
| RIGHT(FIRSTNME,5,OCTETS) | ' rgen' -- x'207267656E' a truncated string |

ROUND

The ROUND function returns a number that is rounded to the specified number of places to the right or left of the decimal place.

The schema is SYSIBM.

numeric-expression-1

An expression that returns a value of any built-in numeric data type.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of ROUND corresponds to a value of ROUND_HALF_UP. If you want a different rounding behavior, use the QUANTIZE function.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

numeric-expression-2

An expression that returns a value that is a built-in numeric, character string or graphic string data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

The absolute value of integer specifies the number of places to the right of the decimal point for the result if *numeric-expression-2* is not negative. If *numeric-expression-2* is negative, *numeric-expression-1* is rounded to the sum of the absolute value of *numeric-expression-2*+1 number of places to the left of the decimal point.

If the absolute value of *numeric-expression-2* is larger than the number of digits to the left of the decimal point, the result is 0. (For example, ROUND(748.58, -4) returns 0.)

If *numeric-expression-1* is positive, a digit value of 5 is rounded to the next higher positive number. If *numeric-expression-1* is negative, a digit value of 5 is rounded to the next lower negative number.

The result of the function has the same data type and length attribute as the first argument except that the precision is increased by one if the argument is DECIMAL and the precision is less than 31. For example, an argument with a data type of DECIMAL(5,2) results in DECIMAL(6,2). An argument with a data type of DECIMAL(31,2) results in DECIMAL(31,2).

The result can be null; if any argument is null, the result is the null value.

Example 1: Calculate the number '873.726' rounded to '2', '1', '0', '-1', and '-2' decimal places respectively.

```
SELECT ROUND(873.726,2),
       ROUND(873.726,1),
       ROUND(873.726,0),
       ROUND(873.726,-1),
```

```
ROUND(873.726,-2),  
ROUND(873.726,-3),  
ROUND(873.726,-4)  
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '0873.730', '0873.700', '0874.000', '0870.000', '0900.000', '1000.000', and '0000.000'.

Example 2: To demonstrate how numbers are rounded in positive and negative values, calculate the numbers '3.5', '3.1', '-3.1', '-3.5' rounded to '0' decimal places.

```
SELECT ROUND(3.5,0),  
       ROUND(3.1,0),  
       ROUND(-3.1,0),  
       ROUND(-3.5,0)  
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '04.0', '03.0', '-03.0', and '-04.0'. (Notice that in the positive value '3.5' is rounded up to the next higher number while in the negative value '-3.5' is rounded down to the next lower negative number.)

ROUND_TIMESTAMP

The ROUND_TIMESTAMP scalar function returns a timestamp that is rounded to the unit that is specified by the timestamp format string.

The schema is SYSIBM.

expression

An expression that returns a value of any of the following built-in data types: a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

format-string

An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. *format-string* contains a template of how the timestamp represented by *expression* should be rounded. For example, if *format-string* is 'DD', the timestamp that is represented by *expression* is rounded to the nearest day. *format-string* must be a valid template for a timestamp, and not include leading or trailing blanks.

Allowable values for *format-string* are listed in the following table.

Table 71. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models

| Format model | Rounding or truncating unit | ROUND_TIMESTAMP example | TRUNC_TIMESTAMP example |
|--|--|---|---|
| CC SCC | Century Rounds up to the start of the next century after the 50th year of the century (for example on 1951-01-01-00.00.00). | Input Value: 1897-12-04-12.22.22.000000 Result: 1901-01-01-00.00.00.000000 | Input Value: 1897-12-04-12.22.22.000000 Result: 1801-01-01-00.00.00.000000 |
| SYYYY YYYY YEAR SYEAR YYY YY Y | Year (Rounds up on July 1st) | Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-01-00.00.00.000000 | Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-01-00.00.00.000000 |
| IYYY IYY IY I | ISO Year (Rounds up on July 1st) | Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-03-00.00.00.000000 | Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-04-00.00.00.000000 |

Table 71. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

| Format model | Rounding or truncating unit | ROUND_TIMESTAMP example | TRUNC_TIMESTAMP example |
|--------------------------|--|---|---|
| Q | Quarter (Rounds up on the sixteenth day of the second month of the quarter) | Input Value: 1999-06-04-12.12.30.000000 Result: 1999-07-01-00.00.00.000000 | Input Value: 1999-06-04-12.12.30.000000 Result: 1999-04-01-00.00.00.000000 |
| MONTH MON MM RM | Month (Rounds up on the sixteenth day of the month) | Input Value: 1999-06-18-12.12.30.000000 Result: 1999-07-01-00.00.00.000000 | Input Value: 1999-06-18-12.15.00.000000 Result: 1999-06-01-00.00.00.000000 |
| WW | Same day of the week as the first day of the year (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the year) | Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-06-00.00.00.000000 | Input Value: 2000-05-05-12.15.00.000000 Result: 2000-04-29-00.00.00.000000 |

If *expression* does not have data type `TIMESTAMP WITHOUT TIME ZONE`, *expression* is cast as follows:

- If *expression* is a `TIMESTAMP WITH TIME ZONE` value, *expression* is cast to `TIMESTAMP WITHOUT TIME ZONE`, with the same precision as *expression*.
- Otherwise, *expression* is cast to `TIMESTAMP(6) WITHOUT TIME ZONE`.

The result of the function has the same data type as the data type to which *expression* is cast.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Set the host variable `RND_TMSTMP` with the input timestamp rounded to the nearest year value.

```
SET :RND_TMSTMP = ROUND_TIMESTAMP(TIMESTAMP_FORMAT('2000-08-14 17:30:00',
                                                    'YYYY-MM-DD HH24:MI:SS'), 'YEAR');
```

The value set is '2001-01-01-00.00.00.000000'.

Example 2: Assume `PRSTSZ` is an SQL variable with the `TIMESTAMP WITH TIME ZONE` value '2008-04-15.20.00.000000-08:30'. The input value is first cast to `TIMESTAMP WITHOUT TIME ZONE` (as '2008-04-15.20.00.000000') for the `ROUND_TIMESTAMP` function.

```
SELECT ROUND_TIMESTAMP(PRSTSZ)
FROM PROJECT;
```

The `ROUND_TIMESTAMP` function returns a `TIMESTAMP WITHOUT TIME ZONE` value of '2008-04-16.00.00.000000'.

ROWID

The ROWID function returns a row ID representation of its argument.

```
▶—ROWID(expression)—◀
```

The schema is SYSIBM.

The argument must be an expression that returns a value of a built-in character string data type, other than a CLOB, with a maximum length that is no greater than 255 bytes. Although the character string can contain any value, it is recommended that the character string contain a ROWID value that was previously generated by DB2 to ensure a valid ROWID value is returned. For example, the function can be used to convert a ROWID value that was cast to a CHAR value back to a ROWID value.

If the actual length of *expression* is less than 40, the result is not padded. If the actual length of *expression* is greater than 40, the result is truncated. If non-blank characters are truncated, a warning is returned.

The result of the function is a ROWID value.

The length attribute of the result is 40. The actual length of the result is the length of *expression*.

The result can be null; if the argument is null, the result is the null value.

A null ROWID value cannot be used as the value for a row ID column in the database.

Example: Assume that table EMPLOYEE contains a row ID column, 'EMP_ROWID'. Also assume that the table contains a row that is identified by a ROWID value that is equivalent to X'F0DFD230E3C0D80D81C201AA0A28010000000000203'. Using direct row access, select the employee number for that row.

```
SELECT EMPNO
FROM EMPLOYEE
WHERE EMP_ROWID=ROWID(X'F0DFD230E3C0D80D81C201AA0A28010000000000203');
```

RPAD

The RPAD function returns a string that is padded on the right with blanks or a specified string.

The schema is SYSIBM.

The RPAD function returns a string composed of *string-expression* padded on the right, with *pad* or blanks. The RPAD function treats leading or trailing blanks in *string-expression* as significant. Padding will only occur if the actual length of *string-expression* is less than *integer*, and *pad* is not an empty string.

string-expression

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

integer

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is 32704 if *string-expression* is a character or binary string, or where *n* is 16352 if *string-expression* is a graphic string.

pad

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- DBCS blank character if *string-expression* is a graphic string.
- Hexadecimal zero (X'00'), if *string-expression* is a binary string.

The result of the function is a varying length string that has the same CCSID of *string-expression*. *string-expression* and *pad* must have compatible data types. If the string expressions have different CCSID sets, then *pad* is converted to the CCSID set of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA, no character conversion occurs. The actual length of the result is determined from *integer*.

The length attribute of the result depends on *integer*. If *integer* is greater than 0, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1.

The actual length of the result is determined from *integer*. If *integer* is 0, the actual length is 0, and the result is the empty string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

The result can be null; if any argument is null, the result is the null value.

Example 1: Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will completely pad out a value on the right with periods.

```
SELECT RPAD(NAME,15,'.' ) AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
Chris.....
Meg.....
Jeff.....
```

Example 2: Similar to Example 1, the following query will completely pad out a value on the right with *pad* (note that in some cases there is a partial instance of the padding specification):

```
SELECT RPAD(NAME,15,'123' ) AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
Chris1231231231
Meg123123123123
Jeff12312312312
```

Example 3: Similarly, the following query will only pad each value to a length of 5:

```
SELECT RPAD(NAME,5,'.') AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
Chris
Meg..
Jeff.
```

Example 4: Assume that NAME is a CHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. Note that the result of RTRIM in the following example is a varying length string with the blanks removed:

```
SELECT RPAD(RTRIM(NAME),15,'.') AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
-----
Chris.....
Meg.....
Jeff.....
```

RTRIM

The RTRIM function removes bytes from the end of a string expression based on the content of a trim expression.

The diagram shows the function signature: RTRIM(—string-expression— [, —trim-expression—]). The string-expression and trim-expression are enclosed in brackets, and the entire function call is enclosed in a larger set of brackets with arrows at the ends.

The schema is SYSIBM.

The RTRIM function removes all of the characters contained in *trim-expression* from the end of *string-expression*. The search is done by comparing the binary representation of each character (which consists of one or more bytes) in *trim-expression* to the bytes at the end of *string-expression*. If *string-expression* is defined as FOR BIT DATA, the search is done by comparing each byte in *trim-expression* to the byte at the end of *string-expression*.

string-expression

An expression that specifies the source string. The argument must be an expression that returns a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated. If *string-expression* is not FOR BIT DATA, *trim-expression* must not be FOR BIT DATA.

trim-expression

An expression that specifies the characters to remove from the end of *string-expression*. The expression must return a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated.

The default for *trim-expression* depends on the data type of *string-expression*:

- A DBCS blank if *string-expression* is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if *string-expression* is a Unicode graphic string.
- A value of X'00' if *string-expression* is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. When not EBCDIC, X'20' represents a blank.

string-expression and *trim-expression* must have compatible data types. If *string-expression* and *trim-expression* have different CCSID sets, *trim-expression* is converted to the CCSID of *string-expression*.

The result of the function depends on the data type of *string-expression*.

- VARCHAR if *string-expression* is a character string. If *string-expression* is defined as FOR BIT DATA, the result is FOR BIT DATA.
- VARGRAPHIC if *string-expression* is a graphic string.

- VARBINARY if *string-expression* is a binary string.

The length attribute of the result is the same as the length attribute of *string-expression*.

The actual length of the result for a character or binary string is the length of *string-expression* minus the number of bytes removed. The actual length of the result for a graphic string is the length (in number of double byte characters) of *string-expression* minus the number of double byte characters removed. If all of the characters are removed, the result is an empty string (the length is zero).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Example: Use the RTRIM function to remove individual numbers in the second argument from the end (right side) of the first argument:

```
SELECT RTRIM ('123DEFG123', '321'),  
       RTRIM ('12322XYZ12322222', '123'),  
       RTRIM ('12321', '213'),  
       RTRIM ('123XYX', '321')  
FROM SYSIBM.SYSDUMMY1
```

The result is '123DEFG', '12322XYZ', '' (empty string - all characters removed), and '123XYX' (no characters removed).

The RTRIM function does not remove instances of '1', '2', and '3' on the left side of the string, before characters that are not '1', '2', or '3'.

Example: Use the RTRIM function to remove individual characters in the second argument from the end (right side) of the first argument:

```
SELECT RTRIM ('((-78.0))', '-0.()')  
FROM SYSIBM.SYSDUMMY1
```

The result is '((-78'.

Example: Use the RTRIM function to remove dollar signs and periods in the second argument from the end (right side) of the first argument:

```
SELECT RTRIM ('...$VAR$...', '$.')
```

The result is '...\$VAR'.

SCORE

The SCORE function searches a text search index using criteria that are specified in a search argument and returns a relevance score that measures how well a document matches the query.

►► SCORE (*column-name* , *search-argument* (1) , *string-constant*)

Notes:

- 1 *string-constant* must conform to the rules for the *search-argument-options*.

search-argument-options:

(1)

| | | |
|---------------|---|-----------|
| QUERYLANGUAGE | = | value |
| RESULTLIMIT | = | value |
| SYNONYM | = | OFF ON |

Notes:

- 1 The same clause must not be specified more than once.

The schema is SYSIBM.

column-name

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, either directly or through another nested view.

search-argument

Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

string-constant

Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

QUERYLANGUAGE = *value*

Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US.

RESULTLIMIT = *value*

Specifies the maximum number of results that are to be returned from the underlying search engine. The *value* can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

SYNONYM = OFF or SYNONYM = ON

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

OFF Do not use a synonym dictionary.

ON Use the synonym dictionary that is associated with the text search index.

The result of the function is a double-precision floating-point number. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is greater than 0 but less than 1 if the column contains a match for the search criteria that the search argument specifies. The better a document matches the query, the more relevant the score and the larger the result value. If the column does not contain a match, the result is 0.

SCORE is a non-deterministic function.

Example

The following statement generates a list of employees in the order of how well their resumes matches the query "programmer AND (java OR cobol)", along with a relevance value that is normalized between 0 (zero) and 100.

```
SELECT EMPNO, INTEGER(SCORE(RESUME, 'programmer AND
(java OR cobol)') * 100) AS RELEVANCE
FROM EMP_RESUME
WHERE RESUME_FORMAT = 'ascii'
AND CONTAINS(RESUME, 'programmer AND (java OR cobol)') = 1
ORDER BY RELEVANCE DESC
```

DB2 first evaluates the CONTAINS predicate in the WHERE clause, and therefore, does not evaluate the SCORE function in the SELECT list for every row of the table. In this case, the arguments for SCORE and CONTAINS must be identical.

SECOND

The SECOND function returns the seconds part of a value with optional fractional seconds.

```
SECOND(expression [, -integer-constant])
```

The schema is SYSIBM.

expression

expression must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 145.

integer-constant

integer-constant must be an integer constant that represents the scale for the fractional seconds portion of *expression*. The value must be in the range 0 through 12. If *integer-constant* is not specified, the result does not include fractional seconds.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function with a single argument is a large integer. The result of the function with two arguments is DECIMAL(2+s,s) where *s* is the value of *integer-constant*.

The result can be null; if the first argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of a time or a timestamp:

The result is the seconds part of the value (0 to 59) and any fractional seconds that are included in the value. If the second argument is specified, the result includes *integer-constant* digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value, zeros are returned.

If the argument is a time duration or timestamp duration:

The result is the seconds part of the value (-99 to 99) and any fractional seconds that are included in the value. If the second argument is specified, the result includes *integer-constant* digits of the fractional seconds part of

| the value where applicable. If there are no fractional seconds in the value,
| zeros are returned. A nonzero result has the same sign as the *expression*.

Example 1: Assume that the variable *TIME_DUR* is declared in a PL/I program as *DECIMAL(6,0)* and can therefore be interpreted as a time duration. When *TIME_DUR* has the value 153045, the following function returns the value 45.

```
SECOND(:TIME_DUR)
```

Example 2: Assume that *RECEIVED* is a *TIMESTAMP* column and that one of its values is the internal equivalent of '1988-12-25-17.12.30.000000'. The following function returns the value 30.

```
SECOND(RECEIVED)
```

| *Example 3:* The following invocations of the *SECOND* function returns the same
| result:

```
| SELECT SECOND('2003-01-02-20.10.05.123456'),  
|         SECOND('2003-01-02-12.10.05.123456-08:00'),  
|         SECOND('2003-01-03-05.10.05.123456+09:00')  
| FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the *SECOND* function in this *SELECT* statement, the result
| is 5.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the *SELECT* statement all have the same UTC representation:
| 2003-01-02-20.10.05.123456. The second portion of the UTC representation is 5.

| *Example 4:* Return the seconds with fractional seconds from a current timestamp
| with milliseconds.

```
| SELECT SECOND(CURRENT_TIMESTAMP(3),3)  
| FROM SYSIBM.SYSDUMMY1;
```

| The *SELECT* statement returns a *DECIMAL(5,3)* value that is based on the current
| timestamp and could be something like 54.321.

SIGN

The SIGN function returns an indicator of the sign of the argument.

▶—SIGN(*numeric-expression*)—▶

The schema is SYSIBM.

The returned value is one of the following values:

- 1 if the argument is less than zero
- 0 if the argument is DECFLOAT negative zero
- 0 if the argument is zero
- 1 if the argument is greater than zero

The argument must be an expression that returns a value of any built-in numeric data type, except DECIMAL(31,31).

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result has the same data type and length attribute as the argument, except that precision is increased by one if the argument is DECIMAL and the scale of the argument is equal to its precision. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(6,5).

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *PROFIT* is a large integer with a value of 50000.

```
SELECT SIGN(:PROFIT)
FROM SYSIBM.SYSDUMMY1;
```

This example returns the value 1.

SIN

The SIN function returns the sine of the argument, where the argument is an angle, expressed in radians.

►►—SIN(*numeric-expression*)—◄◄

The schema is SYSIBM.

The SIN and ASIN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *SINE* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.99.

```
SELECT SIN(:SINE)
FROM SYSIBM.SYSDUMMY1;
```

SINH

The SINH function returns the hyperbolic sine of the argument, where the argument is an angle, expressed in radians.

►►—SINH(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *HSINE* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.12.

```
SELECT SINH(:HSINE)
FROM SYSIBM.SYSDUMMY1;
```

SMALLINT

The SMALLINT function returns a small integer representation either of a number or of a string representation of a number.

Numeric to Smallint:

```
▶▶—SMALLINT(numeric-expression)—————▶▶
```

String to Smallint:

```
▶▶—SMALLINT(string-expression)—————▶▶
```

The schema is SYSIBM.

Numeric to Smallint

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a small integer column or variable. If the whole part of the argument is not within the range of small integers, an error occurs. If present, the decimal part of the argument is truncated.

String to Smallint

string-expression

An expression that returns a value of character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes for a character string or 127 for a graphic string. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS SMALLINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL integer constant. The fractional part of the argument is truncated.

The result of the function is a small integer.

The result can be null; if the argument is null, the result is the null value.

Recommendation: To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 254.

Example: Using sample table DSN8A10.EMP, find the average education level (EDLEVEL) of the employees in department 'A00'. Round the result to the nearest full education level.

```
SELECT SMALLINT(AVG(EDLEVEL)+.5)
FROM DSN8A10.EMP
WHERE DEPT = 'A00';
```

Assuming that the five employees in the department have education levels of '19', '18', '14', '18', and '14', the result is '17'.

SOUNDEX

The SOUNDEX function returns a 4-character code that represents the sound of the words in the argument. The result can be compared to the results of the SOUNDEX function of other strings.

```
▶—SOUNDEX(expression)—▶
```

The schema is SYSIBM.

expression

An *expression* that must return a value of any built-in numeric, character, or graphic string data type that is not a LOB. A numeric, mixed character, or graphic string value is cast to a Unicode SBCS character string before the function is evaluated. For more information about converting numeric data to a character string, see “VARCHAR” on page 641. For more information about converting mixed or graphic strings to Unicode SBCS, see “CAST specification” on page 254.

The data type of the result is CHAR(4).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the Unicode SBCS CCSID.

The SOUNDEX function is useful for finding strings for which the sound is known but the precise spelling is not. It makes assumptions about the way that letters and combinations of letters sound that can help to search for words with similar sounds. The comparison of words can be done directly or by passing the strings as arguments to the DIFFERENCE function. For more information, see “DIFFERENCE” on page 428.

Example 1: Use the SOUNDEX function to find a row where the sound of the LASTNAME value closely matches the phonetic spelling of 'Loucesy':

```
SELECT EMPNO, LASTNAME
FROM DSN910.EMPLOYEE
WHERE SOUNDEX(LASTNAME) = SOUNDEX('Loucesy');
```

This example returns the following row:

```
000110 LUCCHESI;
```

SOAPHTTPC and SOAPHTTPV

The SOAPHTTPC function returns a CLOB representation of XML data that results from a SOAP request to the web service that is specified by the first argument. The SOAPHTTPV function returns a VARCHAR representation of XML data that results from a SOAP request to the web service that is specified by the first argument.

The schema is DB2XML.

These functions are deprecated and might not be available in future releases of DB2.

endpoint_url

An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies the URL of the web service endpoint for which DB2 is acting as a client.

soap_action

An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies a SOAP action URI reference. If it is required for the web service that is specified in *endpoint_url*, the required value is defined in the WSDL of that web service.

soap_body

An expression that returns a value of a built-in character string data type that is defined as VARCHAR(3072) or CLOB(1M). The value specifies the name of an operation with the requested namespace URI, an encoding style, and input arguments. *soap_body* can include well-formed XML content for the SOAP body. The specific operations and arguments for a web service are defined in the WSDL of the specified web service.

If the arguments can be null, the result can be null; if all of the arguments are null, the result is the null value.

The result can be null; if all of the arguments are null, the result is the null value.

Example 1: The following SQL statement retrieves information (as VARCHAR data) about a web service:

```
SELECT DB2XML.SOAPHTTPV(  
    'http://www.myserver.com/services/db2sample/ivt.dadx/SOAP',  
    'http://tempuri.org/db2sample/ivt.dadx',  
    '<testInstallation xmlns="http://tempuri.org/db2sample/ivt.dadx" />')  
FROM SYSIBM.SYSDUMMY1
```

Example 2: The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```
INSERT INTO EMPLOYEE(XMLCOL)  
VALUES (DB2XML.SOAPHTTPC(  
    'http://www.myserver.com/services/db2sample/list.dadx/SOAP',
```

```
'http://tempuri.org/db2sample/list.dadx',  
'<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">  
  <deptNo>A00</deptNo>  
</listDepartments>')')
```

SOAPHTTPNC and SOAPHTTPNV

The SOAPHTTPNC and SOAPHTTPNV functions allow you to specify a complete SOAP message as input and to return complete SOAP messages from the specified web service. The returned SOAP messages are CLOB or VARCHAR representations of the returned XML data.

The schema is DB2XML.

endpoint_url

| Specifies the URL of the web service for which DB2 is acting as a client.
| *endpoint_url* is defined as a VARCHAR(4096) value. The URL is in the
| following format:
| proto://[user[:password]@]hostname[:port]/[path]

| Where *proto* can be http or https.

soap_action

| Specifies a SOAP action URI reference. *soap_action* is defined as a
| VARCHAR(4096) value. Depending on the web server, *soap_action* might be
| required. If it is required for the web service that is specified in *endpoint_url*,
| the required value is defined in the WSDL of that web service.

soap_input

| Specifies an XML document that contains the complete SOAP message.
soap_input can contain optional SOAP headers and must contain a SOAP body
| that specifies the operation name and parameters to the web service. *soap_input*
| should be well-formed XML that is defined as VARCHAR(32672) or
| CLOB(1M).

Example 1: The following SQL statement retrieves information (as VARCHAR data) about a web service:

```
SELECT DB2XML.SOAPHTTPNV(
  'http://rpc.geocoder.us/service/soap/',
  '"http://rpc.geocoder.us/Geo/Coder/US#geocode_address"',
  '<?xml version="1.0" encoding="UTF-8" ?>' ||
  '<SOAP-ENV:Envelope ' ||
  'xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" ' ||
  'xmlns:xsd="http://www.w3.org/2001/XMLSchema" ' ||
  'xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">' ||
  '<SOAP-ENV:Body>' ||
  '<ns0:geocode_address ' ||
  'xmlns:ns0="http://rpc.geocoder.us/Geo/Coder/US/" ' ||
  'SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">' ||
  '<address xsi:type="xsd:string">555 Bailey Avenue, San Jose,' ||
  'CA,95141</address>' ||
  '</ns0:geocode_address>' ||
  '</SOAP-ENV:Body>' ||
  '</SOAP-ENV:Envelope>')
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```

INSERT INTO EMPLOYEE(XMLCOL)
VALUES (DB2XML.SOAPHHTTPNC(
    'http://www.myserver.com/services/db2sample/list.dadx/SOAP',
    'http://tempuri.org/db2sample/list.dadx',
    '<?xml version="1.0" encoding="UTF-8" ?>' ||
    '<SOAP-ENV:Envelope ' ||
    'xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" ' ||
    'xmlns:xsd="http://www.w3.org/2001/XMLSchema" ' ||
    'xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">' ||
    '<SOAP-ENV:Body>' ||
    '<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">
        <deptNo>A00</deptNo>
    </listDepartments>' ||
    '</SOAP-ENV:Body>' ||
    '</SOAP-ENV:Envelope>'))

```

SPACE

The SPACE function returns a character string that consists of the number of SBCS blanks that the argument specifies.

►—SPACE(*numeric-expression*)—►

The schema is SYSIBM.

numeric-expression

An expression that returns the value of any built-in integer data type. The expression specifies the number of SBCS blanks for the result, and it must be between 0 and 32767.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a varying-length character string (VARCHAR) that contains SBCS data.

If *numeric-expression* is a constant, the length attribute of the result is the constant. Otherwise, the length attribute of the result is 4000. The actual length of the result is the value of *numeric-expression*. The actual length of the result must not be greater than the length attribute of the result.

The result can be null; if the argument is null, the result is the null value.

Example: The following statement returns a character string that consists of 5 blanks followed by a zero-length string.

```
SELECT SPACE(5), SPACE(0)
FROM SYSIBM.SYSDUMMY1;
```

Related concepts:

“Character string encoding schemes” on page 86

“Varying-length character strings” on page 85

SQRT

The SQRT function returns the square root of the argument.

►►—SQRT(*numeric-expression*)—◄◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type. If the argument is DECFLOAT, the operation is performed in DECFLOAT. Otherwise, the argument is converted to a double precision floating-point number for processing by the functions.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the result of the function is a double precision floating-point number. If the argument is a special decimal floating point value, the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 235 for more information.

The result can be null; if the argument is null, the result is the null value.

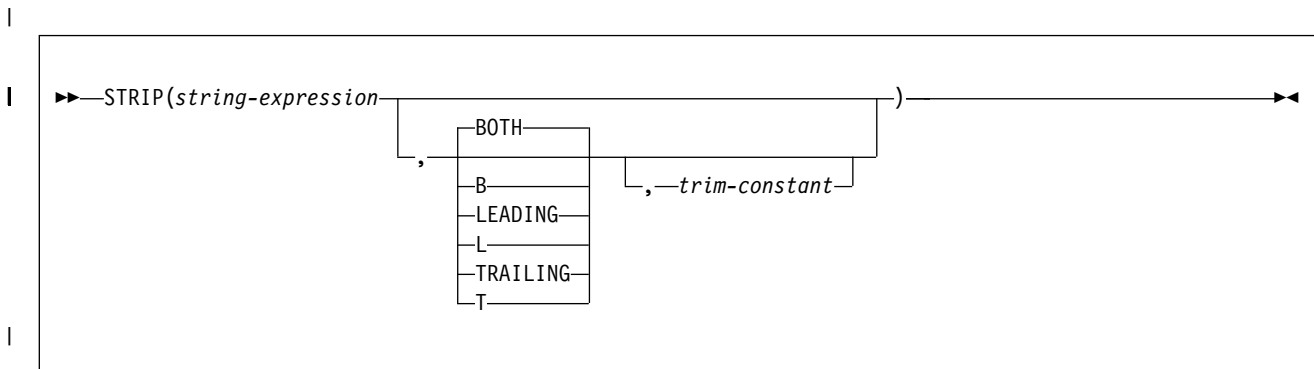

Example: Assume that host variable *SQUARE* is defined as DECIMAL(2,1) and has a value of 9.0. Find the square root of *SQUARE*.

```
SELECT SQRT(:SQUARE)
FROM SYSIBM.SYSDUMMY1;
```

This example returns a double precision floating-point number with an approximate value of 3.

STRIP

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.

The schema is SYSIBM.

The STRIP function is similar to the TRIM scalar function.

Related reference:

“TRIM” on page 624

SUBSTR

The SUBSTR function returns a substring of a string.

The schema is SYSIBM.

string-expression

An expression that specifies the string from which the result is derived. The string must be a character, graphic, or binary string. If *string-expression* is a character string, the result of the function is a character string. If it is a graphic string, the result of the function is a graphic string. If it is a binary string, the result of the function is a binary string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

A substring of *string-expression* is zero or more contiguous characters of *string-expression*. If *string-expression* is a graphic string, a character is a DBCS character. If *string-expression* is a character string or a binary string, a character is a byte. The SUBSTR function accepts mixed data strings. However, because SUBSTR operates on a strict byte-count basis, the result will not necessarily be a properly formed mixed data string.

start

An expression that specifies the position within *string-expression* to be the first character of the result. The value of the large integer must be between 1 and the length attribute of *string-expression*. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first character of the substring is the first character of *string-expression*.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length

An expression that specifies the length of the resulting substring. If specified, *length* must be an expression that returns a value that is a built-in large integer data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value. The value must be greater than or equal to 0 and less than or equal to n , where n is the length attribute of $\text{string-expression} - \text{start} + 1$. The specified length must not, however, be the large integer constant 0.

If *length* is explicitly specified, *string-expression* is effectively padded on the right with the necessary number of characters so that the specified substring of *string-expression* always exists. Hexadecimal zeros are used as the padding character when *string-expression* is binary data. Otherwise, a blank is used as the padding character.

If *string-expression* is a fixed-length string, omission of *length* is an implicit specification of `LENGTH(string-expression) - start + 1`, which is the number of characters (or bytes) from the character (or byte) specified by *start* to the last character (or byte) of *string-expression*. If *string-expression* is a varying-length string, omission of *length* is an implicit specification of the greater of zero or `LENGTH(string-expression) - start + 1`. If the resulting length is zero, the result is an empty string.

If *length* is explicitly specified by a large integer constant that is 255 or less, and *string-expression* is not a LOB, the result is a fixed-length string with a length attribute of *length*. If *length* is not explicitly specified, but *string-expression* is a fixed-length string and *start* is an integer constant, the result is a fixed-length string with a length attribute equal to `LENGTH(string-expression) - start + 1`. In all other cases, the result is a varying-length string. If *length* is explicitly specified by a large integer constant, the length attribute of the result is *length*; otherwise, the length attribute of the result is the same as the length attribute of *string-expression*.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the CCSID of *string-expression*.

Example 1: `FIRSTNME` is a `VARCHAR(12)` column in sample table `DSN8A10.EMP`. When `FIRSTNME` has the value 'MAUDE':

| Function: | Returns: |
|----------------------|----------------------------------|
| SUBSTR(FIRSTNME,2,3) | -- 'AUD' |
| SUBSTR(FIRSTNME,2) | -- 'AUDE' |
| SUBSTR(FIRSTNME,2,6) | -- 'AUDE' followed by two blanks |
| SUBSTR(FIRSTNME,6) | -- a zero-length string |
| SUBSTR(FIRSTNME,6,4) | -- four blanks |

Example 2: Sample table `DSN8A10.PROJ` contains column `PROJNAME`, which is defined as `VARCHAR(24)`. Select all rows from that table for which the string in `PROJNAME` begins with 'W L PROGRAM'.

```
SELECT * FROM DSN8A10.PROJ
WHERE SUBSTR(PROJNAME,1,12) = 'W L PROGRAM ';
```

Assume that the table has only the rows that were supplied by DB2. Then the predicate is true for just one row, for which `PROJNAME` has the value 'W L PROGRAM DESIGN'. The predicate is not true for the row in which `PROJNAME` has the value 'W L PROGRAMMING' because, in the predicate's string constant, 'PROGRAM' is followed by a blank.

Example 3: Assume that a LOB locator named *my_loc* represents a LOB value that has a length of 1 gigabyte. Assign the first 50 bytes of the LOB value to host variable `PORTION`.

```
SET :PORTION = SUBSTR(:my_loc,1,50);
```

Example 4: Assume that host variable `RESUME` has a CLOB data type and holds an employee's resume. This example shows some of the statements that find the section of department information in the resume and assign it to host variable `DeptBuf`. First, the `POSSTR` function is used to find the beginning and ending location of the department information. Within the resume, the department information starts with the string 'Department Information Section' and ends immediately before the string 'Education Section'. Then, using these beginning and ending positions, the `SUBSTR` function assigns the information to the host variable.

```
SET :DInfoBegPos = POSSTR(:RESUME, 'Department Information Section');  
SET :DInfoEnPos = POSSTR(:RESUME, 'Education Section');  
SET :DeptBuf = SUBSTR(:RESUME, :DInfoBegPos, :DInfoEnPos - :DInfoBegPos);
```

SUBSTRING

The SUBSTRING function returns a substring of a string.

Character:

Graphic:

Binary:

The schema is SYSIBM.

Character

character-expression

An expression that specifies the string from which the result is derived. The string must be a built-in character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The result of the function is a character string.

A substring of *character-expression* is zero or more contiguous units of *character-expression*. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character. If OCTETS is specified, a unit is a byte.

start

An expression that specifies the position within the *character-expression* that is to be the first string unit of the result. *start* is expressed in the specified string unit, and must return an integer value.

The argument can also be another numeric value, a character string, or a graphic string data type. The input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value. The value of *start* can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of *character-expression*.

length

An expression that specifies the maximum length of the resulting substring.

If *character-expression* is a fixed-length string, omission of *length* is an implicit specification of `CHARACTER_LENGTH(character-expression) - start + 1`, which is the number of string units (CODEUNITS16, CODEUNITS32, or OCTETS) from *start* to the last position of *character-expression*.

If *character-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(character-expression) - start + 1`, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be an expression that returns a value of an integer data type.

The argument can also be another numeric value, a character string, or a graphic string data type. The input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *character-expression - start + 1*, then *n* is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

For more information, see Rigorous description of the actual length and result.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express *start* and *length*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

Graphic

graphic-expression

An expression that specifies the string from which the result is derived. The string must be a built-in graphic string. The result of the function is a graphic string. A partial surrogate character in the expression is replaced with a blank.

A substring of *graphic-expression* is zero or more contiguous units of *graphic-expression*. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character.

start

An expression that specifies the position within the *graphic-expression* that is to be the first string unit of the result. *start* is expressed in the specified string

unit, and must return an integer value. The value of *start* can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of *graphic-expression*.

The argument can also be another numeric value, a character string, or a graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length

An expression that specifies the maximum length of the resulting substring.

If *graphic-expression* is a fixed-length string, omission of *length* is an implicit specification of `CHARACTER_LENGTH(graphic-expression) - start + 1`, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, from the start position to the last position of *graphic-expression*. If *graphic-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(graphic-expression) - start + 1`, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be an expression that returns a value of an integer data type.

The argument can also be another numeric value, a character string, or a graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *graphic-expression - start + 1*, then *n* is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

For more information, see Rigorous description of the actual length and result.

CODEUNITS16 or CODEUNITS32

Specifies the string unit that is used to express *start* and *length*.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

Binary

binary-expression

An expression that specifies the string from which the result is derived. The string must be a built-in binary string. The result of the function is a binary string.

A substring of *binary-expression* is zero or more contiguous units of *binary-expression*.

start

An expression that specifies the position within *binary-expression* to be the first byte of the result. It must be an integer value. *start* can be negative or zero.

(The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first byte of the substring is the byte unit of *binary-expression*.

length

An expression that specifies the length of the resulting substring.

If *binary-expression* is a fixed-length string, omission of *length* is an implicit specification of $\text{LENGTH}(\text{binary-expression}) - \text{start} + 1$ from the start position to the last position of *binary-expression*. If *binary-expression* is a varying length string, omission of *length* is an implicit specification of zero or $\text{CHARACTER_LENGTH}(\text{binary-expression}) - \text{start} + 1$, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be a value of an integer data type. The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *binary-expression* - start + 1, then *n* is used as the length of the resulting substring.

For more information, see Rigorous description of the actual length and result.

Rigorous description of the actual length and result

In this description, the term *character* means the “unit specified by string units” or “bytes” if the input is binary.

Let *C* be the value of the first argument, let *LC* be the length in characters of *C*, and let *S* be the value of the *start*.

- If *length* is specified, let *L* be the value of *length* and let *E* be *S*+*L*. Otherwise, let *E* be the larger of *LC* + 1 and *S*.
- If either *C*, *S*, or *L* is the null value, the result of the function is the null value.
- If *E* is less than *S*, an exception condition is raised: data exception — substring error.
- Otherwise:
 - If *S* is greater than *LC* or if *E* is less than 1 (one), the result of the function is a zero-length string.
 - Otherwise:
 - Let *S1* be the larger of *S* and 1 (one). Let *E1* be the smaller of *E* and *LC*+1. Let *L1* be *E1*–*S1*.
 - The result of the function is a character string that contains the *L1* characters of *C* starting at character number *S1* in the same order that the characters appear in *C*.

The data type of the result depends on the data type of the first argument, as shown in the following table.

Table 72. Data type of the result of SUBSTRING

| Data type of the first argument | Data type of the result |
|---------------------------------|---|
| CHAR or VARCHAR | VARCHAR |
| CLOB | CLOB |
| | If <i>character-expression</i> is mixed data, the result is mixed data. Otherwise, the result is SBCS data. |
| GRAPHIC or VARGRAPHIC | VARGRAPHIC |
| DBCLOB | DBCLOB |
| BINARY or VARBINARY | VARBINARY |

Table 72. Data type of the result of SUBSTRING (continued)

| Data type of the first argument | Data type of the result |
|---------------------------------|-------------------------|
| BLOB | BLOB |

The length attribute of the result is equal to the length attribute of the first argument. If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

The result can be null; if any argument is null, the result is the null value.

If the first argument is character or graphic data, the CCSID of the result is the same as that of the first argument.

Example 2: C1 is a VARCHAR(12) column in table T1. One of its values is the string 'ABCDEFGF'. When C1 has the value 'ABCDEFGF':

| Function: | Returns: |
|---------------------------|-------------------------|
| ----- | |
| SUBSTRING(C1,-2,2,OCTETS) | -- a zero-length string |
| SUBSTRING(C1,-2,4,OCTETS) | 'A' |
| SUBSTRING(C1,-2,OCTETS) | 'ABCDEFGF' |
| SUBSTRING(C1,0,1,OCTETS) | -- a zero-length string |

Example 1: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the value 'Jürgen':

| Function: | Returns: |
|--------------------------------------|--------------------------------------|
| ----- | |
| SUBSTRING(FIRSTNAME,1,2,CODEUNITS32) | 'Jü' -- x'4AC3BC' |
| SUBSTRING(FIRSTNAME,1,2,CODEUNITS16) | 'Jü' -- x'4AC3BC' |
| SUBSTRING(FIRSTNAME,1,2,OCTETS) | 'J ' -- x'4A20' (a truncated string) |
| SUBSTRING(FIRSTNAME,8,CODEUNITS16) | -- a zero-length string |
| SUBSTRING(FIRSTNAME,8,4,OCTETS) | -- a zero-length string |

TAN

The TAN function returns the tangent of the argument, where the argument is an angle, expressed in radians.

```
▶▶—TAN(numeric-expression)—▶▶
```

The schema is SYSIBM.

The TAN and ATAN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *TANGENT* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 14.10 .

```
SELECT TAN(:TANGENT)
FROM SYSIBM.SYSDUMMY1;
```

TANH

The TANH function returns the hyperbolic tangent of the argument, where the argument is an angle, expressed in radians.

▶▶—TANH(*numeric-expression*)—◀◀

The schema is SYSIBM.

The TANH and ATANH functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *HTANGENT* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.90.

```
SELECT TANH(:HTANGENT)
FROM SYSIBM.SYSDUMMY1;
```

TIME

The TIME function returns a time that is derived from a value.

►—TIME(*expression*)—◄

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a `TIMESTAMP WITH TIME ZONE` value, *expression* is first cast to `TIMESTAMP WITHOUT TIME ZONE`, with the same precision as *expression*.

If *expression* is not a `TIME` value, *expression* is cast as follows:

- If *expression* is a `TIMESTAMP WITH TIME ZONE` value, *expression* is cast to `TIMESTAMP WITHOUT TIME ZONE`, with the same precision as *expression*.
- If *expression* is a string, *expression* is cast to `TIME`.

The result of the function is a time.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time

the result is that time.

If the argument is a timestamp

the result is the time part of the timestamp.

If the argument is a string

the result is the time or time part of the timestamp represented by the string. If the `CCSID` of the string is not the same as the corresponding default `CCSID` at the server, the string is first converted to that `CCSID`.

The result `CCSID` is the appropriate `CCSID` of the argument encoding scheme and the result subtype is the appropriate subtype of the `CCSID`.

Example: Assume that a table named `CLASSES` contains one row for each scheduled class. Assume also that the class starting times are in the `TIME` column named `STARTTM`. Using these assumptions, select those rows in `CLASSES` that represent classes that start at 1:30 P.M.

```
SELECT *
  FROM CLASSES
 WHERE TIME(STARTTM) = '13:30:00';
```

TIMESTAMP

The `TIMESTAMP` function returns a `TIMESTAMP WITHOUT TIME ZONE` value from its argument or arguments.

See “`TIMESTAMP_TZ`” on page 613 for a similar function.

▶—TIMESTAMP(*expression-1* [, *expression-2*])—▶

The schema is `SYSIBM`.

The rules for the arguments depend on whether the second argument is specified.

- **If only one argument is specified:**

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression-1* is a character or graphic string, it must not be a CLOB or DBCLOB and it must have one of the following values:

- A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 101.
- A character string or graphic string with an actual length of 8 that is assumed to be a System z[®] Store Clock value.
- A character string with an actual length of 13 that is assumed to be a result from the `GENERATE_UNIQUE` function.
- A character string or graphic string with an actual length of 14 that represents a valid date and time in the form *yyyyxxddhhmmss*, where *yyyy* is the year, *xx* is the month, *dd* is the day, *hh* is the hour, *mm* is the minute, and *ss* is the seconds.²¹

- **If both arguments are specified:**

- If the data type of the second argument is not an integer:

The first argument must be an expression that returns a value of one of the following built-in data types: a date, a character string, or a graphic string. The second argument must be an expression that returns a value of one of the following built-in data types: a time, a character string, or a graphic string. A character string or graphic string must be a valid string representation of a time.

If *expression-1* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date with an actual length that is not greater than 255 bytes. If *expression-2* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and times, see “String representations of datetime values” on page 101.

- If the data type of the second argument is integer:

21. A character or graphic string with an actual length of 14 that represents a valid date and time (as allowed for the `TIMESTAMP` function) is also allowed as input to other scalar functions that accept a timestamp as an input argument.

The first argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a date, a character string, or a graphic string. The second argument must be an integer constant in the range 0 to 12 that represents the timestamp precision.

If *expression-1* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp or a date with an actual length that is not greater than 255 bytes.

The result of the function is a `TIMESTAMP WITHOUT TIME ZONE` value.

The timestamp precision and other rules depend on whether the second argument is specified:

If both arguments are specified and the second argument is not an integer:

The result is a `TIMESTAMP(6) WITHOUT TIME ZONE` value with the date that is specified by the first argument and the time that is specified by the second argument. The fractional seconds part of the timestamp is zero.

If both arguments are specified and the second argument is an integer:

The result is a `TIMESTAMP WITHOUT TIME ZONE` value with the precision that is specified in the second argument.

If only one argument is specified and it is a `TIMESTAMP(p) WITHOUT TIME ZONE`:

The result is that `TIMESTAMP(p) WITHOUT TIME ZONE` value.

If only one argument is specified and it is a `TIMESTAMP(p) WITH TIME ZONE`:

The result is the argument value, cast to `TIMESTAMP(p) WITHOUT TIME ZONE`. The value is the local timestamp, not UTC.

If only one argument is specified and it is a date:

The result is that date with an assumed time of midnight that is cast to `TIMESTAMP(0) WITHOUT TIME ZONE`.

If only one argument is specified and it is a character or graphic string:

The result is the `TIMESTAMP(6) WITHOUT TIME ZONE` value that is represented by that string extended with any missing time information. If the argument is a string of length 14, the `TIMESTAMP` has a fractional seconds part of zero. The string value must not contain a specification of time zone.

If the arguments include only date information, the time information in the result value is all zeros.

The result can be null; if any argument is null, the result is the null value.

If an argument is a string with a `CCSID` that is not the same as the corresponding default `CCSID` at the server, the string is first converted to that `CCSID`.

The result `CCSID` is the appropriate `CCSID` of the argument encoding scheme and the result subtype is the appropriate subtype of the `CCSID`. If both arguments are specified and their encoding schemes are different, the result `CCSID` is the appropriate `CCSID` of the application encoding scheme.

Notes

Syntax alternatives:

If only one argument is specified, the CAST specification should be used for maximal portability. For more information, see “CAST specification” on page 254.

Examples

Example: **TIMESTAMP** with a DATE column and a TIME column as arguments

Assume that table TABLEX contains a DATE column named DATECOL and a TIME column named TIMECOL. For some row in the table, assume that DATECOL represents 25 December 2008 and TIMECOL represents 17 hours, 12 minutes, and 30 seconds after midnight. The following function returns the value '2008-12-25-17.12.30.000000'.

```
TIMESTAMP(DATECOL, TIMECOL)
```

Example: **TIMESTAMP** with a timestamp with time zone argument

Assume that host variable PRSTSZ contains '2008-02-29.20.00.000000 -08.30'. The following statement returns the value '2008-02-29.20.00.000000':

```
SELECT TIMESTAMP(:PRSTSZ)
FROM PROJECT;
```

Example: **TIMESTAMP** with a timestamp and an integer as arguments

The following invocation of the **TIMESTAMP** function converts a timestamp string with 7 digits of fractional seconds to a **TIMESTAMP(9) WITHOUT TIME ZONE** value and returns a value of '2007-09-24-15.53.37.216247400':

```
TIMESTAMP('2007-09-24-15.53.37.2162474',9);
```

TIMESTAMPADD

The `TIMESTAMPADD` function returns the result of adding the specified number of the designated interval to the timestamp value.

►—`TIMESTAMPADD(interval,number,expression)`—►

The schema is `SYSIBM`.

interval

An expression that returns a value of a built-in `SMALLINT` or `INTEGER` data type. The following values are valid values for *interval*:

Table 73. Valid values for intervals

| Valid values for <i>interval</i> | equivalent intervals |
|----------------------------------|----------------------|
| 1 | Microseconds |
| 2 | Seconds |
| 4 | Minutes |
| 8 | Hours |
| 16 | Days |
| 32 | Weeks |
| 64 | Months |
| 128 | Quarters |
| 256 | Years |

number

An expression that returns a value of a built-in `SMALLINT` or `INTEGER` data type.

expression

An expression that returns a value of a built-in `TIMESTAMP WITHOUT TIME ZONE` data type.

The result of the function is the same timestamp data type with the same timestamp precision as *expression*.

The result can be null; if any argument is null, the result is the null value.

The result is determined using the normal rules for datetime arithmetic. See “Datetime arithmetic in SQL” on page 244. When the interval to add is expressed as weeks, the result is calculated as if *number* × 7 days had been specified. When the interval to add is expressed as quarters, the result is calculated as if *number* × 3 months had been specified.

Example 1: The following example will add 40 years to the specified timestamp. An interval of 256 designates years, while 40 specifies the number of intervals to add. The following statement returns the value '2005-07-27-15.30.00.000000'.

```
SELECT TIMESTAMPADD(256,40,TIMESTAMP('1965-07-27-15.30.00'))
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following example will add 18 months to the specified timestamp. An interval of 64 designates months, while 18 specifies the number of intervals to add. The following statement returns the value '2008-07-20-08.08.00.000000'.

```
SELECT TIMESTAMPADD(64,18,TIMESTAMP('2007-01-20-08.08.00'))
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following example will subtract 16 quarters (4 years) from the specified timestamp. An interval of 128 designates quarters, while -16 specifies the number of intervals to add (the '-' adds a negative amount). The following statement returns the value '2003-09-28-05.30.00.000000'.

```
SELECT TIMESTAMPADD(128,-16,TIMESTAMP('2007-09-28-05.30.00'))
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following example will add 18 weeks to the specified timestamp. An interval of 32 designates weeks, while 18 specifies the number of intervals to add. The following statement returns the value '2007-05-27-08.08.00.000000'.

```
SELECT TIMESTAMPADD(32,18,TIMESTAMP('2007-01-20-08.08.00'))
FROM SYSIBM.SYSDUMMY1;
```

TIMESTAMPDIFF

The `TIMESTAMPDIFF` function returns an estimated number of intervals of the type that is defined by the first argument, based on the difference between two timestamps.

►—`TIMESTAMPDIFF(numeric-expression,string-expression)`—►

The schema is `SYSIBM`.

numeric-expression

An expression that returns a value that is a built-in `SMALLINT` or `INTEGER` data type. The value specifies the interval that is used to determine the difference between two timestamps. The following table lists the valid values for *numeric-expression*:

Table 74. Valid values for *numeric-expression* and equivalent intervals that are used to determine the difference between two timestamps

| Valid values for <i>numeric-expression</i> | equivalent intervals |
|--|----------------------|
| 1 | Microseconds |
| 2 | Seconds |
| 4 | Minutes |
| 8 | Hours |
| 16 | Days |
| 32 | Weeks |
| 64 | Months |
| 128 | Quarters |
| 256 | Years |

string-expression

An expression that returns a value of a built-in character string or a graphic string data type that is not a LOB. The value is expected to be the result of subtracting two timestamps and converting the result to a character string of length 22. The string value must not have more than 6 digits to the right of a decimal point. If the supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The following table describes the elements of *string-expression*:

Table 75. `TIMESTAMPDIFF` String Elements

| String elements | Valid values | Character position from the decimal point (negative is left) |
|-----------------|-----------------|--|
| Years | 1-9998 or blank | -14 to -11 |
| Months | 0-11 or blank | -10 to -9 |
| Days | 0-30 or blank | -8 to -7 |
| Hours | 0-24 or blank | -6 to -5 |

Table 75. *TIMESTAMPDIFF* String Elements (continued)

| String elements | Valid values | Character position from the decimal point (negative is left) |
|-------------------|---------------|--|
| Minutes | 0-59 or blank | -4 to -3 |
| Seconds | 0-59 | -2 to -1 |
| Decimal separator | period | 0 |
| Microsecond | 000000-999999 | 1 to 6 |

The result of the function is an integer with the same sign as the second argument.

The result can be null; if any argument is null, the result is the null value.

The returned value is determined for each interval as indicated by the following table:

Table 76. *TIMESTAMPDIFF* Computations

| Result interval | Computation using duration elements |
|--|---|
| Years | years |
| Quarters | integer value of $(\text{months} + (\text{years} * 12)) / 3$ |
| Months | $\text{months} + (\text{years} * 12)$ |
| Weeks | integer value of $((\text{days} + (\text{months} * 30)) / 7) + (\text{years} * 52)$ |
| Days | $\text{days} + (\text{months} * 30) + (\text{years} * 365)$ |
| Hours | $\text{hours} + ((\text{days} + (\text{months} * 30) + (\text{years} * 365)) * 24)$ |
| Minutes (the absolute value of the duration must not exceed 40850913020759.999999) | $\text{minutes} + (\text{hours} + ((\text{days} + (\text{months} * 30) + (\text{years} * 365)) * 24)) * 60$ |
| Seconds (the absolute value of the duration must be less than 680105031408.000000) | $\text{seconds} + (\text{minutes} + (\text{hours} + ((\text{days} + (\text{months} * 30) + (\text{years} * 365)) * 24)) * 60) * 60$ |
| Microseconds (the absolute value of the duration must be less than 3547.483648) | $\text{microseconds} + (\text{seconds} + (\text{minutes} * 60)) * 1000000$ |

The following assumptions are used in estimating a difference:

- One year has 365 days
- One year has 52 weeks
- One year has 12 months
- One month has 30 days
- One day has 24 hours
- One hour has 60 minutes
- One minute has 60 seconds

The use of these assumptions imply that some result values are an estimate of the interval. Consider the following examples:

- Difference of 1 month where the month has less than 30 days.

```
TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00'))
- TIMESTAMP('1997-02-01-00.00.00'))
```

The result of the timestamp arithmetic is a duration of 00000100000000.000000, or 1 month. When the *TIMESTAMPDIFF* function is invoked with 16 for the interval argument (days), the assumption of 30 days in a month is applied and the result is 30.

- Difference of 1 day less than 1 month where the month has less than 30 days.

```
TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00'))
- TIMESTAMP('1997-02-02-00.00.00'))
```

The result of the timestamp arithmetic is a duration of 00000027000000.000000, or 27 days. When the `TIMESTAMPDIFF` function is invoked with 16 for the interval argument (days), the result is 27.

- Difference of 1 day less than 1 month where the month has 31 days.

```
TIMESTAMPDIFF(64, CHAR(TIMESTAMP('1997-09-01-00.00.00'))
- TIMESTAMP('1997-08-02-00.00.00'))
```

The result of the timestamp arithmetic is a duration of 00000030000000.000000, or 30 days. When the `TIMESTAMPDIFF` function is invoked with 64 for the interval argument (months), the result is 0. The days portion of the duration is 30, but it is ignored because the interval specified months.

Example: The following statement estimates the age of employees in months and returns that value as `AGE_IN_MONTHS`:

```
SELECT
  TIMESTAMPDIFF(64, CAST(CURRENT_TIMESTAMP-CAST(BIRTHDATE AS TIMESTAMP)
                        AS CHAR(22)))
  AS AGE_IN_MONTHS
FROM EMPLOYEE;
```

TIMESTAMP_FORMAT

The `TIMESTAMP_FORMAT` function returns a `TIMESTAMP WITHOUT TIME ZONE` value that is based on the interpretation of the input string using the specified format.

```
▶▶—TIMESTAMP_FORMAT—(—string-expression—,—format-string—  
┌,—6—  
└,—precision-constant—┘)—▶▶
```

The schema is `SYSIBM`.

string-expression

An expression that returns a value of any built-in character or graphic string data type, other than a `CLOB` or `DBCLOB`, with an actual length that is not greater than 255 bytes. The *string-expression* must contain the components of a timestamp that correspond to the format that is specified in *format-string*, except for hour, minute, second, or fractional seconds.

format-string

The expression must return a value that is a built-in character or graphic string data type, other than a `CLOB` or `DBCLOB`, with a length attribute that is not greater than 255 bytes. The actual length must not be greater than 255 bytes. The value is a template for how *string-expression* is interpreted and then converted to a timestamp value.

A valid *format-string* must contain at least one format element, must not contain multiple specifications for any component of a timestamp, and can contain any combination of the format elements, unless otherwise noted in the following table. For example, *format-string* cannot contain both `YY` and `YYYY`, because both are used to interpret the year component of a *string-expression*. Two format elements can be separated by one or more of the following separator characters:

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ()

Separator characters can also be specified at the start or end of *format-string*. These separator characters can be used in any combination in the format string, for example `'YYYY/MM-DD HH:MM.SS'`. Separator character that is specified in a *string-expression* are used to separate components and are not required to match the separator character that is specified in the *format-string*.

Table 77. Format elements for the `TIMESTAMP_FORMAT` function

| Format element | Related component of a timestamp | Description |
|--|----------------------------------|--|
| AM or PM ¹ | hour | Meridian indicator (morning or evening) without periods. This format element uses the exact strings "AM" or "PM". |
| A.M. or P.M. ¹ | hour | Meridian indicator (morning or evening) with periods. This format element uses the exact strings "A.M." or "P.M." |
| D ¹ | none | Day of the week (1-7). |
| DD | day | Day of the month (0-31). |
| DDD | month, day | Day of the year (001-366). |
| FF or FF n | fractional seconds | Fractional seconds (0-999999999999). The number n is used to specify the number of digits that is expected in the <i>string-expression</i> . Valid values for n are 1-12 with no leading zeros. Specifying FF is equivalent to specifying FF6. When the component in <i>string-expression</i> that corresponds to the FF format element is followed by a separator character or is the last component, the number of digits for the fractional seconds can be less than what is specified by the format element. In this case, zero digits are padded onto the right of the number of specified digits. |
| HH | hour | HH behaves the same as HH12. |
| HH12 | hour | Hour of the day (01-12) in 12-hour format. AM is the default meridian indicator. |
| HH24 | hour | Hour of the day (00-24) in 24-hour format. |
| J | year, month, and day | Julian day (number of days since January 1, 4713 BC). |
| MI | minute | Minute (00-59). |
| MM | month | Month (01-12). |
| MONTH, Month, or month ^{1, 2} | month | Name of the month in English. |
| MON, Mon, or mon ^{1, 2} | month | Abbreviated name of the month in English. |

Table 77. Format elements for the `TIMESTAMP_FORMAT` function (continued)

| Format element | Related component of a timestamp | Description |
|----------------|----------------------------------|--|
| NNNNNN | microseconds | Microseconds (000000-999999). |
| RR | year | Last two digits of the adjusted year (00-99). |
| RRRR | year | Four digit adjusted year (0000-9999). |
| SS | seconds | Seconds (00-59). |
| SSSS | hours, minutes, and seconds | Seconds since the previous midnight (00000 - 86400). |
| Y | year | Last digit of the year (0-9). First three digits of the current year are used to determine the full 4-digit year. |
| YY | year | Last two digits of the year (00-99). First two digits of the current year are used to determine the full 4-digit year. |
| YYY | year | Last three digits of the year (000-999). First digit of the current year is used to determine the full 4-digit year. |
| YYYY | year | 4-digit year (0000-9999). |

Notes:

1. This format element is case sensitive.
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.
3. The D format element does not contribute to any components of the resulting timestamp. However, a specified value for this format element must be correct for the combination of the day component of the resulting timestamp. For example, a value of '5' for *string-expression* is valid for a format string value of 'D'. However, value of '9' for *string-expression* would result in an error for the same *format-string*.

The RR and RRRR format elements can be used to change how a specification for a year is to be interpreted by adjusting the value to produce a 2-digit or a 4-digit value depending on the leftmost two digits of the current year according to the following table:

Table 78. Correspondence of adjusted year value and timestamp component

| Digits of the current year | Two-digit year in <i>string-expression</i> | First two digits of the year component of timestamp |
|----------------------------|--|---|
| 00-50 | 00-49 | First two digits of the current year |
| 51-99 | 00-49 | First two digits of the current year + 1 |
| 00-50 | 50-99 | First two digits of the current year -1 |

Table 78. Correspondence of adjusted year value and timestamp component (continued)

| Digits of the current year | Two-digit year in <i>string-expression</i> | First two digits of the year component of timestamp |
|----------------------------|--|---|
| 51-99 | 50-99 | First two digits of the current year |

For example, if the current year is 2007, '86' with format 'RR' means 1986, but if the current year is 2052, it means 2086.

The following defaults are used when a format-string does not include a format element for one of the following components of a timestamp:

| Timestamp component | Default |
|---------------------|--|
| year | current year, as 4 digits |
| month | current month. as 2 digits |
| day | 01 (first day of the month) |
| hour | 00 |
| minute | 00 |
| second | 00 |
| fractional seconds | a number of zeros to match the timestamp precision of the result |

If *string-expression* does not include a value that corresponds to an hour, minute, second, or fractional seconds format element that is specified in the *format-string*, the same defaults are used.

Leading zeros can be specified for any component of the timestamp value (that is, month, day, hour, minutes, seconds) that does not have the maximum number of significant digits for the corresponding format element in the *format-string*.

A substring of the *string-expression* that represents a component of a timestamp (such as year, month, day, hour, minutes, seconds) can include fewer than the maximum number of digits for that component of the timestamp that is indicated by the corresponding format element. Any missing digits default to zero. For example, with a format-string of 'YYYY-MM-DD HH24:MI:SS', an input value of '999-3-9 5:7:2' produces the same result as '0999-03-09 05:07:02'.

precision-constant

An integer constant that specifies the timestamp precision of the result. The value must be in the range 0 to 12. If *precision-constant* is not specified, the timestamp precision defaults to 6.

The result of the function is a `TIMESTAMP` with a precision that is based on *precision-constant*.

If either of the first two arguments can be null, the result can be null; if either of the first two arguments is null, the result is the null value.

The result `CCSID` is the appropriate `CCSID` of the encoding scheme of the first argument and the result subtype is the appropriate subtype of the `CCSID`.

Notes

Julian and Gregorian calendar:

The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

Determinism:

TIMESTAMP_FORMAT is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT_TIMESTAMP.

- *format-string* is not a constant
- *format-string* is a constant and includes format elements that are locale sensitive
- *format-string* is a constant and does not include a format element that fully defines the year (that is, J or YYYY). In this case the current year is used.
- *format-string* is a constant and does not include a format element that fully defines the month (for example, J, MM, MONTH, or MON). In this case the current month is used.

These invocations, which depend on the value of a special register, cannot be used wherever special registers cannot be used.

Using the 'D', 'Y', and 'y' format elements:

DB2 for z/OS does not support the 'DY', 'dy', and 'Dy' format elements that are supported by other platforms. If 'DY' or 'Dy' is specified in the format string, it is interpreted as the 'D' format element followed by the 'Y' or 'y' format element. This behavior might change in a future release. To ensure that a 'D' followed by 'Y' or 'y' is interpreted as two separate format elements, include a separator character after the 'D' format element.

Syntax alternatives:

TO_DATE can be specified as a synonym for TIMESTAMP_FORMAT.

Example 1:

Insert a row into the IN_TRAY table with a receiving timestamp that is equal to one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59).

```
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT('1999-12-31 23:59:59', 'YYYY-MM-DD HH24:MI:SS'))
```

Example 2:

An application receives strings of date information into a variable called INDATEVAR. This value is not strictly formatted and might include two or four digits for years, and one or two digits for months and days. Date components might be separated with minus sign (-) or forward-slash (/) characters and are expected to be in day, month, and year order. Time information consists of hours (in 24-hour format) and minutes, and is usually separated by a colon. Sample values include '15/12/98 13:48' and '9-3-2004 8:02'. Insert such values into the IN_TRAY table.

```
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT(:INDATEVAR, 'DD/MM/RRRR HH24:MI'))
```

The use of 'RRRR' in the format allows for 2-digit and 4-digit year values and assigns the missing first two digits based on the current year. If 'YYYY' is used, input values with a 2-digit year will have leading zeros. The

forward-slash separator also allows the minus sign character. Assuming a current year of 2007, resulting timestamp values from the sample values are as follows:

```
'15/12/98 13:48' --> 1998-12-15-13.48.00.000000  
'9-3-2004 8:02' --> 2004-03-09-08.02.00.000000
```

TIMESTAMP_ISO

The `TIMESTAMP_ISO` function returns a timestamp value that is based on a date, a time, or a timestamp argument.

►—`TIMESTAMP_ISO(expression)`—◄

The schema is `SYSIBM`.

If the argument is a date, `TIMESTAMP_ISO` inserts a value of zero for the time and the partial seconds parts of the timestamp. If the argument is a time, `TIMESTAMP_ISO` inserts the value of `CURRENT DATE` for the date part of the timestamp and a value of zero for the partial seconds part of the timestamp.

expression

An expression that returns a value of one of the following built-in data types:

- a `TIMESTAMP WITHOUT TIME ZONE`
- a date
- a time
- a character string
- or a graphic string

If *expression* is a character or graphic string, it must not be a `CLOB` or `DBCLOB` and its value must be a valid string representation of a date, a time, or a timestamp. For the valid formats of string representations of dates, times, and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp, the result of the function is the same timestamp data type with the same precision as *expression*. Otherwise, the result of the function is a `TIMESTAMP (6) WITHOUT TIME ZONE`.

The result can be null; if the argument is null, the result is the null value.

Recommendation: Use the `CAST` specification for maximum portability. For more information, see “`CAST` specification” on page 254.

Example: Assume the following date value '1965-07-27'. The following statement returns the value '1965-07-27-00.00.00.000000'.

```
SELECT TIMESTAMP_ISO( DATE( '1965-07-27' ) )
FROM SYSIBM.SYSDUMMY1
```

TIMESTAMP_TZ

The `TIMESTAMP_TZ` function returns a `TIMESTAMP WITH TIME ZONE` value from the input arguments.

```
▶▶—TIMESTAMP_TZ(expression-1 [,expression-2])—▶▶
```

The schema is `SYSIBM`.

expression-1

An expression that returns a value of one of the following built-in data types:

- a timestamp without time zone
- a timestamp with time zone
- a character string
- a graphic string

If *expression-1* is a character string or a graphic string, it must conform to the following rules:

- It must not be a `CLOB` or `DBCLOB`
- Its value must be a valid string representation of a timestamp without a time zone or a timestamp with a time zone value
- It must have an actual length that is not greater than 255 bytes

For the valid formats of string representations of datetime values, see “String representations of datetime values” on page 101.

If *expression-2* is specified, *expression-1* must be a timestamp without a time zone, or a string representation of a timestamp without a time zone.

expression-2

An expression that returns a character string or a graphic string.

If *expression-2* is a character string or graphic string, it must not be a `CLOB` or `DBCLOB`, and its value must be a valid string representation of a time zone in the format of `'±th:tm'` with values ranging from `-12:59` to `+14:00`, where *th* represents time zone hour and *tm* represents time zone minute.

The result of the function is equivalent to invoking the `CAST` specification, as indicated in the following table:

Table 79. `TIMESTAMP_TZ` function and equivalent `CAST` specification

| TIMESTAMP_TZ function syntax | Equivalent CAST specification syntax |
|---|---|
| <code>TIMESTAMP_TZ(timestamp_wo_tz)</code> | <code>CAST(timestamp_wo_tz AS TIMESTAMP WITH TIME ZONE)</code> |
| <code>TIMESTAMP_TZ(timestamp_wo_tz, n)</code> | <code>CAST(timestamp_wo_tz AS TIMESTAMP(n) WITH TIME ZONE)</code> |
| <code>TIMESTAMP_TZ(timestamp_wo_tz, timezone)</code> | <code>CAST(CONCAT(VARCHAR(timestamp_wo_tz, timezone) AS TIMESTAMP WITH TIME ZONE)</code> |
| <code>TIMESTAMP_TZ(timestamp_wo_tz, timezone, n)</code> | <code>CAST(CONCAT(VARCHAR(timestamp_wo_tz, timezone) AS TIMESTAMP(n) WITH TIME ZONE)</code> |

Table 79. *TIMESTAMP_TZ* function and equivalent CAST specification (continued)

| TIMESTAMP_TZ function syntax | Equivalent CAST specification syntax |
|--|--|
| <i>TIMESTAMP_TZ</i> (<i>timestamp_w_tz</i>) | CAST(<i>timestamp_w_tz</i> AS TIMESTAMP WITH TIME ZONE) |
| <i>TIMESTAMP_TZ</i> (<i>timestamp_w_tz</i> , <i>n</i>) | CAST(<i>timestamp_w_tz</i> AS TIMESTAMP(<i>n</i>) WITH TIME ZONE) |
| <i>TIMESTAMP_TZ</i> (<i>timestamp_w_tz</i> , <i>timezone</i>) | N/A |
| <i>TIMESTAMP_TZ</i> (<i>timestamp_w_tz</i> , <i>timezone</i> , <i>n</i>) | N/A |

timestamp_wo_tz

A timestamp without time zone value.

timestamp_w_tz

A timestamp with time zone value.

timezone

A time zone value.

n

The precision value.

When a string representation of a timestamp is a single-byte character set (SBCS) with a CCSID that is not the same as the default CCSID for SBCS data, that value is converted to the default CCSID for SBCS data before it is interpreted and converted to a timestamp value.

Syntax alternatives:

- If only one argument is specified, the CAST specification should be used to ensure maximal portability. For more information, see “CAST specification” on page 254
- FROM_TZ can be specified as a synonym for TIMESTAMP_TZ when TIMESTAMP_TZ specifies both *expression-1* and *expression-2*.

Example 1: Assume that *TIMES* is a host variable with the value 2008-02-29-20.00.00.000000 and that *TZ* is a host variable with the value -3:00. Convert the value of *TIMES* and *TZ* to a timestamp with time zone.

```
SET :TIMESZ = TIMESTAMP_TZ(:TIMES, :TZ);
```

The host variable *TIMESZ* is set with the value that represents the timestamp with time zone as 2008-02-29-20.00.00.000000 -03:00.

TO_CHAR

The TO_CHAR function returns a character string representation of a timestamp value that has been formatted using a specified character template.

Character to VARCHAR

►► TO_CHAR (—*character-expression*—) ◀◀

Timestamp to VARCHAR

►► TO_CHAR (—*timestamp-expression*—, —*format-string*—) ◀◀

Decimal floating-point to VARCHAR

►► TO_CHAR (—*decimal-floating-point-expression*— [—*format-string*—]) ◀◀

The schema is SYSIBM.

The TO_CHAR scalar function is a synonym for the VARCHAR_FORMAT scalar function.

TO_DATE

The TO_DATE function returns a timestamp value that is based on the interpretation of the input string using the specified format.

The schema is SYSIBM.

The TO_DATE scalar function is a synonym for the TIMESTAMP_FORMAT scalar function. Refer to the description of the TIMESTAMP_FORMAT function for information about how to use the TO_DATE function.

TO_NUMBER

The TO_NUMBER function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

►► TO_NUMBER (—string-expression— , —format-string—) ◀◀

The schema is SYSIBM.

The TO_NUMBER scalar function is a synonym for the DECFLOAT_FORMAT scalar function.

TOTALORDER

The TOTALORDER function returns an ordering for DECFLOAT values. The TOTALORDER function returns a small integer value that indicates how *expression1* compares with *expression2*.

►—TOTALORDER(*expression1*,*expression2*)—►

The schema is SYSIBM.

expression1

An expression that returns a built-in DECFLOAT value.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

expression2

An expression that returns a built-in DECFLOAT value.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

Numeric comparison is exact, and the result is determined for finite operands as if range and precision are unlimited. An overflow or underflow conditions cannot occur.

If one value is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

TOTALORDER determines ordering based on the total order predicate rules of IEEE 754R, with the following result:

- -1 if the first argument is lower in order compared to the second.
- 0 if both arguments have the same order.
- 1 if the first argument is higher in order compared to the second.

The ordering of the special values and finite numbers is as follows:

-NAN<-SNAN<-INFINITY<-0.10<-0.100<-0<0<0.100<0.10<INFINITY<SNAN<NAN

The result of the function is a SMALLINT value.

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples show the use of the TOTALORDER function to compare decimal floating point values:

```
TOTALORDER(-INFINITY, -INFINITY)           = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.0))  = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.00)) = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-0.5))  = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(0.5))   = -1
TOTALORDER(DECFLOAT(-1.0), INFINITY)        = -1
TOTALORDER(DECFLOAT(-1.0), SNAN)            = -1
TOTALORDER(DECFLOAT(-1.0), NAN)             = -1
TOTALORDER(NAN, DECFLOAT(-1.0))             = 1
```

| | |
|--------------------------|-----|
| TOTALORDER(-NAN, -NAN) | = 0 |
| TOTALORDER(-SNAN, -SNAN) | = 0 |
| TOTALORDER(NAN, NAN) | = 0 |
| TOTALORDER(SNAN, SNAN) | = 0 |

TRANSLATE

The TRANSLATE function returns a value in which one or more characters of the first argument might have been converted to other characters.

The schema is SYSIBM.

string-expression

| An expression that specifies the string to be converted. *string-expression* must
| return a value that is a built-in character or graphic string data type that is not
| a LOB. If *string-expression* is an EBCDIC or ASCII graphic string and
| *string-expression* is the only argument that is specified, the locale name that is
| specified by the CURRENT LOCALE LC_CTYPE special register must be a
| non-blank string.

| The argument can also be a numeric data type. The numeric argument is
| implicitly cast to a VARCHAR data type.

to-string

An expression that specifies the characters to which certain characters in *string-expression* are to be converted. This string is sometimes called the *output translation table*. *to-string* must return a value that is a built-in character or graphic string data type that is not a LOB.

| The argument can also be a numeric data type. The numeric argument is
| implicitly cast to a VARCHAR data type.

If the length of *to-string* is less than the length of *from-string*, *to-string* is padded to the length of *from-string* with the *pad* or a blank. If the length of *to-string* is greater than *from-string*, the extra characters in *to-string* are ignored without warning.

from-string

An expression that specifies the characters that if found in *string-expression* are to be converted. This string is sometimes called the *input translation table*. When a character in *from-string* is found, the character in *string-expression* is converted to the character in *to-string* that is in the corresponding position of the character in *from-string*.

from-string must return a value that is a built-in character or graphic string data type that is not a LOB.

| The argument can also be a numeric data type. The numeric argument is
| implicitly cast to a VARCHAR data type.

If *from-string* contains duplicate characters, the first occurrence of the character is used, and no warning is issued. The default value for *from-string* is a string that starts with the character X'00' and ends with the character X'FF' (decimal 255).

pad

An expression that specifies the character with which to pad *to-string* if its length is less than *from-string*. *pad* is an expression that must return a value that is a built-in character or graphic string data type that is not a LOB and has a length of 1. A length of 1 is one single byte for character strings and one double byte string for graphic strings. The default is a blank that is appropriate for *string-expression*.

If *string-expression* is the only argument that is specified, the string is converted to uppercase based on the locale name that is specified by the CURRENT LOCALE LC_CTYPE special register, as follows:

- blank — SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z. For optimal performance, specify a blank string unless your data must be processed by using rules that are defined by a specific locale.
- UNI — The conversion uses both the NORMAL and SPECIAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User's Guide and Reference). You must not specify UNI when *string-expression* is EBCDIC data.
- locale name — The locale defines the rules for conversion to lowercase characters.

For Unicode data, usage of the TRANSLATE function (the TRANSLATE function with one argument is equivalent to the UPPER function) can result in expansion if certain characters are processed. You should ensure that the result string is large enough to contain the result of the expression.

If more than one argument is specified, the result string is built character-by-character from *string-expression* with each character in *from-string* being converted to the corresponding character in *to-string*. For each character in *string-expression*, the *from-string* is searched for the same character. If the character is found to be the *n*th character in *from-string*, the resulting string will contain the *n*th character from *to-string*. If *to-string* is less than *n* characters long, the resulting string will contain the *pad*. If the character is not found in *from-string*, it is moved to the result string without being converted.

The string can contain mixed data. If only one argument is specified, the UPPER function is performed on the argument, and the rules for operating on mixed data in the UPPER function are observed. Full-width Latin lowercase a-z are converted to full-width Latin uppercase letters A-Z. Otherwise, the function operates on a strict byte-count basis, and the result is not necessarily a properly formed mixed data character string.

The encoding scheme of the result is the same as *string-expression*. The data type of the result of the function depends on the data type of *string-expression*, *to-string*, *from-string*, and *pad*:

- VARCHAR if *string-expression* is a character string. The CCSID of the result depends on the arguments:
 - If *string-expression*, *to-string*, *from-string*, or *pad* is bit data, the result is bit data.
 - If *string-expression*, *to-string*, *from-string*, and *pad* are all SBCS:
 - If *string-expression*, *to-string*, *from-string*, and *pad* are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.

- If *string-expression* is SBCS Unicode data, and *to-string*, *from-string*, or *pad* are not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
- Otherwise, the CCSID of the result is the same as the CCSID of *string-expression*.
- Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *string-expression*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *string-expression*.
- VARGRAPHIC if *string-expression* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.

The result can be null; if the first argument is null, the result is the null value.

Example 1: Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```
SELECT TRANSLATE ('abcdef')
FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

Example 2: Assume that host variable *SITE* has a data type of VARCHAR(30) and contains 'Hanauma Bay'.

```
SELECT TRANSLATE (:SITE)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HANAUMA BAY'. The result is all uppercase characters because only one argument is specified.

```
SELECT TRANSLATE (:SITE, 'j', 'B')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hanauma jay'.

```
SELECT TRANSLATE (:SITE, 'ei', 'aa')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Heneume Bey'.

```
SELECT TRANSLATE (:SITE, 'bA', 'Bay', '%')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HAnAumA bA%'.

```
SELECT TRANSLATE (:SITE, 'r', 'Bu')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hana ma ray'.

Example 3: Assume that host variable *SITE* has a data type of VARCHAR(30) and contains 'Pivabiska Lake Place'.

```
SELECT TRANSLATE (:SITE, '$$', 'Ll')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Pivabiska \$ake P\$ace'.

```
SELECT TRANSLATE (:SITE, 'pLA', 'Place', '.')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'pivAbiskA LAk. pLA..'.

 [z/OS Unicode Services User's Guide and Reference](#)

TRIM

The TRIM function removes bytes from the beginning, from the end, or from both the beginning and end of a string expression.

The schema is SYSIBM.

The first argument, if specified, indicates whether characters are removed from the end or the beginning of the string. If the first argument is not specified, the characters are removed from both the end and the beginning of the string.

trim-constant

Specifies a constant that indicates the binary, SBCS, or DBCS character that is to be removed. If *string-expression* is a character string, *trim-constant* must be an SBCS or DBCS single-character (2 bytes) constant. If *string-expression* is a binary string, *trim-constant* must be a single-byte binary string constant. If *string-expression* is a DBCS graphic or DBCS-only string, *trim-constant* must be a graphic constant that consists of a single DBCS character.

The default for *trim-constant* depends on the data type of *string-expression*:

- A DBCS blank if *string-expression* is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if *string-expression* is a Unicode graphic string.
- A value of X'00' if *string-expression* is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. When not EBCDIC, X'20' represents a blank.

string-expression

An expression that returns a value that is a built-in character string data type, graphic data type, binary string data type, or numeric data type. *string-expression* must not be a LOB. If *string-expression* is numeric, it is cast to a character string before the function is evaluated. For more information about converting numeric to a character string, see "VARCHAR" on page 641.

string-expression and *trim-expression* must have compatible data types.

The data type of the result depends on the data type of *string-expression*:

- If *string-expression* is a character string data type, the result is VARCHAR. If *string-expression* is defined as FOR BIT DATA the result is FOR BIT DATA.

- If *string-expression* is a graphic string data type, the result is VARGRAPHIC.
- If *string-expression* is a binary string data type, the result is VARBINARY.

The length attribute of the result is the same as the length attribute of *string-expression*. The actual length of the result is the length of *string-expression* minus the number of characters removed. If all of the characters are removed, the result is an empty string.

If *string-expression* can be null, the result can be null; if *string-expression* is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Example: Assume the host variable *HELLO* of type CHAR(9) has a value of 'Hello '.

```
SELECT TRIM(:HELLO), TRIM(TRAILING FROM :HELLO)
FROM SYSIBM.SYSDUMMY1
```

Results in 'Hello' and ' Hello' respectively.

Example: Assume the host variable *BALANCE* of type CHAR(9) has a value of '000345.50'.

```
SELECT TRIM(L '0' FROM :BALANCE)
FROM SYSIBM.SYSDUMMY1
```

Results in '345.50'

“STRIP” on page 586

TRUNCATE or TRUNC

The TRUNCATE function returns the first argument, truncated as specified. Truncation is to the number of places to the right or left of the decimal point this is specified by the second argument.

The schema is SYSIBM.

numeric-expression-1

An expression that returns a value of any built-in numeric data type.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of TRUNCATE corresponds to a value of ROUND_DOWN. If you want a different rounding behavior, use the QUANTIZE function.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

numeric-expression-2

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The absolute value of the integer specifies the number of places to truncate. The value of *numeric-expression-2* determines whether truncation is to the right or left of the decimal point.

If *numeric-expression-2* is not negative, *numeric-expression-1* is truncated to the absolute value of *numeric-expression-2* places to the right of the decimal point.

If *numeric-expression-2* is negative, *numeric-expression-1* is truncated to 1 + (the absolute value of *numeric-expression-2*) places to the left of the decimal point. If 1 + (the absolute value of *numeric-expression-2*) is greater than or equal to the number of digits to the left of the decimal point, the result is 0. For example, TRUNCATE(748.58, -4) returns 0.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34), which is then assigned to an INTEGER value.

The result of the function has the same data type and length attribute as the first argument.

The result can be null; if any argument is null, the result is the null value.

Example 1: Using sample employee table DSN8A10.EMP, calculate the average monthly salary for the highest paid employee. Truncate the result to two places to the right of the decimal point.

```
SELECT TRUNCATE(MAX(SALARY/12),2)
FROM DSN8A10.EMP;
```

Because the highest paid employee in the sample employee table earns \$52750.00 per year, the example returns the value 4395.83.

Example 2: Return the number 873.726 truncated to 2, 1, 0, -1, -2, -3, and -4 decimal places respectively.

```
SELECT TRUNC(873.726,2),  
       TRUNC(873.726,1),  
       TRUNC(873.726,0),  
       TRUNC(873.726,-1),  
       TRUNC(873.726,-2),  
       TRUNC(873.726,-3),  
       TRUNC(873.726,-4)  
FROM TABLEX  
WHERE INTCOL = 1234;
```

This example returns the values 873.720, 873.700, 873.000, 870.000, 800.000, 0000.000, and 0000.000.

Example 3: Calculate both positive and negative numbers.

```
SELECT TRUNCATE( 3.5, 0),  
       TRUNCATE( 3.1, 0),  
       TRUNCATE(-3.1, 0),  
       TRUNCATE(-3.5, 0)  
FROM TABLEX;
```

This example returns: the values 3.0, 3.0, -3.0, -3.0.

TRUNC_TIMESTAMP

The TRUNC_TIMESTAMP function returns a `TIMESTAMP WITHOUT TIME ZONE` value that is the *expression*, truncated to the unit that is specified by the *format-string*.

```
TRUNC_TIMESTAMP(expression, format-string)
```

The schema is SYSIBM.

expression

An expression that returns a value of any of the following built-in data types: a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

format-string

An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. *format-string* contains a template of how the timestamp represented by *expression* should be truncated. For example, if *format-string* is 'DD', the timestamp that is represented by *expression* is truncated to the nearest day. *format-string* must be a valid template for a timestamp, and not include leading or trailing blanks. Allowable values for *format-string* are listed in the following table.

Table 80. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models

| Format model | Rounding or truncating unit | ROUND_TIMESTAMP example | TRUNC_TIMESTAMP example |
|--|--|---|---|
| CC SCC | Century Rounds up to the start of the next century after the 50th year of the century (for example on 1951-01-01-00.00.00). Not valid for a TIME argument. | Input Value: 1897-12-04-12.22.22.000000 Result: 1901-01-01-00.00.00.000000 | Input Value: 1897-12-04-12.22.22.000000 Result: 1801-01-01-00.00.00.000000 |
| SYYYY YYYY YEAR SYEAR YYY YY Y | Year (Rounds up on July 1st) | Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-01-00.00.00.000000 | Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-01-00.00.00.000000 |

Table 80. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

| Format model | Rounding or truncating unit | ROUND_TIMESTAMP example | TRUNC_TIMESTAMP example |
|--------------------------|--|---|---|
| IYYY IYY IY I | ISO Year (Rounds up on July 1st) | Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-03-00.00.00.000000 | Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-04-00.00.00.000000 |
| Q | Quarter (Rounds up on the sixteenth day of the second month of the quarter) | Input Value: 1999-06-04-12.12.30.000000 Result: 1999-07-01-00.00.00.000000 | Input Value: 1999-06-04-12.12.30.000000 Result: 1999-04-01-00.00.00.000000 |
| MONTH MON MM RM | Month (Rounds up on the sixteenth day of the month) | Input Value: 1999-06-18-12.12.30.000000 Result: 1999-07-01-00.00.00.000000 | Input Value: 1999-06-18-12.15.00.000000 Result: 1999-06-01-00.00.00.000000 |
| WW | Same day of the week as the first day of the year (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the year) | Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-06-00.00.00.000000 | Input Value: 2000-05-05-12.15.00.000000 Result: 2000-04-29-00.00.00.000000 |
| IW | Same day of the week as the first day of the ISO year (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the ISO year) | Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-08-00.00.00.000000 | Input Value: 2000-05-05-12.15.00.000000 Result: 2000-05-01-00.00.00.000000 |
| W | Same day of the week as the first day of the month (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the month) | Input Value: 2000-05-17-12.12.30.000000 Result: 2000-05-15-00.00.00.000000 | Input Value: 2000-05-17-12.15.00.000000 Result: 2000-05-15-00.00.00.000000 |
| DDD DD J | Day (Rounds up on the 12th hour of the day) | Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-18-00.00.00.000000 | Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-17-00.00.00.000000 |
| DAY DY D | Starting day of the week (Rounds up with respect to the 12th hour of the third day of the week. The first day of the week is always Sunday). | Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-21-00.00.00.000000 | Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-14-00.00.00.000000 |
| HH HH12 HH24 | Hour (Rounds up at 30 minutes) | Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-18-00.00.00.000000 | Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-17-23.00.00.000000 |
| MI | Minute (Rounds up at 30 seconds) | Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.59.00.000000 | Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.58.00.000000 |
| SS | Second (Rounds up at 500000 microseconds) | Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.46.000000 | Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.45.000000 |

| If *expression* is not a `TIMESTAMP WITH TIME ZONE` value, *expression* is cast as
| follows:

- | • If *expression* is a `TIMESTAMP WITH TIME ZONE` value, *expression* is cast to
| `TIMESTAMP WITHOUT TIME ZONE`, with the same precision as *expression*.
- | • Otherwise, *expression* is cast to `TIMESTAMP(6) WITHOUT TIME ZONE`.

| The result of the function is a timestamp.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example: Set the host variable `TRNK_TMSTMP` with the specified date rounded to the nearest year value.

```
SET :TRNK_TMSTMP = TRUNC_TIMESTAMP('2008-03-14-17.30.00', 'YEAR');
```

The host variable `TRNK_TMSTMP` is set with the value '2008-01-01-00.00.00.000000'.

UCASE

The UCASE function returns a string in which all the characters have been converted to uppercase characters, based on the CCSID of the argument. The UCASE function is identical to the UPPER function.

The schema is SYSIBM.

For more information, see “UPPER” on page 635.

UNICODE

The UNICODE function returns the Unicode UTF-16 code value of the leftmost character of the argument as an integer.

►►—UNICODE(*string-expression*)—◄◄

The schema is SYSIBM.

string-expression can be of any built-in string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If the argument is ASCII, EBCDIC, or Unicode UTF-8, it is first converted to a Unicode UTF-16 string (CCSID 1200) before the function is executed.

The result of the function is an INTEGER.

The result can be null; if the argument is null, the result is the null value.

Example: The following example returns the Unicode value of 峰 as an integer and assigns the value to the host variable *hv*:

Set :hv = UNICODE('峰'); *hv* is set to an integer with a value '23792'.

UNICODE_STR

The `UNICODE_STR` function returns a string in Unicode UTF-8 or UTF-16, depending on the specified option. The string represents a Unicode encoding of the input string.

The schema is SYSIBM.

string-expression

| An expression that returns a value of a built-in character or graphic string. A
| character string must not be bit data. Values that are preceded by a backslash
| ('\') are treated as Unicode UTF-16 characters (for example '\0041' is the
| Unicode UTF-16 representation for 'A'). A double backslash '\\\' indicates a
| backslash in the string. A partial surrogate character in the expression is
| replaced with a blank.

| The argument can also be a numeric data type. The numeric argument is
| implicitly cast to a VARCHAR data type.

UTF8 or UTF16

Specifies the Unicode encoding of the result. If UTF8 is specified, the result is returned as a Unicode UTF-8 character string. If UTF16 is specified, the result is returned as a Unicode UTF-16 graphic string. UTF8 is the default.

The result of the function depends on the second argument:

- VARCHAR if **UTF8** is specified
- VARGRAPHIC if **UTF16** is specified

The length attribute of the result is depends on the second argument (**UTF8** or **UTF16**). The length attribute of the result is calculated using the formulas in Table 33 on page 141. If the result is a character string, the length attribute of the result is $\text{MAX}(n, 32704)$. If the result is a graphic string, the length attribute of the result is $\text{MAX}(n, 16352)$. Where n is the result of applying the formulas in Table 33 on page 141 based on input and output data types.

If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

UNISTR can be specified as a synonym for `UNICODE_STR`.

Example: The following example sets the host variable `HV1` to a VARCHAR value that represents the Unicode UTF-8 string that corresponds to the argument:

```
SET :HV1 = UNICODE_STR('Hi, my name is \5CF0');
```

HV1 is assigned a Unicode UTF-8 string with the following value 'Hi, my name is

峰 ,

UPPER

The UPPER function returns a string in which all the characters have been converted to uppercase characters.

```
UPPER(string-expression [, locale-name-string] [, integer])
```

The schema is SYSIBM.

string-expression

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB. If *string-expression* is an EBCDIC graphic string, a blank string must not be specified for *locale-name-string*. If *string-expression* is bit data, *locale-name-string* must not be specified.

locale-name-string

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name-string* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name-string* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name-string* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see *z/OS C/C++ Programming Guide*. Some examples of locales include:

```
Fr_BE  
Fr_FR@EURO  
En_US  
Ja_JP
```

The conversion process is determined by the value that is specified for the locale name, as follows:

- blank — SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z. For optimal performance, specify a blank string unless your data must be processed by using the rules that are defined by a specific locale.
- UNI — The conversion uses both the NORMAL and SPECIAL casing capabilities as described in *Select the conversions (z/OS: Unicode Services User's Guide and Reference)*. You must not specify UNI when *string-expression* is EBCDIC data.
- locale name — The locale defines the rules for conversion to lowercase characters.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

- left justified within the host variable

- padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length CHAR or GRAPHIC data type

If *locale-name-string* is not specified, the locale is determined by special register CURRENT LOCALE LC_CTYPE. For information about the special register, see “CURRENT LOCALE LC_CTYPE” on page 174.

If the UPPER function is referenced in an expression-based index, *locale-name-string* must be specified

integer

An integer value that specifies the length attribute of the result. If specified, *integer* must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of *string-expression*.

If *integer* is not specified, the length attribute of the result is the same as the length of *string-expression*.

For Unicode data, usage of the UPPER function can result in expansion if certain characters are processed. For example, UPPER(UX'FB03') will result in UX'004600460049'. You should ensure that the result string is large enough to contain the result of the expression.

The result can be null; if the argument is null, the result is the null value.

Example 1: Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```
SELECT UPPER('abcdef')
FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

Example 2: Return the string 'ffi' in the uppercase characters ('FFI'). Assume that the locale in effect is "UNI".

```
SELECT UPPER(UX'FB03')
FROM SYSIBM.SYSDUMMYU;
```

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

```
SELECT UPPER(CAST(UX'FB03' AS VARCHAR(3)))
FROM SYSIBM.SYSDUMMYU;
```

The result of the preceding statement is the value 'FFI'.

Example 3: Create an index EMPLOYEE_NAME_UPPER for table EMPLOYEE based on built-in function UPPER with locale name 'Fr_FR@EURO'.

```
CREATE INDEX EMPLOYEE_NAME_UPPER
ON EMPLOYEE (UPPER(LASTNAME, 'Fr_FR@EURO', 60),
UPPER(FIRSTNAME, 'Fr_FR@EURO', 60),
ID);
```

The result is the value 'ABCDEF'.

Related concepts:

 [z/OS Unicode Services User's Guide and Reference](#)

Related reference:

VALUE

The VALUE function returns the value of the first non-null expression.

The schema is SYSIBM.

Syntax alternatives: The VALUE function can be specified in place of the COALESCE function. COALESCE should be used for conformance to SQL 2003 Core. For more information, see “COALESCE” on page 384.

VARBINARY

The VARBINARY function returns a VARBINARY (varying-length binary string) representation of a string of any type.

The schema is SYSIBM.

string-expression

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

integer

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 32704 inclusive. If integer is not specified:

- If the *string-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the *string-expression*, unless the *string-expression* is a graphic string. In this case, the length attribute of the result is twice the length attribute of the *string-expression*.

The result of the function is a varying-length binary string.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of the *string-expression* (or twice the length of the *string-expression* if *string-expression* returns a graphic string). If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed, and a warning is returned unless the *string-expression* is a character string and all the truncated characters are blanks, or the *string-expression* is a graphic string and all the truncated characters are double-byte blanks.

Example 1: The following function returns a varying-length binary string with a length attribute 1, actual length 0, and a value of empty string:

```
SELECT VARBINARY('')
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a varying-length binary string with a length attribute 5, actual length 3, and a value BX'D2C2C8':

```
SELECT VARBINARY('KBH',5)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8'

```
SELECT VARBINARY('KBH ',3)
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8', a warning is also returned.

```
SELECT VARBINARY('KBH-93',3)
FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'C1C2C3', a warning is also returned.

```
SELECT VARBINARY(BINARY('ABC',5),3)
FROM SYSIBM.SYSDUMMY1;
```

VARCHAR

The VARCHAR function returns a varying-length character string representation of the value specified by the first argument.

The syntax of the VARCHAR function depends on the data type of the input argument. The following types of input arguments are accepted.

Integer to Varchar:

►► VARCHAR(*integer-expression*) ◄◄

Decimal to Varchar:

►► VARCHAR(*decimal-expression* [, *decimal-character*]) ◄◄

Floating-point to Varchar:

►► VARCHAR(*floating-point-expression*) ◄◄

Decimal floating point to Varchar:

►► VARCHAR(*decimal-floating-point-expression*) ◄◄

Character to Varchar:

►► VARCHAR(*character-expression* [, *integer* [, *CODEUNITS16* | *CODEUNITS32* | *OCTETS*]]) ◄◄

Graphic to Varchar:

Datetime to Varchar:

Row ID to Varchar:

The schema is SYSIBM.

The result of the function is a varying-length character string (VARCHAR).

The result can be null; if the first argument is null, the result is the null value.

Integer to Varchar

integer-expression

An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, BIGINT).

The result is a varying-length character string representation (VARCHAR) of the argument in the form of an SQL integer constant.

The length attribute of the result depends on whether the argument is a small or large integer as follows:

- If the argument is a small integer, the length attribute of the result is 6 bytes.
- If the argument is a large integer, the length attribute of the result is 11 bytes.
- If the argument is a big integer, the length attribute of the result is 20 bytes.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit.

The CCSID of the result is the SBCS CCSID of the appropriate encoding scheme.

Decimal to Varchar

decimal-expression

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the expression's value, apply the DECIMAL function to the expression before applying the VARCHAR function.

decimal-character

Specifies the single-byte character constant (CHAR or VARCHAR) that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see "Decimal point representation" on page 309.

The result is a varying-length character string representation of the argument. The result includes a decimal character and up to p digits where p is the precision of *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned.

The length attribute of the result is $2+p$ where p is the precision of *decimal-expression*.

The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see "Determining the encoding scheme and CCSID of a string" on page 51.

Floating point to Varchar

floating-point-expression

An expression that returns a value that is a built-in floating-point data type.

The result is a varying-length character string representation (VARCHAR) of the argument in the form of an SQL floating-point constant.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by a period and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is '0E0'.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see "Determining the encoding scheme and CCSID of a string" on page 51.

Decimal floating-point to Varchar

decimal-floating-point-expression

An expression that returns a value that is the built-in DECFLOAT data type.

The result is the varying-length character string representation of the argument in the form of an SQL decimal floating-point constant.

If the DECFLOAT value is one of the special values Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', or 'NAN', respectively, are returned. If the special value is negative, a minus sign is the first character in the returned string. The DECFLOAT special value sNaN does not result in an exception when it is converted to a string.

The length attribute of the result is 42 bytes.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Character to Varchar

character-expression

An expression that returns a value that is a built-in character data type.

integer

Specifies the length attribute for the resulting varying-length character string. The value must be between 1 and 32767, expressed in the units that are either implicitly or explicitly specified. If the length is not specified, the length of the result is the same as the length of *character-expression*.

If CODEUNITS16, CODEUNITS32, or OCTETS is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

If a length attribute is not specified and if the *character-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 87.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

If *character-expression* is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

Graphic to Varchar

graphic-expression

An expression that returns a value that is a built-in graphic data type.

integer

The length attribute for the resulting varying-length graphic string. The value must be between 1 and 32704, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

If a length attribute is not specified, the length attribute of the result is determined as follows (where *n* is the length attribute of the first argument):

- If the *graphic-expression* is the empty graphic string constant, the length attribute of the result is 1.
- If the result is SBCS data, the result length is *n*.
- If the result is mixed data, the result length is $3 * (\text{length}(\text{graphic-expression}))$.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 or CODEUNITS32, see “String unit specifications” on page 87.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of the graphic expression is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters were blanks appropriate for *graphic-expression*, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

Datetime to Varchar

datetime-expression

An expression whose value has one of the following three built-in data types:

date The result is a varying-length character string representation of the date in the format that is specified by the DATE precompiler option, if one is provided, or else field DATE FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, field LOCAL DATE LENGTH on

installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 10.

LOCAL denotes the local format at the DB2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that DB2.

An error occurs if the second argument is specified and is not a valid value.

time The result is a varying-length character string representation of the time in the format specified by the TIME precompiler option, if one is provided, or else field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 8.

LOCAL denotes the local format at the DB2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that DB2.

An error occurs if the second argument is specified and is not a valid value.

timestamp

The result is the character string representation of the timestamp with time zone. The second argument must not be specified.

- If *datetime-expression* is a `TIMESTAMP (0) WITHOUT TIME ZONE`, the length of the result is 19.
- If *datetime-expression* is a `TIMESTAMP (p) WITHOUT TIME ZONE`, the length of the result is $20+p$ where p is the timestamp precision. The second argument must not be specified.
- If *datetime-expression* is a `TIMESTAMP (0) WITH TIME ZONE`, the length of the result is 25.
- If *datetime-expression* is a `TIMESTAMP (p) WITH TIME ZONE`, the length of the result is $26 + p$ where p is the timestamp precision. The second argument must not be specified.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Row ID to Varchar

row-ID-expression

An expression that returns a value that is a built-in row ID data type.

The result is a varying-length character string representation (VARCHAR) of the argument. It is bit data.

The length attribute of the result is 40. The actual length of the result is the length of *row-ID-expression*.

Examples

Example 1: Assume that host variable *JOB_DESC* is defined as *VARCHAR(8)*. Using sample table *DSN8A10.EMP*, set *JOB_DESC* to the varying-length string equivalent of the job description (column *JOB* defined as *CHAR(8)*) for the employee with the last name of 'QUINTANA'.

```
SELECT VARCHAR(JOB)
       INTO :JOB_DESC
       FROM DSN8A10.EMP
       WHERE LASTNAME = 'QUINTANA';
```

Example 2: *FIRSTNME* is a *VARGRAPHIC(6)* column in a Unicode table *T1*. One of its values is the string 'Jürgen' (X'004A00FC007200670055006E'). When *FIRSTNME* has this value:

| Function ... | Returns ... |
|---------------------------------|----------------------|
| VARCHAR(FIRSTNME,3,CODEUNITS32) | 'Jür' -- x'4AC3BC72' |
| VARCHAR(FIRSTNME,3,CODEUNITS16) | 'Jür' -- x'4AC3BC72' |
| VARCHAR(FIRSTNME,3,OCTETS) | 'Jü' -- x'4AC3BC' |

 [BIF COMPATIBILITY field \(BIF_COMPATIBILITY subsystem parameter\) \(DB2 Installation and Migration\)](#)

VARCHAR_FORMAT

The VARCHAR_FORMAT function returns a character string representation of the first argument in the format indicated by *format-string*.

Character to VARCHAR

►► VARCHAR_FORMAT(*character-expression*) ◄◄

Timestamp to VARCHAR

►► VARCHAR_FORMAT(*timestamp-expression*,*format-string*) ◄◄

Decimal floating-point to VARCHAR

►► VARCHAR_FORMAT(*decimal-floating-point-expression* [*,—format-string*]) ◄◄

The schema is SYSIBM.

Character to VARCHAR

character-expression

An expression that returns a value that must be a built-in CHAR or VARCHAR data type. If a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function.

The result is a VARCHAR value with a length attribute that matches the length attribute of the argument. The value of the result is the same as the value of *character-expression*.

If *character-expression* returns graphic data, the CCSID of the result is the character mixed CCSID that corresponds to the graphic argument. If *character-expression* returns bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

Timestamp to VARCHAR

timestamp-expression

An expression that returns a value that must be a DATE or TIMESTAMP, or a valid character string or graphic string representation of a date or timestamp that is not a CLOB or DBCLOB. If the argument is a graphic string representation of a data or timestamp, it is first converted to a character string before evaluating the function.

If *timestamp-expression* is a DATE or a valid string representation of a date, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00). If the HH12 format element is specified and the time component of the first argument is 24:00:00, the input timestamp value is adjusted to 00:00:00 and the date is incremented by one day.

For the valid formats of string representations of datetime values, see “String representations of datetime values” on page 101.

format-string

An expression that returns a built-in character string or graphic string data type that is not a LOB and has a length attribute that is not greater than 255 bytes. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before the function is evaluated. Leading and trailing blanks are removed from the string. If the argument returns timestamp data type, the resulting substring must conform to the rules for formatting a timestamp. If *expression* returns timestamp with a time zone, the resulting substring must conform to the rules for formatting a timestamp with time zone.

The value is a template for how *timestamp-expression* is to be formatted.

A valid *format-string* can contain a combination of the format elements listed below. Two format elements can be separated by one or more of the following separator characters.

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ()

Separator characters can also be specified at the start or end of *format-string*. *format-string* can also be an empty string, a string of blanks, or a string of separator characters.

The following table lists the valid format elements that *format-string* can contain.

Table 81. Valid format elements of *format-string*

| Format element | Description (assuming the default is to return leading zeros) |
|---------------------------|---|
| AM or PM ¹ | Meridian indicator (morning or evening) without periods. This format element uses the exact strings “AM” or “PM”. |
| A.M. or P.M. ¹ | Meridian indicator (morning or evening) with periods. This format element uses the exact strings “A.M.” or “P.M.”. |
| CC | Century (00-99). If the last two digits of the four digit year are zero, the result is the first two digits of the year. Otherwise, the result is the first two digits of the year plus one. |

Table 81. Valid format elements of format-string (continued)

| Format element | Description (assuming the default is to return leading zeros) |
|--|--|
| D ¹ | Day of the week (1-7). 1 is Sunday and 7 is Saturday. |
| DD | Day of the month (01-31). |
| DDD | Day of the year (001-366). |
| FF or FF n | Fractional seconds (0-999999). The number n is used to specify the number of digits to include in the returned value. Valid values for n are 1-12 (FF1-FF12) with no leading zeros. Specifying FF is equivalent to specifying FF6. If the timestamp precision of <i>timestamp-expression</i> is less than what is specified by the format, zero digits are padded onto the right of the specified digits. |
| HH | Hour of the day (01-12). |
| HH12 | Hour of the day (01-12). |
| HH24 | Hour of the day (00-24). |
| I | ISO year (0-9). The last digit of the year based on the ISO week that is returned. |
| ID | ISO day of the week (1-7). 1 is Monday and 7 is Sunday. |
| IW | ISO week of the year (01-53). The week starts on Monday and includes 7 days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week of the year to contain January 4. |
| IY | ISO year (00-99). The last two digits of the year based on the ISO week that is returned. |
| IYY | ISO year (000-999). The last three digits of the year based on the ISO week that is returned. |
| IYYY | ISO year (0000-9999). The last four digits of the year based on the ISO week that is returned. |
| J | Julian date (0000000-9999999). |
| MI | Minute (00-59). |
| MM | Month (01-12). January is 01. |
| MONTH, Month, or month ^{1, 2} | Name of the month in uppercase, sentence case, or lowercase format in English. |
| MON, Mon, or mon ^{1, 2} | Three-character abbreviated name of the month in uppercase, sentence case, or lowercase format in English. |

Table 81. Valid format elements of format-string (continued)

| Format element | Description (assuming the default is to return leading zeros) |
|--|--|
| NNNNNN | Microseconds (000000-999999). This format is equivalent to specifying FF6. |
| Q | Quarter (1-4). January through March is 1. |
| RRRR | Year (0000-9999). RRRR behaves the same as YYYY. |
| RR | Last two digits of the year (00-99). RR behaves the same as YY. |
| SS | Seconds (00-59). |
| SSSS | Seconds since the previous midnight (00000-86400). |
| TZH | Time zone hour. (-24 to +24, This range accommodates daylight saving time changes.) |
| TZM | Time zone minute (00-59). |
| W | Week of the month (1-5). Week 1 starts on the first day of the month and ends on the seventh day. |
| WW | Week of the year (01-53). Week 1 begins on January 1 and ends on January 7. |
| Y | Last digit of the year (0-9). |
| YY | Last two digits of the year (00-99). |
| YYY | Last three digits of the year (000-999). |
| YYYY | Year (0000-9999). |
| Notes: | |
| 1. This format element is case sensitive. In cases where the format elements are ambiguous, the case insensitive format elements will be considered first. | |
| 2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned. | |

| If *expression* is a `TIMESTAMP WITHOUT TIME ZONE` value, *format-string* must not contain TZH or TZM

The result is a representation of *timestamp-expression* in the format specified by *format-string*. *format-string* is interpreted as a series of format elements that can be separated by one or more separator characters. A string of characters in *format-string* is interpreted as the longest matching format element in the previous table. If two format elements that contain the same characters are not delimited by a separator character, the specification is interpreted, starting from the left, as the longest matching element in the table, and continues until matches are found for the remainder of the format string. For example, 'YYYYYYDD' is interpreted as the format elements, 'YYYY', 'YY', and 'DD'.

If the first argument is timestamp with time zone, or the second argument is a constant that contains a format element for a time zone, the resulting string contains a timestamp with time zone. Otherwise, the resulting string does not contain a time zone.

The result is the varying-length character string that contains *expression* in the format that is specified by *format-string*. If *format-string* is a constant, The length attribute of the result is the maximum of 255 and the length attribute of *format-string*. Otherwise, the length attribute is 255. The *format-string* determines the actual length of the result. The actual length must not be greater than the length attribute of the result.

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51.

Decimal floating-point to VARCHAR

decimal-floating-point-expression

An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing.

format-string

An expression that must return a value that is a built-in CHAR, VARCHAR, or numeric data type. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before evaluating the function. If the supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. The actual length must not be greater than 254 bytes.

The value is a template for how *decimal-floating-point-expression* is to be formatted. A *format-string* must contain a valid combination of the listed format elements according to the following rules:

- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
- Alphabetic format elements must be specified in upper case
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements.
- A comma format element must not be the first format element that is not a prefix format element. There can be any number of comma format elements.
- Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored when formatting the result.

Table 82. Format elements for the `VARCHAR_FORMAT` (decimal floating-point to `VARCHAR`) function

| Format element | Description |
|--------------------------|--|
| 0 | Represents a digit. Leading zeros in a number are formatted as zeros. |
| 9 | Represents a digit that can be included at the specified location. Leading zeros in a number are formatted as blanks. |
| S | Prefix If <i>decimal-floating-point-expression</i> is a negative number, a leading minus sign (-) is included at the specified location in the result. If <i>decimal-floating-point-expression</i> is a positive number, a leading plus sign (+) is included in the result. |
| \$ | Prefix A dollar sign (\$) is included at the specified location in the result. |
| MI | Suffix If <i>decimal-floating-point-expression</i> is a negative number, a trailing minus sign (-) is included in the result. If <i>decimal-floating-point-expression</i> is a positive number, a trailing blank is included in the result. |
| PR | Suffix If <i>decimal-floating-point-expression</i> is a negative number, a leading less than character (<) and a trailing greater than character (>) are included in the result. If <i>decimal-floating-point-expression</i> is a positive number, a leading blank and a trailing blank are included in the result. |
| , (comma) | Each comma represents a group separator that is included at the specified location in the result provided there would be a character to the left of it that is not a prefix character. |
| . (period/decimal point) | A period represents the decimal point that is included at the specified location in the result. |

If *format-string* is not specified, the function is equivalent to `VARCHAR(decimal-floating-point-expression)`.

The result is a representation of the *decimal-floating-point-expression* value (which might be rounded) in the format that is specified by *format-string*. Prior to being formatted, the value of *decimal-floating-point-expression* is rounded by using the `ROUND` function, if the number of digits to the right of the decimal point is less than the number of digit format elements ('0' or '9') to the right of the decimal point in *format-string*. *format-string* is applied according to the following rules:

- The result does not include any digit characters to the left of the decimal point if all of the following conditions are true:
 - $-1 < rounded-input-value < 1$
 - *format-string* does not include a '0' format element to the left of the decimal point
 - *format-string* includes at least one digit format element ('0' or '9') to the right of the decimal point
- The result includes a single 0 character immediately before the implicit or explicit decimal point if all of the following conditions are true:
 - The value of *rounded-input-value* is 0 or -0
 - *format-string* includes only the '9' digit format elements to the left of the implicit or explicit decimal point
 - *format-string* does not include any digit format elements to the right of the decimal point
- If *format-string* includes both '0' and '9' format elements to the left of the decimal point, the position of the first digit format element from the left side of the format string determines the presence of leading blanks or zeroes. All '9' format elements specified after the leftmost '0' format element to the left of the implicit or explicit decimal point are treated the same as if a '0' format element had been specified. For example, the *format-string* value '99099' is the same as the value '99000'.
- If the number of digits to the right of the decimal point in *rounded-input-value* is less than the number of digit format elements to the right of the decimal point in *format-string*, the result includes the number of digit characters to the right of the decimal point that corresponds to the number of digit format elements to the right of the decimal point in *format-string*, padded to the right with zeros.
- If the number of digits to the left of the decimal point in *rounded-input-value* is greater than the number of digit format elements to the left of the decimal point in *format-string*, the result is a string of number sign (#) characters that matches the length that *format-string* produces in the result for valid values.
- If the value of *rounded-input-value* represents any of the positive or negative special values, Infinity, sNaN, or NaN, the string 'INFINITY', 'SNAN', 'NAN', '-INFINITY', '-SNAN', or '-NAN' is returned without using the format that is specified by *format-string*. The decimal floating-point special value sNaN does not result in an exception when converted to a string.
- If *format-string* does not include any of the sign format elements 'S', 'MI', or 'PR', and the value of *rounded-input-value* is negative, a minus sign (–) is included in the result. Otherwise, a blank is included in the resulting string. The minus sign or blank immediately precedes the first digit of the result to the left of the decimal point, or the decimal point if there are no digits to the left of the decimal point.

The result is a varying-length character string representation of *rounded-input-value*. If a single argument is specified the length attribute is 42. Otherwise the length attribute is 254. The actual length of the result is determined by *format-string*, if specified. Otherwise, the actual length of the result is the smallest number of characters that can represent the value of *rounded-input-value*. If the resulting string exceeds the length attribute of the result, the result will be truncated.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 51

Notes

Julian and Gregorian calendar:

For timestamp to a varying length character string, the transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

Determinism:

`VARCHAR_FORMAT` is a deterministic function.

Using the 'D', 'Y', and 'y' format elements:

DB2 for z/OS does not support the 'DY', 'dy', and 'Dy' format elements that are supported by other platforms. If 'DY' or 'Dy' is specified in the format string, it is interpreted as the 'D' format element followed by the 'Y' or 'y' format element. This behavior might change in a future release. To ensure that a 'D' followed by 'Y' or 'y' is interpreted as two separate format elements, include a separator character after the 'D' format element.

Syntax alternatives:

`TO_CHAR` can be specified as a synonym for `VARCHAR_FORMAT`.

Example: Timestamp to VARCHAR

Set the character variable `TVAR` to a string representation of the timestamp value of `RECEIVED` from `CORPDATA.IN_TRAY`, formatted as 'YYYY-MM-DD HH24:MI:SS'.

```
SELECT VARCHAR_FORMAT(RECEIVED, 'YYYY-MM-DD HH24:MI:SS')
       INTO :TVAR
       FROM CORPDATA.IN_TRAY;
```

Assuming that the value in the `RECEIVED` column is 'January 1, 2000 at 10am', the following string is returned:

```
'2000-01-01 10:00:00'
```

Assuming that the value in the `RECEIVED` column is now one second before the beginning of the year 2000 ('December 31, 1999 at 23:59:59pm', the following string is returned:

```
'1999-12-31 23:59:59'
```

The result would be different if `HH12` had been specified instead of `HH24` in the format string:

```
'1999-12-31 11:59:59'
```

Example: Timestamp to VARCHAR

Assume that the variable `TMSTAMP` is defined as a `TIMESTAMP` and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result data type in each case is `VARCHAR(255)`.

| Function invocation | Result |
|---|-------------------|
| <code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHHMISSFF3')</code> | 20070309020738123 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHH24MISS')</code> | 20070309140738 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHHMI')</code> | 200703090207 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'DD/MM/YY')</code> | 09/03/07 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'MM-DD-YYYY')</code> | 03-09-2007 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'J')</code> | 2454169 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'Q')</code> | 1 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'W')</code> | 2 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'IW')</code> | 10 |
| <code>VARCHAR_FORMAT(TMSTAMP, 'WW')</code> | 10 |

| | |
|---------------------------------|-------|
| VARCHAR_FORMAT(TMSTAMP,'Month') | March |
| VARCHAR_FORMAT(TMSTAMP,'MONTH') | MARCH |
| VARCHAR_FORMAT(TMSTAMP,'MON') | MAR |

Example: Timestamp to VARCHAR

Assume that the variable *DTE* is defined as a DATE and has the value of '2007-03-09'. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(255):

| Function invocation | Result |
|--|----------------|
| ----- | ----- |
| VARCHAR_FORMAT(DTE,'YYYYMMDD') | 20070309 |
| VARCHAR_FORMAT(DTE,'YYYYMMDDHH24MISS') | 20070309000000 |

Assuming that today is May 26, 2008, the function returns:

26-MAY-2007

If the format string is 'YYYY-MON-YYYY', the result would be:

2007-MAY-2007

Example: Timestamp to VARCHAR

Format the hour of the specified string representation of a timestamp using a 12 hour clock and a 24 hour clock:

```
SELECT
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH24')
FROM SYSIBM.SYSDUMMY1;
```

The previous SELECT statement returns the following values:

'02' '02' '14' '12' '12' '12' '12' '12' '12' '12' '00' '12' '24'

Note that the values '00' and '24' on a 24 hour scale both map to a value of '12' on a 12 hour scale.

Example: Timestamp to VARCHAR

Format the month, day, and hour of the specified string representation of a timestamp using a 24 hour clock, and indicate that the result should not contain leading zeros for the components:

```
SELECT
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-09.14.00.000000'),
    'FM MM DD HH24'),
FROM SYSIBM.SYSDUMMY1;
```

The previous SELECT statement returns the following values:

4 7 9

Example: Timestamp with time zone to VARCHAR

Assume that column PRSTSZ contains a timestamp with time zone value of '2008-02-29.20.00.000000 -08:00'. The following statement returns the value '2008-02-29 20:00:00.000000 -08:00'.

```
SELECT VARCHAR_FORMAT(PRSTSZ, 'YYYY-MM-DD HH24:MI:SS.NNNNNN TZH:TZM')
FROM PROJECT;
```

Example: decimal floating-point to VARCHAR

Assume that the variables *POSNUM* and *NEGNUM* are defined as *DECFLOAT(34)* and have the following values: '1234.56' and '-1234.56', respectively. The following examples show several invocations of the function and the resulting string values. The result data type in each case is *VARCHAR(254)*.

| Function invocation | Result |
|--|---------------|
| <code>VARCHAR_FORMAT(POSNUM)</code> | '1234.56' |
| <code>VARCHAR_FORMAT(NEGNUM)</code> | '-1234.56' |
| <code>VARCHAR_FORMAT(POSNUM, '9999.99')</code> | ' 1234.56' |
| <code>VARCHAR_FORMAT(NEGNUM, '9999.99')</code> | '-1234.56' |
| <code>VARCHAR_FORMAT(POSNUM, '99999.99')</code> | ' 1234.56' |
| <code>VARCHAR_FORMAT(NEGNUM, '99999.99')</code> | ' -1234.56' |
| <code>VARCHAR_FORMAT(POSNUM, '00000.00')</code> | ' 01234.56' |
| <code>VARCHAR_FORMAT(NEGNUM, '00000.00')</code> | '-01234.56' |
| <code>VARCHAR_FORMAT(POSNUM, '9999.99MI')</code> | '1234.56 ' |
| <code>VARCHAR_FORMAT(NEGNUM, '9999.99MI')</code> | '1234.56-' |
| <code>VARCHAR_FORMAT(POSNUM, 'S9999.99')</code> | '+1234.56' |
| <code>VARCHAR_FORMAT(NEGNUM, 'S9999.99')</code> | '-1234.56' |
| <code>VARCHAR_FORMAT(POSNUM, '9999.99PR')</code> | ' 1234.56 ' |
| <code>VARCHAR_FORMAT(NEGNUM, '9999.99PR')</code> | '<1234.56>' |
| <code>VARCHAR_FORMAT(POSNUM, 'S\$9,999.99')</code> | '+\$1,234.56' |
| <code>VARCHAR_FORMAT(NEGNUM, 'S\$9,999.99')</code> | '-\$1,234.56' |

VARGRAPHIC

The VARGRAPHIC function returns a varying-length graphic string representation of the first argument. The first argument can be a character string value or a graphic string value.

Character to Vargraphic:

Graphic to Vargraphic:

The schema is SYSIBM.

The result of the function is a varying-length graphic string (VARGRAPHIC).

The result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

Character to Vargraphic

character-expression

An expression that returns a value of a built-in character string data type that contains an EBCDIC-encoded or Unicode-encoded character string value. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 84 for these rules.)

integer

The length attribute of the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If `CODEUNITS16` or `CODEUNITS32` is specified, see "Determining the length attribute of the final result" on page 90 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and if the *character-expression* is an empty string constant or has a value X'0E0F', the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression*, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFE'.

For EBCDIC input data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'*xx*' for EBCDIC is X'42*xx*', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the

result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*.

The result is derived from *S* using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

Graphic to Vargraphic

graphic-expression

An expression that returns a value of a built-in graphic string data type that contains an EBCDIC-encoded or Unicode-encoded graphic string value.

integer

The length attribute for the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 90 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and if the *graphic-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 87.

The actual length of the result depends on the number of characters in *graphic-expression*. If the length of *graphic-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

Example 1: Assume that *GRPHCOL* is a *VARGRAPHIC* column in table *TABLEX* and *MIXEDSTRING* is a character string host variable that contains mixed data. For various rows in *TABLEX*, an application uses a positioned *UPDATE* statement to replace the value of *GRPHCOL* with the value of *MIXEDSTRING*. Before *GRPHCOL* can be updated, the current value of *MIXEDSTRING* must be converted to a varying-length graphic string. The following statement shows how to code the *VARGRAPHIC* function within the *UPDATE* statement to ensure this conversion.

```
EXEC SQL UPDATE TABLEX
      SET GRPHCOL = VARGRAPHIC(:MIXEDSTRING)
      WHERE CURRENT OF CRSNAME;
```

Example 2: *FIRSTNAME* is a *VARCHAR(12)* column in table *T1*. One of its values is the string 'Jürgen'. When *FIRSTNAME* has this value:

| Function ... | Returns ... |
|-------------------------------------|-------------------------------------|
| VARGRAPHIC(FIRSTNAME,3,CODEUNITS32) | 'Jür' -- x'004A00FC0072' |
| VARGRAPHIC(FIRSTNAME,3,CODEUNITS16) | 'Jür' -- x'004A00FC0072' |
| VARGRAPHIC(FIRSTNAME,3,OCTETS) | An error because OCTETS not allowed |

VERIFY_GROUP_FOR_USER

The VERIFY_GROUP_FOR_USER function returns a value that indicates whether the primary authorization ID and the secondary authorization IDs that are associated with the first argument are in the authorization names that are specified in the list of the second argument.

The schema is SYSIBM.

SESSION_USER or USER

Specifies the value of the SESSION_USER (or USER) special register.

group-name-expression

An expression that specifies an authorization name. The existence of the authorization name at the current server is not verified. *group-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if the primary or secondary authorization IDs that are associated with the user that is identified by the SESSION_USER (or USER) special register is in the list that is specified by *group-name-expression*. Otherwise, the result is 0.

The VERIFY_GROUP_FOR_USER function is deterministic within a connection. It is not deterministic across connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Example: In the following example, the EMPLOYEE table has column access control enabled. If the connection is established outside a trusted context and Mary, who has a secondary authorization ID of "MGR", queries the social security number of Tom from the EMPLOYEE table, the social security number is returned. When Mary is no longer a manager, the same query displays the last four digits of Tom's social security number.

Assume that a user who has SECADM authority has created the following column mask:

```
CREATE MASK SSN_MASK ON EMPLOYEE
FOR COLUMN SSN
RETURN
CASE WHEN VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR') = 1
THEN SSN
ELSE 'XXX-XX-' || SUBSTR(SSN, 8, 4)
```

```
|
|       END
|       ENABLE;
|
|     COMMIT;
```

| An ALTER TABLE statement is then issued to activate the column mask on the
| EMPLOYEE table:

```
|     ALTER TABLE EMPLOYEE
|         ACTIVATE COLUMN ACCESS CONTROL;
|
|     COMMIT;
```

| Mary connects to DB2, issues the following query, then disconnects from DB2:

```
|     SELECT SSN
|     FROM EMPLOYEE
|     WHERE NAME = 'Tom';
```

| Mary receives Tom's social security number.

| When Mary is no longer a manager, the secondary authorization ID, MGR is
| removed for her authorization ID. The next time Mary connects to DB2 and issues
| the following command, only the last four digits of Tom's social security number
| are displayed because of the column mask SSN_MASK:

```
|     SELECT SSN
|     FROM EMPLOYEE
|     WHERE NAME = 'Tom';
```

VERIFY_ROLE_FOR_USER

The VERIFY_ROLE_FOR_USER function returns a value that indicates whether the roles that are associated with the authorization ID that is specified in the first argument are included in the role names that are specified in the list of the second argument.

If the only way to acquire a role is under a trusted connection that is associated with a trusted context, the VERIFY_ROLE_FOR_USER function is equivalent to the VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function.

The schema is SYSIBM.

SESSION_USER or USER

Specifies the value of the SESSION_USER (or USER) special register.

role-name-expression

An expression that specifies a role name. The existence of the role name at the current server is not verified. *role-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if any of the roles that are associated with the user that is identified by the SESSION_USER (or USER) special register is in the list of roles specified by *role-name-expression*. Otherwise, the result is 0.

The VERIFY_ROLE_FOR_USER function is deterministic within a trusted connection. It is not deterministic across trusted connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Example 1: Assume that the following statements have been issued to create specific roles and the trusted context CTX1:

```
CREATE ROLE EMPLOYEE;
COMMIT;

CREATE ROLE MGR;
COMMIT;

CREATE ROLE PAYROLL;
COMMIT;

CREATE TRUSTED CONTEXT CTX1
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
  ATTRIBUTES (ADDRESS '9.30.131.203', ENCRYPTION 'LOW')
  DEFAULT ROLE EMPLOYEE
```

```
|
|      ENABLE
|      WITH USE FOR SAM, JOE ROLE MGR WITH AUTHENTICATION;
|
| COMMIT;
```

| Joe, who is a manager, issues the following dynamic query through the trusted
| connection CTX1 to view the salaries of the employees in the DSN8910.EMP table
| that are in his department:

```
| SELECT SALARY FROM DSN8910.EMP
|      WHERE VERIFY_ROLE_FOR_USER(SESSION_USER, 'MGR', 'PAYROLL')= 1
|      AND WORKDEPT = ?;
```

| *Example 2:* For the following example, suppose that a user with SECADM authority
| needs to control access for specific users who execute a statement that is accessing
| a table:

| **Is the current user, B, using role X to run a statement owned by user C**

```
|      SESSION_USER = B AND
|      VERIFY_ROLE_FOR_USER(SESSION_USER, 'X')
```

| **Is the current user, B, using role X to run a statement owned by role D**

```
|      SESSION_USER = B AND
|      VERIFY_ROLE_FOR_USER(SESSION_USER, 'X')
```

| **Is the current user, B, using role B to execute a dynamic statement**

```
|      SESSION_USER = B AND
|      VERIFY_ROLE_FOR_USER(SESSION_USER, 'B')
```

VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER

The VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function returns a value that indicates whether the authorization ID that is associated with first argument has acquired a role in a trusted connection and whether that acquired role is included in the role names that are specified in the list of the second argument.

```
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER ( (SESSION_USER | USER), role-name-expression )
```

The schema is SYSIBM.

SESSION_USER or USER

Specifies the value of the SESSION_USER (or USER) special register.

role-name-expression

An expression that specifies a role name. The existence of the role name at the current server is not verified. *role-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if the user that is identified by the SESSION_USER (or USER) special register has acquired a role under a trusted connection that is associated with a trusted context and that role is in the list of *role-name-expression*. Otherwise, the result is 0.

The VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function is deterministic within a trusted connection. It is not deterministic across trusted connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Example 1: Assume that the following statements have been issued to create specific roles and the trusted context CTX1:

```
CREATE ROLE EMPLOYEE;  
COMMIT;  
  
CREATE ROLE MGR;  
COMMIT;  
  
CREATE ROLE PAYROLL;  
COMMIT;  
  
CREATE TRUSTED CONTEXT CTX1  
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001  
  ATTRIBUTES (ADDRESS '9.30.131.203', ENCRYPTION 'LOW')  
  DEFAULT ROLE EMPLOYEE  
  ENABLE  
  WITH USE FOR SAM, JOE ROLE MGR WITH AUTHENTICATION;  
  
COMMIT;
```

| Joe, who is a manager, issues the following dynamic query through the trusted
| connection CTX1 to view the salaries of the employees in the DSN8910.EMP table
| that are in his department:

```
| SELECT SALARY FROM DSN8910.EMP  
| WHERE VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'MGR', 'PAYROLL')= 1  
| AND WORKDEPT = ?;
```

| *Example 2:* For the following example, suppose that a user with SECADM authority
| needs to control access for specific users who execute a statement that is accessing
| a table:

| **Is the current user, B, using role X to run a statement owned by user C**

```
| SESSION_USER = B AND  
| VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'X')
```

| **Is the current user, B, using role X to run a statement owned by role D**

```
| SESSION_USER = B AND  
| VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'X')
```

| **Is the current user, B, using role B to execute a dynamic statement**

```
| SESSION_USER = B AND  
| VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'B')
```

WEEK

The WEEK function returns an integer in the range of 1 to 54 that represents the week of the year. The week starts with Sunday, and January 1 is always in the first week.

►—WEEK(*expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.PROJ, set the integer host variable WEEK to the week of the year that project 'AD2100' ended.

```
SELECT WEEK(PRENDATE)
      INTO :WEEK
      FROM DSN8A10.PROJ
      WHERE PROJNO = 'AD2100';
```

The result is that WEEK is set 6.

Example 2: The following invocations of the WEEK function returns the same result:

```
SELECT WEEK('1993-08-10-20.00.00'),
      WEEK('1993-08-10-20.00.00-08:00'),
      WEEK('1993-08-10-20.00.00+09:00')
      FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the WEEK function in this SELECT statement, the result is 33.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00'.

WEEK_ISO

The WEEK_ISO function returns an integer in the range of 1 to 53 that represents the week of the year. The week starts with Monday and includes seven days. Week 1 is the first week of the year that contains a Thursday, which is equivalent to the first week that contains January 4.

►► WEEK_ISO(*expression*) ◄◄

With the WEEK_ISO function, the first one, two, or three days in January might be included in the last week of the previous year. Likewise, the last one, two, or three days in December might be included in the first week of the next year.

The schema is SYSIBM.

The argument must be a date, a timestamp, or a valid string representation of a date or timestamp. A string representation must not be a CLOB or DBCLOB value and must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8A10.PROJ, set the integer host variable WEEKISO to the week of the year that project 'AD2100' ended.

```
SELECT WEEK_ISO(PRENDATE)
       INTO :WEEKISO
       FROM DSN8A10.PROJ
       WHERE PROJNO = 'AD2100';
```

Example 2: The following list shows what is returned by the WEEK_ISO function for various dates.

| DATE: | WEEK_ISO returns: |
|------------|-------------------|
| 2003-12-28 | 52 |
| 2003-12-31 | 1 |
| 2004-01-01 | 1 |
| 2005-01-01 | 53 |
| 2005-01-04 | 1 |
| 2005-12-31 | 52 |
| 2006-01-01 | 52 |
| 2006-01-03 | 1 |

Example 3: The following invocations of the WEEK_ISO function returns the same result:

```
| SELECT WEEK_ISO('1993-08-10-20.00.00'),  
| WEEK_ISO('1993-08-10-20.00.00-08:00'),  
| WEEK_ISO('1993-08-10-20.00.00+09:00')  
| FROM SYSIBM.SYSDUMMY1;
```

| For each invocation of the WEEK_ISO function in this SELECT statement, the
| result is 32.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| '1993-08-10-20.00.00' .

XMLATTRIBUTES

The XMLATTRIBUTES function constructs XML attributes from the arguments. This function can be used as an argument only for the XMLELEMENT function.

The schema is SYSIBM.

The result is an XML sequence that contains an XQuery attribute node for each non-null *attribute-value-expression* argument.

attribute-value-expression

An expression that returns a value for the attribute. The data type of *attribute-value-expression* must not be ROWID, a LOB, a distinct type that is based on a ROWID or a LOB, or XML.

The result of *attribute-value-expression* is mapped to an XML value according to the rules for mapping an SQL value to an XML value. If the expression is not a simple column reference, an attribute name must be specified.

AS *attribute-name*

Specifies an attribute name. The name is an SQL identifier that must be in the form of an XML qualified name, or QName. If *attribute-name* is a qualified name, the namespace prefix must be declared within the scope of the qualified name.

attribute-name cannot be 'xmlns' or prefixed with 'xmlns:'. A namespace is declared using the function XMLNAMESPACES. The attribute names for an element must be unique for the XML element to be well-formed.

If *attribute-name* is not specified, the expression for *attribute-value* must be a column name. The attribute name will be created from the column name using the fully escaped mapping from a column name to an XML attribute name.

The result of the function is an XML value. The result can be null; if all *attribute-value-expression* arguments are null, the result is the null value.

XMLCOMMENT

The XMLCOMMENT function returns an XML value with a single comment node from a string expression. The content of the comment node is the value of the input string expression, mapped to Unicode (UTF-8).

►—XMLCOMMENT(*string-expression*)—◄

The schema is SYSIBM.

string-expression

An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The result of *string-expression* is converted to UTF-8 and then parsed to check for conformance to the content of XML comment as specified by the following rules:

- '--' (double-hyphen) must not occur in the string expression
- The string expression must not end with a hyphen ('-')
- Each character of the string can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'

If *string-expression* does not conform to the previous rules, an error is returned.

The result of the function is an XML value that is an XML sequence that contains one XML comment node.

The result can be null; if the argument is null, the result is the null value.

Example: Generate an XML comment:

```
SELECT XMLCOMMENT('This is an XML comment')
FROM SYSIBM.SYSDUMMY1;
```

The result of the query would look similar to the following result:

```
<!--This is an XML comment-->
```

XMLCONCAT

The XMLCONCAT function returns an XML sequence that contains the concatenation of a variable number of XML input arguments.

The schema is SYSIBM.

XML-expression

An expression that returns an XML value.

The data type of the result is XML. The result of the function is an XML sequence that contains the concatenation of the non-null input XML values. Null values in the input are ignored. The result can be null; if the result of every input value is null, the result is the null value.

Example: Concatenate first name and last name elements by using 'first' and 'last' element names for each employee.

```
SELECT XMLSERIALIZE( XMLCONCAT
                    ( XMLELEMENT ( NAME "first", e.fname),
                      XMLELEMENT ( NAME "last", e.lname)
                    ) ) AS "result"
FROM employees e;
```

The result of the query would look similar to the following result:

result

```
<first>John</first><last>Smith</last>
<first>Mary</first><last>Smith</last>
```

XMLDOCUMENT

The XMLDOCUMENT function returns an XML value with a single document node and zero or more nodes as its children. The content of the generated XML document node is specified by a list of expressions.

The schema is SYSIBM.

XML-expression

An expression that returns an XML value. A sequence item in the XML value must not be an attribute node. If *XML-expression* returns a null value, it is ignored for further processing. However, if all *XML-expression* values are null, the result of the function is the null value.

The result of the function is an XML value.

The result can be null; if all of the arguments are null, the result is the null value.

The resulting XML value is built from the list of *XML-expression* arguments. The children of the resulting document node are constructed as follows:

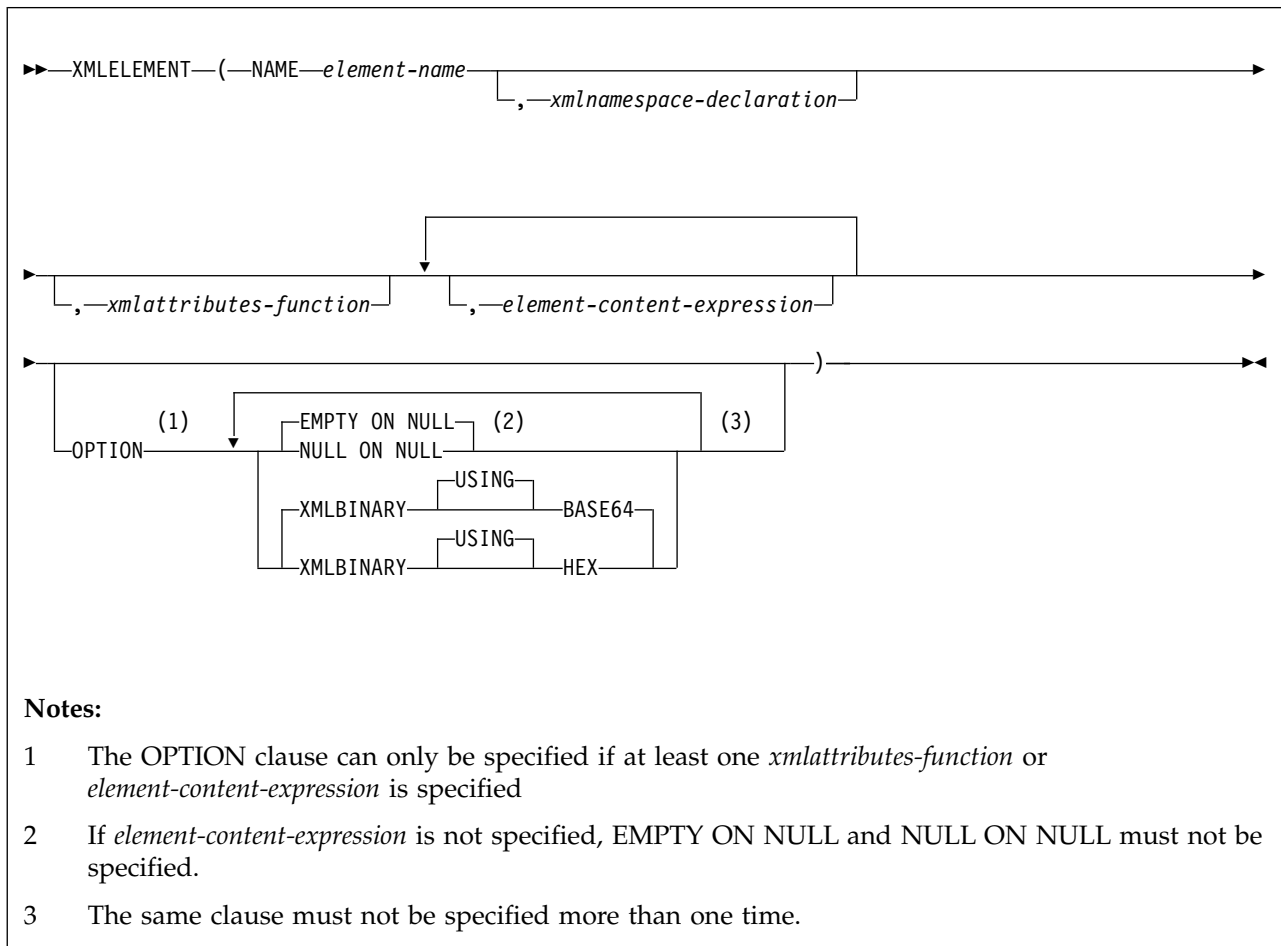

1. All of the non-null XML values that are returned by *XML-expression* are concatenated together. The result is a sequence of nodes or atomic values, which is referred to in the following steps as the *input sequence*. Any document node in the input sequence is replaced by copies of its children.
2. For each node in the input sequence, a new deep copy of the node is constructed. A *deep copy* of a node is a copy of the whole subtree that is rooted at that node, including the node itself and its descendants and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation 'xdt:untyped', and copied attribute nodes are given the type annotation 'xdt:untypedAtomic'. For each adjacent sequence of one or more atomic values that is returned in the input sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. The resulting sequence of nodes is called the *content sequence*. Adjacent text nodes in the content sequence are merged into a single text node by concatenating the contents of the text nodes with no intervening blanks. After concatenation, any text node that contains a zero-length string is deleted from the content sequence.
3. The nodes in the content sequence become the children of the new document node.

Example 1: Insert a constructed document into an XML column:

```
INSERT INTO T1 VALUES(123,
  (SELECT XMLDOCUMENT(XMLELEMENT(NAME "Emp",
    e.fname || ' ' || e.lname),
    XMLCOMMENT('This is just a simple example'))
  FROM EMPLOYEE e
  WHERE e.empid = 123));
```

XMLELEMENT

The XMLELEMENT function returns an XML value that is an XML element node.

The schema is SYSIBM.

NAME *element-name*

Specifies the name of an XML element. *element-name* is an SQL identifier that must be in the form of an XML qualified name, or QName. If the name is qualified, the namespace prefix must be declared within the scope.

xmlnamespaces-declaration

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLELEMENT function. The namespaces apply to any nested XML functions within the XMLELEMENT function, regardless of whether or not they appear inside another subselect. See “XMLNAMESPACES” on page 686 for more information on declaring XML namespaces.

If *xmlnamespaces-declaration* is not specified, namespace declarations are not associated with the constructed XML element node.

xmlattributes-function

Specifies the attributes for the XML element. The attributes are the result of the XMLATTRIBUTES function. See “XMLATTRIBUTES” on page 671 for more information on constructing attributes.

If *xmlattributes-function* is not specified, attributes are not explicitly part of the constructed XML element node.

element-content-expression

The content of the generated XML element node is specified by an expression or a list of expressions. Each *element-content-expression* must return a value of any built-in data type or distinct type. The expression is used to construct the namespace declarations, attributes, and content of the constructed element node.

If *element-content-expression* is not specified, an empty string is used as the content for the element and NULL ON NULL or EMPTY ON NULL must not be specified.

OPTION

Specifies additional options for constructing the XML element. This clause has no impact on nested invocations of the XMLELEMENT function invocations that are specified in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL

Specifies if a null value or an empty element is returned when the values of each *element-content-expression* is a null value. This option only affects null handling of element contents, not attribute values. The option is not inherited by a nested invocation of XMLELEMENT function within an *element-content-expression*.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

EMPTY ON NULL is the default.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

This function takes an element name, an optional collection of namespace declarations, an optional collection of attributes, and zero or more optional arguments that make up the content of the XML element. The result is an XML sequence that contains an XML element node or the null value. If the results of all *element-content-expression* arguments are empty strings, the result is an XML sequence that contains an empty element.

The result of the function is an XML value. The result can be null; if all *element-content-expression* arguments are null and the NULL ON NULL option is in effect, the result is the null value.

Constructing an element node: The resulting element node is constructed as follows:

1. *xmlnamespace-declaration* adds a set of in-scope namespaces for the constructed element. Each in-scope namespace associates a namespace prefix (or the default namespace) with a namespace URI. The in-scope namespaces define the set of namespace prefixes that are available for interpreting QNames within the scope of the element.
2. If the *xmlattributes-function* is specified, it is evaluated and the result is a sequence of attribute nodes.
3. Each *element-content-expression* is evaluated and the result is converted into a sequence of nodes as follows:
 - If the result type is not XML, it is converted to an XML text node that contains the result of the *element-content-expression* this is mapped to XML.
 - If the result type is XML, the result is a sequence of items. Some of the items in that sequence might be document nodes. Each document node in the sequence is replaced by the sequence of its top-level children. Then for each node in the resulting sequence, a new deep copy of the node is constructed, including its children and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation `xd:untyped`, and copied attribute nodes are given the type annotation `xd:untypedAtomic`. For each adjacent sequence of one or more atomic values that are returned in the sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. If any of these atomic values cannot be cast into a string, an error is returned.
4. The result sequence of *xmlattributes-function* and the resulting sequences of all *element-content-expression* clauses are concatenated into one sequence which is called the *content sequence*. Any sequence of adjacent text nodes in the content sequence is merged into a single text node by concatenating their contents, with no intervening blanks. After concatenation, any text node that is a zero-length string is deleted from the content sequence.
5. If the content sequence contains an attribute node that follows a node that is not an attribute node, an error is returned. Attribute nodes that occur in the content sequence become attributes of the new element node. If two or more of these attribute nodes have the same name, an error is returned. A namespace declaration is created that corresponds to any namespace that is used in the names of the attribute nodes if the namespace URI is not in the in-scope namespaces of the constructed element.
6. Element, text, comment, and processing instruction nodes in the content sequence become the children of the constructed element node.

7. The constructed element node is given a type annotation of `xdt:untyped`, and each of its attributes is given a type annotation of `xdt:untypedAtomic`. The node name of the constructed element node is the XML element name that is specified after the `NAME` keyword.

Rules for using namespaces within `XMLELEMENT`: The following rules describe scoping of namespaces:

- The namespaces that are declared in the `XMLNAMESPACES` function are the in-scope namespaces of the element node that are constructed by the `XMLELEMENT` function. If the element node is serialized, each of its in-scope namespaces will be serialized as a namespace attribute unless it is an in-scope namespace of the parent of the element node and the parent element is also serialized.
- The scope of these namespaces is the lexical scope of the `XMLELEMENT` function, including the element name, the attribute names that are specified in the `XMLATTRIBUTES` function, and all *element-content-expressions*. These are used to resolve the `QNames` in the scope.
- If an `XMLQUERY` or `XMLEXISTS` function is in an *element-content-expression*, the namespaces become the *statically known namespaces* of the XQuery expression of the `XMLQUERY` or `XMLEXISTS` function. Statically known namespaces are used to resolve the `QNames` that are in the XQuery expression. If the XQuery prolog declares a namespace that has the same prefix within the scope of the XQuery expression, the namespace that is declared in the prolog will override the namespaces that are declared in the `XMLNAMESPACES` function.
- If an attribute of the constructed element comes from *element-content-expression*, its namespace might not already be declared as an in-scope namespace of the constructed element. In this case, a new namespace is created for it. If the prefix of the attribute name is already bound to a different URI by a in-scope namespace, DB2 generates a different prefix to be used in the attribute name. A namespace is created for this generated prefix. The name of the generated prefix follows the following pattern: `db2ns-xx`, where `xx` is a pair of characters chosen from the set `[A-Z,a-z,0-9]`.

Example 1: The following statement uses the `XMLELEMENT` function to create an XML element that contains an employee's name. The statement also stores the employee number as an attribute named `serial`. If there is a null value in the referenced column, the function returns the null value:

```
SELECT e.empno, e.firstnme, e.lastname,
       XMLELEMENT ( NAME "foo:Emp",
                   XMLNAMESPACES('http://www.foo.com' AS "foo"),
                   XMLATTRIBUTES(e.empno as "serial"),
                   e.firstnme,
                   e.lastname
                   OPTION NULL ON NULL ) AS "Result"
FROM EMP e
WHERE e.edlevel = 12;
```

The result of the query would look similar to the following result:

| EMPNO | FIRSTNME | LASTNAME | Result |
|--------|----------|----------|---|
| A0001 | John | Parker | <foo:Emp xmlns:foo="http://www.foo.com" serial="A0001">JohnParker</foo:Emp> |
| B0001 | (null) | Smith | <foo:Emp xmlns:foo="http://www.foo.com" serial="B0001">Smith</foo:Emp> |
| B0002 | (null) | (null) | (null) |
| (null) | (null) | (null) | (null) |

Example 2: The following example is similar to Example 1, however, when a null value is in one of the referenced columns, an empty element is returned:

```

SELECT e.empno, e.firstname, e.lastname,
       XMLELEMENT (NAME "foo:Emp",
                   XMLNAMESPACES('http://www.foo.com' AS "foo"),
                   XMLATTRIBUTES(e.empno as "serial"),
                   e.firstname,
                   e.lastname
                   OPTION EMPTY ON NULL) AS "Result"
FROM EMP e
WHERE e.edlevel = 12;

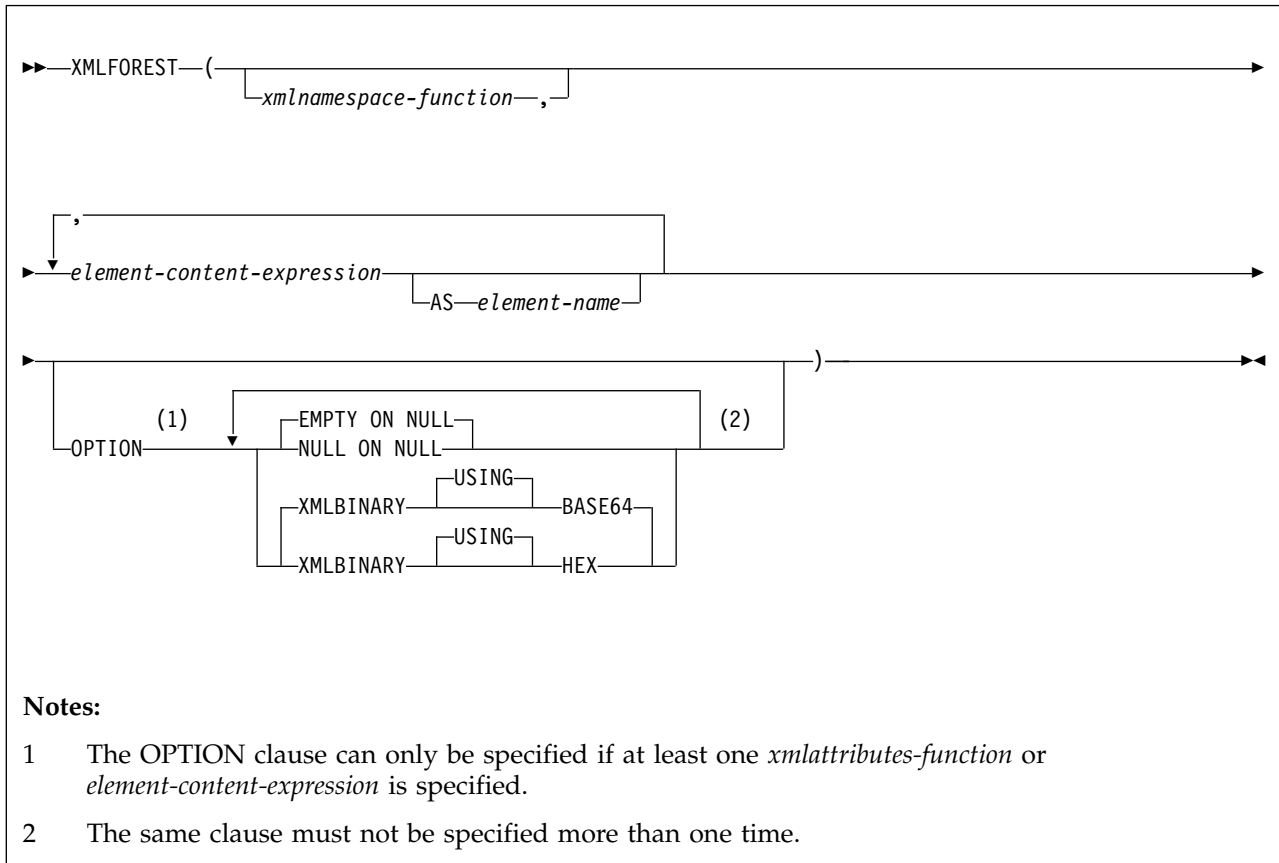

```

The result of the query would look similar to the following result:

| EMPNO | FIRSTNME | LASTNAME | Result |
|--------|----------|----------|---|
| ----- | ----- | ----- | ----- |
| A0001 | John | Parker | <foo:Emp xmlns:foo="http://www.foo.com" serial="A0001">JohnParker</foo:Emp> |
| B0001 | (null) | Smith | <foo:Emp xmlns:foo="http://www.foo.com" serial="B0001">Smith</foo:Emp> |
| B0002 | (null) | (null) | <foo:Emp xmlns:foo="http://www.foo.com" serial="B0002"/> |
| (null) | (null) | (null) | <foo:Emp xmlns:foo="http://www.foo.com"/> |

XMLFOREST

The XMLFOREST function returns an XML value that is a sequence of XML element nodes.

Notes:

- 1 The OPTION clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified.
- 2 The same clause must not be specified more than one time.

The schema is SYSIBM.

xmlnamespace-function

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLFOREST function. The namespaces apply to any nested XML functions within the XMLFOREST function, regardless of whether or not those functions appear inside another subselect. See "XMLNAMESPACES" on page 686 for more information on declaring XML namespaces.

If *xmlnamespace-function* is not specified, namespace declarations are not associated with the constructed sequence of XML element nodes.

element-content-expression

Specifies an expression that returns a value that is used for the content of a generated XML element. The result of the expression is mapped to an XML value according to the mapping rules from an SQL value to an XML value. If the expression is not a simple column reference, *element-name* must be specified.

AS *element-name*

Specifies an identifier that is used for the XML element name.

An XML element name must be an XML QName. If the name is qualified, the namespace prefix must be declared within the scope.

If *element-name* is not specified, *element-content-expression* must be a column name. The element name is created from the column name using the fully escaped mapping from a column name to a QName.

OPTION

Specifies options for the result for NULL values, binary data, and bit data. The options will not be inherited by the XMLELEMENT or XMLFOREST functions that appear in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL

Specifies if a null value or an empty element is returned when the values of each *element-content-expression* is a null value. EMPTY ON NULL and NULL ON NULL only affect null handling of the *element-content-expression* arguments, not the handling of values from an *xmlattributes-function* argument.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

EMPTY ON NULL is the default.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

The XMLFOREST function can be expressed using the XMLCONCAT and XMLELEMENT functions.

This function takes an optional set of namespace declarations and one or more arguments that make up the name and element content for one or more element nodes. The result is an XML sequence containing a sequence of element nodes or the null value.

The result of the function is an XML value. The result can be null; if all the *element-content-expression* arguments are null and the NULL ON NULL option is in effect, the result is the null value.

Example: Generate an "Emp" element for each employee. Use employee name as its attribute and two subelements generated from columns HIRE and DEPT by using XMLFOREST as its content. The element names for the two subelements are "HIRE" and "department".

```
SELECT e.id, XMLSERIALIZE ( XMLELEMENT
  ( NAME "Emp",
    XMLATTRIBUTES ( e.fname || ' ' || e.lname
      AS "name" ),
    XMLFOREST ( e.hire,
      e.dept AS "department" )
    ) ) AS "result"
FROM employees e;
```

The result of the query would be similar to the following result:

| ID | result |
|------|---|
| 1001 | <Emp name="John Smith"> <HIRE>2000-05-24</HIRE> <department>Accounting</department> </Emp> |
| 1001 | <Emp name="Mary Martin"> <HIRE>1996-02-01</HIRE> <department>Shipping</department> </Emp> |

XMLMODIFY

The XMLMODIFY function returns an XML value that might have been modified by the evaluation of an XQuery updating expression and XQuery variables that are specified as input arguments.

The schema is SYSIBM.

xquery-update-constant

Specifies an SQL character string constant that is interpreted as an XQuery updating expression that uses supported XQuery language syntax. *xquery-update-constant* must be an insert expression, a delete expression, or a replace expression. *xquery-update-constant* must not be an empty string or a string of all blanks.

xquery-variable expression

xquery-variable-expression specifies an SQL expression whose value is available to the XQuery expression that is specified by *xquery-update-constant* during execution.

The data type of *xquery-variable-expression* can be XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-variable-expression* must not return a ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string that is bit data, and *xquery-variable-expression* must not reference a sequence expression. If the result value is of type XML, it is passed by reference, which means that the original values, not copies, are used in the evaluation of the XQuery expression. A null XML value is converted to an XML empty sequence. If the resulting value is not of type XML, the result of the expression must be castable to an XML value. A null value is converted to an XML empty sequence. The non-XML values creates a new copy of the value during the cast to XML.

An XQuery variable is created for each *xquery-variable-expression* this is specified, and the XQuery variable is set to a value that is equal to the *input-xml-value*.

AS *identifier*

Specifies that the value that is generated by *xquery-variable-expression* is passed to *xquery-update-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. If the length of the name is longer than 128 bytes, an error is returned. The leading dollar sign (\$) that precedes variable names in the XQuery language is not included in *identifier*. The name must be an XML 1.0 NCName that is not the same as the identifier for another *xquery-variable-expression* in the same PASSING clause. If the identifier is not an XML 1.0 NCName an error is returned. If more than one *xquery-variable-expression* have the same name, an error is returned. If the result of an *xquery-variable expression* is null, an empty sequence is assigned to the corresponding XQuery variable.

The XMLMODIFY function can only be used in an SQL UPDATE statement or within the update clause of an SQL MERGE statement. The XMLMODIFY function must be the topmost expression on the right hand side of the SET assignment clause of the update.

1. Insert operations that use ordering keywords such as before, after, as first, or as last
2. Replace operations in which the keyword value of is not specified
3. Replace operations in which the keyword value of is specified, and the target node is an element node
4. All delete operations

The *target-xml-column* is the XML column in the SET assignment clause that is to be updated by the value that is returned by the XMLMODIFY function. The initial context item in the XQuery updating expression is the value of the *target-xml-column* that is passed by reference. Only the value of the *target-xml-column* can be modified by the XQuery updating expression. In other words, the target expression nodes in the XQuery updating expression must be a node in the value of *target-xml-column*. The *target-xml-column* must be an XML column that is defined in the XML versioning format.

The value of *target-xml-column* that is modified by the XQuery updating expression is returned by the function. If the value of *target-xml-column* is null, the function returns null. Otherwise, the result of the XMLMODIFY function must be a well-formed XML document. If the XQuery updating expressions makes no modifications to the value of *target-xml-column*, the unmodified XML value is returned by the function. The XMLMODIFY function preserves the original node identities and the document order of *target-xml-column*. Although XMLMODIFY modifies *target-xml-column* by reference, for each row that is updated by the SQL UPDATE statement, any reference to *target-xml-column* in the SQL UPDATE statement is the value of the *target-xml-column* before the row is updated.

Example 1: The following is an example of an XMLMODIFY function with an XQuery insert expression. Assume that a table contains a column named PO that contains an XML document, 'purchaseOrders':

```
UPDATE purchaseOrders
  SET PO = XMLMODIFY('declare namespace ipo="http://www.example.com/IP0";
                    declare namespace pyd="http://www.examplepayment.com";
                    insert node $payment/@pyd:paidDate
                    as first into /ipo:purchaseOrder/billTo',
                    XMLPARSE(DOCUMENT
                    '<payment xmlns:pyd="http://www.examplepayment.com"
                    pyd:paidDate="2000-01-07">278.94
                    </payment>') AS "payment")
```

The result of the purchaseOrders XML document in the PO column is as follows:

```
<ipo:purchaseOrder
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:ipo="http://www.example.com/IP0"
  xmlns:pyd="http://www.examplepayment.com"
  orderDate="1999-12-01" pyd:paidDate="2000-01-07">
  <shipTo exportCode="1" xsi:type="ipo:UKAddress">
  <name>Helen Zoe</name>
    <street>47 Eden Street</street>
    <city>Cambridge</city>
    <postcode>CB1 1JR</postcode>
  </shipTo>
```

|
|
|
|
|
|

.
.
.
</ipo:purchaseOrder>

XMLNAMESPACES

The XMLNAMESPACES function constructs namespace declarations from the arguments. This function can be used as an argument only for specific functions, such as the XMLELEMENT function and the XMLFOREST function.

Notes:

- 1 The DEFAULT or NO DEFAULT clause can only be specified one time.

The schema is SYSIBM.

The result is one or more XML namespace declarations containing in-scope namespaces for each non-null input value.

namespace-uri

Specifies an SQL character string constant that contains the namespace name or a universal resource identifier (URI). The character string constant must not be an empty string if it is used with *namespace-prefix*. *namespace-uri* cannot be `http://www.w3.org/XML/1998/namespace` or `http://www.w3.org/2000/xmlns/`.

AS *namespace-prefix*

Specifies a namespace prefix. The prefix is an SQL identifier that must be in the form of an XML NCName. The prefix must not be "xml" or "xmlns". The prefix must be unique within the list of namespace declarations.

The following namespace prefixes are pre-defined in SQL/XML: "xml", "xs", "xsd", "xsi", and "sqlxml". Their bindings are:

- `xmlns:xml = "http://www.w3.org/XML/1998/namespace"`
- `xmlns:xs = "http://www.w3.org/2001/XMLSchema"`
- `xmlns:xsd = "http://www.w3.org/2001/XMLSchema"`
- `xmlns:xsi = "http://www.w3.org/2001/XMLSchema-instance"`
- `xmlns:sqlxml = "http://standards.iso.org/iso/9075/2003/sqlxml"`

DEFAULT *namespace-uri* **or NO DEFAULT**

Specifies whether a default namespace is to be used within the scope of this namespace declaration.

The scope of this namespace declaration is the specified XML element and all XML expressions that are contained in the specified XML element.

DEFAULT *namespace-uri*

Specifies the default namespace to use within the scope of this namespace declaration. The *namespace-uri* applies for unqualified names in the scope unless it is overridden in a nested scope by another DEFAULT declaration or by a NO DEFAULT declaration.

namespace-uri specifies an SQL character string constant that contains a namespace name or universal resource identifier (URI). The character string constant can be an empty string in the context of the DEFAULT clause.

NO DEFAULT

Specifies that no default namespace is to be used within the scope of this namespace declaration. There is no default namespace in the scope unless the NO DEFAULT clause is overridden in a nested scope by a DEFAULT declaration.

The result of the function is an XML value that is an XML sequence that contains an XML namespace declaration for each specified namespace. The result cannot be null.

Example 1: Generate an "employee" element for each employee. The employee element is associated with XML namespace "urn:bo", which is bound to prefix "bo". The element contains attributes for names and a hiredate subelement.

```
SELECT e.empno, XMLSERIALIZE(XMLELEMENT(NAME "bo:employee",
                                     XMLNAMESPACES('urn:bo' as "bo"),
                                     XMLATTRIBUTES(e.lastname, e.firstnme),
                                     XMLELEMENT(NAME "bo:hiredate", e.hiredate)) AS CLOB(50))
FROM employee e where e.edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <bo:employee xmlns:bo="urn:bo" LASTNAME="PARKER" FIRSTNME="JOHN">
      <bo:hiredate>198-5-3</bo:hiredate>
</bo:employee>
00031 <bo:employee xmlns:bo="urn:bo" LASTNAME="SETRIGHT"
      FIRSTNME="MAUDE">
      <bo:hiredate>1964-9-12</bo:hiredate>
</bo:employee>
```

Example 2: Generate two elements for each employee using XMLFOREST. The first "lastname" element is associated with the default namespace "http://hr.org", and the second "job" element is associated with XML namespace "http://fed.gov", which is bound to prefix "d".

```
SELECT empno, XMLSERIALIZE(XMLFOREST(
                                     XMLNAMESPACES(DEFAULT 'http://hr.org', 'http://fed.gov' AS "d"),
                                     lastname, job AS "d:job") AS CLOB(50))
FROM employee where edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">PARKER
</LASTNAME>
      <d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">
OPERATOR</d:job>
00031 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">
SETRIGHT</LASTNAME>
      <d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">
OPERATOR</d:job>
```

XMLPARSE

The XMLPARSE function parses the argument as an XML document and returns an XML value.

The schema is SYSIBM.

DOCUMENT

Specifies that the character string expression to be parsed must evaluate to a well-formed XML document that conforms to XML 1.0.

string-expression

An expression that returns a character, graphic, or binary string.

string-expression must evaluate to a character string that conforms to the definition of a well-formed XML document as defined in XML 1.0.

XML-host-variable

An XML host variable that contains a well-formed XML document as defined in XML 1.0. *XML-host-variable* must not be binary XML data.

STRIP WHITESPACE or PRESERVE WHITESPACE

Specifies whether whitespace is to be removed or preserved. Any DTD attributes for `xml:space` have no impact on whitespace handling.

STRIP WHITESPACE

Specifies that whitespace (space that is between element nodes without any non-whitespace text nodes) will be stripped unless the nearest containing element has a value of 'preserve' for the `xml:space` attribute.

STRIP WHITESPACE is the default.

PRESERVE WHITESPACE

Specifies that all whitespace is preserved, even when the nearest containing element has a value of 'default' for the `xml:space` attribute.

The result of the function is XML. If *string-expression* can be null, the result can be null; if *string-expression* is null, the result is the null value.

Direct use of XMLPARSE with character string input: Applications should avoid direct use of the XMLPARSE function with character string input and should send strings that contain XML documents directly by using host variables to maintain the match between the external encoding and the encoding in the XML declaration. If XMLPARSE must be used in this situation, a BLOB type should be specified as the argument to avoid code page conversion.

Example 1: The following example inserts an XML document into the EMP table and preserves the whitespace in the original XML document. Assume that *hv* contains the value, '<a xml:space='preserve'> <c>c</c>b ':

```
INSERT INTO EMP (id, xvalue) VALUES(1001,  
XMLPARSE(DOCUMENT :hv  
PRESERVE WHITESPACE));
```

XMLPARSE will treat the value in *hv* for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'> <b> <c>c</c>b </b>
</a>
```

Example 2: The following example inserts an XML document into the EMP table and strips the whitespace in the original XML document. Assume that *hv* contains the value, '<a xml:space='preserve'> <b xml:space='default'> <c>c</c>b ':

```
INSERT INTO EMP (id, xvalue) VALUES(1001,
    XMLPARSE(DOCUMENT :hv
              STRIP WHITESPACE));
```

XMLPARSE will treat the value in *hv* for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'>
<b xml:space='default'><c>c</c>b </b>
</a>
```

XMLPI

The XMLPI function returns an XML value with a single processing instruction node.

The schema is SYSIBM.

NAME *pi-name*

Specifies the name of a processing instruction. The name is an SQL identifier that must be in the form of an XML NCName. The name must not contain "xml" in any case combination.

string-expression

An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The resulting string will be converted to UTF-8 and parsed to check for conformance to the content of XML processing instruction as specified by the following rules:

- The string must not contain the substring '?>' as this terminates a processing instruction.
- Each character can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'.

If the resulting string does not conform to the preceding rules, an error is returned. The resulting string becomes the contents of the constructed processing instruction node. If *string-expression* is not specified or is an empty string, the contents of the processing instruction node are empty.

The result of the function is an XML value. The result can be null; if the *string-expression* argument is null, the result is the null value.

Example: Generate an XML processing instruction node:

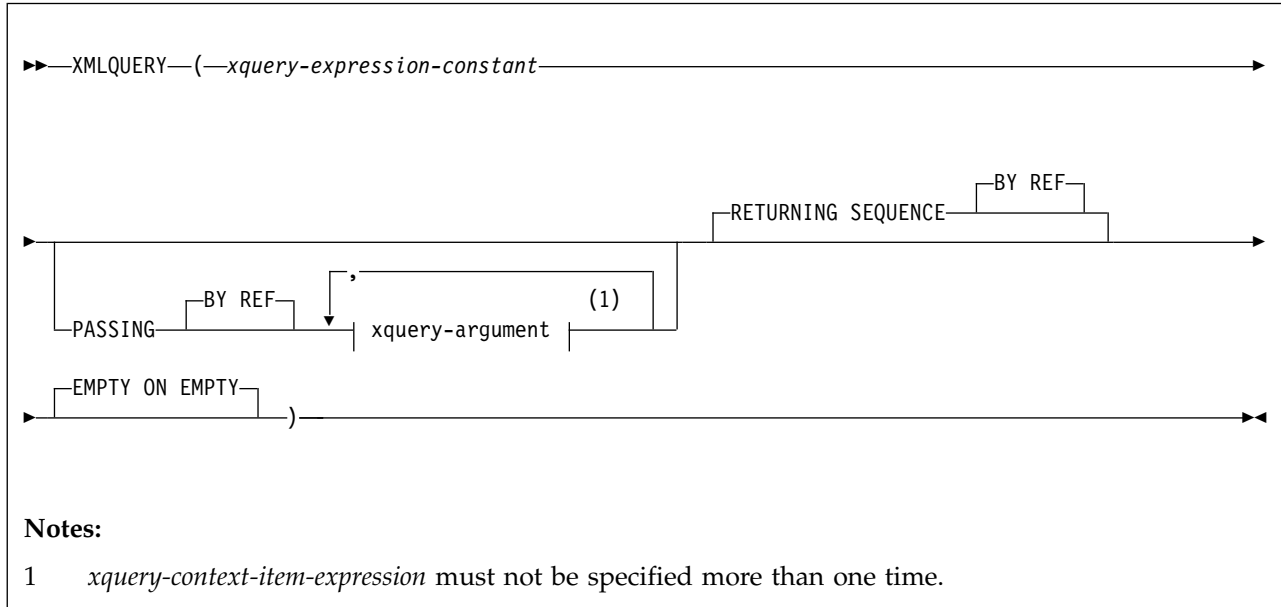

```
SELECT XMLPI(NAME "Instruction", 'Push the red button')
FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

```
<?Instruction Push the red button?>
```

XMLQUERY

The XMLQUERY function returns an XML value from the evaluation of an XQuery expression, by using specified input arguments, a context item, and XQuery variables.

xquery-argument:

The schema is SYSIBM.

xquery-expression-constant

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. See *DB2 XML Guide* for information about the supported XQuery expressions. *xquery-expression-constant* cannot be an XQuery updating expression. The XQuery expression is evaluated with the arguments specified in *xquery-argument*, and returns an output sequence that is also returned as the result of the XMLQUERY function. *xquery-expression-constant* must not be an empty string or a string of all blanks.

PASSING

Specifies input values and the manner in which these values are passed to the XQuery expression that is specified by *xquery-expression-constant*.

BY REF

Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees which preserves all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving

some nodes that are contained between the two input arguments might refer to nodes that are within the same XML node tree.

BY REF has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

xquery-argument

Specifies an argument that is passed to the XQuery expression that is specified by *xquery-expression-constant*. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-argument* must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression.

xquery-argument specifies both a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XQuery expression depends on whether the argument is specified as *xquery-context-item-expression* or *xquery-variable-expression*. *xquery-argument* includes an SQL expression that is evaluated before passing the result to the XQuery expression.

- If the resulting value is of type XML, it becomes an *input-xml-value*. It is passed by reference, which means that the original values, not copies, are used in the evaluation of the XQuery expression. A null XML value is converted to an XML empty sequence.
- If the resulting value is not of type XML, the result of the expression must be able to be cast to an XML value. A null value is converted to an XML empty sequence. The converted value becomes an *input-xml-value*.

When *xquery-expression-constant* is evaluated, an XQuery variable receives a value that is equal to *input-xml-value* and a name as specified by the AS clause.

xquery-context-item-expression

xquery-context-item-expression specifies the initial context item in the XQuery expression specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-context-item-expression must not be a sequence of more than one item. If *input-xml-value* is an empty XML string, the XQuery expression is evaluated with the initial context item set to an empty XML string. If the value of *input-xml-value* is null, the function returns a null value.

If the *xquery-context-item-expression* is not specified or is an empty sequence, the initial context item in the XQuery expression is undefined and the XQuery expression must not reference the initial context item.

An XQuery variable is not created for the context item expression.

xquery-variable-expression

xquery-variable-expression specifies an SQL expression whose value is available to the XQuery expression that is specified by *xquery-expression-constant* during execution. The sequence cannot contain a sequence reference.

An XQuery variable is created for each *xquery-variable-expression*, and the XQuery variable is set to a value equal to *input-xml-value*. For example, `PASSING T.A + T.B AS "sum"` creates an XQuery variable named `sum`. The scope of the XQuery variables that are created from the PASSING clause is the XQuery expression that is specified by *xquery-expression-constant*.

AS identifier

Specifies that the value that is generated by *xquery-variable-expression* is passed to *xquery-expression-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. The leading dollar sign (\$) that precedes variable names in the XQuery language is not included in *identifier*. The name must be an XML 1.0 NCName that is not the same as the identifier for another *xquery-variable-expression* in the same PASSING clause.

RETURNING SEQUENCE

Specifies that the XQuery expression returns a sequence.

BY REF

Specifies that the result of the XQuery expression is returned by reference. If this value contains nodes, any expression that is using the return value of the XQuery expression will receive node references directly, preserving all node properties including the original node identities and document order.

EMPTY ON EMPTY

Specifies that an empty sequence that results from processing the XQuery expression is returned as an empty sequence.

The result of the function is an XML value, and the result can be null. For example, if *xquery-context-item-expression* is specified and if its value is null, the result of the function is the null value.

If the evaluation of the XQuery expression results in an error, the XMLQUERY function returns the XQuery error.

Implicit casting of a non XML value to an XML value: If the result of *xquery-argument* is not an XML type, the value is cast to XML as follows. The SQL data type of the expression is mapped to a corresponding XML Schema data type according to the following table:

Table 83. SQL data types and corresponding XML schema data types

| SQL data type | XML schema data type |
|---------------------|----------------------|
| CHAR, VARCHAR | xs:string |
| GRAPHIC, VARGRAPHIC | xs:string |
| SMALLINT | xs:integer |
| INTEGER | xs:integer |
| BIGINT | xs:integer |
| DECIMAL | xs:decimal |
| DOUBLE | xs:double |
| FLOAT | xs:double |

Let *V* be the value of the expression. An atomic value of the corresponding XML schema data type is constructed such that the result of cast (*V* as varchar) is a lexical representation of the constructed atomic value. For example, an SQL VARCHAR value '123' is converted to an atomic value '123' of xs:string type. An SQL integer '12' is converted to an atomic value '12' of xs:integer. An SQL decimal value '1.20' is converted to an atomic value '1.2' of xs:decimal.

Example 1: The following example returns an XML value from evaluation of the specified XQuery expression:

```
SELECT XMLQUERY('//item[productName=$n]'
                PASSING PO.POrder,
                :hv AS "n") AS "Result"
FROM PurchaseOrders PO;
```

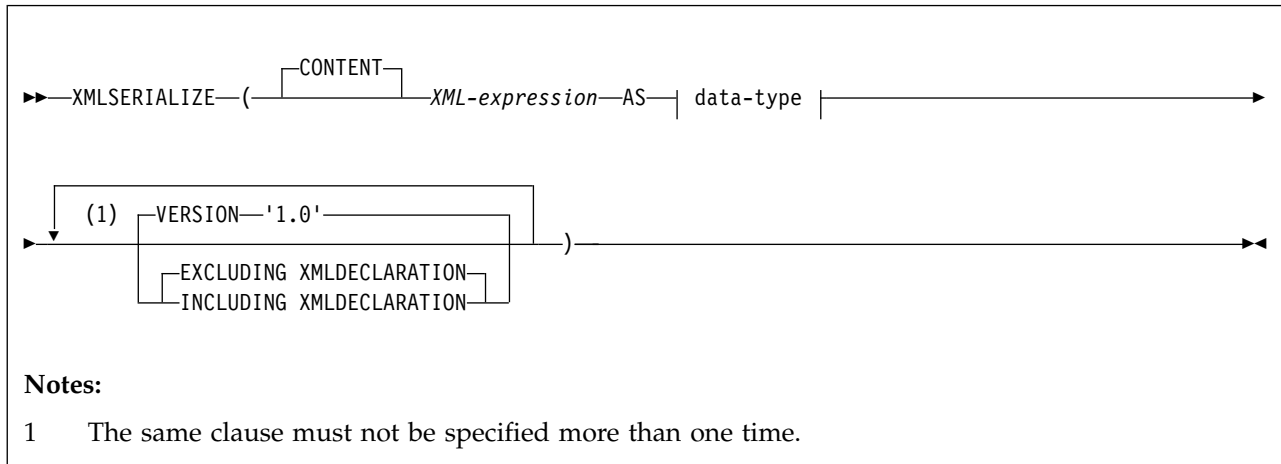

Assume that the value of the host variable *hv* is 'Baby Monitor', the result is similar to the following results:

Result

```
-----
<item partNum="926-AA"><productName>Baby Monitor</productName><quantity>1
</quantity><USPrice>39.98</USPrice><shipDate>1999-05-21</shipDate></item>
```

XMLSERIALIZE

The XMLSERIALIZE function returns a serialized XML value of the specified data type that is generated from the first argument.

data-type

The schema is SYSIBM.

CONTENT

Specifies that any XML value can be specified and the result of the serialization is based on this input value.

XML-expression

An expression that returns an XML value that is not an attribute node. The atomic values in the input sequence must be able to be cast to xs:string. *XML-expression* is the input to the serialization process.

AS data type

Specifies the data type of the result. The implicit or explicit length attribute for the specified result data type must be sufficient to contain the serialized output.

The CCSID of a resulting character or graphic string is determined by the data type of the result:

- If the result is a CLOB, the CCSID for mixed Unicode data (1208).
- If the result is a DBCLOB, the CCSID for graphic Unicode data (1200).

VERSION '1.0'

Specifies the XML version of the serialized value. The only version that is supported is '1.0', which must be specified as a string constant.

EXCLUDING XMLDECLARATION or INCLUDING XMLDECLARATION

Specifies whether an XML declaration is included in the result.

EXCLUDING XMLDECLARATION

Specifies that an XML declaration is not included in the result.

EXCLUDING XMLDECLARATION is the default.

INCLUDING XMLDECLARATION

Specifies that an XML declaration is included in the result. The XML declaration contains values for XML serialization version 1.0 and an encoding specification of UTF-8. An XML sequence is effectively converted to have a single document node by applying the XMLDOCUMENT function to *XML-expression* prior to serializing the resulting XML nodes.

The data type and length attribute of the result are determined from the specified *data-type*. The result can be null; if the *XML-expression* argument is null, the result is the null value.

Serializing a sequence: The value of the input argument to XMLSERIALIZE is a sequence. Before a sequence is serialized, it is normalized. The purpose of sequence normalization is to create a sequence that can be serialized as a well-formed XML document or external general parsed entity, that also reflects the content of the input sequence to the extent possible. If the input sequence is an XML empty string, the result of serialization is an empty string. Otherwise, the result is constructed as follows:

- For each item in the sequence, if the item is atomic, the lexical representation of the item is obtained by casting it to an xs:string
- Each subsequence of adjacent strings in the sequence is merged into a single string with the values of the adjacent strings separated by a single space.
- For each item in the sequence, if the item is a string, a text node is created with a value that is equal to the string.
- For each node in the sequence, if the node is a document node, it is replaced it by its children.
- Each node must not be an attribute node.
- Each subsequence of adjacent text nodes in the sequence are merged into a single text node that with the values of the adjacent text nodes concatenated in order without a space between each node. Any text nodes of zero length are dropped.
- A document node is created and the sequence of nodes that was generated is copied as the children of the new document node.

Let *S* be any sequence, the normalization described in the preceding list is equivalent to XMLDOCUMENT(*S*). Therefore, the following two expressions produce the same result:

- XMLSERIALIZE(*S* AS CLOB)
- XMLSERIALIZE(XMLDOCUMENT(*S*) AS CLOB)

Each instance of the following characters that appear in the content of a text node or in the value of an attribute node is mapped as following during serialization:

| Character in content of text node | during serialization, the character is mapped to |
|-----------------------------------|--|
| '&' (X'26') | '&' |
| '<' (X'3C') | '<' |
| '>' (X'3E') | '>' |
| carriage return (X'0D') | '' |
| quote (X'22) ¹ | '"' |

Note: The quote character is only mapped if it is inside of an attribute value.

Syntax alternatives: XML2CLOB(*XML-expression*) can be specified as an alternative to XMLSERIALIZE(*XML-expression* AS CLOB(2G)). XML2CLOB is supported only for compatibility with previous releases of DB2.

Example 1: Serialize into CLOB of UTF-8, the XML value that is returned by the XMLELEMENT function, which is a simple XML element with "Emp" as the element name, and an employee name as the element content:

```
SELECT e.id, XMLSERIALIZE(XMLELEMENT ( NAME "Emp",
                                     e.fname || ' ' || e.lname)
                        AS CLOB(100)) AS "result"
FROM employees e;
```

The result looks similar to the following results:

```
ID      result
---      -
1001    <Emp>John Smith</Emp>
1206    <Emp>Mary Martin</Emp>
```

Example 2: Serialize into a string of BLOB type, the XML value that is returned by the XMLELEMENT function:

```
SELECT XMLSERIALIZE(XMLELEMENT(NAME "emp",
                               e.fname || ' ' || e.lname))
       AS BLOB(1K)
       VERSION '1.0') AS result
FROM employee e WHERE e.id = '1001';
```

The result looks similar to the following results:

```
result
-----
<emp>John Smith</emp>
```

XMLTEXT

The XMLTEXT function returns an XML value with a single text node that contains the value of the argument.

```
►►—XMLTEXT—(—string-expression—)—————►►
```

The schema is SYSIBM.

string-expression

An expression that returns a value of a built-in character or graphic string that is not bit data. Any character in the resulting string must be a valid XML 1.0 character when it is converted to UTF-8.

If *string-expression* is an empty string, an empty text node is returned.

The result of the function is an XML value.

The result can be null; if the argument is null, the result is the null value.

Example 1: The following example returns an XML value with a single text node that contains the specified value:

```
SELECT XMLTEXT('The stock symbol for Johnson&Johnson is JNJ.') AS "Result"
FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

Result

```
-----
The stock symbol for Johnson&Johnson is JNJ.
```

Example 2: The XMLTEXT function enables the XMLAGG function to construct mixed content, as in the following example:

```
SELECT XMLELEMENT(NAME "para",
  XMLAGG(XMLCONCAT( XMLTEXT( plaintext),
    XMLELEMENT( NAME "emphasis",
      emphtext ))
  ORDER BY seqno ), '.' ) as "result"
FROM T;
```

Suppose that the content of the table T is as the following example:

| seqno | plaintext | emphertext |
|-------|---|---------------|
| 1 | This query shows how to construct | mixed content |
| 2 | using XMLAGG and XMLTEXT. Without | XMLTEXT |
| 3 | XMLAGG cannot group text nodes with other nodes, therefore, cannot generate | mixed content |

The result looks like the following result:

result

```
-----
<para>This query shows how to construct <emphasis>mixed content</emphasis>
using XMLAGG and XMLTEXT. Without <emphasis>XMLTEXT</emphasis>, XMLAGG
cannot group text nodes with other nodes, therefore, cannot generate
<emphasis>mixed content</emphasis>.</para>
```

XMLXSROBJECTID

The XMLXSROBJECTID function returns the XSR object identifier of the XML schema that is used to validate the XML document specified in the argument.

```
►► XMLXSROBJECTID(xml-value-expression) ◄◄
```

The schema is SYSIBM.

xml-value-expression

An expression that results in a value with a data type of XML. The resulting XML value must be an XML sequence with a single item that is an XML document or the null value.

The XSR object identifier is returned as a BIGINT value and provides the key to a single row in the SYSIBM.XSROBJECTS table.

The result can be null; if the argument is null, the result is the null value.

If *xml-value-expression* does not specify a validated XML document, the function returns 0.

Note: The XML schema that corresponds to an XSR object ID returned by the function might no longer exist, because an XML schema can be dropped without affecting XML values that were validated using that XML schema. Therefore, queries that use the XSR object ID to fetch further XML schema information from the SYSIBM.XSROBJECTS table might return an empty result set.

Example 1: Use the XMLXSROBJECTID function in conjunction with the DSN_XMLVALIDATE function to find all XML documents that are not validated in a table and validate them:

```
UPDATE orders
  SET content = dsn_xmlvalidate(content, 'SYSXSR.P01')
  WHERE XMLXSROBJECTID(content) = 0;
```

Example 2: Use the XMLXSROBJECTID function to find the names and target namespaces of the XML schemas that are used to validate the XML documents in a table:

```
SELECT DISTINCT s.XSROBJECTNAME, s.targetNamespace
  FROM orders o, XSROBJECTS s
  WHERE XMLXSROBJECTID(o.content) = s.XSROBJECTID;
```

XSLTRANSFORM

The XSLTRANSFORM function transforms an XML document into a different data format. The output can be any form possible for the XSLT processor, including but not limited to XML, HTML, and plain text.

►—XSLTRANSFORM(*xml-document*,*xsl-stylesheet*,*xsl-parameters*)—◄

The schema is SYSFUN.

xml-document

An expression that returns a well-formed XML document with a data type of CHAR, VARCHAR, or CLOB(2 MB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The *xml-document* is transformed with the XSL style sheet that is specified in *xsl-stylesheet*. The XML document must at minimum be single-rooted and well-formed.

xsl-stylesheet

An expression that returns a well-formed XML document with a data type of CHAR, VARCHAR, or CLOB(256 KB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The document is an XSL style sheet that conforms to the W3C XSLT Version 1.0 Recommendation. This style sheet is applied to transform the value that is specified in *xml-document*.

xsl-parameters

An expression that returns a well-formed XML document or empty string with a data type of CHAR, VARCHAR, or CLOB(64 KB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The *xsl-parameters* provides parameter values to the XSL style sheet specified in *xsl-stylesheet*. The value of the parameter can be specified as an attribute, or as a text node. If both are specified, the value in the attribute is used. The *xsl-stylesheet* document must have matching param name attribute values. The syntax of the parameter document is as follows:

```
<params xmlns="http://www.ibm.com/XSLTransformParameters">
  <param name="..." value="..."/>
  <param name="...">enter value here</param>
  ...
</params>
```

Important: If *xsl-parameters* are not needed, you still must supply an empty string or the function result is null.

The result of the function is of type CLOB(2 MB).

This user-defined function requires IBM SDK for z/OS, Java Technology Edition Version 6.

This user-defined function uses the XSLT support that is provided by the W3C XSL Transformations V1.0 Recommendation.

Tip: To create your own variation of XSLTRANSFORM, start with the CREATE FUNCTION shown in sample member DSNTESR. Change the function name and size of the definition of the input parameters for your environment.

Example 1: This example illustrates how to use XSLT as a formatting engine in a C program.

```
EXEC SQL BEGIN DECLARE SECTION;
SQL TYPE IS CLOB(2M)    xmldoc;
SQL TYPE IS CLOB(256K) stylesheet;
SQL TYPE IS CLOB(64K)  xslparms;
SQL TYPE IS CLOB(2M)   result;
EXEC SQL END DECLARE SECTION;

EXEC SQL
SET :xmldoc = CLOB('<?xml version="1.0"?><hi>Hello</hi>');

EXEC SQL SET :stylesheet = CLOB( '<?xml version="1.0"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
<xsl:output indent="yes"/>
<xsl:param name="parm" select="'World'"/>
<xsl:template match="hi">
  <out>
    <xsl:value-of select="."/>
    <xsl:text>, </xsl:text>
    <xsl:value-of select="$parm"/>
    <xsl:text>!!!</xsl:text>
  </out>
</xsl:template>
</xsl:stylesheet>');

EXEC SQL SET :xslparms = CLOB(
'<params xmlns="http://www.ibm.com/XSLTransformParameters">
  <param name="parm">Silicon Valley</param>
</params>');

EXEC SQL
  SELECT SYSFUN.XSLTRANSFORM(:xmldoc, :stylesheet :xslparms)
  INTO :result FROM SYSIBM.SYSDUMMY1;
```

The XML document is transformed by the XSL style sheet. The result of the transformation is:

```
<?xml version="1.0" encoding="UTF-8"?>
<out>Hello, Silicon Valley!!!</out>
```

YEAR

The YEAR function returns the year part of a value that is a character or graphic string. The value must be a valid string representation of a date or timestamp.

►►—YEAR(*expression*)—►►

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 101.
- If *expression* is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see “Datetime operands” on page 145.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument specified:

If the argument is a date, a timestamp, or a string representation of either, the result is the year part of the value, which is an integer between 1 and 9999.

If the argument is a date duration or a timestamp duration, the result is the year part of the value, which is an integer between -9999 and 9999. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: From the table DSN8A10.EMP, select all rows for employees who were born in 1941.

```
SELECT *
  FROM DSN8A10.EMP
 WHERE YEAR(BIRTHDATE) = 1941;
```

Example 2: The following invocations of the YEAR function returns the same result:

```
SELECT YEAR('1993-08-10-20.00.00'),
       YEAR('1993-08-10-20.00.00-08:00'),
       YEAR('1993-08-10-20.00.00+09:00')
  FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the YEAR function in this SELECT statement, the result is 1993.

| When the input argument contains a time zone, the result is determined from the
| UTC representation of the input value. The string representations of a timestamp
| with a time zone in the SELECT statement all have the same UTC representation:
| '1993-08-10-20.00.00'.

Table functions

A table function can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table created through a CREATE TABLE statement. Table functions can be qualified with a schema name.

ADMIN_TASK_LIST

The ADMIN_TASK_LIST function returns a table with one row for each of the tasks that are defined in the administrative task scheduler task list.

Authorization

The user who calls this function must have MONITOR1 privilege.

The schema is DSNADM.

The result of the function is a table with the format shown in the following table. All the columns are nullable except TASK_NAME.

Table 84. Format of the resulting table for ADMIN_TASK_LIST

| Column name | Data type | Contains |
|---------------------|-----------|--|
| BEGIN_ TIMESTAMP | TIMESTAMP | Contains the timestamp of when the task can first run. When the task begins to run depends on what values this and other columns contain: <ul style="list-style-type: none">• If BEGIN_TIMESTAMP contains a non-null value:<ul style="list-style-type: none">– If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values, the task begins to run at the timestamp in BEGIN_TIMESTAMP– If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined at or after the timestamp in BEGIN_TIMESTAMP– If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes or after the timestamp in BEGIN_TIMESTAMP• If BEGIN_TIMESTAMP contains a null value:<ul style="list-style-type: none">– If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values, the task begins to run immediately– If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined– If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes |
| END_ TIMESTAMP | TIMESTAMP | Contains the timestamp of when the task is last able to run. If this column is NULL, there are no restrictions as to when the task must not run. |

Table 84. Format of the resulting table for ADMIN_TASK_LIST (continued)

| Column name | Data type | Contains |
|-----------------------|--------------|---|
| MAX_ INVOCATIONS | INTEGER | <p>Contains the maximum number of times the task can run. The maximum number applies to all types of schedules: triggered by events, scheduled by time interval, or by point in time. If this column is null, the task has no limit on the number of times it can be run.</p> <p>If both END_TIMESTAMP and MAX_INVOCATIONS contain values, the value in END_TIMESTAMP takes precedence over the value for MAX_INVOCATIONS. That is, if the value in END_TIMESTAMP is reached, even though the number of times the task has run has not reached the value for MAX_INVOCATIONS, the task will not run again</p> |
| INTERVAL | INTEGER | <p>Contains an integer that indicates the duration between the start of one instance of a task and the start of the next instance of the same task. If the value of this column is NULL, the task is not scheduled to run at a regular interval.</p> |
| POINT_IN_ TIME | VARCHAR(400) | <p>Contains one or more points in time (in UNIX cron format) for which the task is scheduled to run. If the value of this column is NULL, the task is not scheduled to run at a specific point in time.</p> <p>The format contains the following pieces of information separated by blanks: given hour, given minute, given day of the week, given day of the month, given month of the year.</p> |
| TRIGGER_ TASK_NAME | VARCHAR(128) | <p>Contains the task name of the task that, when its execution is complete, will trigger the running of the task that is described in the row.</p> <p>Task name DB2STOP is reserved for DB2 stop events and task name DB2START is reserved for DB2 start events. Those events are handled by the administrative task scheduler that is associated with the DB2 subsystem that is starting or stopping.</p> <p>If the value of this column is NULL, the task that is described in this row will not be triggered to run by another task.</p> |

Table 84. Format of the resulting table for ADMIN_TASK_LIST (continued)

| Column name | Data type | Contains |
|-------------------|-----------|---|
| TRIGGER_TASK_COND | CHAR(2) | <p>Contains the type of comparison that is to be made to the return code after the running of task that is indicated in TRIGGER_TASK_NAME. The following values are possible:</p> <p>GT Greater than</p> <p>GE Greater than or equal to</p> <p>EQ Equal to</p> <p>LT Less than</p> <p>LE Less than or equal to</p> <p>NE Not equal to</p> <p>If this column contains NULL, the task is triggered to run without consideration of the return code of the task that is indicated in TRIGGER_TASK_NAME.</p> |
| TRIGGER_TASK_CODE | INTEGER | <p>Contains the return code from running the task indicated in TRIGGER_TASK_NAME.</p> <p>If the running of this task is triggered by a stored procedure, TRIGGER_TASK_CODE contains the SQLCODE that must be returned by the stored procedure in order for this task to run.</p> <p>If the running of this task is triggered by a JCL job, TRIGGER_TASK_CODE contains the MAXRC that must be returned by the job in order for this task to run.</p> <p>“ADMIN_TASK_STATUS” on page 711 returns the SQLCODE or MAXRC value in the SQLCODE or MAXRC column.</p> <p>If TRIGGER_TASK_COND is NULL, this column will also be NULL.</p> |

Table 84. Format of the resulting table for ADMIN_TASK_LIST (continued)

| Column name | Data type | Contains |
|------------------|---------------|--|
| DB2_SSID | VARCHAR(4) | <p>Contains the DB2 subsystem ID of the DB2 subsystem that is associated with the administrative task scheduler that should run this task.</p> <p>The value in this column is used in a data sharing environment where, for example different DB2 members have different configurations and running the task relies on a certain environment. A value in DB2_SSID will prevent an administrative scheduler of other members to run this task, so that the task can only be run as long as the administrative task scheduler of the subsystem indicated in DB2_SSID is running.</p> <p>For a task that is being triggered by a DB2 start or DB2 stop event as indicated in the TRIGGER_TASK_NAME column, a value in DB2_SSID will allow the task to be run only when the indicated subsystem is starting or stopping. If no value is indicated in DB2_SSID, each subsystem that starts or stops will trigger a the task to be run locally, provided that the triggered task is run serially.</p> <p>If this column is NULL, any administrative scheduler can run this task.</p> |
| PROCEDURE_SCHEMA | VARCHAR(128) | Contains the schema of the DB2 stored procedure that this task will run. If the value of this column is null, DB2 uses a default schema. |
| PROCEDURE_NAME | VARCHAR(128) | Contains the name of the DB2 stored procedure that this task will run. If the value of this column is NULL, no stored procedure will be called when this task is run. |
| PROCEDURE_INPUT | VARCHAR(4096) | Contains a statement that returns one row of data. The returned value will be used as the input parameter of the stored procedure that this task will run. If this column contains the null value, no parameters are passed to the stored procedure when this task is run. |
| JCL_LIBRARY | VARCHAR(44) | Contains the name of the data set that contains the JCL job that is run when this task is run. If the value of this column is the null value, no JCL job will be run when this task is run. |
| JCL_MEMBER | VARCHAR(8) | Contains the name of the library member that contains the JCL job that is run when this task is run. If the value of this column is the null value, the data set that is specified in JCL_LIBRARY is sequential and contains the JCL job that is run when this task is run. |

Table 84. Format of the resulting table for ADMIN_TASK_LIST (continued)

| Column name | Data type | Contains |
|---------------|--------------|---|
| JOB_WAIT | VARCHAR(8) | Contains one of the following values, which indicates whether the JCL job can be run synchronously. If the value in the column is not null, this column contains one of the following values: NO Runs asynchronously YES Runs synchronously PURGE Runs synchronously and then the job status in z/OS is purged |
| TASK_NAME | VARCHAR(128) | Contains the unique name that is assigned to this task. |
| DESCRIPTION | VARCHAR(128) | Contains a description of the task if one exists. |
| USERID | VARCHAR(128) | Contains the authorization ID of the user under which the task will be invoked. If this column is NULL, the task is invoked by the default authorization ID that is associated with the administrative task scheduler. |
| CREATOR | VARCHAR(128) | Contains the authorization ID that added the task to the administrative task scheduler task list. |
| LAST_MODIFIED | TIMESTAMP | Timestamp of when the task was added or last modified. |

Example 1: Retrieve information about all of the tasks that are defined in the administrative task scheduler task list:

```
SELECT *
  FROM TABLE (DSNADM.ADMIN_TASK_LIST()) AS T;
```

ADMIN_TASK_OUTPUT

For an execution of a stored procedure, the ADMIN_TASK_OUTPUT function returns the output parameter values and result sets, if available. If the task that was executed is not a stored procedure or the requested execution status is not available, the function returns an empty table.

Authorization

The user who calls this function must have MONITOR1 privilege.

```
▶▶ ADMIN_TASK_OUTPUT(-task-name-,-num-invocations-)▶▶
```

The schema is DSNADM.

Important: The ADMIN_TASK_OUTPUT function returns as many output parameter values and result sets as possible. However, this information is not always available. The administrative task scheduler cannot store output that exceeds 32,180 bytes in length. Therefore, some output parameters and result set values might be null if the values are too long to be stored by the administrative task scheduler. Also, if the result sets are too large to be stored, only some of the most recent rows of each result set might be available (for example, the first rows missing).

task-name

Specifies the unique name of the task whose execution output you want returned. This is an input parameter of type VARCHAR(128).

num-invocations

Specifies the execution number of the task whose output you want returned. This value must be a valid value in the NUM_INVOCATIONS column of the returned table of DSNADM.ADMIN_TASK_STATUS(NULL) for the specified task. This is an input parameter of type INTEGER.

The result of the function is a table with the format shown in the following table. This function might return an empty table for the output of a stored procedure for the following reasons:

- The stored procedure does not have output parameters or result sets.
- The output of the stored procedure was not stored at execution time, because the SYSIBM.ADMIN_TASKS_HIST table was not available.
- The *num-invocations* parameter is not valid.
- The output for the task that is specified by the *num-invocations* parameter is no longer stored, because the task is older than the value that is specified for the MAXHIST parameter of the administrative task scheduler. (The MAXHIST parameter specifies the maximum number of execution statuses to keep for each task.)

Table 85. Format of the resulting table for ADMIN_TASK_OUTPUT

| Column name | Data type | Contains |
|-------------|----------------|---|
| RESULT_SET | SMALLINT | Contains the stored procedure result set number with a value beginning at 1, or NULL if this value is for an output parameter of the stored procedure. |
| ROW | SMALLINT | Contains the result set row number with a value beginning at 1, or NULL if this value is for an output parameter of the stored procedure. |
| COLUMN | SMALLINT | Contains the result set column number, or the index of an output parameter of the stored procedure parameters, with a value beginning at 1. Only the values of output parameters are returned, and the results include the index in all parameters of the stored procedure. |
| TYPE | CHAR(8) | <p>Contains the type of the returned string. Possible types are:</p> <ul style="list-style-type: none"> • DATE • TIME • TIMESTMP • CHAR • VARCHAR • FLOAT • BIGINT • INTEGER • SMALLINT • OTHER <p>The value OTHER includes all other data types that are not supported in this stored procedure.</p> |
| VALUE | VARCHAR(32180) | Contains the string representation of the output parameter value or the result set column value. This column is null if the TYPE column contains OTHER. |

Related tasks:

 [Displaying the results of a stored procedure task \(DB2 Administration Guide\)](#)

ADMIN_TASK_STATUS

The ADMIN_TASK_STATUS function returns a table with one row for each task that is defined in the administrative task scheduler task list. Each row indicates the status of the task for the last time it was run.

Optionally, if you specify the *max-history* parameter, the function returns a row of data for each execution of a task (up to the *max-history* value). For tasks that have not been executed, this function returns a row of data with a NULL status.

Authorization

The user who calls this function must have MONITOR1 privilege.

```
ADMIN_TASK_STATUS(  
    [max-history]  
)
```

The schema is DSNADM.

max-history

Specifies the maximum number of execution statuses per task to be returned. The most recent execution statuses are returned.

If the parameter is set to NULL, all available task execution statuses are returned. If the parameter is set to 1, only the status for the last time the task was run is returned, which is the same result as not specifying this option.

This is an input parameter of type INTEGER.

The result of the function is a table with the format shown in the following table.

Table 86. Format of the resulting table for ADMIN_TASK_STATUS

| Column name | Data type | Contains |
|-------------|--------------|---|
| TASK_NAME | VARCHAR(128) | Contains the name of the task that has run, is running, or has been bypassed. |

Table 86. Format of the resulting table for ADMIN_TASK_STATUS (continued)

| Column name | Data type | Contains |
|------------------|-------------|---|
| STATUS | VARCHAR(10) | <p>Contains one of the following values that indicates task status:</p> <p>RUNNING The task is currently running</p> <p>COMPLETED The task has finished running. For asynchronous tasks (JCL jobs), this column contains COMPLETED whenever the job is submitted to be run. Otherwise, this column contains COMPLETED only after the task has finished running.</p> <p>NOTRUN The task was not run at the scheduled invocation time. The MSG column contains the error or warning message that indicates why the task was not run.</p> <p>UNKNOWN The scheduler shut down while the task was running. The scheduler is started again but cannot know the execution status of this interrupted task.</p> |
| NUM_ INVOCATIONS | INTEGER | Contains the number of times the administrative task scheduler attempted to run the task, including the current time if the task is currently running. The values in this column does not indicate if the task was successfully run. |
| START_ TIMESTAMP | TIMESTAMP | Contains the time when the task started running if the STATUS column contains COMPLETED, RUNNING, or UNKNOWN. Otherwise, this column contains the time that the task should have started to run but could not. |
| END_ TIMESTAMP | TIMESTAMP | Contains the time when the task finished running. |
| JOB_ID | CHAR(8) | Contains the job ID that is assigned to the JCL job submitted by the administrative task scheduler. This column contains NULL if the task is a stored procedure or if the STATUS column does not contain COMPLETED. |
| MAXRC | INTEGER | <p>Contains the highest return code from submitting a JCL job. If the task is synchronous, the value in this column is changed to the return code that is returned when the job finishes running.</p> <p>This column is set to NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if a synchronous task is finished and has run with JES3 in a z/OS 1.7 or earlier system.</p> |

Table 86. Format of the resulting table for ADMIN_TASK_STATUS (continued)

| Column name | Data type | Contains |
|---------------------|--------------|---|
| COMPLETION_ TYPE | INTEGER | <p>Contains one of the following values that indicates the completion type of the JCL job submitted by the administrative task scheduler:</p> <p>0 No completion information</p> <p>1 Job ended normally</p> <p>2 Job ended by completion code</p> <p>3 Job had a JCL error</p> <p>4 Job was canceled</p> <p>5 Job abended</p> <p>6 Converter abended while processing the job</p> <p>7 Job failed security checks</p> <p>8 Job failed in end-of-memory</p> <p>This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.</p> |
| SYSTEM_ ABENDCD | INTEGER | <p>Contains the system abend code returned by a failed JCL job that was submitted by the administrative task scheduler.</p> <p>This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.</p> |
| USER_ABENDCD | INTEGER | <p>Contains the user abend code returned by a failed JCL job that was submitted by the administrative task scheduler.</p> <p>This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.</p> |
| MSG | VARCHAR(128) | Contains the error or warning message from the last time the task was run. |
| SQLCODE | INTEGER | Contains the SQLCODE set by DB2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED. |
| SQLSTATE | CHAR(5) | Contains the SQLSTATE set by DB2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED. |

Table 86. Format of the resulting table for ADMIN_TASK_STATUS (continued)

| Column name | Data type | Contains |
|-------------|--------------|--|
| SQLERRP | VARCHAR(8) | Contains the SQLERRP set by DB2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED. |
| SQLERRMC | VARCHAR(70) | Contains the SQLERRMC set by DB2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED. |
| DB2_SSID | VARCHAR(4) | Contains the DB2 subsystem ID that is associated with the administrative task scheduler that ran the task or should have run the task. |
| USERID | VARCHAR(128) | Contain the user ID that the task ran under. |

Example 1: Retrieve status information about all of the tasks that have run in the administrative task scheduler task list:

```
SELECT *
  FROM TABLE (DSNADM.ADMIN_TASK_STATUS()) AS T;
```

MQREADALL

The MQREADALL function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

The schema is DB2MQ.

The MQREADALL function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

Table 87. Format of the resulting table for MQREADALL

| Column name | Data type | Contains |
|-------------|---------------|---|
| MSG | VARCHAR(4000) | The contents of the MQSeries message |
| CORRELID | VARCHAR(24) | The correlation ID that is used to relate messages |
| TOPIC | VARCHAR(40) | The topic that the message was published with, if available |
| QNAME | VARCHAR(48) | The name of the queue from which the message was received |
| MSGID | CHAR(24) | The unique, MQSeries-assigned identifier for the message |
| MSGFORMAT | VARCHAR(8) | The format of the message, as defined by MQSeries |

Example 1: Read all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM SYSIBM.SYSDUMMY1 (MQREADALL()) AS T;
```

The messages and all the metadata are returned as a table.

Example 2: Read all the messages from the beginning of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
  FROM SYSIBM.SYSDUMMY1 (MQREADALL ('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned.

Example 3: Read all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). Only messages with a CORRELID of '1234' are returned.

```
SELECT *
  FROM SYSIBM.SYSDUMMY1 (MQREADALL(10)) AS T
 WHERE T.CORRELID = '1234';
```

All columns are returned.

Example 4: Retrieve the first 10 messages from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM SYSIBM.SYSDUMMY1 (MQREADALL(10)) AS T;
```

The first 10 messages and all the columns are returned as a table.

MQREADALLCLOB

The MQREADALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

The schema is DB2MQ.

The MQREADALLCLOB function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type

whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns in the table are nullable.

Table 88. Format of the resulting table for MQREADALLCLOB

| Column name | Data type | Contains |
|-------------|-------------|---|
| MSG | CLOB(1M) | The contents of the MQSeries message |
| CORRELID | VARCHAR(24) | The correlation ID that is used to relate messages |
| TOPIC | VARCHAR(40) | The topic that the message was published with, if available |
| QNAME | VARCHAR(48) | The name of the queue from which the message was received |
| MSGID | CHAR(24) | The unique, MQSeries-assigned identifier for the message |
| MSGFORMAT | VARCHAR(8) | The format of the message, as defined by MQSeries |

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Read all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB()) AS T;
```

The messages and all the metadata are returned as a table.

Example 2: Read all the messages from the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
  FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned as a table.

Example 3: Read all the messages from the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY), with a correlation identifier of '1234'.

```
SELECT *
  FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB('MYSERVICE')) AS T
 WHERE T.CORRELID = '1234';
```

All columns are returned.

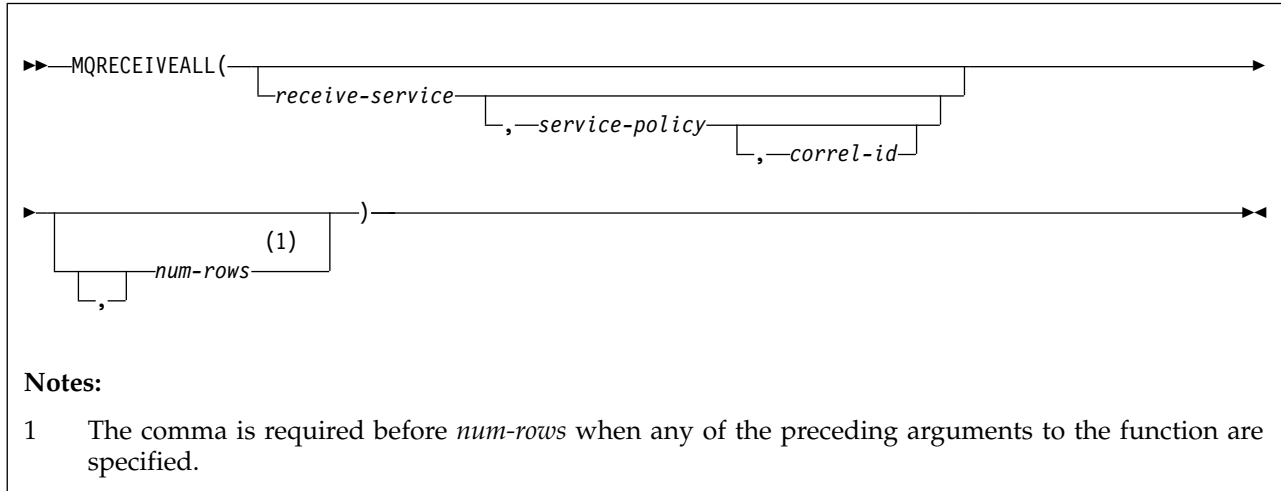

Example 4: Read the first 10 messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB('10')) AS T;
```

All columns are returned.

MQRECEIVEALL

The MQRECEIVEALL function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

The schema is DB2MQ.

The MQRECEIVEALL function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

Table 89. Format of resulting table for MQRECEIVEALL

| Column name | Data type | Contains |
|-------------|---------------|---|
| MSG | VARCHAR(4000) | The contents of the MQSeries message |
| CORRELID | VARCHAR(24) | The correlation ID that is used to relate messages |
| TOPIC | VARCHAR(40) | The topic that the message was published with, if available |
| QNAME | VARCHAR(48) | The name of the queue from which the message was received |
| MSGID | CHAR(24) | The unique, MQSeries-assigned identifier for the message |
| MSGFORMAT | VARCHAR(8) | The format of the message, as defined by MQSeries |

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *  
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL()) AS T;
```

The messages and all the metadata are returned as a table and the messages are removed from the queue.

Example 2: Retrieve all the messages from the the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned. The messages are removed from the queue.

Example 3: Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY, with a correlation identifier of '1234'.

```
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL('MYSERVICE','MYPOLICY','1234')) AS T;
```

Only the MSG and CORRELID columns are returned. The messages are removed from the queue.

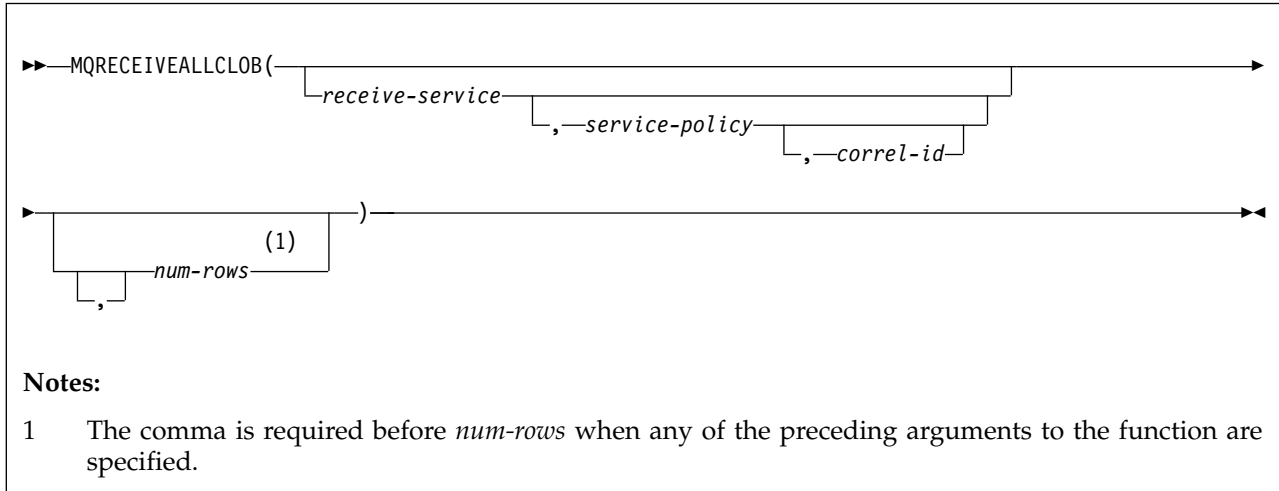

Example 4: Retrieve the first 10 messages from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL(10)) AS T;
```

All columns are returned. The messages are removed from the queue.

MQRECEIVEALLCLOB

The MQRECEIVEALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

The schema is DB2MQ.

The MQRECEIVEALLCLOB function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

Table 90. Format of resulting table for MQRECEIVEALLCLOB

| Column name | Data type | Contains |
|-------------|-------------|---|
| MSG | CLOB(1M) | The contents of the MQSeries message |
| CORRELID | VARCHAR(24) | The correlation ID that is used to relate messages |
| TOPIC | VARCHAR(40) | The topic that the message was published with, if available |
| QNAME | VARCHAR(48) | The name of the queue from which the message was received |
| MSGID | CHAR(24) | The unique, MQSeries-assigned identifier for the message |
| MSGFORMAT | VARCHAR(8) | The format of the message, as defined by MQSeries |

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

Example 1: Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *  
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB()) AS T;
```

The messages and all the metadata are returned as a table, and the messages are removed.

Example 2: Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy (DB2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned as a table, and the messages removed from the queue.

Example 3: Retrieve all the messages from the queue specified by the service MYSERVICE, using the policy "MYPOLICY", with a correlation identifier of '1234'.

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB('MYSERVICE','MYPOLICY','1234')) AS T;
```

All columns are returned, and the messages removed from the queue.

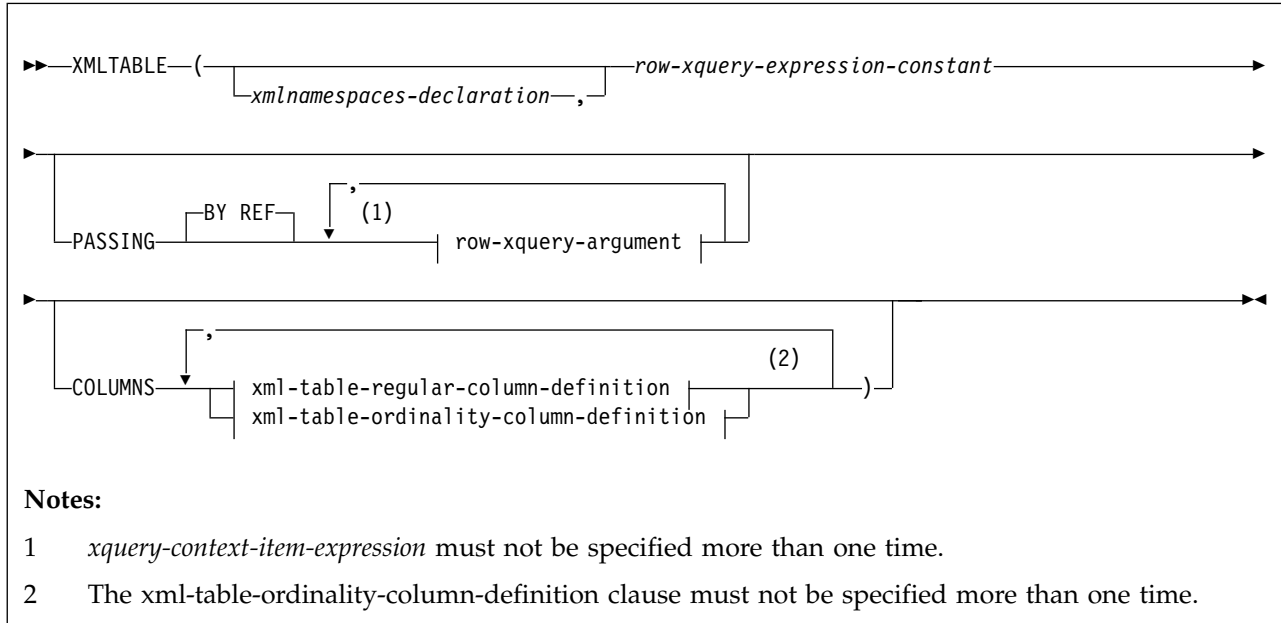

Example 4: Retrieve the first 10 messages from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB(10)) AS T;
```

All columns are returned, and the messages removed from the queue.

XMLTABLE

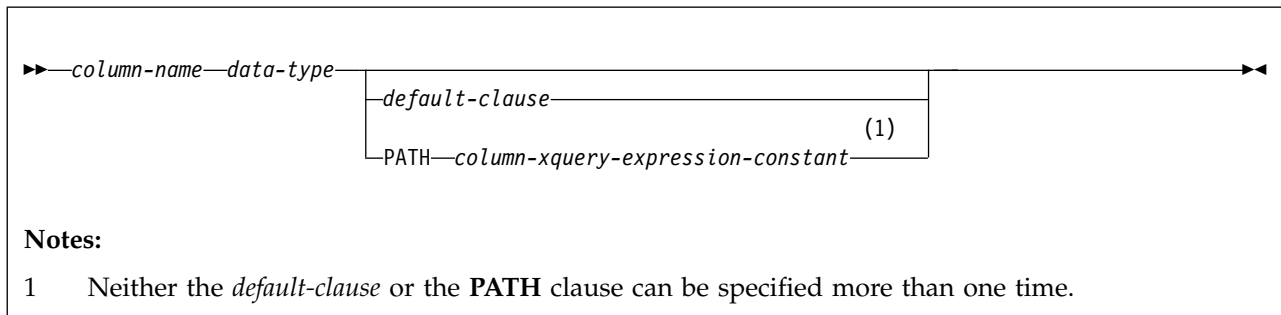

The XMLTABLE function returns a result table from the evaluation of XQuery expressions, possibly by using specified input arguments as XQuery variables. Each item in the result sequence of the row XQuery expression represents one row of the result table.

row-xquery-argument

xml-table-regular-column-definition

xml-table-ordinality-column-definition

► *column-name* FOR ORDINALITY ◄

The schema is SYSIBM.

The function name cannot be specified as a qualified name.

xmlnamespaces-declaration

Specifies one or more XML namespace declarations, using the XMLNAMESPACES function, that become part of the static context of the *row-xquery-expression-constant* and the *column-xquery-expression-constant*. The set of statically known namespaces for XQuery expressions which are arguments of XMLTABLE is the combination of the pre-established set of statically known namespaces and the namespace declarations specified in this clause. The XQuery prolog within an XQuery expression can override these namespaces.

If *xmlnamespaces-declaration* is not specified, only the pre-established set of statically known namespaces apply to the XQuery expressions.

row-xquery-expression-constant

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. *row-xquery-expression-constant* cannot be an XQuery updating expression. This expression determines the number of rows in the result table. The expression is evaluated using the optional set of input XML values that is specified in *row-xquery-argument*, and returns an output XQuery sequence where one row is generated for each item in the sequence. If the sequence is empty, the result of XMLTABLE is an empty table. *row-xquery-expression-constant* must not contain an empty string or a string of all blanks.

PASSING

Specifies input values and the manner in which these values are passed to *row-xquery-expression-constant*.

BY REF

Specifies that any XML input arguments are, by default, passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any exist, directly from the specified input expressions and preserves all properties, including the original node identities and document order.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

row-xquery-argument

Specifies an argument that is to be passed to the XQuery expression specified by *row-xquery-expression-constant*. *row-xquery-argument* is an SQL expression that returns a value that is not a ROWID, LOB, DATE, TIME, TIMESTAMP, BINARY, VARBINARY, REAL, DECFLOAT, or character string with FOR BIT DATA attribute.

How *row-xquery-argument* is used in the XQuery expression depends on whether the argument is specified as an *xquery-context-item-expression* or an *xquery-variable-expression*.

If the data type of *row-xquery-argument* is not XML, the result of the expression for the argument is implicitly cast to XML. A null value is converted to an XML empty sequence if the argument is *xquery-variable-expression*.

row-xquery-argument must not contain NEXT VALUE or PREVIOUS VALUE expressions or OLAP specifications.

xquery-context-item-expression

An expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-context-item-expression* must not be a character string that is bit data.

xquery-context-item-expression specifies the initial context item for the *row-xquery-expression*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-variable-expression

Specifies an SQL expression whose value is available to the XQuery expression specified by *row-xquery-expression-constant* during execution. The expression must return a value that is XML, integer, decimal, or a character or graphic string that is not a LOB.

xquery-variable-expression specifies an argument that will be passed to *row-xquery-expression-constant* as an XQuery variable. If *xquery-variable-expression* is a null value, the XQuery variable is set to an XML empty sequence. The scope of the XQuery variables that are created from the PASSING clause is the XQuery expression specified by *row-xquery-expression-constant*.

AS *identifier*

Specifies that the value generated by *xquery-variable-expression* will be passed to *row-xquery-expression-constant* as an XQuery variable. The variable name will be *identifier*. The leading dollar sign (\$) that precedes variable names in the XQuery language is not included in *identifier*. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier.

COLUMNS

Specifies the output columns of the result table including the column name, data type, and how the column value is computed for each row. If this clause is not specified, a single unnamed column of data type XML is returned, with the value based on the sequence item from evaluating the XQuery expression in the *row-xquery-expression-constant* (equivalent to specifying PATH '.'). To reference the result column, a *column-name* must be specified in the *correlation-clause* following the function.

xml-table-regular-column-definition

Specifies one output column of the result table including the column name, data type, and an XQuery expression to extract the value from the sequence item for the row.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

data-type

Specifies the data type of the column. See CREATE TABLE for the

syntax and a description of types available. A *data-type* can be used in XMLTABLE if there is a supported XMLCAST from the XML data type to the specified *data-type*.

default-clause

Specifies a default value for the column. See CREATE TABLE for the syntax and a description of the *default-clause*. For XMLTABLE result columns, the default is applied when the processing of the XQuery expression contained in *column-xquery-expression-constant* returns an empty sequence. This default value will not be inherited by declared global temporary tables even when the INCLUDING COLUMN DEFAULTS clause is specified in the definition of the declared global temporary table.

PATH *column-xquery-expression-constant*

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. The *column-xquery-expression-constant* specifies an XQuery expression that determines the column value with respect to an item that is the result of evaluating the XQuery expression in *row-xquery-expression-constant*. Given an item from the result of processing the *row-xquery-expression-constant* as the externally provided context item, the *column-xquery-expression-constant* is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows.

- If the output sequence contains zero items, the *default-clause* provides the value of the column.
- If an empty sequence is returned and no *default-clause* was specified, a null value is assigned to the column.
- If a non-empty sequence is returned, the value is cast to the *data-type* specified for the column using the XMLCAST expression. An error could be returned from processing this XMLCAST.

The value for *column-xquery-expression-constant* must not be an empty string or a string of all blanks. If this clause is not specified, the default XQuery expression is simply the *column-name*.

xml-table-ordinality-column-definition

Specifies the ordinality column of the result table.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

FOR ORDINALITY

Specifies that *column-name* is the ordinality column of the result table. The data type of this column is BIGINT. The value of this column in the result table is the sequential number of the item for the row in the resulting sequence from evaluating the XQuery expression in *row-xquery-expression-constant*.

The result of the function is a table. The encoding scheme of the table is Unicode. If the evaluation of any of the XQuery expressions results in an error, the XMLTABLE function returns the XQuery error.

Example: List as a table result the purchase order items for orders with a status of 'NEW':

```

SELECT U."PO ID", U."Part #", U."Product Name",
       U."Quantity", U."Price", U."Order Date"
FROM PURCHASEORDER P,
     XMLTABLE(XMLNAMESPACES('http://podemo.org' AS "pod"),
              '$po/PurchaseOrder/itemlist/item' PASSING P.PORDER as "po"
              COLUMNS "PO ID"          INTEGER      PATH '../@POid',
                       "Part #"         CHAR(6)      PATH 'product/@pid',
                       "Product Name"   CHAR(50)     PATH 'product/pod:name',
                       "Quantity"       INTEGER      PATH 'quantity',
                       "Price"          DECIMAL(9,2)  PATH 'product/pod:price',
                       "Order Date"     TIMESTAMP    PATH '../dateTime'
              ) AS U
WHERE P.STATUS = 'NEW'

```

Row functions

A row function can be used only in contexts that are specifically described for the function.

UNPACK

The UNPACK function returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function.

The schema is SYSIBM.

expression

An expression that returns the string value to be unpacked. The *expression* must be a binary string that is not a BLOB and that is not null. The format of the binary string must match the one that is produced by the PACK function.

The UNPACK function can only be specified in the SELECT list.

The result of the function is a row of fields corresponding to the data elements that were encoded in the input packed string. The result is not null.

Example 1: Assume that a user-defined function named myUDF returns a VARBINARY result. The body of the function includes the following invocation of the PACK function to pack some data into a binary string:

```
SET :udf_result = PACK(CCSID 1208, 'Alina', DATE('1977-08-01'),
                      DOUBLE(0.5));
```

The following SELECT statement unpacks the result of the myUDF function and returns a row of individual column values:

```
SELECT UNPACK(myUDF(C1)).* AS(Name VARCHAR(40) CCSID UNICODE,
                             DOB DATE,
                             Score DOUBLE)
FROM T1;
```

The use of ".*" indicates that the result of the UNPACK function should be flattened into a list of result column values. When the UNPACK function is used in a select clause, an AS clause is specified to provide the names and data types for the resulting values.

Example 2: Assume that a user-defined function UDF_SCORE returns a VARBINARY result. The PACK function is invoked to return a binary string in which the column values of table T1 are encoded and packed. The UNPACK function returns the individual data values for a row with column names ID, SCORE, and CONF:

```
SELECT T1.C1, T1.C2, T1.C3, T1.C4,
       UNPACK( UDF_SCORE( PACK(CCSID 1208, T1.C1, T1.C2, T1.C3) )).*
       AS (ID INT, SCORE DOUBLE, CONF DOUBLE)
FROM T1;

SELECT UNPACK(myUDF(C1)).* AS(MSG VARCHAR(10) CCSID UNICODE,
                             DOB DATE,
                             NAME VARCHAR(20) CCSID EBCDIC)
FROM T1;
```

Chapter 5. Procedures that are supplied with DB2

A *procedure* is an application program that can be started through the SQL CALL statement. The procedure is specified by a procedure name, which may be followed by arguments that are enclosed within parentheses. This information contains syntax diagrams, semantic descriptions, rules, and examples of the use of the system supplied procedures.

Important: Do not create additional versions of DB2-supplied procedures by specifying the VERSION keyword. Only versions that are supplied with DB2 are supported. Additional versions of such routines cause the installation and configuration of DB2-supplied routines to fail.

Related concepts:

“Procedures” on page 36

ADMIN_COMMAND_DB2 stored procedure

The SYSPROC.ADMIN_COMMAND_DB2 stored procedure executes one or more DB2 commands on a connected DB2 subsystem, or on a DB2 data sharing group member. This stored procedure also returns the command output messages.

GUIP

Environment

ADMIN_COMMAND_DB2 must run in a WLM-established stored procedure address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCD
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

To execute the DB2 command, you must use a privilege set that includes the authorization to execute the DB2 command. For more information, see Privileges and authorization IDs for DB2 commands (DB2 Commands).

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶ CALL SYSPROC.ADMIN_COMMAND_DB2 ( (DB2-command, command-length, processing-type,
▶▶ DB2-member, commands-executed, IFI-return-code, IFI-reason-code, excess-bytes,
▶▶ group-IFI-reason-code, group-excess-bytes, return-code, message) )
```

Option descriptions

DB2-command

Specifies any DB2 command, such as -DISPLAY THREAD(*), or multiple DB2 commands. With multiple DB2 commands, use a null value (CHAR string of '\0') to delimit the commands. The DB2 command is executed using the authorization ID of the user who invoked the stored procedure.

If you specify *processing-type*, you must specify the command name in full, such as "-DISPLAY THREAD". You cannot abbreviate DB2 commands, such as "-DIS THD".

This is an input parameter of type VARCHAR(32704) and cannot be null.

| ***command-length***

| Specifies the length of the DB2 command or commands. When multiple DB2
| commands are specified in *DB2-command*, *command-length* is the sum of all of
| those commands, including the '\0' command delimiters.

| This is an input parameter of type INTEGER and cannot be null.

| ***processing-type***

| Identifies the action that you want ADMIN_COMMAND_DB2 to complete.
| You can request ADMIN_COMMAND_DB2 to parse the output messages of a
| command and provide the formatted result in a global temporary table, or you
| can request for a command to run synchronously.

| If you specify *processing-type*, you must specify *DB2-command* as a full
| command name, such as "-DISPLAY THREAD". You cannot abbreviate DB2
| commands, such as "-DIS THD".

| To request output message parsing, specify one of the following values:

- | **BP** Parse "-DISPLAY BUFFERPOOL" command output messages.
- | **DB** Parse "-DISPLAY DATABASE" command output messages and return
| database information.
- | **TS** Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output
| messages and return table spaces information.
- | **IX** Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output
| messages and return index spaces information.
- | **THD** Parse "-DISPLAY THREAD" command output messages.
- | **UT** Parse "-DISPLAY UTILITY" command output messages.
- | **GRP** Parse "-DISPLAY GROUP" command output messages.
- | **DDF** Parse "-DISPLAY DDF" command output messages.

| To request for a command to run synchronously, specify:

| **SYC** Issue the command synchronously.

| Only the following commands can be processed synchronously. For all
| other commands, SYC is ignored.

- | • -ALTER BUFFERPOOL
- | • -SET LOG
- | • -SET SYSPARM
- | • -STOP DATABASE

| This is an input parameter of type VARCHAR(3) and cannot be null.

| ***DB2-member***

| Specifies the name of a single data sharing group member on which an IFI
| request is to be executed

| This is an input parameter of type VARCHAR(8).

| ***commands-executed***

| Provides the number of commands that were executed

| This is an output parameter of type INTEGER.

| ***IFI-return-code***

| Provides the IFI return code

| This is an output parameter of type INTEGER.

| ***IFI-reason-code***

| Provides the IFI reason code

| This is an output parameter of type INTEGER.

| ***excess-bytes***

| Indicates the number of bytes that did not fit in the return area

| This is an output parameter of type INTEGER.

| ***group-IFI-reason-code***

| Provides the reason code for the situation in which an IFI call requests data
| from members of a data sharing group, and not all the data is returned from
| group members.

| This is an output parameter of type INTEGER.

| ***group-excess-bytes***

| Indicates the total length of data that was returned from other data sharing
| group members and did not fit in the return area

| This is an output parameter of type INTEGER.

| ***return-code***

| Provides the return code from the stored procedure. Possible values are:

| 0 The stored procedure did not encounter an SQL error during
| processing. Check the *IFI-return-code* value to determine whether the
| DB2 command issued using the instrumentation facility interface (IFI)
| was successful or not.

| 12 The stored procedure encountered an SQL error during processing. The
| *message* output parameter contains messages describing the SQL error.

| This is an output parameter of type INTEGER.

| ***message***

| Contains messages describing the SQL error encountered by the stored
| procedure. If no SQL error occurred, then no message is returned.

| The first messages in this area are generated by the stored procedure. Messages
| that are generated by DB2 might follow the first messages.

| This is an output parameter of type VARCHAR(1331).

| **Example**

| The following C language sample shows how to invoke
| ADMIN_COMMAND_DB2:

```
| #include <stdio.h>
| #include <stdlib.h>
| #include <string.h>
|
| /***** DB2 SQL Communication Area *****/
| EXEC SQL INCLUDE SQLCA;
|
| int main( int argc, char *argv[] ) /* Argument count and list */
| {
|     /***** DB2 Host Variables *****/
|     EXEC SQL BEGIN DECLARE SECTION;
|
|     /* SYSPROC.ADMIN_COMMAND_DB2 parameters */
|     char command[32705]; /* DB2 command */
|     short int ind_command; /* Indicator variable */
|     long int lencommand; /* DB2 command length */
| }
```

```

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 734:

- *commands-executed*
- *IFI-return-code*
- *IFI-reason-code*
- *excess-bytes*
- *group-IFI-reason-code*
- *group-excess-bytes*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns two result sets.

The first result set is returned in the created global temporary table SYSIBM.DB2_CMD_OUTPUT and contains the DB2 command output messages that were not parsed.

The following table shows the format of the first result set:

Table 91. Result set row for first ADMIN_COMMAND_DB2 result set

| Column name | Data type | Contents |
|-------------|-----------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| TEXT | CHAR(80) | DB2 command output message line |

The format of the second result set varies, depending on the DB2 command issued and the *processing-type* value.

- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = “BP”)
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = “THD”)
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = “UT”)
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = “DB” or “TS” or “IX”)
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = “GRP”)
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = “DDF”)

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BUFFERPOOL_STATUS when *processing-type* = “BP”:

Table 92. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "BP")

| Column name | Data type | Contents |
|-------------|------------|---|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| BPNAME | CHAR(6) | Buffer pool name |
| VPSIZE | INTEGER | Buffer pool size |
| VPSEQT | INTEGER | Sequential steal threshold for the buffer pool |
| VPPSEQT | INTEGER | Parallel sequential threshold for the buffer pool |
| VPXPSEQT | INTEGER | Assisting parallel sequential threshold for the buffer pool |
| DWQT | INTEGER | Deferred write threshold for the buffer pool |
| PCT_VDWQT | INTEGER | Vertical deferred write threshold for the buffer pool (as a percentage of virtual buffer pool size) |
| ABS_VDWQT | INTEGER | Vertical deferred write threshold for the buffer pool (as absolute number of buffers) |
| PGSTEAL | CHAR(4) | Page-stealing algorithm that DB2 uses for the buffer pool |
| ID | INTEGER | Buffer pool internal identifier |
| USE_COUNT | INTEGER | The number of open table spaces or index spaces that reference this buffer pool |
| PGFIX | CHAR(3) | Specifies whether the buffer pool should be fixed in real storage when it is used |
| AUTOSIZE | VARCHAR(3) | Specifies whether automatic buffer pool adjustment is on or off |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DB2_THREAD_STATUS when *processing-type* = "THD":

Table 93. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "THD")

| Column name | Data type | Contents |
|-------------|-----------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |

Table 93. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "THD") (continued)

| Column name | Data type | Contents |
|-------------|---------------|--|
| TYPE | INTEGER | Thread type: 0 Unknown 1 Active 2 Inactive 3 Indoubt 4 Postponed |
| NAME | CHAR(8) | Connection name used to establish the thread |
| STATUS | CHAR(11) | Status of the conversation or socket |
| ACTIVE | CHAR(1) | Indicates whether a thread is active or not. An asterisk means that the thread is active within DB2. |
| REQ | CHAR(5) | Current number of DB2 requests on the thread |
| ID | CHAR(12) | Recovery correlation ID associated with the thread |
| AUTHID | CHAR(8) | Authorization ID associated with the thread |
| PLAN | CHAR(8) | Plan name associated with the thread |
| ASID | CHAR(4) | Address space identifier |
| TOKEN | CHAR(6) | Unique thread identifier |
| COORDINATOR | CHAR(46) | Name of the two-phase commit coordinator |
| RESET | CHAR(5) | Indicates whether or not the thread needs to be reset to purge info from the indoubt thread report |
| URID | CHAR(12) | Unit of recovery identifier |
| LUWID | CHAR(35) | Logical unit of work ID of the thread |
| WORKSTATION | CHAR(18) | Client workstation name |
| USERID | CHAR(16) | Client user ID |
| APPLICATION | CHAR(32) | Client application name |
| ACCOUNTING | CHAR(247) | Client accounting information |
| LOCATION | VARCHAR(4050) | Location name of the remote system |
| DETAIL | VARCHAR(4050) | Additional thread information |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.UTILITY_JOB_STATUS when *processing-type* = "UT":

Table 94. Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "UT")

| Column name | Data type | Contents |
|-------------|---------------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| CSECT | CHAR(8) | Name of the command program CSECT that issued the message |
| USER | CHAR(8) | User ID of the person running the utility |
| MEMBER | CHAR(8) | Utility job is running on this member |
| UTILID | CHAR(16) | Utility job identifier |
| STATEMENT | INTEGER | Utility statement number |
| UTILITY | CHAR(20) | Utility name |
| PHASE | CHAR(20) | Utility restart from the beginning of this phase |
| COUNT | INTEGER | Number of pages or records processed in a utility phase |
| STATUS | CHAR(18) | Utility status |
| DETAIL | VARCHAR(4050) | Additional utility information |
| NUM_OBJ | INTEGER | Total number of objects in the list of objects the utility is processing |
| LAST_OBJ | INTEGER | Last object that started |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DB_STATUS when *processing-type* = "DB" or "TS" or "IX":

Table 95. Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "DB" or "TS" or "IX")

| Column name | Data type | Contents |
|-------------|-----------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| DBNAME | CHAR(8) | Name of the database |
| SPACENAM | CHAR(8) | Name of the table space or index |
| TYPE | CHAR(2) | Status type: DB Database TS Table space IX Index |
| PART | SMALLINT | Individual partition or range of partition |

Table 95. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DB" or "TS" or "IX") (continued)

| Column name | Data type | Contents |
|-------------|-----------|--|
| STATUS | CHAR(18) | Status of the database, table space or index |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DATA_SHARING_GROUP when *processing-type* = "GRP":

Table 96. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "GRP")

| Column name | Data type | Contents |
|-------------|-----------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| DB2_MEMBER | CHAR(8) | Name of the DB2 group member |
| ID | INTEGER | ID of the DB2 group member |
| SUBSYS | CHAR(4) | Subsystem name of the DB2 group member |
| CMDPREF | CHAR(8) | Command prefix for the DB2 group member |
| STATUS | CHAR(8) | Status of the DB2 group member |
| DB2_LVL | CHAR(3) | DB2 version, release and modification level |
| SYSTEM_NAME | CHAR(8) | Name of the z/OS system where the member is running, or was last running in cases when the member status is QUIESCED or FAILED |
| IRLM_SUBSYS | CHAR(4) | Name of the IRLM subsystem to which the DB2 member is connected |
| IRLMPROC | CHAR(8) | Procedure name of the connected IRLM |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DDF_CONFIG when *processing-type* = "DDF":

Table 97. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF")

| Column name | Data type | Contents |
|-------------|----------------------|--|
| ROWNUM | INTEGER NOT NULL | Sequence number of the table row, from 1 to <i>n</i> |
| STATUS | CHAR(6) NOT NULL | Operational status of DDF |
| LOCATION | CHAR(18) NOT NULL | Location name of DDF |

Table 97. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF") (continued)

| Column name | Data type | Contents |
|-----------------|----------------------|--|
| LUNAME | CHAR(17) NOT NULL | Fully qualified LUNAME of DDF |
| GENERICLU | CHAR(17) NOT NULL | Fully qualified generic LUNAME of DDF |
| IPV4ADDR | CHAR(17) NOT NULL | IPV4 address of DDF |
| IPV6ADDR | CHAR(39) | IPV6 address of DDF |
| TCPPOINT | INTEGER NOT NULL | SQL listener port used by DDF |
| RESPORT | INTEGER NOT NULL | Resync listener port used by DDF |
| SQL_DOMAIN | CHAR(45) NOT NULL | Domain name associated with the IP address in IPV4ADDR or IPV6ADDR |
| RSYNC_DOMAIN | CHAR(45) | Domain name associated with a specific member IP address |
| SECPPOINT | INTEGER | Secure SQL listener TCP/IP port number |
| IPNAME | CHAR(8) | IPNAME used by DDF |
| ALIASNAME1 | CHAR(18) | An alias name value specified in the BSDS DDF record. |
| ALIASPORT1 | INTEGER | TCP/IP port associated with ALIASNAME1 |
| ALIASSECPPOINT1 | INTEGER | Secure TCP/IP port associated with ALIASNAME1 |
| ALIASNAME2 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT2 | INTEGER | TCP/IP port associated with ALIASNAME2 |
| ALIASSECPPOINT2 | INTEGER | Secure TCP/IP port associated with ALIASNAME2 |
| ALIASNAME3 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT3 | INTEGER | TCP/IP port associated with ALIASNAME3 |
| ALIASSECPPOINT3 | INTEGER | Secure TCP/IP port associated with ALIASNAME3 |
| ALIASNAME4 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT4 | INTEGER | TCP/IP port associated with ALIASNAME4 |

Table 97. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF") (continued)

| Column name | Data type | Contents |
|-----------------|-----------|--|
| ALIASSECPORT4 | INTEGER | Secure TCP/IP port associated with ALIASNAME4 |
| ALIASNAME5 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT5 | INTEGER | TCP/IP port associated with ALIASNAME5 |
| ALIASSECPORT5 | INTEGER | Secure TCP/IP port associated with ALIASNAME5 |
| ALIASNAME6 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT6 | INTEGER | TCP/IP port associated with ALIASNAME6 |
| ALIASSECPORT6 | INTEGER | Secure TCP/IP port associated with ALIASNAME6 |
| ALIASNAME7 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT7 | INTEGER | TCP/IP port associated with ALIASNAME7 |
| ALIASSECPORT7 | INTEGER | Secure TCP/IP port associated with ALIASNAME7 |
| ALIASNAME8 | CHAR(18) | An alias name value specified in the BSDS DDF record |
| ALIASPORT8 | INTEGER | TCP/IP port associated with ALIASNAME8 |
| ALIASSECPORT8 | INTEGER | Secure TCP/IP port associated with ALIASNAME8 |
| MEMBER_IPV4ADDR | CHAR(17) | IPV4 address associated with the specific member of a data sharing group |
| MEMBER_IPV6ADDR | CHAR(39) | IPV6 address associated with the specific member of a data sharing group |

ADMIN_COMMAND_DSN stored procedure

The SYSPROC.ADMIN_COMMAND_DSN stored procedure executes a BIND, REBIND, or FREE DSN subcommand and returns the output from the DSN subcommand execution.

Environment

ADMIN_COMMAND_DSN runs in a WLM-established stored procedures address space. TCB=1 is also required.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_COMMAND_DSN stored procedure
- Ownership of the stored procedure
- SYSADM authority

To execute the DSN subcommand, you must use a privilege set that includes the authorization to execute the DSN subcommand.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_COMMAND_DSN—(—DSN-subcommand,—message—)————▶▶
```

Option descriptions

DSN-subcommand

Specifies the DSN subcommand to be executed. If the DSN subcommand passed to the stored procedure is not BIND, REBIND, or FREE, an error message is returned. The DSN subcommand is performed using the authorization ID of the user who invoked the stored procedure.

ADMIN_COMMAND_DSN does not support three-part names if a wildcard character is specified in the package name.

This parameter is case sensitive. You must specify *DSN-subcommand* in uppercase characters.

This is an input parameter of type VARCHAR(32704) and cannot be null.

message

Contains messages if an error occurs during stored procedure execution.

The stored procedure might not return a result set if *message* is not blank. Even if *message* is not blank, the stored procedure might return a result set if the error described in *message* occurred after the stored procedure executed at least

one DSN subcommand, and the stored procedure can successfully insert the DSN subcommand output message in the result set and open the result set cursor.

A blank *message* does not mean that the DSN subcommand completed successfully. The calling application must read the result set to determine if the DSN subcommand was successful or not.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_COMMAND_DSN:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_COMMAND_DSN parameters */
    char      subcmd[32705];          /* BIND, REBIND or FREE DSN */
                                          /* subcommand */
    char      errmsg[1332];          /* Error message */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int  rownum;                /* Sequence number of the */
                                          /* table row */
    char      text[256];              /* DSN subcommand output row */
    EXEC SQL END DECLARE SECTION;

    /***** Set input parameter to execute a REBIND PLAN DSN subcommand *****/
    strcpy(subcmd, "REBIND PLAN (DSNACCOB) FLAG(W)");

    /***** Call stored procedure SYSPROC.ADMIN_COMMAND_DSN *****/
    EXEC SQL CALL SYSPROC.ADMIN_COMMAND_DSN (:subcmd, :errmsg);

    /***** Retrieve result set when the SQLCODE from the call is +446, *****/
    /* which indicates that result sets were returned *****/
    if (SQLCODE == +446) /* Result sets were returned */
    {
        /* Establish a link between the result set and its locator */
        EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
            WITH PROCEDURE SYSPROC.ADMIN_COMMAND_DSN;

        /* Associate a cursor with the result set */
        EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

        /* Perform fetches using C1 to retrieve all rows from the */
        /* result set */
    }
}
```

```

EXEC SQL FETCH C1 INTO :rownum, :text;
while(SQLCODE==0)
{
EXEC SQL FETCH C1 INTO :rownum, :text;
}

EXEC SQL CLOSE C1;
}

return;
}

```

Output

This stored procedure returns an error message, *message*, if an error occurs.

The stored procedure returns one result set that contains the DSN subcommand output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DSN_SUBCMD_OUTPUT:

Table 98. Result set row for ADMIN_COMMAND_DSN result set

| Column name | Data type | Contents |
|-------------|--------------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| TEXT | VARCHAR(255) | DSN subcommand output message line |

[The DSN command and its subcommands \(DB2 Commands\)](#)

ADMIN_COMMAND_MVS stored procedure

The SYSPROC.ADMIN_COMMAND_MVS stored procedure issues the QUERY COPYPOOL, LIST COPYPOOL, DB2 START, DB2 STOP, DUMP, or DISPLAY WLM command.

Environment

The icon consists of the letters 'GUPI' in a bold, sans-serif font, enclosed within a yellow arrow-shaped box pointing to the right.

The load module for the ADMIN_COMMAND_MVS stored procedure, DSNADMCM, must reside in an APF-authorized library. The ADMIN_COMMAND_MVS stored procedure runs in a WLM-established stored procedures address space, and all of the libraries that are specified in the STEPLIB DD statement must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the stored procedure
- Ownership of the stored procedure
- SYSADM authority

ADMIN_COMMAND_MVS uses an extended MCS console to issue the requested command.

The caller of ADMIN_COMMAND_MVS must have READ access to the MVS.MCSOPER.* or MVS.MCSOPER.xxxxxxxx (where xxxxxxxx is the name of the extended console) resource profile of the RACF OPERCMDS class. By default, unless overwritten by CONSNAME which is specified in the *subparameters* input parameter of ADMIN_COMMAND_MVS, the name of the extended MCS console is DSNADMCM. If MVS.MCSOPER.xxxxxxxx exists, the ADMIN_COMMAND_MVS caller must have READ access to this profile. Otherwise, the caller must have READ access to MVS.MCSOPER.*.

In the OPERPARM segment of the extended MCS console's user profile (defined in a security product, such as RACF), specify the following console attributes:

- STORAGE= 512 or higher
- AUTH= ALL
- UD= NO
- HC= NO
- INTIDS= NO
- UNKNIDS= NO

You must also set the ROUTCODE, LEVEL, and MSCOPE console attributes. The attributes that you specify depend on the type of command:

START DB2, STOP DB2, DISPLAY WLM, LIST COPYPOOL, or QUERY COPYPOOL commands

Specify:

- ROUTCODE=NONE
- LEVEL=NB

- MSCOPE=*

DUMP command

Specify:

- ROUTCODE=ALL
- LEVEL=NB ALL
- MSCOPE=*

STOP DB2 command when DB2 is already stopping

Specify:

- ROUTCODE=ALL
- LEVEL=NB ALL
- MSCOPE=*ALL

Important: Specify ROUTCODE=ALL and MSCOPE=*ALL only when you anticipate that DB2 is already stopping when the STOP DB2 command is issued by ADMIN_COMMAND_MVS, and plan to increase the STORAGE value in these cases.

If the OPERPARM segment of the extended MCS console's user profile is not defined, default values are applied for all console attributes, except for the following attributes:

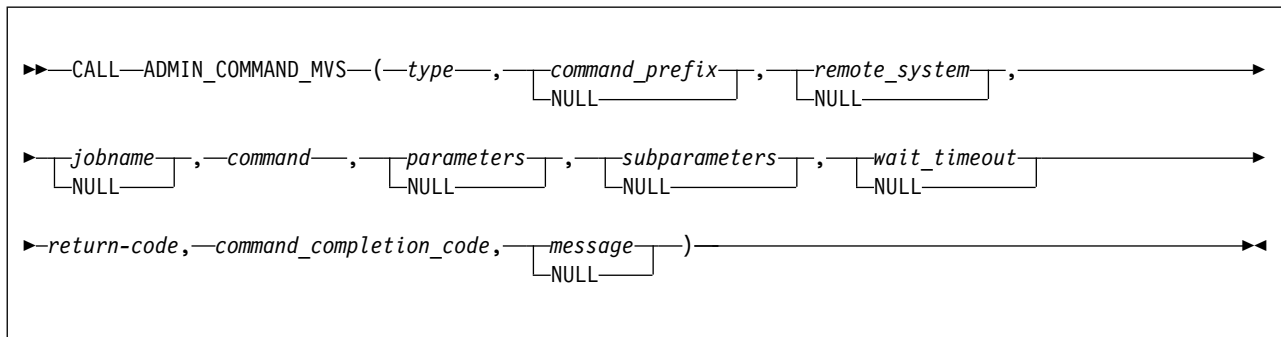

- STORAGE=512
- AUTH=ALL
- LEVEL=NB
- MSCOPE=*

For more information about controlling attributes for users of extended MCS consoles, see Defining console attributes for extended MCS consoles (z/OS MVS Planning: Operations).

The extended MCS console must be authorized to execute the requested command.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

Option descriptions

type

Specifies the type of command to be issued.

Valid values are:

- HSM
- DB2
- DUMP
- WLM

This parameter is an input parameter of type VARCHAR(24) and cannot be null.

command_prefix

Specifies the command prefix that identifies which DB2 subsystem to direct the command to.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if the *type* parameter is set to DB2.

remote_system

Specifies the z/OS system to which the DB2 command is to be routed.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if both of the following conditions apply:

- DB2 is the *type* parameter
- The DB2 command will be routed to a z/OS system that is different from the system where the stored procedure is executing

jobname

Specifies the name of the batch job or started task to be modified.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if HSM is the *type* parameter.

command

Specifies the command to be executed.

Valid values depend on the value of the *type* parameter.

- When the *type* parameter is set to DB2, valid values are:
 - START
 - STOP
- When the *type* parameter is set to DUMP, the valid value is DUMP.
- When the *type* parameter is set to HSM, valid values are:
 - QUERY COPYPOOL
 - LIST COPYPOOL
- When the *type* parameter is set to WLM, the valid value is DISPLAY.

This parameter is an input parameter of type VARCHAR(126) and cannot be null.

parameters

Specifies the parameters of the command, or the program parameters that will be passed to the started task.

Valid values depend on the value of the *command* parameter.

This parameter is an input parameter of type VARCHAR(124).

You cannot specify null for this parameter if the *type* parameter is set to HSM, DUMP, or WLM.

subparameters

Specifies the sub-parameters of the command. The following keyword-value pairs are supported:

CONSNAME=console-name

The name of the console that the stored procedure activates. If not specified, the default is DSNADMCM.

IRLMPROC=procedure-name

The procedure name of the connected IRLM. The stored procedure performs the following actions if IRLMPPROC is specified:

- If DB2 is already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring IRLM termination after the DSN9022I message is received.
- If DB2 is not stopped or is not already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring IRLM termination after message DSN3100I is received.

Monitoring occurs within the specified *wait-timeout period* and ends when the IRLM address space terminates or the wait timeout period expires. The stored procedure reports DB2 normal termination only after it determines that IRLM address space is terminated.

The IRLM procedure name is 1 - 8 characters. The first character must be a letter A - Z, #, \$, or @; the remaining characters can be A through Z, 0 - 9, or #, \$, or @.

This keyword-value pair can only be specified when the *type* parameter is DB2, the *command* parameter is STOP, and the SSNM keyword is not specified.

SSNM=subsystem-name

The DB2 subsystem name. The stored procedure performs the following actions:

- If DB2 is already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring *ssnmMSTR* termination after the DSN9022I message is received.
- If DB2 is not stopped or is not already stopping when the stored procedure issues the STOP DB2 command, the keyword is ignored and no monitoring of *ssnmMSTR* termination occurs.

Monitoring occurs within the specified *wait-timeout period* and ends when the *ssnmMSTR* address space terminates or the wait timeout period expires. The stored procedure reports DB2 normal termination only after it determines that the *ssnmMSTR* address space is terminated.

The subsystem name is 1 - 4 characters. The first character must be a letter A - Z, #, \$, or @; the remaining characters can be A through Z, 0 - 9, or #, \$, or @.

This keyword-value pair can be specified only when the *type* parameter is DB2, the *command* parameter is STOP, and the IRLMPROC keyword is not specified.

LIST_CP_KEYWORDS=DUMPVOLS

This keyword-value pair can be specified only when the *type* parameter is HSM and the *command* parameter is LIST COPYPOOL.

QUERY_CP_BACKUP=number-of-versions

The number of copy pool backup versions. This key-value pair can be specified only when the *command* parameter is set to QUERY COPYPOOL.

Alternatively, if no key-value pairs specified for *subparameters*, the following values are supported:

- DUMPVOLS, when the *command* parameter is LIST COPYPOOL.
- The number of copy pool backup versions, when *command* parameter is QUERY COPYPOOL.

This parameter is an input parameter of type VARCHAR(124).

You cannot specify null for this parameter if both of the following conditions apply:

- The *type* parameter is set to HSM
- The *command* parameter is set to QUERY COPYPOOL

wait_timeout

Specifies the amount of time (in seconds) that this procedure waits for the command to complete and for the message to be routed to the console. If the console is already active, the wait time includes the time that the procedure waits for the console to become available. If stopping DB2 and the IRLM or *ssnm*MSTR address space termination is being monitored, the wait time includes the time the procedure monitors the status of these address spaces.

For DB2 START and DB2 STOP, valid values are 1-900, and the default wait time is 180 seconds. Otherwise, valid values are 1-120, and the default wait time is 5 seconds.

This parameter is an input parameter of type INTEGER.

return_code

Provides the return code from the stored procedure.

Possible values are:

0 The stored procedure did not encounter any errors during processing. However, this return code does not indicate that the command executed successfully. The *command_completion_code* output parameter indicates whether the command executed successfully or not.

4 The stored procedure issued the command but was unable to determine the command execution status based on the command messages that were retrieved within the prescribed wait time. For example, the wait time might have expired.

When *return_code* is 4, the *command_completion_code* parameter is set to 8 or 16.

All command messages that were retrieved within the prescribed wait time are returned in the result set.

8 The stored procedure issued the command but was unable to determine the command execution status because it was unable to retrieve all the command messages that were queued to the extended MCS console. When *return_code* is 8, the *command_completion_code* parameter is set to 8 or 16. All the command messages that were

retrieved so far are returned in the result set. For STOP DB2, the latest IRLM or DB2 MSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully. For STOP DB2, the latest IRLM or DB2 MSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully.

- 12** The stored procedure encountered an error during processing. The *message* output parameter contains messages that describe the error.

This parameter is an output parameter of type INTEGER.

command_completion_code

Indicates the completion status of the command.

Possible values are:

0

One of the following conditions applies:

- The command completed successfully.
- If the *command* parameter is QUERY COPYPOOL, there is no FlashCopy[®] process that is active in the background.

For details about *command_completion_code* 0, see Table 99.

4

One of the following conditions applies:

- The command was not processed. For example, DB2 was already stopped when STOP DB2 was requested.
- If the *command* parameter is QUERY COPYPOOL, one or more FlashCopy processes are active in the background.

For details about *command_completion_code* 4, see Table 100 on page 756.

8

The command started but the completion status is unknown. For details about *command_completion_code* 8, see Table 101 on page 756.

12

The command completed abnormally. For details about *command_completion_code* 12, see Table 102 on page 758.

16

The command output does not satisfy the conditions that are listed for *command_completion_code* 0, 4, 8, or 12.

This parameter is an output parameter of type INTEGER.

The following tables describe the messages that ADMIN_COMMAND_MVS looks for when assigning a specific value to *command_completion_code*.

Table 99. Description of command_completion_code 0

| Command | Command completion code description | Messages received |
|-------------|-------------------------------------|---|
| DISPLAY WLM | DISPLAY WLM completed successfully. | Message IWM029I was received. |
| DUMP | DUMP completed successfully. | Both of the following messages were received: <ul style="list-style-type: none"> • IEA794I • IEA911E or IEA611I |

Table 99. Description of command_completion_code 0 (continued)

| Command | Command completion code description | Messages received |
|----------------|--|--|
| LIST COPYPOOL | The list of copy pools that was output by LIST COPYPOOL is complete. | Both of the following messages were received: <ul style="list-style-type: none"> COPYPOOL=xx...xx, where xx...xx is the name of the copy pool that is specified in the <i>parameters</i> input parameter ARC0140I |
| QUERY COPYPOOL | No FlashCopy processes are active in the background. | Message ARC1821I was received. The number of copy pool backup versions (as specified in the <i>subparameters</i> input parameter) and the number of copy pool versions that are not in active FlashCopy relationships is the same. Message ARC1820I was not received. |
| START DB2 | START DB2 completed successfully. | Message DSN9022I <i>cmd_prefix</i> was received, which indicates that DB2 START completed normally. |
| STOP DB2 | STOP DB2 completed successfully. | <ul style="list-style-type: none"> DSN3100I <i>cmd_prefix</i> Message 'irlm_procname NOT FOUND' was found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status. |

Table 100. Description of command_completion_code 4

| Command | Command completion code description | Messages received |
|----------------|--|--|
| QUERY COPYPOOL | One or more FlashCopy processes are active in the background. | One or more ARC1820I messages and zero or more ARC1821I messages were received. The number of copy pool backup versions (as specified in the <i>subparameters</i> input parameter) and the number of copy pool versions that are in active and not in active FlashCopy relationships is the same. |
| START DB2 | DB2 is already active when the command was issued. | Message DSNY003I <i>cmd_prefix</i> was received. |
| STOP DB2 | One of the following scenarios applies: <ul style="list-style-type: none"> DB2 was already stopped when the command was issued. DB2 was in the process of stopping when the command was issued, and it stopped successfully. | DB2 was already stopped: <ul style="list-style-type: none"> DSN3106I <i>cmd_prefix</i> DB2 was in the process of stopping: <ul style="list-style-type: none"> DSNY004I <i>cmd_prefix</i> and DSN9022I <i>cmd_prefix</i>, where DSN9022I <i>cmd_prefix</i> indicates that DB2 STOP completed normally, and either message 'ssnmMSTR NOT FOUND' was found in the 'D A, ssnmMSTR' command output when the stored procedure checked the <i>ssnmMSTR</i> address space status, or message 'irlm_procname NOT FOUND' was found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status. |

Table 101. Description of command_completion_code 8

| Command | Command completion code description | Messages received | Expected completion messages not received |
|---------|--|-------------------------------|--|
| DUMP | The dump was captured but not written. | Message IEA794I was received. | One of the following messages was not received: <ul style="list-style-type: none"> IEA911E IEA611I |

Table 101. Description of command_completion_code 8 (continued)

| Command | Command completion code description | Messages received | Expected completion messages not received |
|-------------------|---|--|---|
| LIST COPYPOOL | The listing from LIST COPYPOOL is truncated. | Message COPYPOOL=xx...xxx was received, where xx...xx is the name of the copy pool that is specified in the <i>parameters</i> input parameter. | Message ARC0140I was not received. |
| QUERY COPYPOOL | One or more FlashCopy processes are active or not active in the background. | One or more ARC1820I or ARC1821I messages was received. | The total number of ARC1820I and ARC1821I messages is not equal to the total number of copy pool backup versions that is specified in the <i>subparameters</i> input parameter. |
| START DB2 | DB2 is in the process of starting, but the completion status of START DB2 is unknown. | Message DSNY024I <i>cmd_prefix</i> was received. | One of the following messages was not received: <ul style="list-style-type: none"> • DSN9023I <i>cmd_prefix</i> • DSNV086E <i>cmd_prefix</i> • DSN3104I <i>cmd_prefix</i> • DSN9022I <i>cmd_prefix</i>, which indicates that DB2 START completed normally • DSN3100I <i>cmd_prefix</i> |

| Command | Command completion code description | Messages received | Expected completion messages not received |
|----------|--|---|---|
| STOP DB2 | DB2 is in the process of stopping, but the completion status of STOP DB2 is unknown. | <p>One of the following messages was received:</p> <ul style="list-style-type: none"> • DSNY002I <i>cmd_prefix</i> • DSNY004I <i>cmd_prefix</i> | <p>DSNY002I <i>cmd_prefix</i> received:</p> <ul style="list-style-type: none"> • None of the following messages were received: <ul style="list-style-type: none"> – DSN3100I <i>cmd_prefix</i> – DSN3107I <i>cmd_prefix</i> – DSN9023I <i>cmd_prefix</i> – Or, message DSN3100I <i>cmd_prefix</i> was received but message 'irlm_procname NOT FOUND' was not found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address soace status. <p>DSNY004I <i>cmd_prefix</i> received:</p> <ul style="list-style-type: none"> • None of the following messages were received: <ul style="list-style-type: none"> – DSN9022I <i>cmd_prefix</i>, which indicates that DB2 STOP completed normally – DSN9023I <i>cmd_prefix</i> • Or, message DSN9022I <i>cmd_prefix</i> was received but either message 'irlm_procname NOT FOUND' was not found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status, or message 'ssnmMSTR NOT FOUND' was not found in the 'D A, ssnmMSTR' command output when the stored procedure checked the ssnmMSTR address space status. |

Table 102. Description of command_completion_code 12

| Command | Command completion code description | Messages received |
|-------------|-------------------------------------|--|
| DISPLAY WLM | DISPLAY WLM completed abnormally. | <p>One of the following messages was received:</p> <ul style="list-style-type: none"> • IWM002I • IWM003I • IWM030I |

Table 102. Description of command_completion_code 12 (continued)

| Command | Command completion code description | Messages received |
|---------------|---|--|
| LIST COPYPOOL | No output was generated from LIST COPYPOOL. | Message ARC0140I was received, but message COPYPOOL=xx...xxx was not received, where xx...xxx is the name of the copy pool that is specified in the <i>parameters</i> input parameter. |
| START DB2 | START DB2 completed abnormally. | One of the following messages was received: <ul style="list-style-type: none"> • DSN9023I <i>cmd_prefix</i> • DSNV086E <i>cmd_prefix</i> • DSN3106I <i>cmd_prefix</i> • DSN3107I <i>cmd_prefix</i> • DSN3104I <i>cmd_prefix</i> • DSN3100I <i>cmd_prefix</i> |
| STOP DB2 | STOP DB2 completed abnormally. | One of the following messages was received: <ul style="list-style-type: none"> • DSN3107I <i>cmd_prefix</i> • DSN9023I <i>cmd_prefix</i> |

message

Contains messages that describe the error that was encountered by the stored procedure.

This parameter is an output parameter of type VARCHAR(1331).

Example

The following C language example shows how to invoke ADMIN_COMMAND_MVS.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;
int main( int argc, char *argv[] ) /* Argument count and list */
{
/***** DB2 Host Variables *****/
EXEC SQL BEGIN DECLARE SECTION;
/* SYSPROC.ADMIN_COMMAND_MVS parameters */
EXEC SQL BEGIN DECLARE SECTION;
/* SYSPROC.ADMIN_COMMAND_MVS parameters */
char ptype[25]; /* Command type */
char pcprefix[9]; /* DB2 subsystem command prefix */
char prmtsys[9]; /* Remote system */
char pjobnm[9]; /* Started task job name */
char pcmd[127]; /* Command to be executed */
char pparms[125]; /* Command parameters */
char psubparms[125]; /* Command subparameters */
long int pwait; /* Command completion wait time */
long int prc; /* Return code */
long int pccc; /* Command completion code */
char pmsg[1332]; /* Error message */

short int ind_ptype; /* Indicator variable */
short int ind_pcprefix; /* Indicator variable */
short int ind_prmtsys; /* Indicator variable */
short int ind_pjobnm; /* Indicator variable */
short int ind_pcmd; /* Indicator variable */
short int ind_pparms; /* Indicator variable */
```

```

short int  ind_psubparms;      /* Indicator variable */
short int  ind_pwait;         /* Indicator variable */
short int  ind_prc;          /* Indicator variable */
short int  ind_pccc;         /* Indicator variable */
short int  ind_pmsg;         /* Indicator variable */

/* Result set locators */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;
/* Result set row */
long int   rownum;           /* Sequence number of the */
/* table row */
char       text[2001];      /* Message */
EXEC SQL END DECLARE SECTION;
/*****
/* Clear temporary table SYSIBM.MVS_CMD_OUTPUT */
EXEC SQL DELETE FROM SYSIBM.MVS_CMD_OUTPUT;
/*****
/* Set procedure input parameters */
/*****
strcpy(ptype, "WLM");

ind_pjobnm = -1;
ind_pcmd = 0;
ind_pparms = 0;
ind_psubparms = -1;
ind_pwait = -1;
/*****
/* Call stored procedure SYSPROC.ADMIN_COMMAND_MVS */
/*****
EXEC SQL CALL SYSPROC.ADMIN_COMMAND_MVS (
           :ptype:ind_ptype,
           :pcprefix:ind_pcprefix,
           :prmtsys:ind_prmtsys,
           :pjobnm:ind_pjobnm,
           :pcmd:ind_pcmd,
           :pparms:ind_pparms,
           :psubparms:ind_psubparms,
           :pwait:ind_pwait,
           :prc:ind_prc,
           :pccc:ind_pccc,
           :pmsg:ind_pmsg);
/*****
/* Retrieve result set when the SQLCODE from the call is +446, */
/* which indicates that result sets were returned */
/*****
if (SQLCODE == +466)          /* Result sets were returned */
{
/* Establish a link between the result set and its locator */
EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
      WITH PROCEDURE SYSPROC.ADMIN_COMMAND_MVS;
/* Associate a cursor with the result set */
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
/* Perform fetches using C1 to retrieve all rows from the */
/* result set */
EXEC SQL FETCH C1 INTO :rownum, :text;
      while(SQLCODE=0)
      {
EXEC SQL FETCH C1 INTO :rownum, :text;
      }
}
return;
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 751:

- *return-code*
- *command_completion_code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the command messages. For STOP DB2, the latest IRLM or DB2 *ssnm*MSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully.

For DB2 START, DB2 STOP, and DUMP commands, both solicited messages (which are command responses) and unsolicited messages (which are other system messages) are retrieved and returned. Otherwise, only solicited messages are returned.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.MVS_CMD_OUTPUT:

Table 103. Result set row for ADMIN_COMMAND_MVS result set

| Column name | Data type | Contents |
|-------------|---------------------------|--|
| ROWNUM | INTEGER NOT NULL | Sequence number of the table row (1...n) |
| TEXT | VARCHAR(2000) NOT NULL | A command message line |

ADMIN_COMMAND_UNIX stored procedure

The SYSPROC.ADMIN_COMMAND_UNIX stored procedure executes a z/OS UNIX System Services command and returns the output.

Environment

GUPI

ADMIN_COMMAND_UNIX runs in a WLM-established stored procedure address space.

The load module for ADMIN_COMMAND_UNIX, DSNADMCU, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMCU to program control, see installation job DSNTIJRA.

Authorization

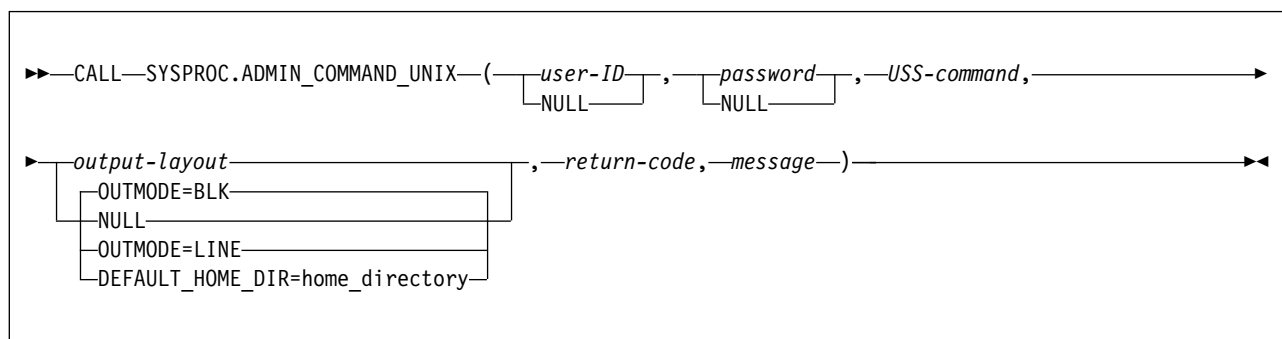

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCU
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user specified in the *user-ID* input parameter of the SQL CALL statement must have the appropriate authority to execute the z/OS UNIX System Services command.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

Option descriptions

user-ID

Specifies the user ID under which the z/OS UNIX System Services command is issued.

If *user-ID* is NULL, *password* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see Defining servers to process users without passwords or password phrases.

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

USS-command

Specifies the z/OS UNIX System Services command to be executed.

This is an input parameter of type VARCHAR(32704) and cannot be null.

output-layout

Specifies how the output from the z/OS UNIX System Services command is returned and the default home directory of the specified *user-ID*.

The output from the z/OS UNIX System Services command is a multi-line message. Possible values are:

OUTMODE=LINE

Each line is returned as a row in the result set.

OUTMODE=BLK

The lines are blocked into 32677 blocks and each block is returned as a row in the result set.

You specify the default home directory for *user-ID* as follows:

DEFAULT_HOME_DIR=home_directory

If the home directory of the specified *user-ID* does not exist, or *user-ID* does not have a home directory, the SYSPROC.ADMIN_COMMAND_UNIX stored procedure runs the command under the default home directory that you specify.

The maximum length of *home_directory* is 1007.

If you need to specify both OUTMODE and DEFAULT_HOME_DIR, consider the following examples:

```
OUTMODE=LINE,DEFAULT_HOME_DIR=/tmp
```

```
DEFAULT_HOME_DIR=/tmp,OUTMODE=LINE
```

If a null or empty string is provided, the default option OUTMODE=BLK is used.

This is an input parameter of type VARCHAR(1024).

return-code

Provides the return code from the stored procedure. Possible values are:

- 0** The call completed successfully.
- 4** The stored procedure used the default home directory.
- 12** The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_COMMAND_UNIX:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_COMMAND_UNIX parameters */
    char    userid[129];          /* User ID */
    short int ind_userid;        /* Indicator variable */
}
```

```

char      password[25];          /* Password */
short int ind_password;         /* Indicator variable */
char      command[32705];       /* USS command */
short int ind_command;         /* Indicator variable */
char      layout[1025];        /* Command output layout */
short int ind_layout;          /* Indicator variable */
long int  retcd;                /* Return code */
short int ind_retcd;           /* Indicator variable */
char      errmsg[1332];        /* Error message */
short int ind_errmsg;          /* Indicator variable */

/* Result set locators */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

/* Result set row */
long int  rownum;               /* Sequence number of the
/* table row */
char      text[32678];          /* A row in USS command output*/
EXEC SQL END DECLARE SECTION;

/*****
/* Assign values to input parameters to execute a USS command */
/* Set the indicator variables to 0 for non-null input parameters */
/* Set the indicator variables to -1 for null input parameters */
*****/
strcpy(userid, "USRT001");
ind_userid = 0;
strcpy(password, "NICETEST");
ind_password = 0;
strcpy(command, "ls");
ind_command = 0;
ind_layout = -1;

/*****
/* Call stored procedure SYSPROC.ADMIN_COMMAND_UNIX */
*****/
EXEC SQL CALL SYSPROC.ADMIN_COMMAND_UNIX
              (:userid   :ind_userid,
              :password  :ind_password,
              :command   :ind_command,
              :layout    :ind_layout,
              :retcd     :ind_retcd,
              :errmsg    :ind_errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446,
/* which indicates that result sets were returned */
*****/
if (SQLCODE == +446) /* Result sets were returned */
{
  /* Establish a link between the result set and its locator */
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_COMMAND_UNIX;

  /* Associate a cursor with the result set */
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

  /* Perform fetches using C1 to retrieve all rows from the
  /* result set */
  EXEC SQL FETCH C1 INTO :rownum, :text;
  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1 INTO :rownum, :text;
  }

  EXEC SQL CLOSE C1;

```

```

    }
    return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 762:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the z/OS UNIX System Services command output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.USS_CMD_OUTPUT:

Table 104. Result set row for ADMIN_COMMAND_UNIX result set

| Column name | Data type | Contents |
|-------------|----------------|---|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| TEXT | VARCHAR(32677) | A block of text or a line from the output messages of a z/OS UNIX System Services command |

ADMIN_DS_BROWSE stored procedure

The SYSPROC.ADMIN_DS_BROWSE stored procedure returns either text or binary records from certain data sets or their members. You can browse a physical sequential (PS) data set, a generation data set, a partitioned data set (PDS) member, or a partitioned data set extended (PDSE) member. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

Environment

GUPI

The load module for ADMIN_DS_BROWSE, DSNADMDB, must reside in an APF-authorized library. ADMIN_DS_BROWSE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDB
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_BROWSE caller also needs authorization from an external security system, such as RACF, in order to browse or view an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_BROWSE—(—data-type,—data-set-name,—member-name,—dump-option,—  
▶—return-code,—message—)▶▶
```

Option descriptions

data-type

Specifies the type of data to be browsed and how the data set will be allocated. Possible values are:

- 1 Text data with exclusive access
- 2 Binary data with exclusive access
- 3 Text data with shared access. This value is valid only if browsing a library member.

4 Binary data with shared access. This value is valid only if browsing a library member.

This is an input parameter of type INTEGER and cannot be null.

data-set-name

Specifies the name of the data set, or of the library that contains the member to be browsed. Possible values are:

PS data set name

If reading from a PS data set, the *data-set-name* contains the name of the PS data set.

PDS or PDSE name

If reading from a member that belongs to this PDS or PDSE, the *data-set-name* contains the name of the PDS or PDSE.

GDS name

If reading from a generation data set, the *data-set-name* contains the name of the generation data set, such as USERGDG.FILE.G0001V00.

This is an input parameter of type CHAR(44) and cannot be null.

member-name

Specifies the name of the PDS or PDSE member, if reading from a PDS or PDSE member. Otherwise, a blank character.

This is an input parameter of type CHAR(8) and cannot be null.

dump-option

Specifies whether to use the DB2 standard dump facility to dump the information necessary for problem diagnosis when an SQL error occurred or when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

Possible values are:

Y Generate a dump.

N Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_BROWSE:

```

#include <stdio.h>
#include <stdlib.h>
#include <string>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_BROWSE parameters */
    long int datatype; /* Data type */
    char dsname[45]; /* Data set name */
    char mbrname[9]; /* Library member name */
    char dumpopt[2]; /* Dump option */
    long int retcd; /* Return code */
    char errmsg[1332]; /* Error message */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int rownum; /* Sequence number of the */
    /* table row */
    char text_rec[81]; /* A data set record */
    EXEC SQL END DECLARE SECTION;

    /***** Assign values to input parameters to browse a library member *****/
    datatype = 1;
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(mbrname, "MEMBER0A");
    strcpy(dumpopt, "N");

    /***** Call stored procedure SYSPROC.ADMIN_DS_BROWSE *****/
    EXEC SQL CALL SYSPROC.ADMIN_DS_BROWSE
                (:datatype, :dsname, :mbrname, :dumpopt,
                :retcd, :errmsg);

    /***** Retrieve result set when the SQLCODE from the call is +446, *****/
    /* which indicates that result sets were returned */
    /***** *****/
    if (SQLCODE == +446) /* Result sets were returned */
    {
        /* Establish a link between the result set and its locator */
        EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
                WITH PROCEDURE SYSPROC.ADMIN_DS_BROWSE;

        /* Associate a cursor with the result set */
        EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

        /* Perform fetches using C1 to retrieve all rows from the */
        /* result set */
        EXEC SQL FETCH C1 INTO :rownum, :text_rec;
        while(SQLCODE==0)
        {
            EXEC SQL FETCH C1 INTO :rownum, :text_rec;
        }

        EXEC SQL CLOSE C1;
    }
}

```

```

    }
    return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 767:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the text or binary records read.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.TEXT_REC_OUTPUT containing text records read:

Table 105. Result set row for ADMIN_DS_BROWSE result set (text records)

| Column name | Data type | Contents |
|-------------|-------------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> . |
| TEXT_REC | VARCHAR(80) | Record read (text format). |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BIN_REC_OUTPUT containing binary records read:

Table 106. Result set row for ADMIN_DS_BROWSE result set (binary records)

| Column name | Data type | Contents |
|-------------|--------------------------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> . |
| BINARY_REC | VARCHAR(80) FOR BIT DATA | Record read (binary format). |

ADMIN_DS_DELETE stored procedure

The SYSPROC.ADMIN_DS_DELETE stored procedure deletes certain data sets or their members. You can delete a physical sequential (PS) data set, a partitioned data set (PDS), a partitioned data set extended (PDSE), a generation data set (GDS), or a member of a PDS or PDSE.

Environment

GUPI

The load module for ADMIN_DS_DELETE, DSNADMDD, must reside in an APF-authorized library. ADMIN_DS_DELETE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_DS_DELETE stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_DS_DELETE caller also needs authorization from an external security system, such as RACF, in order to delete an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_DELETE—(—data-set-type,—data-set-name,—parent-data-set-name,—  
▶—dump-option,—return-code,—message—)————▶▶
```

Option descriptions

data-set-type

Specifies the type of data set to delete. Possible values are:

- 1 Partitioned data set (PDS)
- 2 Partitioned data set extended (PDSE)
- 3 Member of a PDS or PDSE
- 4 Physical sequential data set (PS)
- 6 Generation data set (GDS)

This is an input parameter of type INTEGER and cannot be null.

| ***data-set-name***

| Specifies the name of the data set, library member, or GDS absolute generation
| number to be deleted. Possible values are:

| **PS, PDS, or PDSE name**

| If *data-set-type* is 1, 2, or 4, the *data-set-name* contains the name of the
| PS, PDS, or PDSE to be deleted.

| **PDS or PDSE member name**

| If *data-set-type* is 3, the *data-set-name* contains the name of the PDS or
| PDSE member to be deleted.

| **absolute generation number**

| If *data-set-type* is 6, the *data-set-name* contains the absolute generation
| number of the GDS to be deleted, such as G0001V00.

| This is an input parameter of type CHAR(44) and cannot be null.

| ***parent-data-set-name***

| Specifies the name of the library that contains the member to be deleted, or of
| the GDG that contains the GDS to be delete. Otherwise blank. Possible values
| are:

| **blank** If *data-set-type* is 1, 2, or 4, the *parent-data-set-name* is left blank.

| **PDS or PDSE name**

| If *data-set-type* is 3, the *parent-data-set-name* contains the name of the
| PDS or PDSE whose member is to be deleted.

| **GDG name**

| If *data-set-type* is 6, the *parent-data-set-name* contains the name of the
| GDG that the GDS to be deleted belongs to.

| This is an input parameter of type CHAR(44) and cannot be null.

| ***dump-option***

| Specifies whether to use the DB2 standard dump facility to dump the
| information necessary for problem diagnosis when a call to the IBM routine
| IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

| Possible values are:

| **Y** Generate a dump.

| **N** Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

| ***return-code***

| Provides the return code from the stored procedure. Possible values are:

| **0** Data set, PDS member, PDSE member, or GDS was deleted
| successfully.

| **12** The call did not complete successfully. The *message* output parameter
| contains messages describing the error.

| This is an output parameter of type INTEGER.

| ***message***

| Contains messages describing the error encountered by the stored procedure. If
| no error occurred, then no message is returned.

| The first messages in this area are generated by the stored procedure. Messages
| that are generated by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_DELETE:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_DELETE parameters */
    long int dstype; /* Data set type */
    char dsname[45]; /* Data set name ,
                    /* member name, or
                    /* generation # (G0001V00)
    char parentds[45]; /* PDS, PDSE, GDG or blank
    char dumpopt[2]; /* Dump option
    long int retcd; /* Return code
    char errmsg[1332]; /* Error message
    EXEC SQL END DECLARE SECTION;

    /***** Assign values to input parameters to delete a data set *****/
    dstype = 4;
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(parentds, " ");
    strcpy(dumpopt, "N");

    /***** Call stored procedure SYSPROC.ADMIN_DS_DELETE *****/
    EXEC SQL CALL SYSPROC.ADMIN_DS_DELETE
                (:dstype, :dsname, :parentds, :dumpopt,
                :retcd, :errmsg);

    return(retcd);
}
```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 771:

- *return-code*
- *message*

 GUPI

ADMIN_DS_LIST stored procedure

The SYSPROC.ADMIN_DS_LIST stored procedure returns a list of data set names, a generation data group (GDG), a partitioned data set (PDS) member, a partitioned data set extended (PDSE) member, or generation data sets of a GDG.

Environment

The load module for ADMIN_DS_LIST, DSNADMDL, must reside in an APF-authorized library. ADMIN_DS_LIST runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDL
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_LIST caller also needs authorization from an external security system, such as RACE, in order to perform the requested operation on an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_LIST—(—data-set-name,—list-members,—list-generations,—  
▶—max-results,—dump-option,—return-code,—message—)————▶▶
```

Option descriptions

data-set-name

Specifies the data set name. You can use masking characters, except for when you list members of a PDS/PDSE (*list-members* = 'Y') or the generation data sets of a GDG (*list-generations* = 'Y'). For example: USER.* or USER.A*CD. In addition, the specified data set name cannot start with a masking character.

If no masking characters are used, only one data set will be listed.

This is an input parameter of type CHAR(44) and cannot be null.

list-members

Specifies whether to list PDS or PDSE members. Possible values are:

Y List members. Only set to Y when *data-set-name* is a fully qualified PDS or PDSE.

N Do not list members.

This is an input parameter of type CHAR(1) and cannot be null.

list-generations

Specifies whether to list generation data sets. Possible values are:

Y List generation data sets. Only set to Y when *data-set-name* is a fully qualified GDG.

N Do not list generation data sets.

This is an input parameter of type CHAR(1) and cannot be null.

max-results

Specifies the maximum number of result set rows. This option is applicable only when both list-members and list-generations are 'N'.

This is an input parameter of type INTEGER and cannot be null.

dump-option

Specifies whether to use the DB2 standard dump facility to dump the information necessary for problem diagnosis when any of the following errors occur:

- SQL error.
- A call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.
- Load Catalog Search Interface module error.

Possible values are:

Y Generate a dump.

N Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

4 Processing completed, but some data sets received catalog management errors. Data set information is returned for the data sets that did not receive catalog management errors. Error information is returned for the data sets that received catalog management errors.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_LIST:

```
#pragma csect(CODE,"SAMDLPGM")
#pragma csect(STATIC,"PGMDLSAM")
#pragma runopts(plist(os))

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_LIST parameters */
    char dsname[45]; /* Data set name or filter */
    char listmbr[2]; /* List library members */
    char listgds[2]; /* List GDS */
    long int maxresult; /* Maximum result set rows */
    char dumpopt[2]; /* Dump option */
    long int retcd; /* Return code */
    char errmsg[1332]; /* Error message */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    char dsnamer[45]; /* Data set name,
                    /* library member name, or
                    /* absolute generation number */
    long int createyr; /* Create year */
    long int createday; /* Create day */
    long int type; /* Data set type */
    char volume[7]; /* Data set volume */
    long int primaryext; /* Size of first extent */
    long int secondext; /* Size of secondary extent */
    char measure[10]; /* Extent unit of measurement */
    long int extinuse; /* Current allocated extents */
    char dasduse[9]; /* DASD usage */
    char harba[7]; /* High allocated RBA */
    char hurba[7]; /* High used RBA */
    EXEC SQL END DECLARE SECTION;

    char * ptr;
    int i = 0;
    /*****
    /* Assign values to input parameters to list all members of
    /* a library
    *****/
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(listmbr, "Y");
    strcpy(listgds, "N");
    maxresult = 1;
    strcpy(dumpopt, "N");

    /*****
    /* Call stored procedure SYSPROC.ADMIN_DS_LIST
    *****/
    EXEC SQL CALL SYSPROC.ADMIN_DS_LIST
                (:dsname, :listmbr, :listgds, :maxresult,
                :dumpopt, :retcd, :errmsg);
```

```

/*****
/* Retrieve result set when the SQLCODE from the call is +446, */
/* which indicates that result sets were returned */
/*****
if (SQLCODE == +466) /* Result sets were returned */
{
/* Establish a link between the result set and its locator */
EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
WITH PROCEDURE SYSPROC.ADMIN_DS_LIST;

/* Associate a cursor with the result set */
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

/* Perform fetches using C1 to retrieve all rows from the */
/* result set */
EXEC SQL FETCH C1 INTO :dsnamer, :createyr, :createday,
:type, :volume, :primaryext,
:secondext, :measure, :extinuse,
:dasduse, :harba, :hurba;

while(SQLCODE==0)
{
EXEC SQL FETCH C1 INTO :dsnamer, :createyr, :createday,
:type, :volume, :primaryext,
:secondext, :measure, :extinuse,
:dasduse, :harba, :hurba;
}

EXEC SQL CLOSE C1;
}
return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 774:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the list of data sets, GDGs, PDS or PDSE members, or generation data sets that were requested.

The following table shows the format of the result set:

Table 107. Result set row for ADMIN_DS_LIST result set

| Column name | Data type | Contents |
|-------------|-------------|--|
| DSNAME | VARCHAR(44) | <ul style="list-style-type: none"> • Data set name, if <i>list-members</i> is “N” and <i>list-generations</i> is “N”. • Member name, if <i>list-members</i> is “Y”. • Absolute generation number (of the form G0000V00) from a generation data set name, if <i>list-generations</i> is “Y”. |

Table 107. Result set row for ADMIN_DS_LIST result set (continued)

| Column name | Data type | Contents |
|------------------|-----------|---|
| CREATE_YEAR | INTEGER | The year that the data set was created. Not applicable for member and VSAM cluster. |
| CREATE_DAY | INTEGER | The day of the year that the data set was created, as an integer in the range of 1 to 366 where 1 represents January 1). Not applicable for member and VSAM cluster. |
| TYPE | INTEGER | Type of data set. Possible values are: <ul style="list-style-type: none"> 0 Unknown type of data set 1 PDS data set 2 PDSE data set 3 Member of PDS or PDSE 4 Physical sequential data set 5 Generation data group 6 Generation data set 8 VSAM cluster 9 VSAM data component 10 VSAM index component |
| VOLUME | CHAR(6) | Volume where data set resides. Not applicable for member and VSAM cluster. |
| PRIMARY_EXTENT | INTEGER | Size of first extent. Not applicable for member and VSAM cluster. |
| SECONDARY_EXTENT | INTEGER | Size of secondary extent. Not applicable for member and VSAM cluster. |
| MEASUREMENT_UNIT | CHAR(9) | Unit of measurement for first extent and secondary extent. Possible values are: <ul style="list-style-type: none"> • BLOCKS • BYTES • CYLINDERS • KB • MB • TRACKS Not applicable for member and VSAM cluster. |

Table 107. Result set row for ADMIN_DS_LIST result set (continued)

| Column name | Data type | Contents |
|----------------|----------------------|--|
| EXTENTS_IN_USE | INTEGER | Current allocated extents. Not applicable for member and VSAM cluster. |
| DASD_USAGE | CHAR(8) FOR BIT DATA | Disk usage. For VSAM data and VSAM index only. |
| HARBA | CHAR(6) FOR BIT DATA | High allocated RBA. For VSAM data and VSAM index only. |
| HURBA | CHAR(6) FOR BIT DATA | High used RBA. For VSAM data and VSAM index only. |
| ERRMSG | VARCHAR(256) | An error message that explains the first data set-related failure that was encountered by the stored procedure while gathering the attributes of a data set. Some possible error messages are DSN A661I, DSN A662I, and DSN A635I. If an error did not occur while gathering data set attributes, this column is blank. |

When a data set spans more than one volume, one row is returned for each volume that contains a piece of the data set. The VOLUME, EXTENTS_IN_USE, DASD_USAGE, HARBA, and HURBA columns reflect information for the specified volume.

If a data set entry error is encountered, the ADMIN_DS_LIST stored procedure returns the data set that caused the error in the result set, along with data sets that did not have errors. In the result set, the attribute columns for the data set that caused the error are set to specific values, as shown in the following table.

Table 108. Values of data set attributes when an error is encountered

| Attribute | Value |
|------------------|-----------------------------|
| CREATE_YEAR | 0 |
| CREATE_DAY | 0 |
| TYPE | 0 |
| VOLUME | blank |
| PRIMARY_EXTENT | -1 |
| SECONDARY_EXTENT | -1 |
| MEASUREMENT_UNIT | blank |
| EXTENTS_IN_USE | -1 |
| DASD_USAGE | -1 (x'FFFFFFFFFFFFFFFF') |
| HARBA | -1 (x'FFFFFFFFFFFFFFFF') |

Table 108. Values of data set attributes when an error is encountered (continued)

| Attribute | Value |
|-----------|-------------------------|
| HURBA | -1 (x'FFFFFFFFFFFF') |

 **GUPI**

ADMIN_DS_RENAME stored procedure

The SYSPROC.ADMIN_DS_RENAME stored procedure renames a physical sequential (PS) data set, a partitioned data set (PDS), a partitioned data set extended (PDSE), or a member of a PDS or PDSE.

Environment

GUPI

The load module for ADMIN_DS_RENAME, DSNADMDR, must reside in an APF-authorized library. ADMIN_DS_RENAME runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_DS_RENAME stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_DS_RENAME caller also needs authorization from an external security system, such as RACF, in order to rename an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_DS_RENAME ( data-set-type, data-set-name, parent-data-set-name,  
new-data-set-name, dump-option, return-code, message )
```

Option descriptions

data-set-type

Specifies the type of data set to rename. Possible values are:

- 1 Partitioned data set (PDS)
- 2 Partitioned data set extended (PDSE)
- 3 Member of a PDS or PDSE
- 4 Physical sequential data set (PS)

This is an input parameter of type INTEGER and cannot be null.

data-set-name

Specifies the data set or member to be renamed. Possible values are:

| **PS, PDS, or PDSE name**

| If *data-set-type* is 1, 2, or 4, the *data-set-name* contains the name of the
| PS, PDS, or PDSE to be renamed.

| **PDS or PDSE member name**

| If *data-set-type* is 3, the *data-set-name* contains the name of the PDS or
| PDSE member to be renamed.

| This is an input parameter of type CHAR(44) and cannot be null.

| ***parent-data-set-name***

| Specifies the name of the PDS or PDSE, if renaming a PDS or PDSE member.
| Otherwise, a blank character. Possible values are:

| **blank** If *data-set-type* is 1, 2, or 4, the *parent-data-set-name* is left blank.

| **PDS or PDSE name**

| If *data-set-type* is 3, the *parent-data-set-name* contains the name of the
| PDS or PDSE whose member is to be renamed.

| This is an input parameter of type CHAR(44) and cannot be null.

| ***new-data-set-name***

| Specifies the new data set or member name. Possible values are:

| **new data set name**

| If *data-set-type* is 1, 2, or 4, the *new-data-set-name* contains the new data
| set name.

| **new member name**

| If *data-set-type* is 3, the *new-data-set-name* contains the new member
| name.

| This is an input parameter of type CHAR(44) and cannot be null.

| ***dump-option***

| Specifies whether to use the DB2 standard dump facility to dump the
| information necessary for problem diagnosis when any of the following errors
| occurred:

- | • A call to the IBM routine IEFDB476 to get messages about an unsuccessful
| SVC 99 call failed.
- | • Load IDCAMS program error.

| Possible values are:

| **Y** Generate a dump.

| **N** Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

| ***return-code***

| Provides the return code from the stored procedure. Possible values are:

| **0** The data set, PDS member, or PDSE member was renamed
| successfully.

| **12** The call did not complete successfully. The *message* output parameter
| contains messages describing the error.

| This is an output parameter of type INTEGER.

| ***message***

| Contains messages based on *return-code* and *data-set-type* combinations.

| <i>return-code</i> | <i>data-set-type</i> | Content |
|--------------------|----------------------|---|
| 0 | 1, 2, or 4 | Contains IDCAMS messages. |
| 0 | 3 | No message is returned. |
| Not 0 | not applicable | Contains messages describing the error encountered by the stored procedure. The first messages are generated by the stored procedure and messages that are generated by z/OS might follow these first messages. The first messages can also be generated by z/OS. |

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_RENAME:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_RENAME parameters */
    long int  dstype; /* Data set type */
    char      dsname[45]; /* Data set or member name */
    char      parentds[45]; /* Parent data set (PDS or PDSE) name or blank */
    char      newsname[45]; /* New data set or member name */
    char      dumpopt[2]; /* Dump option */
    long int  retcd; /* Return code */
    char      errmsg[1332]; /* Error message */
    EXEC SQL END DECLARE SECTION;

    /***** Assign values to input parameters to rename a library member *****/
    dstype = 3;
    strcpy(dsname, "MEMBER01");
    strcpy(parentds, "USER.DATASET.PDS");
    strcpy(newsname, "MEMBER0A");
    strcpy(dumpopt, "N");

    /***** Call stored procedure SYSPROC.ADMIN_DS_RENAME *****/
    EXEC SQL CALL SYSPROC.ADMIN_DS_RENAME
                (:dstype, :dsname, :parentds, :newsname,
                 :dumpopt, :retcd, :errmsg);

    return(retcd);
}
```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 781:

- *return-code*
- *message*

ADMIN_DS_SEARCH stored procedure

The SYSPROC.ADMIN_DS_SEARCH stored procedure determines if certain data sets are cataloged, or if a library member of a cataloged data set exists. You can search for a physical sequential (PS) data set, a partitioned data set (PDS), a partitioned data set extended (PDSE), a generation data group (GDG), a generation data set (GDS), or the library member of a cataloged PDS or PDSE.

Environment

GUPI

The load module for ADMIN_DS_SEARCH, DSNADMDE, must reside in an APF-authorized library. ADMIN_DS_SEARCH runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_DS_SEARCH stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_DS_SEARCH caller also needs authorization from an external security system, such as RACF, in order to perform the requested operation on an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_SEARCH—(—data-set-name,—member-name,—dump-option,—  
▶—data-set-exists,—return-code,—message—)——▶▶
```

Option descriptions

data-set-name

Specifies the name of a PS data set, PDS, PDSE, GDG or GDS.

This is an input parameter of type CHAR(44) and cannot be null.

member-name

Specifies the name of a PDS or PDSE member. Set this parameter to a blank character if you only want to check the existence of the PDS or PDSE.

This is an input parameter of type CHAR(8) and cannot be null.

| **dump-option**

| Specifies whether to use the DB2 standard dump facility to dump the
| information necessary for problem diagnosis when any of the following errors
| occurred:

- | • A call to the IBM routine IEFDB476 to get messages about an unsuccessful
| SVC 99 call failed.
- | • Load IDCAMS program error.

| Possible values are:

- | Y Generate a dump.
- | N Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

| **data-set-exists**

| Indicates whether a data set or library member exists or not. Possible values
| are:

- | -1 Call did not complete successfully. Unable to determine if data set or
| member exists.
- | 0 Data set or member was found
- | 1 Data set not found
- | 2 PDS or PDSE member not found

| This is an output parameter of type INTEGER.

| **return-code**

| Provides the return code from the stored procedure. Possible values are:

- | 0 The call completed successfully.
- | 12 The call did not complete successfully. The *message* output parameter
| contains messages describing the error.

| This is an output parameter of type INTEGER.

| **message**

| Contains IDCAMS messages if *return-code* is 0. Otherwise, contains messages
| describing the error encountered by the stored procedure. The first messages
| are generated by the stored procedure and messages that are generated by
| z/OS might follow these first messages.

| This is an output parameter of type VARCHAR(1331).

| **Example**

| The following C language sample shows how to invoke ADMIN_DS_SEARCH:

```
| #include <stdio.h>  
| #include <stdlib.h>  
| #include <string.h>  
|  
| /***** DB2 SQL Communication Area *****/  
| EXEC SQL INCLUDE SQLCA;  
|  
| int main( int argc, char *argv[] ) /* Argument count and list */  
| {  
| /***** DB2 Host Variables *****/  
| EXEC SQL BEGIN DECLARE SECTION;  
|  
| /* SYSPROC.ADMIN_DS_SEARCH parameters */
```

```

char      dsname[45];          /* Data set name or GDG      */
char      mbrname[9];         /* Library member name       */
char      dumpopt[2];        /* Dump option               */
long int  exist;              /* Data set or library member */
                                      /* existence indicator        */
long int  retcd;              /* Return code               */
char      errmsg[1332];      /* Error message             */
EXEC SQL END DECLARE SECTION;

/*****
/* Assign values to input parameters to determine whether a
/* library member exists or not
*****/
strcpy(dsname, "USER.DATASET.PDS");
strcpy(mbrname, "MEMBER0A");
strcpy(dumpopt, "N");

/*****
/* Call stored procedure SYSPROC.ADMIN_DS_SEARCH
*****/
EXEC SQL CALL SYSPROC.ADMIN_DS_SEARCH
              (:dsname, :mbrname, :dumpopt,
              :exist, :retcd, :errmsg);

return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 785:

- *data-set-exists*
- *return-code*
- *message*

ADMIN_DS_WRITE stored procedure

The SYSPROC.ADMIN_DS_WRITE stored procedure writes either text or binary records that are passed in a global temporary table to data sets or their members. You can write to a physical sequential (PS) data set, a partitioned data set (PDS) member, a partitioned data set extended (PDSE) member, or a generation data set (GDS).

This stored procedure can either append or replace an existing PS data set, PDS or PDSE member, or GDS. Also, this stored procedure can create a new PS data set, PDS or PDSE data set or member, or a new GDS for an existing generation data group (GDG) as needed. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

Environment

GUPI

The load module for ADMIN_DS_WRITE, DSNADMDW, must reside in an APF-authorized library. ADMIN_DS_WRITE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDW
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_WRITE caller also needs authorization from an external security system, such as RACF, in order to write to an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►►—CALL—SYSPROC.ADMIN_DS_WRITE—(—data-type,—data-set-name,—member-name,—processing-option,—  
►—dump-option,—return-code,—message—)—————►
```

Option descriptions

This stored procedure takes the following input options:

| ***data-type***

| Specifies the type of data to be saved. Possible values are:

- | 1 Text data
| 2 Binary data

| This is an input parameter of type INTEGER and cannot be null.

| ***data-set-name***

| Specifies the name of the data set, GDG that contains the GDS, or library that
| contains the member, to be written to. Possible values are:

| **PS data set name**

| Name of the PS data set, if writing to a PS data set.

| **GDG name**

| Name of the GDG, if writing to a GDS within this GDG.

| **PDS or PDSE name**

| Name of the PDS or PDSE, if writing to a member that belongs to this
| library.

| This is an input parameter of type CHAR(44) and cannot be null.

| ***member-name***

| Specifies the relative generation number of the GDS, if writing to a GDS, or the
| name of the PDS or PDSE member, if writing to a PDS or PDSE member.
| Otherwise, a blank character. Possible values are:

| **GDS relative generation number**

| Relative generation number of a GDS, if writing to a GDS. For
| example: -1, 0, +1

| **PDS or PDSE member name**

| Name of the PDS or PDSE member, if writing to a library member.

| **blank** In all other cases, blank.

| This is an input parameter of type CHAR(8) and cannot be null.

| ***processing-option***

| Specifies the type of operation. Possible values are:

- | **R** Replace
| **A** Append
| **NM** New member
| **ND** New PS, PDS, PDSE, or GDS data set

| This is an input parameter of type CHAR(2) and cannot be null.

| ***dump-option***

| Specifies whether to use the DB2 standard dump facility to dump the
| information necessary for problem diagnosis when an SQL error has occurred
| or when a call to the IBM routine IEFDB476 to get messages about an
| unsuccessful SVC 99 call failed.

| Possible values are:

- | **Y** Generate a dump.
| **N** Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Additional input

In addition to the input parameters, the stored procedure reads records to be written to a file from a created global temporary table. If the data to be written is text data, then the stored procedure reads records from SYSIBM.TEXT_REC_INPUT. If the data is binary data, then the stored procedure reads records from the created global temporary table SYSIBM.BIN_REC_INPUT.

The following table shows the format of the created global temporary table SYSIBM.TEXT_REC_INPUT containing text records to be saved:

Table 109. Additional input for text data for the ADMIN_DS_WRITE stored procedure

| Column name | Data type | Contents |
|-------------|-----------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> . |
| TEXT_REC | CHAR(80) | Text record to be saved. |

The following table shows the format of the created global temporary table SYSIBM.BIN_REC_INPUT containing binary records to be saved:

Table 110. Additional input for binary data for the ADMIN_DS_WRITE stored procedure

| Column name | Data type | Contents |
|-------------|--------------------------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> . |
| BINARY_REC | VARCHAR(80) FOR BIT DATA | Binary record to be saved. |

Example

The following C language sample shows how to invoke ADMIN_DS_WRITE:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
```

```

{
/***** DB2 Host Variables *****/
EXEC SQL BEGIN DECLARE SECTION;

/* SYSPROC.ADMIN_DS_WRITE parameters */
long int  datatype;          /* Data type */
char      dsname[45];        /* Data set name or GDG */
char      mbrname[9];        /* Library member name,
                             /* generation # (-1, 0, +1),
                             /* or blank */
char      procopt[3];        /* Processing option */
char      dumpopt[2];        /* Dump option */
long int  retcd;             /* Return code */
char      errmsg[1332];      /* Error message */

/* Temporary table SYSIBM.TEXT_REC_INPUT columns */
long int  rownum;            /* Sequence number of the
                             /* table row */
char      textrec[81];       /* Text record */
EXEC SQL END DECLARE SECTION;

/*****
/* Create the records to be saved */
/*****

    rownum = i+1;
    strcpy(textrec, dsrecord[i]);
    EXEC SQL INSERT INTO SYSIBM.TEXT_REC_INPUT
        ( ROWNUM, TEXT_REC)
        VALUES (:rownum, :textrec);
};

```

```

|
|
|      /*****
|      /* Call stored procedure SYSPROC.ADMIN_DS_WRITE          */
|      *****/
|      EXEC SQL CALL SYSPROC.ADMIN_DS_WRITE
|              (:datatype, :dsname, :mbrname, :procopt,
|              :dumpopt, :retcd, :errmsg );
|
|      return(retcd);
|  }

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 788:

- *return-code*
- *message*

ADMIN_INFO_HOST stored procedure

The SYSPROC.ADMIN_INFO_HOST stored procedure returns the host name of a connected DB2 subsystem or the host name of every member of a data sharing group.

Environment

GUPI

ADMIN_INFO_HOST runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIH
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_INFO_HOST stored procedure internally calls the ADMIN_COMMAND_DB2 stored procedure to execute the following DB2 commands:

- -DISPLAY DDF
- -DISPLAY GROUP

The owner of the package or plan that contains the CALL ADMIN_INFO_HOST statement must also have the authorization required to execute the stored procedure ADMIN_COMMAND_DB2 and the specified DB2 commands.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_HOST ( processing-option , DB2-member , return-code , message )
```

The diagram shows a syntax diagram for the CALL statement. The text is enclosed in a box with arrows pointing to the right. The *DB2-member* parameter has a bracket underneath it with the word NULL below the bracket. The *return-code* and *message* parameters have arrows pointing to the right, indicating they are optional.

Option descriptions

processing-option

Specifies processing option. Possible values are:

- 1 Return the host name of the connected DB2 subsystem or the host name of a specified DB2 data sharing group member.

For a data sharing group member, you must specify *DB2-member*.

2 Return the host name of every DB2 member of the same data sharing group.

This is an input parameter of type INTEGER and cannot be null.

DB2-member

Specifies the DB2 data sharing group member name.

This parameter must be null if *processing-option* is 2.

This is an input parameter of type CHAR(8).

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

4 Unable to list the host name of the connected DB2 subsystem or of every DB2 member of the same data sharing group due to one of the following reasons:

- The IPADDR field returned when the -DISPLAY DDF command is executed on the connected DB2 subsystem or DB2 member contains the value -NONE
- One of the DB2 members is down

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_INFO_HOST:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_INFO_HOST parameters */
    long int  procopt;          /* Processing option */
    short int ind_procopt;     /* Indicator variable */
    char      db2mbr[9];       /* Data sharing group member
                               /* name */
    short int ind_db2mbr;     /* Indicator variable */
    long int  retcd;          /* Return code */
    short int ind_retcd;      /* Indicator variable */
    char      errmsg[1332];    /* Error message */
    short int ind_errmsg;     /* Indicator variable */
}
```

```

/* Result set locators */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

/* Result set row */
long int rownum; /* Sequence number of the */
/* table row */
char db2member[9]; /* DB2 data sharing group */
/* member name */
char hostname[256]; /* Host name of the connected */
/* DB2 subsystem or DB2 */
/* member name */

EXEC SQL END DECLARE SECTION;

/*****
/* Assign values to input parameters to find the host name of */
/* the connected DB2 subsystem */
/* Set the indicator variables to 0 for non-null input parameters */
/* Set the indicator variables to -1 for null input parameters */
*****/
procopt = 1;
ind_procopt = 0;
ind_db2mbr = -1;

/*****
/* Call stored procedure SYSPROC.ADMIN_INFO_HOST */
*****/
EXEC SQL CALL SYSPROC.ADMIN_INFO_HOST
        (:procopt :ind_procopt,
         :db2mbr :ind_db2mbr,
         :retcd :ind_retcd,
         :errmsg :ind_errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446, */
/* which indicates that result sets were returned */
*****/
if (SQLCODE == +446) /* Result sets were returned */
{
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_INFO_HOST;

    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

    /* Use C1 to fetch the only row from the result set */
    EXEC SQL FETCH C1 INTO :rownum, :db2mbr, :hostname;

    EXEC SQL CLOSE C1;
}

return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 793:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the host names.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.SYSTEM_HOSTNAME:

Table 111. Result set row for ADMIN_INFO_HOST result set

| Column name | Data type | Contents |
|-------------|--------------|---|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> . |
| DB2_MEMBER | CHAR(8) | DB2 data sharing group member name. |
| HOSTNAME | VARCHAR(255) | Host name of the connected DB2 subsystem if the <i>processing-option</i> input parameter is 1 and the <i>DB2-member</i> input parameter is null. Otherwise, the host name of the DB2 member specified in the DB2_MEMBER column. |

ADMIN_INFO_SMS stored procedure

The ADMIN_INFO_SMS stored procedure returns space information about copy pools and their storage groups and volumes.

Environment

GUPI

The load module for this stored procedure, DSNADMIV, must reside in an APF-authorized library. ADMIN_INFO_SMS runs in a WLM-established stored procedures address space. All libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIV
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶ CALL SYSPROC.ADMIN_INFO_SMS (—return-code,—message—) ▶▶
```

Option descriptions

return-code

Provides the return code from the stored procedure. The following values are possible:

- 0** The stored procedure completed successfully.
- 4** The stored procedure could not return the volume space statistics for all of the requested objects. The *message* output parameter contains messages that describe the warnings.

This return code is issued when one or more objects that are returned in the result set contains one of the following messages in the ERRMSG column:

- OBJECT NOT FOUND: Indicates that the copy pool, storage group, or volume that is specified in the input table is not found, as reported by the SMS construct access services.

- NO VOLUMES ASSOCIATED WITH STORAGE GROUP: Indicates that the storage group that is specified in the input table does not have any volumes, as reported by the SMS construct access services.
- NO STORAGE GROUPS ASSOCIATED WITH COPY POOL: Indicates that the copy pool that is specified in the input table does not have any storage groups, as reported by the SMS construct access services.
- DSN661I DSNADMIV THE MACRO LSPACE FAILED WITH RETURN CODE=*nn*

12 The call did not complete successfully. The *message* output parameter contains messages that describe a parameter error, an SQL error, or an internal error that was encountered by the stored procedure.

This is an output parameter of type INTEGER.

message

Contains messages that describe a parameter error, an SQL error, or an internal error that was encountered by the stored procedure. If an error did not occur, a message is not returned.

This is an output parameter of type VARCHAR(1331).

Input

This stored procedure reads from the created global temporary table SYSIBM.SMS_OBJECTS to determine which objects' space statistics to return.

The following table shows the format of the SYSIBM.SMS_OBJECTS input table.

Table 112. Input row for the ADMIN_INFO_SMS stored procedure

| Column name | Data type | Contents |
|-------------|-------------------------|---|
| OBJECTID | INTEGER NOT NULL | A unique positive identifier for the object that a set of volume space statistics is associated with. |
| OBJECTTYPE | CHAR(1) NOT NULL | Valid values are: <ul style="list-style-type: none"> • 'C': Copy pool • 'S': Storage group • 'V': Volume |
| OBJECTNAME | VARCHAR(30) NOT NULL | Valid values are: <ul style="list-style-type: none"> • Copy pool name, if OBJECTTYPE is 'C'. Returns all of the volumes that are associated with each storage group in this copy pool, along with the corresponding volume space statistics. • Storage group name, if OBJECTTYPE is 'S'. Returns all of the volumes that are associated with this storage group, along with the corresponding volume space statistics. • Volume name, if OBJECTTYPE is 'V'. Returns the volume space statistics for this volume. |

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 797:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the volume space statistics.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.SMS_INFO. The result set rows are returned in ascending order by ROWNUM and OBJECTID.

Table 113. Result set row for ADMIN_INFO_SMS result set

| Column name | Data type | Contents |
|---------------|---------------------|--|
| ROWNUM | INTEGER NOT NULL | Sequence number of the table row, from 1 to <i>n</i> . |
| OBJECTID | INTEGER NOT NULL | A unique positive identifier for the object that a set of volume space statistics is associated with This ID is used to reference the object in the input table SYSIBM.SMS_OBJECTS. |
| COPYPOOL | VARCHAR(30) | A copy pool. This value is NULL if a storage group or volume is specified. For example, if the corresponding OBJECTTYPE in the SYSIBM.SMS_OBJECTS table is 'S' or 'V'. |
| STORAGEGROUP | VARCHAR(30) | A copy pool storage group. This value is NULL if no storage groups are associated with the specified copy pool, or if a volume is specified. For example, if the corresponding OBJECTTYPE in the SYSIBM.SMS_OBJECTS table is 'V'. |
| VOLUME | VARCHAR(6) | A volume in a copy pool storage group. This value is NULL in the following cases: <ul style="list-style-type: none">• If no volumes are associated with the specified storage group• If no volumes are associated with a storage group that is associated with the specified copy pool• If no storage groups are associated with the specified copy pool |
| TOTALCAPACITY | INTEGER NOT NULL | Total capacity of a volume, in megabytes. The value is -1 if the VOLUME column is NULL. |

Table 113. Result set row for ADMIN_INFO_SMS result set (continued)

| Column name | Data type | Contents |
|----------------|---------------------|--|
| FREESPACE | INTEGER NOT NULL | <p>The total amount of free space in a volume, in megabytes. The value is -1 if the VOLUME column is NULL.</p> <p>For a DB2 volume, this is the amount of space in the copy pool that has not been allocated by DB2 yet. Therefore, disk space that has been allocated by DB2, but is currently not used (like data records that were deleted) would not fall into this category.</p> |
| LARGESTFREEEXT | INTEGER NOT NULL | Largest free extent in a volume, in megabytes. The value is -1 if the VOLUME column is NULL. |
| ERRMSG | VARCHAR(256) | <p>Possible values are:</p> <ul style="list-style-type: none"> • NULL • OBJECT NOT FOUND: Indicates that the copy pool, storage group, or volume that is specified in the input table is not found, as reported by the SMS construct access services. • NO VOLUMES ASSOCIATED WITH STORAGE GROUP: Indicates that the storage group that is specified in the input table does not have any volumes, as reported by the SMS construct access services. • NO STORAGE GROUPS ASSOCIATED WITH COPY POOL: Indicates that the copy pool that is specified in the input table does not have any storage groups, as reported by the SMS construct access services. • DSN A661I DSNADMIV THE MACRO LSPACE FAILED WITH RETURN CODE=<i>nn</i> |

ADMIN_INFO_SSID stored procedure

The SYSPROC.ADMIN_INFO_SSID stored procedure returns the name of the connected DB2 subsystem.

GUIP

Environment

ADMIN_INFO_SSID must run in a WLM-established stored procedure address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_INFO_SSID stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_SSID(—subsystem-ID—, —return-code—, —message—)
```

Option descriptions

subsystem-ID

Identifies the subsystem ID of the connected DB2 subsystem.

This is an output parameter of type VARCHAR(4).

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, no message is returned.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_INFO_SSID:

```

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_INFO_SSID PARAMETERS */
  char      ssid[5]; /* DB2 subsystem identifier */
  long int  retcd; /* Return code */
  char      errmsg[1332]; /* Error message */
  EXEC SQL END DECLARE SECTION;

  /***** Call stored procedure SYSPROC.ADMIN_INFO_SSID *****/
  EXEC SQL CALL SYSPROC.ADMIN_INFO_SSID
              (:ssid, :retcd, :errmsg);

  return(retcd);
}

```

Output

The output of this stored procedure includes the following output parameters, which are described in “Option descriptions” on page 801:

- *subsystem-ID*
- *return-code*
- *message*

ADMIN_INFO_SQL stored procedure

The ADMIN_INFO_SQL stored procedure captures statistics about a DB2 subsystem, its objects, and applications and returns the results in a data set or as a result set. This information can help IBM Software Support re-create and troubleshoot problems, such as a poorly performing SQL query.

PSPI

The output from ADMIN_INFO_SQL is primarily for the use of IBM Software Support. The output might change at any time.

To provide the results to IBM Software Support, you must terse the files and upload them to an FTP site. Then, you update the PMR when the files are available. For more information, see APAR II11945.

Environment

ADMIN_INFO_SQL must run in a WLM-established stored procedures address space, where NUMTCB is a value between 40 and 60.

If you collect information by using PLAN_TABLE, ensure that the view reference table, DSN_VIEWREF_TABLE, exists before you execute EXPLAIN. Especially if the query contains a view, ensuring that DSN_VIEWREF_TABLE is available helps to narrow the view so that it is specific to the query rather than collecting all of the view dependencies.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_INFO_SQL stored procedure
- Ownership of the stored procedure
- SYSADM authority

Optionally, you need authority to create data sets, or access existing data sets, if the information is collected into a data set.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶—CALL—SYSPROC.ADMIN_INFO_SQL—(—table-creator,—table-name,—catalog-creator,—plan-info,—  
▶—collect-ddl,—collect-stats,—collect-column-stats,—edit-ddl,—edit-version-mode,—  
▶—partition-rotation,—output-method,—output-info,—pmr-info,—return-code,—message—)——▶
```

Option descriptions

table-creator

Specifies the explicit qualifier for the object, the list of tables, or the plan table (PLAN_TABLE).

This is an input parameter of type VARCHAR(128) and cannot be null.

table-name

Specifies the name of a single user object, a list of objects, or the plan table (PLAN_TABLE).

Valid options are an object name, LIST_TABLE-table, or PLAN_TABLE. The LIST_TABLE-table option is the name of a DB2 table that contains two columns, CREATOR and TABLE. These two columns drive the program to collect information. The PLAN_TABLE option uses the CREATOR and TNAME columns of the PLAN_TABLE to collect information. This option depends on the *plan_info* parameter to qualify tables as input. The reference point to the plan table must point to a base table only. When you specify PLAN_TABLE, ensure that the view reference table, DSN_VIEWREF_TABLE, exists before you execute EXPLAIN. Making sure that DSN_VIEWREF_TABLE is available helps to minimize the size of the DDL information. DSN_VIEWREF_TABLE must have the same qualifier as the plan table. This qualifier is the *table-creator* value, which is the first input parameter.

The input for a single user object or a list of objects must be one of the following types of objects:

- Base table
- View
- Alias
- Clone table
- Created temporary table
- History table
- Materialized query table
- Implicitly created table for an XML column

The input parameter *table-creator* must be the qualifier for these tables.

This is an input parameter of type VARCHAR(128).

catalog-creator

Specifies the catalog to use for collection. The default catalog is SYSIBM. To use the default catalog, you can specify DEFAULT or SYSIBM.

This is an input parameter of type VARCHAR(128) and cannot be null.

plan-info

Specifies the programs and query numbers from PLAN_TABLE for the tables to be collected.

If you are collecting information from a single table that is not PLAN_TABLE, or a list of tables, specify NONE.

This is an input parameter of type VARCHAR(150) and cannot be null.

collect-ddl

Specifies whether to collect DDL information. Valid values are Y, N, 0 (zero), 1, 2, 3, or 4.

This is an input parameter of type CHAR(1) and cannot be null.

When the input table is not PLAN_TABLE, possible values are:

- N** Do not return the data definition language statements that created the objects.
 - Y** Return the data definition language statements that created:
 - The input objects
 - Foreign keys that reference the input objects
 - Views on the input objects
 - 0** Return the data definition language statements that created:
 - The input objects. Statements that create views on the input objects or foreign keys that reference the input objects are not collected.
 - 1** Return the data definition language statements that created:
 - The input objects
 - Views on the input objects
 - 2** Return the data definition language statements that created:
 - The input objects
 - Foreign keys that reference the input objects
 - 3** Return the data definition language statements that created:
 - The input objects
 - Foreign keys that reference the input objects
 - Views on the input objects
 - Other objects that depend on the input objects, such as materialized query tables
- This option can result in a large amount of data. Do not specify this option for problem analysis by IBM Software Support unless they direct you to do so.
- 4** Return the same data definition language statements that are returned when option Y is specified.

When the input table is PLAN_TABLE, possible values are:

- N** Do not return the data definition language statements that created the objects.
- Y** Return the data definition language statements that created:
 - The objects that are identified by *plan-info*
 - Foreign keys that reference the objects that are identified by *plan-info*
 - If DSN_VIEWREF_TABLE exists and is populated, views or materialized query tables that are used to process the queries that are identified by *plan-info*.
 - If DSN_VIEWREF_TABLE does not exist, views on objects that are identified by *plan-info*.
- 0** Return the data definition language statements that created:
 - The objects that are identified by *plan-info* only. Statements that create views on the objects or foreign keys that reference the objects that are identified by *plan-info* are not collected.
- 1** Return the data definition language statements that created:
 - The objects that are identified by *plan-info*

- If DSN_VIEWREF_TABLE exists and is populated, views or materialized query tables that are used to process the queries that are identified by *plan-info*.
- If DSN_VIEWREF_TABLE does not exist, views on objects that are identified by *plan-info*.

2 Return the data definition language statements that created:

- Foreign keys that reference the objects that are identified by *plan-info*

3 Return the data definition language statements that created:

- The objects that are identified by *plan-info*
- Foreign keys that reference the objects that are identified by *plan-info*
- Views on objects that are identified by *plan-info*
- Other objects that depend on the objects that are identified by *plan-info*, such as materialized query tables

This option can result in a large amount of data. Do not specify this option for problem analysis by IBM Software Support unless they direct you to do so.

4 Return the data definition language statements that created:

- The objects that are identified by *plan-info*
- Foreign keys that reference the objects that are identified by *plan-info*
- Views on objects that are identified by *plan-info*

This option does not use information from DSN_VIEWREF_TABLE.

collect-stats

Specifies whether to collect statistics information. Valid values are Y for yes, or N for no.

This is an input parameter of type CHAR(1) and cannot be null.

collect-column-stats

Specifies whether to collect column-level statistics information. Valid values are Y for yes, or N for no.

To collect column statistics, the *collect-stats* parameter must be set to Y.

This is an input parameter of type CHAR(1) and cannot be null.

edit-ddl

Specifies whether to edit the DDL output. Valid values are Y for yes, or N for no.

If edited, the DDL output contains changes, such as the STOGROUP set to SYSDEFLT, PRIQTY and SECQTY set to minimum values, and FOREIGNKEY definitions commented out. Sometimes IBM Software Support needs DDL output that is not edited. However, if the data to populate the DDL-defined tables will not be sent with the problem report, specify Y for this parameter.

This is an input parameter of type CHAR(1) and cannot be null.

edit-version-mode

Specifies that the output should be formatted for a different version and mode of DB2 for z/OS than the version and mode that is currently running when collecting information. You must specify the version number and the mode, or you can specify NONE so that the output is not converted to another format.

Valid values for mode are C for conversion mode and N for new-function mode. For example, if your DB2 subsystem is running in DB2 10 conversion mode, and you want to generate the output for DB2 9 new-function mode, specify 9-N.

This is an input parameter of type CHAR(4) and cannot be null.

partition-rotation

Specifies whether you want to verify the number of partition rotations that are required to balance the table. Valid values are Y for yes, or N for no.

This is an input parameter of type CHAR(1) and cannot be null.

output-method

Specifies the data set attributes that you want the output to include.

This is an input parameter of type CHAR(1) and cannot be null.

Possible values for *output-method* are:

- Q** Returns dynamically created data sets with size parameters.
- N** Returns the result data sets in an already existing data set in the WLM environment.
- D** Returns dynamically created data sets on a volume that you specify.
- R** Returns a result set in a predetermined format.

Output data sets and result sets contain the following information:

DDL The creation statements for databases, table spaces, tables, and indexes.

SQL INSERT statements for PLAN_TABLE, DSN_PROFILE_TABLE, DSN_PROFILE_ATTRIBUTES, and SYSACCELERATORS if the tables exist.

STATS

Statistical information related to the tables.

COLST

Statistical information related to the columns.

EXPL The output begins with a first-pass analysis report, which contains the following information, if it is available:

- A report on missing EXPLAIN tables
- A report on statistics that are recommended but were not collected
- Results of a preliminary analysis of the EXPLAIN data

The following information is also returned:

- Visual output of the following tables, if they exist: PLAN_TABLE, DSN_PREDICAT_TABLE, DSN_DETCOST_TABLE, DSN_PROFILE_TABLE, DSN_PROFILE_ATTRIBUTES, and SYSACCELERATORS
- Information about the objects, messages, and input parameters.

PARM Subsystem parameter, service, module, and relational data system (RDS) MEPL information.

output-info

Specifies the output information. The values that you specify depend on the value of the *output-method* parameter.

This is an input parameter of type VARCHAR(1024) and cannot be null.

Based on the value of *output-method*, you must format the input for *output-info* as follows:

output-method = Q

This output method has the following format:

qualifier-primary(value or DEFLT)-secondary(value or DEFLT)

You specify a 29-character qualifier, including periods. You also can specify a primary and secondary track value. The default value is 200 for primary and 200 for secondary.

The result data set is created on temporary storage as a data set with one of the following types:

- .DDL
- .SQL
- .STATS
- .COLST
- .EXPL
- .PARM

The file might be deleted in a short period of time, depending on the configuration of your z/OS system. Because the data set is created as a new one, existing data sets with the same name are deleted.

The DEFAULT value creates a data set name with the following format:

PMxxxxx.Dxxxxxx.Txxxxxx.Vx.Type

For example, for PMR 12345, the ADMIN_INFO_SQL stored procedure generates the following files:

- PM12345.D091007.T170318.V9.COLST
- PM12345.D091007.T170318.V9.DDL
- PM12345.D091007.T170318.V9.EXPL
- PM12345.D091007.T170318.V9.PARM
- PM12345.D091007.T170318.V9.SQL
- PM12345.D091007.T170318.V9.STATS

output-method = N

For established data sets in the WLM environment, you must specify the DD name in the following format:

DDL_DDname-SQL_DDname-Stats_DDname-Colst_DDname-Exp1_DDname-
Parm_DDname

The WLM administrator must create these data sets with DD names in the WLM startup procedure and supply those names to the person calling the stored procedure. These data sets can be generational. You must create the data sets as new ones rather than appending existing data sets. The ADMIN_INFO_SQL stored procedure opens the data set at initialization and closes the file when complete.

output-method = D

You specify the volume where you want the data sets created and the names and sizes of the data sets. This output method has the following format but in one continuous line with no spaces:

```
DDL;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
SQL;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
STATS;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
COLST;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
EXPL;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
PARM;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary
```

The DEFAULT value creates the data set name with the same format and types as for output method Q. The data set name must contain the type identifier (for example, .DDL, .SQL, .STATS, etc.). As a result, the data sets can be listed in any order.

These data sets are created with the option disp=(NEW,CATLG,KEEP). Therefore, if a data set with the same name already exists, the ADMIN_INFO_SQL stored procedure generates an error.

output-method = R

You must specify NONE. This output method returns a result set in the following format:

```
EXEC SQL CREATE GLOBAL TEMPORARY TABLE SYSIBM.SERVICE_SQL_OUTPUT
(TID INTEGER NOT NULL, SEQNO INTEGER NOT NULL,
TEXT VARCHAR(4096) NOT NULL);
```

Where TEXT is the information in the result set, such as DDL statements, statistical information, and service and module information. SEQNO is the sequence number in the table, and TID is the table number. For example:

Table 114. Table numbers for result set information

| Table number (TID) | Result set information |
|--------------------|------------------------|
| 1 | DDL |
| 2 | SQL |
| 3 | STATS |
| 4 | COLST |
| 5 | EXPL |
| 6 | PARM |

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.SERVICE_SQL_OUTPUT:

Table 115. Result set row for ADMIN_INFO_SQL result set

| Column name | Data type | Contents |
|-------------|---------------------|---|
| TID | INTEGER NOT NULL | The table number. |
| SEQNO | INTEGER NOT NULL | The sequence number in the table. |
| TEXT | VARCHAR(4096) | The information in the result set, such as DDL statements, statistical information, and service and module information. |

The following DECLARE statement shows the data that is returned for the result set and the order that the data is returned in:

```
EXEC SQL DECLARE DATA_CSR CURSOR WITH RETURN WITH HOLD FOR
SELECT TID, SEQNO, TEXT FROM SYSIBM.SERVICE_SQL_OUTPUT
ORDER BY TID, SEQNO;
```

pmr-info

Specifies the PMR number, branch code, and country code in the following format: xxxxx.xxx.xxx.

This is an input parameter of type VARCHAR(13) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 4 Warning. The *message* output parameter contains messages describing the warning.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error or warning encountered by the stored procedure. If no error occurred, the message states "DSNADMSS completed successfully."

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Examples

You can invoke the call for the ADMIN_INFO_SQL stored procedure from a DB2 command line processor, if you have access to a z/OS server. You also can call this stored procedure by using Java JDBC applications and by using the C language.

In addition, you can use DSNADMSSB, an IBM-supplied program, to call the ADMIN_INFO_SQL stored procedure. The result set is returned in a data set or as part of the job stream.

Example 1: The following example calls the ADMIN_INFO_SQL stored procedure to collect information from the PLAN_TABLE for program APROGRAM and query numbers between 1 and 12345.

```
CALL SYSPROC.ADMIN_INFO_SQL('sysadm','PLAN_TABLE','DEFAULT',
'APROGRAM-1-12345','Y','Y','N','Y','NONE','N','D','DDL;DEFAULT;EDSDMP;
TRK;200;200-SQL;DEFAULT;EDSDMP;TRK;200;200-STATS;DEFAULT;EDSDMP;TRK;200;200
-COLST;DEFAULT;EDSDMP;TRK;200;200-EXPL;DEFAULT;EDSDMP;TRK;200;200
-PARM;DEFAULT;EDSDMP;TRK;200;200','12345.000.000',?,?);
```

The output is created in data sets on volume EDSAMP with 200 primary tracks and 200 secondary tracks. These data sets have the following naming convention, where 'x' is the creation date and 'y' is the creation time:

- PM12345.Dxxxxxx.Tyyyyyy.V9.COLST
- PM12345.Dxxxxxx.Tyyyyyy.V9.DDL
- PM12345.Dxxxxxx.Tyyyyyy.V9.EXPL
- PM12345.Dxxxxxx.Tyyyyyy.V9.PARM
- PM12345.Dxxxxxx.Tyyyyyy.V9.SQL

- PM12345.Dxxxxxx.Tyyyyyy.V9.STATS

Example 2: The following example of the ADMIN_INFO_SQL stored procedure uses the list table T1 to collect data from all of the base tables that are in the list. A list table is a database table that contains the columns CREATOR and TABLE. The following SQL statements show how to create a list table:

```
DROP TABLE TL1;
DROP DATABASE DL1;
COMMIT;
CREATE DATABASE DL1;
CREATE TABLESPACE TSL1 IN DL1;
CREATE TABLE TL1 (CREATOR VARCHAR(128), TABLE VARCHAR(128)) IN DL1.TSL1;
COMMIT;
INSERT INTO TL1 VALUES ('SYSADM','T1');
INSERT INTO TL1 VALUES ('SYSADM','T2');
INSERT INTO TL1 VALUES ('SYSADM','T3');
COMMIT;
```

The following CALL statement for the ADMIN_INFO_SQL stored procedure returns a single result set in the job stream. The list table name must be preceded by 'LIST_TABLE-'.

```
CALL SYSPROC.ADMIN_INFO_SQL('sysadm','LIST_TABLE-T1','DEFAULT','NONE','Y','Y',
'N','Y','NONE','N','R','NONE','12345.000.000',?,?);
```

Even though the column name is TABLE in the list table, the input for a list of objects can be any of the following types of objects:

- Base table
- View
- Alias
- Clone table
- Created temporary table
- History table
- Materialized query table
- Implicitly created table for an XML column

Example 3: You also can call this stored procedure by using Java JDBC applications and by using the C language. The following examples call the ADMIN_INFO_SQL stored procedure to collect information from the PLAN_TABLE for program APROGRAM and query numbers between 1 and 12345, and return a result set.

Java JDBC code snippet example:

```
try
{
    cstmt = conn.prepareStatement("CALL SYSPROC.ADMIN_INFO_SQL(?,?,?,?,?,?,?,
                                ?,?,?,?,?,?)");
                                // Create a CallableStatement object
    cstmt.setString (1, "sysadm");
    cstmt.setString (2, "PLAN_TABLE");
    cstmt.setString (3, "DEFAULT");
    cstmt.setString (4, "APROGRAM-1-12345");
    cstmt.setString (5, "Y");
    cstmt.setString (6, "Y");
    cstmt.setString (7, "Y");
    cstmt.setString (8, "N");
    cstmt.setString (9, "NONE");
    cstmt.setString (10, "N");
    cstmt.setString (11, "R");
    cstmt.setString (12, "NONE");
```

```

cstmt.setString (13, "12345.000.000");
    // Set input parameters (DB2 command)
cstmt.registerOutParameter (14, Types.INTEGER);
cstmt.registerOutParameter (15, Types.VARCHAR);
    // Register output parameters

boolean resultsAvailable = cstmt.execute();
rc = cstmt.getInt(14);    // Get the output parameter values
errbuff = cstmt.getString(15);

while (resultsAvailable)
{
    ResultSet rs = cstmt.getResultSet();
    while (rs.next())
    {
        String s = rs.getString(3);
        System.out.println(s);
    }

    rs.close();
    resultsAvailable = cstmt.getMoreResults();
}

```

C language code snippet example:

```

EXEC SQL CALL SYSPROC.ADMIN_INFO_SQL ('sysadm','PLAN_TABLE'
, 'DEFAULT', 'APROGRAM-1-12345', 'Y', 'Y', 'N', 'Y', '9-N', 'N', 'R',
'NONE', '12345.000.000', :out1, :out2);
printf( "%d CALL SQLCODE\n", SQLCODE);
printf( "%d CALL RC\n", out1);
printf( "%s CALL DETAILS\n", out2);

if(SQLCODE==+466)
{
    EXEC SQL ASSOCIATE LOCATORS (:loc1) WITH
        PROCEDURE SYSPROC.ADMIN_INFO_SQL;
    printf( "%d ASSOC SQLCODE\n", SQLCODE);

    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :loc1;
    printf( "%d ALLOC SQLCODE\n", SQLCODE);

    while(SQLCODE==0)
    {
        DATA.LNG = 0;
        SEQNO = 0;
        TID = 0;

        ind1 = -1;
        ind2 = -1;
        ind3 = -1;

        EXEC SQL FETCH C1 INTO :TID :ind1, :SEQNO :ind2, :DATA :ind3;
        memcpy(output, DATA.THEDATA, DATA.LNG);
        output??(DATA.LNG??) = '\0';
        printf( "%s\n", output);
    }
}
printf( "%d FETCH SQLCODE\n", SQLCODE);

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 804:

- *return-code*
- *message*

In addition, this stored procedure returns output in data sets or a result set. You must ensure that enough space is available for the output. The ADMIN_INFO_SQL stored procedure might generate large amounts of data. Two to three megabytes of space is the average, but larger workloads might generate up to 20 megabytes of data. To conserve space, set the *collect-column-stats* option to N.

ADMIN_INFO_SYSLOG stored procedure

The ADMIN_INFO_SYSLOG stored procedure returns system log entries. You can specify filters, such as search string, system name, begin date and time, end date and time, and maximum number of entries, to limit the number of system log entries that are returned.

Note: This stored procedure is supported for z/OS Version 1 Release 12 and later.

Environment

ADMIN_INFO_SYSLOG runs in a WLM-established stored procedures address space, where TCB=1 is required.

Authorization

To use ADMIN_INFO_SYSLOG, you need to be licensed to use the SDSF utility. The ADMIN_INFO_SYSLOG stored procedure uses the SDSF ISFEXEC host command to issue the SDSF command MAS, and the SDSF ISFLOG host command to access the SYSLOG. These commands are issued under the security context of the user who is calling ADMIN_INFO_SYSLOG. SDSF determines the user command authority in the same way that it does when the user issues the SDSF commands MAS and LOG in an interactive mode. For more information about granting access to SDSF commands, see z/OS SDSF Operation and Customization.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►—CALL—SYSPROC.ADMIN_INFO_SYSLOG—(—search-filter,—system-name,—start-date,—start-time,—  
►—end-date,—end-time,—max-entries,—message—)—————►
```

Option descriptions

search-filter

Specifies a logical expression that is used to filter the SYSLOG records. If this parameter is set to NULL or is empty, filtering is not done.

A logical expression is composed of one or more operands, separated by operators. For example:

operand operator operand operator operand ... operator operand

where:

- operator is one of the following logical operators:
 - AND
 - and
 - OR

– or

- operand is a string of characters, or a string of characters enclosed in quotation marks.

The operand is used unchanged to search and locate a system log record. Therefore, characters such as '*', '%', and '?' are not handled as masking characters.

If an operand is enclosed in quotations marks and you want to include quotation marks in the operand, use two sets of quotation marks. If an operand includes one or more blanks or the logical operators (AND, and, OR, or), enclose the string of characters in quotations marks.

For a multi-line message, each operand in the *search-filter* parameter is checked against each line of the multi-line message. A match is found if the operand is in at least one line of the multi-line message. If the operand is split over several lines, a match is not found. If the whole message satisfies the *search-filter*, the whole message is returned.

JES3 DLOG does not have a column that indicates whether a line is a continuation of a previous line. For a multi-line message, the filter is applied separately on each line in the message, and only matching lines (not the whole message) are returned.

This is an input parameter of type VARCHAR(1300).

system-name

Specifies the system in the sysplex where the system log entries will be processed or searched. Specify NULL if you are retrieving SYSLOG records for the z/OS subsystem where the stored procedure is running. Specify "*" (an asterisk) if you want all of the systems in a sysplex to be processed. The following restrictions apply:

- If the stored procedure is running in a JES2 system, specifying "*" causes the stored procedure to process only the logical SYSLOG of every active JES2 system in the sysplex.
- If the stored procedure is running in a JES3 system, specifying "*" causes the stored procedure to process the logical SYSLOG of every active JES3 system in the sysplex. All DLOG entries in the global SYSLOG that are within the specified time interval, which can contain messages from every JES2 and JES3 system in the sysplex, will also be returned.

This is an input parameter of type VARCHAR(8).

start-date

Specifies the starting date for system log records to be processed. If this parameter is set to NULL, the default is the current date.

This is an input parameter of type DATE.

start-time

Specifies the starting time for system log records to be processed. If this parameter is set to NULL, the default time is 00:00:00.

This is an input parameter of type TIME.

end-date

Specifies the ending date for system log records to be processed. If this parameter is set to NULL, the default is the current date.

This is an input parameter of type DATE.

end-time

Specifies the ending time for system log records to be processed. If this parameter is set to NULL, the default time is 23:59:59.

This is an input parameter of type TIME.

Together, *start-date*, *start-time*, *end-date*, and *end-time* define the date and time range for the SYSLOG records. The starting date and time must be less than the ending date and time. SDSF positions the SYSLOG as close as possible to the requested record. However, due to the precision that is used for timestamps and the time that the record is actually written to SYSLOG, the time parameters might be several lines away from the record that you want. SYSLOG records from before a specified time interval might be returned, while SYSLOG records that are closer to a specified ending date and time might not be returned.

max-entries

Specifies a limit for the number of SYSLOG records to be processed for each system. If this parameter is set to NULL, the default is 500. Valid values are 1 to 99999999 and -1 to -99999999.

If *max-entries* is a positive number, the stored procedure processes only the oldest *max-entries* records for a specified time interval. If the limit for records occurs in the middle of a message, the message will be truncated if returned by the stored procedure.

If *max-entries* is a negative number, the stored procedure processes only the most current *max-entries* records for the specified time interval. If the limit for records occurs in the middle of a message, the message will be truncated if returned by the stored procedure.

Note: If you specified the *search-filter* parameter, the value specified for *max-entries* is not the maximum number of result set rows to be returned for a system. The number of rows that are returned in a result set for a system is always less than or equal to *max-entries*.

This is an input parameter of type INTEGER.

message

Contains messages that describe errors that occurred during stored procedure processing. The first messages are generated by the stored procedure. Messages that are generated by ISFEXEC or ISFLOG might follow the stored procedure messages.

If the stored procedure completed successfully, no message is returned.

This is an output parameter of type VARCHAR(1331).

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 814:

- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the system log records that you requested.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.SYSLOG:

Table 116. Result set row for ADMIN_INFO_SYSLOG result set

| Column name | Data type | Contents |
|-------------|--------------------------|--|
| ROWNUM | INTEGER NOT NULL | Sequence number of the table row, from 1 to <i>n</i> . |
| TEXT | VARCHAR(130) NOT NULL | A system log entry. For multi-line messages, a row is returned for each line in the message. |

The result set rows are returned in ascending order by ROWNUM. The system log records that are returned are grouped by system. Within each system, the system log records are returned in the same order as they appear in the SDSF system log.

ADMIN_INFO_SYSPARM stored procedure

The SYSPROC.ADMIN_INFO_SYSPARM stored procedure returns the system parameters, application defaults module, and IRLM parameters of a connected DB2 subsystem, or member of its data sharing group.

Environment

GUPI

ADMIN_INFO_SYSPARM runs in a WLM-established stored procedures address space, where NUMTCB=1 is required.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIZ
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user who calls this stored procedure must have MONITOR1 privilege.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_SYSPARM ( ( DB2-member | NULL ) , return-code , message )
```

Option descriptions

DB2-member

Specifies the name of the DB2 data sharing group member that you want to get the system parameters, DSNHDECP or a user-specified application defaults module, and IRLM parameters from.

Specify NULL for this parameter if you are retrieving the system parameters, DSNHDECP values, and IRLM parameters from the connected DB2 subsystem.

This is an input parameter of type VARCHAR(8).

return-code

Provides the return code from the stored procedure. The following values are possible:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter

contains messages that describe the IFI error or SQL error that is encountered by the stored procedure.

This is an output parameter of type INTEGER.

message

Contains messages that describe the IFI error or SQL error that was encountered by the stored procedure. If an error did not occur, a message is not returned.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_INFO_SYSPARM:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_INFO_SYSPARM parameters */
  char db2_member[9]; /* Data sharing group member */
  short int ind_db2_member; /* Indicator variable */
  long int retcd; /* Return code */
  short int ind_retcd; /* Indicator variable */
  char errmsg[1332]; /* Error message */
  short int ind_errmsg; /* Indicator variable */
  /* Result set locators */
  volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;
  /* Result set row */
  long int rownum; /* Sequence number of the */
  /* table row (1,...,n) */
  char macro[9]; /* Macro that contains the */
  /* system parameter, or */
  /* DSNHDECP parameter, or the */
  /* name of the IRLM procedure */
  /* that z/OS invokes if IRLM */
  /* is automatically started */
  /* by DB2 */
  char parameter[41]; /* Name of the system */
  /* parameter, DSNHDECP */
  /* parameter, or IRLM */
  /* parameter */
  char install_panel[9]; /* Name of the installation */
  /* panel where the parameter */
  /* value can be changed when */
  /* installing or migrating DB2*/
  short int ind_install_panel; /* Indicator variable */
  char install_field[41]; /* Name of the parameter on */
  /* the installation panel */
  short int ind_install_field; /* Indicator variable */
  char install_location[13]; /* Location of the parameter */
  /* on the installation panel */
  short int ind_install_location; /* Indicator variable */
  char value[2049]; /* Value of the parameter */
  char additional_info[201]; /* Reserved for future use */
  short int ind_additional_info; /* Indicator variable */

  EXEC SQL END DECLARE SECTION;
```

```

/*****
/* Set the db2_member indicator variable to -1 to get the DB2
/* subsystem parameters, DSNHDECP values, and IRLM parameters of
/* the connected DB2 subsystem.
/*****
ind_db2_member = -1;
/*****
/* Call stored procedure SYSPROC.ADMIN_INFO_SYSPARM
/*****
EXEC SQL CALL SYSPROC.ADMIN_INFO_SYSPARM
           (:db2_member :ind_db2_member,
           :retcd       :ind_retcd,
           :errmsg      :ind_errmsg);
/*****
/* Retrieve result set when the SQLCODE from the call is +446,
/* which indicates that result sets were returned
/*****
if (SQLCODE == +466)      /* Result sets were returned
{
  /* Establish a link between the result set and its locator
EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
      WITH PROCEDURE SYSPROC.ADMIN_INFO_SYSPARM;
  /* Associate a cursor with the result set
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
  /* Perform fetches using C1 to retrieve all rows from the
  /* result set
EXEC SQL FETCH C1
      INTO :rownum, :macro, :parameter,
          :install_panel      :ind_install_panel,
          :install_field      :ind_install_field,
          :install_location   :ind_install_location,
          :value,
          :additional_info     :ind_additional_info;

  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1
        INTO :rownum, :macro, :parameter,
            :install_panel      :ind_install_panel,
            :install_field      :ind_install_field,
            :install_location   :ind_install_location,
            :value,
            :additional_info     :ind_additional_info;

  }

  EXEC SQL CLOSE C1;
}
return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 818:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the parameter settings.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.DB2_SYSPARM:

Table 117. Result set row for ADMIN_INFO_SYSPARM result set

| Column name | Data type | Contents |
|------------------|---------------------------|--|
| ROWNUM | INTEGER NOT NULL | Sequence number of the table row, from 1 to <i>n</i> . |
| MACRO | VARCHAR(8) NOT NULL | Macro that contains the system parameter, the <i>dsnhdcp</i> parameter, or the name of the IRLM procedure that z/OS invokes if IRLM is started automatically by DB2. |
| PARAMETER | VARCHAR(40) NOT NULL | Name of the system parameter, <i>dsnhdcp</i> parameter, or IRLM parameter. |
| INSTALL_PANEL | VARCHAR(8) | Name of the installation panel where the parameter value can be changed when installing or migrating DB2. |
| INSTALL_FIELD | VARCHAR(40) | Name of the parameter on the installation panel. |
| INSTALL_LOCATION | VARCHAR(12) | Location of the parameter on the installation panel. |
| VALUE | VARCHAR(2048) NOT NULL | The value of the parameter. |
| ADDITIONAL_INFO | VARCHAR(200) | Specifies whether a parameter can be updated online. If the value is null, the stored procedure could not retrieve the information for the parameter. |

ADMIN_JOB_CANCEL stored procedure

The SYSPROC.ADMIN_JOB_CANCEL stored procedure purges or cancels a job.

Environment

GUPI

The load module for ADMIN_JOB_CANCEL, DSNADMJP, must reside in an APF-authorized library. ADMIN_JOB_CANCEL runs in a WLM-established stored procedure address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN_JOB_CANCEL, DSNADMJP, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMJP to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_JOB_CANCEL stored procedure
- Ownership of the stored procedure
- SYSADM authority

The user specified in the *user-ID* input parameter of the SQL CALL statement also needs authorization from an external security system, such as RACF, in order to perform the requested operation.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶CALL SYSPROC.ADMIN_JOB_CANCEL ( user-ID , password , processing-option , job-ID ,  
  NULL NULL )  
▶▶return-code , message )▶▶
```

Option descriptions

user-ID

Specifies the user ID under which the job is canceled or purged.

If *user-ID* is NULL, *password* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see Defining servers to process users without passwords or password phrases.

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

processing-option

Identifies the type of command to invoke. Possible values are:

- 1 Cancel a job.
- 2 Purge a job.

This is an input parameter of type INTEGER and cannot be null.

job-ID

Specifies the job ID of the job to be canceled or purged. Acceptable formats are:

- Jnnnnnnnn
- JOBnnnnnn

where *n* is a digit between 0 and 9. For example: JOB01035

Both Jnnnnnnnn and JOBnnnnnn must be exactly 8 characters in length.

This is an input parameter of type CHAR(8) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_JOB_CANCEL:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
/***** DB2 Host Variables *****/
EXEC SQL BEGIN DECLARE SECTION;

/* SYSPROC.ADMIN_JOB_CANCEL parameters */
char      userid[129];           /* User ID */
short int ind_userid;           /* Indicator variable */
char      password[25];         /* Password */
short int ind_password;        /* Indicator variable */
long int  procopt;              /* Processing option */
short int ind_procopt;         /* Indicator variable */
char      jobid[9];             /* Job ID */
short int ind_jobid;           /* Indicator variable */
long int  retcd;               /* Return code */
short int ind_retcd;           /* Indicator variable */
char      errmsg[1332];         /* Error message */
short int ind_errmsg;          /* Indicator variable */
EXEC SQL END DECLARE SECTION;

/*****
/* Assign values to input parameters to purge a job
/* Set the indicator variables to 0 for non-null input parameters */
*****/
strcpy(userid, "USRT001");
ind_userid = 0;
strcpy(password, "NICETEST");
ind_password = 0;
procopt = 2;
ind_procopt = 0;
strcpy(jobid, "JOB00105");
ind_jobid = 0;

/*****
/* Call stored procedure SYSPROC.ADMIN_JOB_CANCEL
*****/
EXEC SQL CALL SYSPROC.ADMIN_JOB_CANCEL
              (:userid      :ind_userid,
              :password    :ind_password,
              :procopt     :ind_procopt,
```

```
|                                     :jobid   :ind_jobid,
|                                     :retcd   :ind_retcd,
|                                     :errmsg  :ind_errmsg);
|
|        return(retcd);
|    }
```

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 822:

- *return-code*
- *message*

ADMIN_JOB_FETCH stored procedure

The SYSPROC.ADMIN_JOB_FETCH stored procedure retrieves SYSOUT from JES spool and returns the SYSOUT.

Environment

GUPI

The load module for ADMIN_JOB_FETCH, DSNADMJF, must reside in an APF-authorized library. ADMIN_JOB_FETCH runs in a WLM-established stored procedure address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN_JOB_FETCH, DSNADMJF, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMJF to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMJF
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_JOB_FETCH ( ( user-ID , password , job-ID , return-code ,  
                                NULL      NULL      )  
message )
```

Option descriptions

user-ID

Specifies the user ID under which SYSOUT is retrieved.

If *user-ID* is NULL, *password* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.

- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see Defining servers to process users without passwords or password phrases.

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

job-ID

Specifies the JES2 or JES3 job ID whose SYSOUT data sets are to be retrieved.

This is an input parameter of type CHAR(8) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0** The call completed successfully.
- 12** The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_JOB_FETCH:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_JOB_FETCH parameters */
  char      userid[129];          /* User ID */
  short int ind_userid;          /* Indicator variable */
  char      password[25];        /* Password */
  short int ind_password;        /* Indicator variable */
  char      jobid[9];            /* Job ID */
  short int ind_jobid;           /* Indicator variable */
  long int  retcd;               /* Return code */
  short int ind_retcd;           /* Indicator variable */
  char      errmsg[1332];        /* Error message */
  short int ind_errmsg;          /* Indicator variable */

  /* Result set locators */
  volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

  /* Result set row */
  long int  rownum;              /* Sequence number of the
  /* table row */
  char      text[4097];          /* A row in SYSOUT data set */
  EXEC SQL END DECLARE SECTION;

  /*****
  /* Assign values to input parameters to fetch the SYSOUT of a job */
  /* Set the indicator variables to 0 for non-null input parameters */
  *****/
  strcpy(userid, "USRT001");
  ind_userid = 0;
  strcpy(password, "NICETEST");
  ind_password = 0;
  strcpy(jobid, "JOB00100");
  ind_jobid = 0;

  /*****
  /* Call stored procedure SYSPROC.ADMIN_JOB_FETCH */
  *****/
  EXEC SQL CALL SYSPROC.ADMIN_JOB_FETCH
              (:userid      :ind_userid,
              :password     :ind_password,
              :jobid        :ind_jobid,
              :retcd        :ind_retcd,
              :errmsg        :ind_errmsg);

  /*****
  /* Retrieve result set when the SQLCODE from the call is +446,
  /* which indicates that result sets were returned */
  *****/
  if (SQLCODE == +446) /* Result sets were returned */
  {
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
          WITH PROCEDURE SYSPROC.ADMIN_JOB_FETCH;
```

```

/* Associate a cursor with the result set          */
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

/* Perform fetches using C1 to retrieve all rows from the */
/* result set                                           */
EXEC SQL FETCH C1 INTO :rownum, :text;
while(SQLCODE==0)
{
  EXEC SQL FETCH C1 INTO :rownum, :text;
}

EXEC SQL CLOSE C1;
}

return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 826:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the data from the JES-managed SYSOUT data set that belong to the job ID specified in the input parameter *job-ID*.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.JES_SYSOUT:

Table 118. Result set row for ADMIN_JOB_FETCH result set

| Column name | Data type | Contents |
|-------------|---------------|----------------------------------|
| ROWNUM | INTEGER | Sequence number of the table row |
| TEXT | VARCHAR(4096) | A record in the SYSOUT data set |

ADMIN_JOB_QUERY stored procedure

The SYSPROC.ADMIN_JOB_QUERY stored procedure displays the status and completion information about a job.

Environment

GUPI

The load module for ADMIN_JOB_QUERY, DSNADMJQ, must reside in an APF-authorized library. ADMIN_JOB_QUERY runs in a WLM-established stored procedure address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN_JOB_QUERY, DSNADMJQ, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMJQ to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_JOB_QUERY stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►►CALL SYSPROC.ADMIN_JOB_QUERY( ( user-ID , password , job-ID , status , max-RC ,  
                                NULL      NULL      )  
►►completion-type , system-abend-code , user-abend-code , return-code , message )►►
```

Option descriptions

user-ID

Specifies the user ID under which the job is queried.

If *user-ID* is NULL, *password* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space

does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see Defining servers to process users without passwords or password phrases.

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

job-ID

Specifies the job ID of the job being queried. Acceptable formats are:

- Jnnnnnnn
- JOBnnnnnn

where *n* is a digit between 0 and 9. For example: JOB01035

Both Jnnnnnnn and JOBnnnnnn must be exactly 8 characters in length.

This is an input parameter of type CHAR(8) and cannot be null.

status

Identifies the current status of the job. Possible values are:

- 1 Job received, but not yet run (INPUT).
- 2 Job running (ACTIVE).
- 3 Job finished and has output to be printed or retrieved (OUTPUT).
- 4 Job not found.
- 5 Job in an unknown phase.

This is an output parameter of type INTEGER.

max-RC

Provides the job completion code.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

completion-type

Identifies the job's completion type. Possible values are:

- 0 No completion information is available.
- 1 Job ended normally.
- 2 Job ended by completion code.
- 3 Job had a JCL error.
- 4 Job was canceled.
- 5 Job terminated abnormally.
- 6 Converter terminated abnormally while processing the job.
- 7 Job failed security checks.
- 8 Job failed in end-of-memory .

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

The *completion-type* information is the last six bits in the field STTRMXRC of the IAZSSST mapping macro. This information is returned via SSI 80. For additional information, see the discussion of the SSST macro in *z/OS MVS Data Areas*.

This is an output parameter of type INTEGER.

system-abend-code

Returns the system abend code if an abnormal termination occurs.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

user-abend-code

Returns the user abend code if an abnormal termination occurs.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 4 The job was not found, or the job status is unknown.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_JOB_QUERY:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_JOB_QUERY parameters */
    char      userid[129];          /* User ID */
    short int ind_userid;          /* Indicator variable */
    char      password[25];        /* Password */
    short int ind_password;        /* Indicator variable */
    char      jobid[9];            /* Job ID */
    short int ind_jobid;           /* Indicator variable */
    long int  stat;                /* Job status */
    short int ind_stat;            /* Indicator variable */
    long int  maxrc;               /* Job maxcc */
    short int ind_maxrc;           /* Indicator variable */
    long int  comptype;            /* Job completion type */
    short int ind_comptype;        /* Indicator variable */
    long int  sabndcd;             /* System abend code */
    short int ind_sabndcd;         /* Indicator variable */
    long int  uabndcd;             /* User abend code */
    short int ind_uabndcd;         /* Indicator variable */
    long int  retcd;               /* Return code */
    short int ind_retcd;           /* Indicator variable */
    char      errmsg[132];         /* Error message */
    short int ind_errmsg;          /* Indicator variable */
    EXEC SQL END DECLARE SECTION;

    /***** Assign values to input parameters to query the status and
    /* completion code of a job
    /* Set the indicator variables to 0 for non-null input parameters */
    *****/
    strcpy(userid, "USRT001");
    ind_userid = 0;
    strcpy(password, "NICETEST");
    ind_password = 0;
    strcpy(jobid, "JOB00111");
    ind_jobid = 0;

    /***** Call stored procedure SYSPROC.ADMIN_JOB_QUERY *****/
    EXEC SQL CALL SYSPROC.ADMIN_JOB_QUERY
                (:userid   :ind_userid,
                 :password :ind_password,
                 :jobid    :ind_jobid,
                 :stat     :ind_stat,
                 :maxrc    :ind_maxrc,
                 :comptype :ind_comptype,
                 :sabndcd  :ind_sabndcd,
                 :uabndcd  :ind_uabndcd,
                 :retcd    :ind_retcd,
```

```
|                                     :errmsg   :ind_errmsg);  
|  
|         return(retcd);  
|     }  
|
```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 830:

- *status*
- *max-RC*
- *completion-type*
- *system-abend-code*
- *user-abend-code*
- *return-code*
- *message*

ADMIN_JOB_SUBMIT stored procedure

The SYSPROC.ADMIN_JOB_SUBMIT stored procedure submits a job to a JES2 or JES3 system.

Environment

ADMIN_JOB_SUBMIT runs in a WLM-established stored procedure address space.

The load module for ADMIN_JOB_SUBMIT, DSNADMJS, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMJS to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMJS
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

Option descriptions

user-ID

Specifies the user ID under which the job is submitted.

If *user-ID* is NULL, *password* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid

SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see Defining servers to process users without passwords or password phrases.

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

job-ID

Identifies the JES2 or JES3 job ID of the submitted job.

This is an output parameter of type CHAR(8).

return-code

Provides the return code from the stored procedure. Possible values are:

- | | |
|-----------|---|
| 0 | The call completed successfully. |
| 12 | The call did not complete successfully. The <i>message</i> output parameter contains messages describing the error. |

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Additional input

In addition to the input parameters, the stored procedure submits the job's JCL from the created global temporary table SYSIBM.JOB_JCL for execution.

The following table shows the format of the created global temporary table SYSIBM.JOB_JCL:

Table 119. Additional input for the ADMIN_JOB_SUBMIT stored procedure

| Column name | Data type | Contents |
|-------------|-------------|--|
| ROWNUM | INTEGER | Sequence number of the table row, from 1 to <i>n</i> |
| STMT | VARCHAR(80) | A JCL statement |

Example

The following C language sample shows how to invoke ADMIN_JOB_SUBMIT:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_JOB_SUBMIT parameters */
    char    userid[129];          /* User ID */
    short int ind_userid;        /* Indicator variable */
    char    password[25];        /* Password */
    short int ind_password;      /* Indicator variable */
    char    jobid[9];            /* Job ID */
    short int ind_jobid;         /* Indicator variable */
    long int retcd;              /* Return code */
    short int ind_retcd;         /* Indicator variable */
    char    errmsg[1332];        /* Error message */
    short int ind_errmsg;        /* Indicator variable */

    /* Temporary table SYSIBM.JOB_JCL columns */
    long int rownum;             /* Sequence number of the */
    /* table row */
    char    stmt[81];            /* JCL statement */
    EXEC SQL END DECLARE SECTION;

    /***** */
    /* Create the JCL job to be submitted for execution */
    /***** */
    char jclstmt[12][50] = {
        "//IEBCOPY JOB ,CLASS=K,MSGCLASS=H,MSGLEVEL=(1,1)",
        "//STEP010 EXEC PGM=IEBCOPY",
        "//SYSPRINT DD SYSOUT=*",
        "//SYSUT3 DD SPACE=(TRK,(1,1)),UNIT=SYSDA",
        "//SYSUT4 DD SPACE=(TRK,(1,1)),UNIT=SYSDA",
        "/*",
        "//DDI1 DD DSN=USER.DEV.LOADLIB1,DISP=SHR",
        "//DDO1 DD DSN=USER.DEV.LOADLIB2,DISP=SHR",
        "//SYSIN DD *",
        " COPY OUTDD=DDO1,INDD=DDI1",
        "/*",
        "/*"
    };
    int i = 0; /* loop counter */

    /***** */
    /* Assign values to input parameters */
    /*
```

```

/* Set the indicator variables to 0 for non-null input parameters */
/*****/
strcpy(userid, "USRT001");
ind_userid = 0;
strcpy(password, "NICETEST");
ind_password = 0;

/*****/
/* Clear temporary table SYSIBM.JOB_JCL */
/*****/
EXEC SQL DELETE FROM SYSIBM.JOB_JCL;

/*****/
/* Insert the JCL job into the temporary table SYSIBM.JOB_JCL */
/*****/
for (i = 0; i < 12; i++)
{
    rownum = i+1;
    strcpy(stmt, jclstmt[i]);
    EXEC SQL INSERT INTO SYSIBM.JOB_JCL
        ( ROWNUM, STMT)
        VALUES (:rownum, :stmt);
};

/*****/
/* Call stored procedure SYSPROC.ADMIN_JOB_SUBMIT */
/*****/
EXEC SQL CALL SYSPROC.ADMIN_JOB_SUBMIT
    (:userid      :ind_userid,
     :password    :ind_password,
     :jobid       :ind_jobid,
     :retcd       :ind_retcd,
     :errmsg      :ind_errmsg);

    return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 835:

- *job-ID*
- *return-code*
- *message*

ADMIN_TASK_ADD stored procedure

The SYSPROC.ADMIN_TASK_ADD stored procedure adds a task to the task list of the administrative task scheduler.

GUIP

Environment

ADMIN_TASK_ADD runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2.

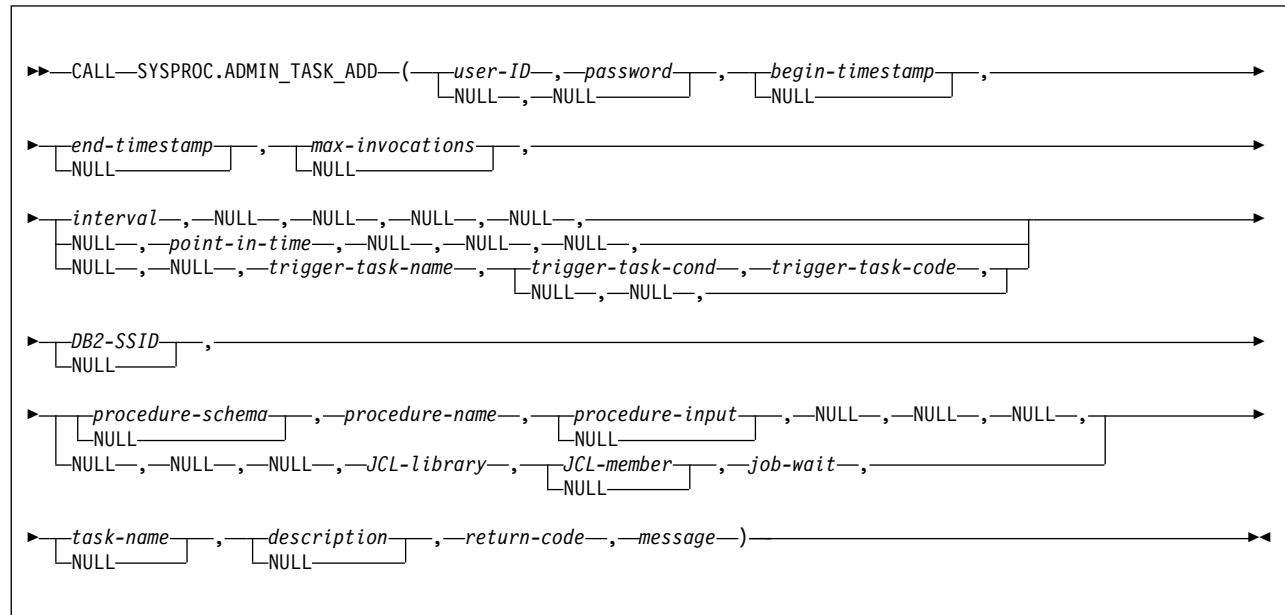

Authorization

Anyone who can execute this DB2 stored procedure is allowed to add a task.

The user who calls this stored procedure must have MONITOR1 privilege.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

Option descriptions

user-ID

Specifies the user ID under which the task execution is performed.

If this parameter is set to NULL, task execution is performed with the default authorization ID associated with the administrative task scheduler instead.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

Recommendation: Have the application that invokes this stored procedure pass an encrypted single-use password called a *passticket*.

This is an input parameter of type VARCHAR(24). This parameter is NULL only when *user-ID* is set to NULL, and must be NULL when *user-ID* is NULL.

begin-timestamp

Specifies when a task can first begin execution. When task execution begins depends on how this and other parameters are set:

Non-null value for *begin-timestamp*

At *begin-timestamp*

The task execution begins at *begin-timestamp* if *point-in-time* and *trigger-task-name* are NULL.

Next point in time defined at or after *begin-timestamp*

The task execution begins at the next point in time defined at or after *begin-timestamp* if *point-in-time* is non-null.

When *trigger-task-name* completes at or after *begin-timestamp*

The task execution begins the next time that *trigger-task-name* completes at or after *begin-timestamp*.

Null value for *begin-timestamp*

Immediately

The task execution begins immediately if *point-in-time* and *trigger-task-name* are NULL.

Next point in time defined

The task execution begins at the next point in time defined if *point-in-time* is non-null.

When *trigger-task-name* completes

The task execution begins the next time that *trigger-task-name* completes.

The value of this parameter cannot be in the past, and it cannot be later than *end-timestamp*.

This is an input parameter of type **TIMESTAMP**.

end-timestamp

Specifies when a task can last begin execution. If this parameter is set to NULL, then the task can continue to execute as scheduled indefinitely.

The value of this parameter cannot be in the past, and it cannot be earlier than *begin-timestamp*.

This is an input parameter of type **TIMESTAMP**.

max-invocations

Specifies the maximum number of executions allowed for a task. This value applies to all schedules: triggered by events, recurring by time interval, and recurring by points in time. If this parameter is set to NULL, then there is no limit to the number of times this task can execute.

For tasks that execute only one time, *max-invocations* must be set to 1 and *interval*, *point-in-time* and *trigger-task-name* must be NULL.

If both *end-timestamp* and *max-invocations* are specified, the first limit reached takes precedence. That is, if *end-timestamp* is reached, even though the number of task executions so far has not reached *max-invocations*, the task will not be executed again. If *max-invocations* have occurred, the task will not be executed again even if *end-timestamp* is not reached.

This is an input parameter of type INTEGER.

interval

Defines a duration in minutes between two executions of a repetitive regular task. The first execution occurs at *begin-timestamp*. If this parameter is set to NULL, the task is not regularly executed. If this parameter contains a non-null value, the parameters *point-in-time* and *trigger-task-name* must be set to NULL.

This is an input parameter of type INTEGER.

point-in-time

Defines one or more points in time when a task is executed. If this parameter is set to NULL, the task is not scheduled at fixed points in time. If this parameter contains a non-null value, the parameters *interval* and *trigger-task-name* must be set to NULL.

The *point-in-time* string uses the UNIX cron format. The format contains the following pieces of information separated by blanks: given minute or minutes, given hour or hours, given day or days of the month, given month or months of the year, and given day or days of the week. For each part, you can specify one or several values, ranges, and so forth.

This is an input parameter of type VARCHAR(400).

trigger-task-name

Specifies the name of the task which, when its execution is complete, will trigger the execution of this task.

Task names of DB2START and DB2STOP are reserved for DB2 stop and start events respectively. Those events are handled by the scheduler associated with the DB2 subsystem that is starting or stopping.

If this parameter is set to NULL, the execution of this task will not be triggered by another task. If this parameter contains a non-null value, the parameters *interval* and *point-in-time* must be set to NULL.

This is an input parameter of type VARCHAR(128).

trigger-task-cond

Specifies the type of comparison to be made to the return code after the execution of task *trigger-task-name*. Possible values are:

- GT Greater than
- GE Greater than or equal to
- EQ Equal to
- LT Less than
- LE Less than or equal to
- NE Not equal to

If this parameter is set to NULL, the task execution is triggered without considering the return code of task *trigger-task-name*. This parameter must be set to NULL if *trigger-task-name* is set to NULL or is either DB2START or DB2STOP.

This is an input parameter of type CHAR(2).

trigger-task-code

Specifies the return code from executing *trigger-task-name*.

If the execution of this task is triggered by a stored procedure, *trigger-task-code* contains the SQLCODE that must be returned by the triggering stored procedure in order for this task to execute.

If the execution of this task is triggered by a JCL job, *trigger-task-code* contains the MAXRC that must be returned by the triggering job in order for this task to execute.

To find out what the MAXRC or SQLCODE of a task is after execution, invoke the user-defined function DSNADM. ADMIN_TASK_STATUS returns these information in the columns MAXRC and SQLCODE.

The following restrictions apply to the value of *trigger-task-code*:

- If *trigger-task-cond* is null, then *trigger-task-code* must also be null.
- If *trigger-task-cond* is non-null, then *trigger-task-code* must also be non-null.

If *trigger-task-cond* and *trigger-task-code* are not null, they are used to test the return code from executing *trigger-task-name* to determine whether to execute this task or not.

For example, if *trigger-task-cond* is set to "GE" and *trigger-task-code* is set to "8", then this task will execute if and only if the previous execution of *trigger-task-name* returned a MAXRC (for a JCL job) or an SQLCODE (for a stored procedure) greater than or equal to 8.

This is an input parameter of type INTEGER.

DB2-SSID

Specifies the DB2 subsystem ID whose associated scheduler should execute the task.

This parameter is used in a data sharing environment where, for example different DB2 members have different configurations and executing the task relies on a certain environment. However, specifying a value in *DB2-SSID* will prevent schedulers of other members to execute the task, so that the task can only be executed as long as the scheduler of *DB2-SSID* is running.

For a task being triggered by a DB2 start or DB2 stop event in *trigger-task-name*, specifying a value in *DB2-SSID* will let the task be executed only when the named subsystem is starting and stopping. If no value is given, each member that starts or stops will trigger a local execution of the task, provided that the executions are serialized.

If this parameter is set to NULL, any scheduler can execute the task.

This is an input parameter of type VARCHAR(4).

procedure-schema

Specifies the schema of the DB2 stored procedure this task will execute. If this parameter is set to NULL, DB2 uses a default schema. This parameter must be set to NULL if *procedure-name* is set to NULL.

This is an input parameter of type VARCHAR(128).

procedure-name

Specifies the name of the DB2 stored procedure this task will execute. If this parameter is set to NULL, no stored procedure will be called. In this case, a JCL job must be specified.

This is an input parameter of type VARCHAR(128).

procedure-input

Specifies the input parameters of the DB2 stored procedure this task will execute. This parameter must contain a DB2 SELECT statement that returns one row of data. The returned values will be passed as parameter to the stored procedure.

If this parameter is set to NULL, no parameters are passed to the stored procedure. This parameter must be set to NULL when *procedure-name* is set to NULL.

This is an input parameter of type VARCHAR(4096).

JCL-library

Specifies the name of the data set where the JCL job to be executed is saved.

If this parameter is set to NULL, no JCL job will be executed. In this case, a stored procedure must be specified.

This is an input parameter of type VARCHAR(44).

JCL-member

Specifies the name of the library member where JCL job to be executed is saved.

If this parameter is set to NULL, the data set specified in *JCL-library* must be sequential and contain the JCL job to be executed. This parameter must be set to NULL if *JCL-library* is set to NULL.

This is an input parameter of type VARCHAR(8).

job-wait

Specifies whether the job can be executed synchronously or not. This parameter can only be set to NULL if *JCL-library* is set to NULL. Otherwise, it must be one of the following values:

NO Asynchronous execution

YES Synchronous execution

PURGE

Synchronous execution after which the job status in z/OS is purged

This is an input parameter of type VARCHAR(8).

task-name

Specifies a unique name assigned to the task.

A unique task name is returned when the task is created with a NULL *task-name* value. This name is of the format "TASK_ID_XXXX" where XXXX is 0001 for the first task named, 0002 for the second task, and so forth.

The following task names are reserved and cannot be given as the value of *task-name*:

- Names starting with "TASK_ID_"
- DB2START
- DB2STOP

This is an input-output parameter of type VARCHAR(128).

description

Specifies a description assigned to the task.

This is an input parameter of type VARCHAR(128).

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following Java sample shows how to invoke ADMIN_TASK_ADD:

```
import java.sql.CallableStatement;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.Timestamp;
import java.sql.Types;

Connection con = DriverManager.getConnection
("jdbc:db2://myserver:myport/mydatabase", "myuser", "mypassword");
CallableStatement callStmt = con.prepareCall
("CALL SYSPROC.ADMIN_TASK_ADD("
+ "? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? , ? )");
// provide the authid
callStmt.setString(1, "myexecuser");
// provide the password
callStmt.setString(2, "myexecpwd");
// set the start time to now
callStmt.setNull(3, Types.TIMESTAMP);
// no end time
callStmt.setNull(4, Types.TIMESTAMP);
// set the max invocation
callStmt.setInt(5, 1);
// This is a non recurrent task
callStmt.setNull(6, Types.INTEGER);
callStmt.setNull(7, Types.VARCHAR);
callStmt.setNull(8, Types.VARCHAR);
callStmt.setNull(9, Types.CHAR);
callStmt.setNull(10, Types.INTEGER);
callStmt.setNull(11, Types.VARCHAR);
// provide the stored procedure schema
callStmt.setString(12, "MYSCHEMA");
// provide the name of the stored procedure to be executed
callStmt.setString(13, "MYPROC");
// provide the stored procedure input parameter
callStmt.setString(14, "SELECT 1 FROM SYSIBM.SYSDUMMY1");
// This is not a JCL job
callStmt.setNull(15, Types.VARCHAR);
callStmt.setNull(16, Types.VARCHAR);
callStmt.setNull(17, Types.VARCHAR);
// add a new task with task name mytask
callStmt.setString(18, "mytask");
callStmt.registerOutParameter(18, Types.VARCHAR);
// provide the task description
callStmt.setString(19, "MY DESCRIPTION");
// register output parameters for error management
callStmt.registerOutParameter(20, Types.INTEGER);
```

```

| callStmt.registerOutParameter(21, Types.VARCHAR);
| // execute the statement
| callStmt.execute();
| // manage the return code
| if ( callStmt.getInt(20) == 0 )
| {
|     System.out.print("\nSuccessfully added task " + callStmt.getString(18));
| }
| else
| {
|     System.out.print("\nError code and message are: "
|         + callStmt.getInt(20) + "/" + callStmt.getString(21));
| }

```

Output

The output of this stored procedure is the task name, *task-name* and the following output parameters, which are described in “Option descriptions” on page 839:

- *return-code*
- *message*

Related tasks:

 [Adding a task \(DB2 Administration Guide\)](#)

ADMIN_TASK_CANCEL stored procedure

The ADMIN_TASK_CANCEL stored procedure attempts to stop the execution of a task that is currently running.

For a task that is running, the stored procedure cancels the DB2 thread or the JES job that the task runs in, and issues a return code of 0 (zero). If the task is not running or if cancellation of the task cannot be initiated, the stored procedure issues a return code of 12.

Not all tasks can be canceled as requested. Only the administrative task scheduler that currently executes the task can cancel a JCL task or a stored procedure task. Call the ADMIN_TASK_CANCEL stored procedure on the DB2 subsystem that is specified in the DB2_SSID column of the task status.

Environment

ADMIN_TASK_CANCEL runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2.

Authorization

To call this stored procedure, you must have MONITOR1 privilege.

Anyone with SYSOPR, SYSCTRL, or SYSADM authority can call this stored procedure on any task. Anyone who has EXECUTE authority on this stored procedure can call it on tasks that they added. If you try to cancel the execution of a task that was added by a different user, an error is returned in the output.

The task is canceled under the authorization context of the user that currently calls the ADMIN_TASK_CANCEL stored procedure, as defined in CURRENT SQLID. To cancel a stored procedure task, you must have authority to call the DB2 command **CANCEL THREAD**. To cancel a JCL task, you must have UPDATE authority in RACF on the resource MVS.CANCEL.JOB.jobname.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►►—CALL—ADMIN_TASK_CANCEL—(—task-name—,—return-code—,—message—)—►►
```

Option descriptions

task-name

Specifies the unique name of the task whose execution you want to cancel. This is an input parameter of type VARCHAR(128).

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by DB2 might follow the stored procedure messages.

This is an output parameter of type VARCHAR(1331).

Output

This stored procedure has the following output parameters, which are described in “Option descriptions” on page 846:

- *return-code*
- *message*

Related tasks:

 [Stopping the execution of a task \(DB2 Administration Guide\)](#)

ADMIN_TASK_REMOVE stored procedure

The SYSPROC.ADMIN_TASK_REMOVE stored procedure removes a task from the task list of the administrative task scheduler.

If the task is running, the task continues to execute until completion and is not removed from the task list. If other tasks depend on the execution of the task that is to be removed, the task is not removed from the task list of the administrative task scheduler.

GUPI

Environment

See the recommended environment in installation job DSNTIJRA.

Authorization

Users with SYSOPR, SYSCTRL, or SYSADM authority can remove any task. Other users who have EXECUTE authority on this stored procedure can remove tasks that they added. Attempting to remove a task that was added by a different user returns an error in the output.

The user who calls this stored procedure must have MONITOR1 privilege.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_TASK_REMOVE (task-name, return-code, message)
```

Option descriptions

task-name

Specifies the name of the task to be removed from the task list of the administrative task scheduler.

This is an input parameter of type VARCHAR(128) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure.

The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by DB2 might follow the stored procedure messages.

This is an output parameter of type VARCHAR(1331).

Example

The following Java sample shows how to invoke ADMIN_TASK_REMOVE:

```
import java.sql.CallableStatement;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.Timestamp;
import java.sql.Types;

Connection con =
    DriverManager.getConnection("jdbc:db2://myserver:myport/mydatabase",
        "myuser", "mypassword");
CallableStatement callStmt =
    con.prepareCall("CALL SYSPROC.ADMIN_TASK_REMOVE(?, ?, ?)");
// provide the id of the task to be removed
callStmt.setString(1, "mytask");
// register output parameters for error management
callStmt.registerOutParameter(2, Types.INTEGER);
callStmt.registerOutParameter(3, Types.VARCHAR);
// execute the statement callStmt.execute();
// manage the return code
if ( callStmt.getInt(2) == 0 )
{
    System.out.print("\nSuccessfully removed task "
        + callStmt.getString(1));
}
else
{
    System.out.print("\nError code and message are: "
        + callStmt.getInt(2) + "/"
        + callStmt.getString(3));
}
```

Output

The output of this stored procedure includes the following output parameters, which are described in “Option descriptions” on page 848:

- *return-code*
- *message*

ADMIN_TASK_UPDATE stored procedure

The ADMIN_TASK_UPDATE stored procedure updates the schedule of a task that is in the task list for the administrative task scheduler. If the task that you want to update is running, the changes go into effect after the current execution finishes.

You must specify all of the parameters for the task that you want to modify the schedule for, even if those parameters have not changed since you created the task by using the ADMIN_TASK_ADD stored procedure.

GUPI

Environment

ADMIN_TASK_UPDATE runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2.

Authorization

To call this stored procedure, you must have MONITOR1 privilege.

Anyone with SYSOPR, SYSCTRL, or SYSADM authority can update any task. Anyone who has EXECUTE authority on this stored procedure can update tasks that they added. If you try to update a task that was added by a different user, an error is returned in the output.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶—CALL—ADMIN_TASK_UPDATE—(—task-name—,—description—,——————▶  
▶—begin_timestamp—,—end_timestamp—,—max_invocations—,—interval—,—————▶  
▶—point-in-time—,—trigger-task-name—,—trigger-task-cond—,—————▶  
▶—trigger-task-code—,—DB2-SSID—,—return-code—,—message—)————▶▶
```

Option descriptions

task-name

Specifies the unique name of the task that is to be updated in the task list of the administrative task scheduler. This is an input parameter of type VARCHAR(128).

description

Specifies a description that is assigned to the task. This is an input parameter of type VARCHAR(128).

begin_timestamp

An input argument of type TIMESTAMP that specifies the earliest time a task can begin execution. The value of this argument cannot be in the past, and it cannot be later than *end_timestamp*.

When the execution of a task begins depends on how this parameter and other parameters are defined:

Non-null value for *begin-timestamp*

At *begin-timestamp*

The task execution begins at *begin-timestamp* if *point-in-time* and *trigger-task-name* are NULL.

Interval in minutes after the last execution of this task

The task execution begins at *begin-timestamp*.

Next point in time defined at or after *begin-timestamp*

The task execution begins at the next point in time that is defined at or after *begin-timestamp* if *point-in-time* is non-null.

When *trigger-task-name* completes after *begin-timestamp*

The task execution begins the next time that *trigger-task-name* completes or after *begin-timestamp*.

Null value for *begin-timestamp*

Immediately

The task execution begins immediately if *point-in-time* and *trigger-task-name* are NULL.

Interval in minutes after the last execution of this task

The task execution begins at *begin-timestamp*.

Next point in time defined

The task execution begins at the next point in time that is defined if *point-in-time* is non-null.

When *trigger-task-name* completes

The task execution begins the next time that *trigger-task-name* completes.

end-timestamp

An input argument of type `TIMESTAMP` that specifies the latest time that a task can begin execution. The value of this argument cannot be in the past, and it cannot be earlier than *begin_timestamp*. If the argument is NULL, the task can continue to execute as scheduled indefinitely.

An executing task will not be interrupted at its *end_timestamp* value.

max-invocations

Specifies the maximum number of executions that are allowed for the modified task. This value applies to all scheduled executions, whether they be triggered by events, recurring by time interval, or recurring by points in time. This value includes the previous executions of the modified task.

If *max-invocations* is smaller than, or equal to the number of times that the task has already been executed, the task will not be executed again. To modify the task to run again, you must specify *max-invocations* as NULL, or as a value that is greater than the current number of times that the task has already been executed. In addition, if *max-invocations*, *interval*, *point-in-time*, and *trigger-task-name* are NULL, the task executes only one more time.

If this parameter is set to NULL, there is no limit to the number of times this task can execute. If both *end-timestamp* and *max-invocations* are specified, the first limit that is reached takes precedence. For example, if the value for *end-timestamp* is reached, the task will not be executed again, even if the number of task executions has not reached the value of *max-invocations*.

Likewise, if the value for *max-invocations* is reached, the task will not be executed again, even if the value for *end-timestamp* is not reached.

This is an input parameter of type INTEGER.

interval

Defines a time duration between two executions of a repetitive regular task. The first execution occurs at *begin-timestamp*.

If this parameter is set to NULL, the task is not regularly executed. If this parameter contains a non-null value, you must set the *point-in-time* and *trigger-task-name* parameters to NULL.

This is an input parameter of type INTEGER.

point-in-time

Specifies one or more points in time when a task is executed. If this parameter is set to NULL, the task is not scheduled at fixed points in time. If this parameter contains a non-null value, the parameters *interval* and *trigger-task-name* must be set to NULL.

The *point-in-time* string uses the UNIX cron format. This format contains the following pieces of information separated by blank spaces:

- Given minute or minutes
- Given hour or hours
- Given day or days of the month
- Given month or months of the year
- Given day or days of the week

For each part, you can specify one or several values and ranges.

This is an input parameter of type VARCHAR(400).

trigger-task-name

Specifies the name of the task that, upon completion, will trigger the execution of this task. The task names DB2START and DB2STOP are reserved for DB2 startup and shutdown events. Those events are handled by the scheduler that is associated with the DB2 subsystem that is starting or stopping.

If this parameter is set to NULL, the execution of this task will not be triggered by another task. If this parameter contains a non-null value, the parameters *interval* and *point-in-time* must be NULL.

This is an input parameter of type VARCHAR(128).

trigger-task-cond

Specifies the type of comparison to be made to the return code after the execution of task *trigger-task-name*. Possible values are:

- GT** Greater than
- GE** Greater than or equal to
- EQ** Equal to
- LT** Less than
- LE** Less than or equal to
- NE** Not equal to

If this parameter is set to NULL, the task execution is triggered without considering the return code of task *trigger-task-name*. This parameter must be set to NULL if *trigger-task-name* is set to NULL or is either DB2START or DB2STOP.

This is an input parameter of type CHAR(2).

trigger-task-code

Specifies the return code from executing the task *trigger-task-name*.

If the execution of this task is triggered by a stored procedure, *trigger-task-code* contains the SQLCODE that must be returned by the triggering stored procedure in order for this task to execute.

If the execution of this task is triggered by a JCL job, *trigger-task-code* contains the MAXRC that must be returned by the triggering job in order for this task to execute.

To find out what the MAXRC or SQLCODE of a task is after execution, invoking the user-defined function DSNADM.ADMIN_TASK_STATUS returns this information in the columns MAXRC and SQLCODE.

The following restrictions apply to the value of *trigger-task-code*:

- If *trigger-task-cond* is NULL, then *trigger-task-code* must also be NULL.
- If *trigger-task-cond* is non-null, then *trigger-task-code* must also be non-null.

If *trigger-task-cond* and *trigger-task-code* are not set to NULL, they are used to test the return code from executing *trigger-task-name* to determine whether to execute this task. For example, if *trigger-task-cond* is set to "GE", and *trigger-task-code* is set to "8", then this task will execute only if the previous execution of *trigger-task-name* returned a MAXRC (for a JCL job) or an SQLCODE (for a stored procedure) that is greater than or equal to 8.

This is an input parameter of type INTEGER.

DB2-SSID

Specifies the DB2 subsystem ID whose associated scheduler should execute the task.

This parameter is used in a data sharing environment, where different DB2 members have different configurations and executing the task relies on a certain environment. However, specifying a value in *DB2-SSID* will prevent the administrative task schedulers of other members from executing the task. Therefore, the task can be executed only if the administrative task scheduler of *DB2-SSID* is running.

For a task that is being triggered by a DB2 start or DB2 stop event in *trigger-task-name*, specifying a value in *DB2-SSID* causes the task to be executed only when the named DB2 subsystem is starting or stopping. If no value is given, each member that starts or stops will trigger a local execution of the task, if the executions are serialized.

If this parameter is set to NULL, any administrative task scheduler can execute the task.

This is an input parameter of type VARCHAR(4).

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by DB2 might follow the stored procedure messages.

This is an output parameter of type VARCHAR(1331).

Output

This stored procedure has the following output parameters, which are described in “Option descriptions” on page 850:

- *return-code*
- *message*

ADMIN_UPDATE_SYSPARM stored procedure

The SYSPROC.ADMIN_UPDATE_SYSPARM stored procedure changes the value of one or more subsystem parameters which are located in one of these macros: DSN6SPRM, DSN6ARVP, DSN6LOGP, DSN6SYSP, DSN6FAC, and DSN6GRP.

GUPI

ADMIN_UPDATE_SYSPARM builds a subsystem parameters load module and, if requested by the user, loads it into storage by issuing the DB2 command SET SYSPARM with the LOAD option. If all of the parameters that are modified cannot be updated online, SET SYSPARM LOAD is not run.

Environment

ADMIN_UPDATE_SYSPARM must run in a WLM-established stored procedure address space. At least one library in this WLM procedure STEPLIB DD concatenation must not be APF-authorized. TCB=1 is also required. By default, the SQL procedure processor (DSNTPSMP) and ADMIN_UPDATE_SYSPARM share the WLM environment.

Authorization

To issue the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_UPDATE_SYSPARM stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_UPDATE_SYSPARM stored procedure internally calls the following stored procedures:

- ADMIN_COMMAND_DB2, to issue the DB2 DISPLAY GROUP and SET SYSPARM commands
- ADMIN_INFO_SYSPARM, to obtain the current subsystem parameters settings

The owner of the package or plan that contains the CALL ADMIN_UPDATE_SYSPARM statement must also have the following authority and privilege:

- Authorization to run these stored procedures and issue the specified DB2 commands
- MONITOR1 privilege

The ADMIN_UPDATE_SYSPARM caller also needs authorization from an external security system, such as RACF, to complete the following tasks:

- Browse the data set that is pointed to by the ZPMDFLTS DD statement in the WLM startup procedure
- Update the library where the sample JCL that assembles and link-edits the new subsystem parameters load module will be saved
- Update the load module library where the new subsystem parameters load module will be saved

Syntax

The following syntax diagram shows the SQL CALL statement for running this stored procedure:

Option descriptions

db2_member

Specifies the name of a single data sharing group member on which the SET SYSPARM command with the LOAD option is to be run.

If this parameter is null, the SET SYSPARM command is run on the connected DB2 subsystem.

This is an input parameter of type VARCHAR(8).

In a data-sharing environment, some additional requirements apply. For example, if ADMIN_UPDATE_SYSPARM is run on member A to update a subsystem parameter setting on member B, the WLM environment for ADMIN_UPDATE_SYSPARM needs to be able to access the following resources:

- The library that is used to store the new subsystem parameters load module for member B
- The library that is used to store the sample JCL that assembles and link-edits the new subsystem parameters load module for member B.

parameter_module

Specifies the name of the subsystem parameters load module that has the new values assembled and linked into it.

If this parameter is null, the default is the last named subsystem parameters load module that was loaded into storage.

This is an input parameter of type VARCHAR(8).

module_library

Specifies the name of the library where the stored procedure saves the new subsystem parameters load module. If the *load* parameter is set to 'Y', this module library is also used to load the subsystem parameters load module.

If this parameter is null, the default is the SDSNEXIT_NAME library that is specified in the data set that is pointed to by the ZPMDFLTS DD statement in the WLM startup procedure.

This is an input parameter of type VARCHAR(44).

source_library

Specifies the name of the library where the stored procedure saves a sample JCL that assembles and link-edits the new subsystem parameters load module offline. This JCL contains the updated subsystem parameters.

This parameter must specify a partitioned data set (PDS) or a partitioned data set extended (PDSE) with record format (RECFM) F or FB and record length (LRECL) 80.

If this parameter is null, the default is the SRCLIB_NAME library that is specified in the data set that is pointed to by the ZPMDFLTS DD statement in the WLM startup procedure.

The name of the library member where the sample JCL is saved is the same as the library member name of the new subsystem parameters load module. This JCL is not used by ADMIN_UPDATE_SYSPARM to assemble and link-edit the subsystem parameters load module. This JCL is generated and saved so that it can be referenced for any subsequent subsystem parameter modification by the DB2 system programmer.

This is an input parameter of type VARCHAR(44).

load

Specifies whether to issue SET SYSPARM with the LOAD option to load the new subsystem parameters load module into storage. Possible values are:

Y Issue SET SYSPARM with the LOAD option.

N Do not issue SET SYSPARM with the LOAD option.

If this parameter is null, the default is 'N'.

If at least one modified subsystem parameter cannot be changed online or if SET SYSPARM synchronous support is not available (PM40501 is not installed), SET SYSPARM with the LOAD option is not issued even if *load* is set to 'Y'. Instead, a value of 4 is returned in the output parameter *return-code*.

This is an input parameter of type CHAR(1).

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

Message DSNA658I is written to the JES SYSLOG, but not to the JES job log of *ssnm*MSTR.

The following information is returned in the result table of the stored procedure:

- Message DSNA658I
- Assembler listing
- Link-edit listing
- SET SYSPARM command with LOAD option messages (if applicable)

4

- The stored procedure modified the value of at least one DB2 subsystem parameter. However, the stored procedure did not complete a required or requested action after the subsystem parameter values were changed:
 - The SET SYSPARM command with the LOAD option was not issued because of one of the following reasons:
 - At least one modified subsystem parameter cannot be changed online.
 - Synchronous processing of the SET SYSPARM command is not supported.

- The stored procedure encountered an error while it was writing a DSN658I message to the JES SYSLOG.

For more information, see message DSN666I.

- The cleanup processing that occurs when the stored procedure completes successfully did not complete successfully because of one of the following reasons:
 - The backup of the library member that the stored procedure replaced with the new JCL that assembles and link-edits the new subsystem parameters load module was not deleted.
 - The backup of the library member that the stored procedure replaced with the new subsystem parameters load module was not deleted.

For more information, see message DSN658I.

Message DSN658I is written to the JES SYSLOG (if applicable), but not to the JES job log of *ssnmMSTR*.

The following information is returned in the result table of the stored procedure:

- Message DSN658I
- Message DSN666I or DSN658I (depending on which reason caused *return_code* to be set to 4)
- Assembler listing
- Link-edit listing
- SET SYSPARM command with LOAD option messages (if applicable)

12

The call did not complete successfully.

Message DSN669I is returned in the result set.

Objects that were replaced by the stored procedure are restored. For more information, see “Backup copies” on page 859.

If the new subsystem parameters load module was loaded into storage, the stored procedure will reload the subsystem parameters load module that was loaded previously.

995

The call did not complete successfully because of a REXX programming violation.

Message DSN669I is displayed in the WLM job log.

996

The call did not complete successfully because of one of the following global temporary table failures:

- The created global temporary table SYSIBM.UPDSYSPARM_MSG does not exist.
- The user does not have authority to use the created global temporary table SYSIBM.UPDSYSPARM_MSG.

Message DSN669I is displayed in the WLM job.

997

The call did not complete successfully because of one of the following DSNREXX failures:

- The DSNREXX package was not found.
- DB2 cannot access a DSNREXX environment. DB2 REXX Language Support is not available.

Message DSNA669I is displayed in the WLM job log.

998 There was an error that occurred while the result set was being returned.

The result set is written to the WLM job log. However, the assembler listing and the link-edit listing are not written to the WLM job log unless the call did not complete successfully because the assembly failed or the link-edit failed. If the assembly failed, the assembler listing is written to the WLM job log. If the link-edit failed, the link-edit listing is written to the WLM job log.

This is an output parameter of type INTEGER.

ADMIN_UPDATE_SYSPARM input row

In addition to the input parameters, the stored procedure reads from the created global temporary table SYSIBM.SYSPARM_SETTINGS to retrieve the subsystem parameters to be modified. The following table shows the format of the created global temporary table SYSIBM.SYSPARM_SETTINGS:

Table 120. Format of the input subsystem parameters table

| Column name | Data type | Contents |
|-------------|---------------|---|
| ROWNUM | INTEGER | A unique positive identifier for each row. |
| | NOT NULL | When you insert multiple rows, increment ROWNUM by 1, starting at 0 for every insert. |
| MACRO | VARCHAR(8) | Macro that contains the DB2 subsystem parameter to be modified. |
| | NOT NULL | Valid values are: DSN6SPRM, DSN6ARVP, DSN6LOGP, DSN6SYSP, DSN6FAC, and DSN6GRP. |
| PARAMETER | VARCHAR(40) | Name of the DB2 subsystem parameter to be modified. |
| | NOT NULL | |
| NEW_VALUE | VARCHAR(2048) | New value of the DB2 subsystem parameter to be modified. This parameter is not validated by the stored procedure. |
| | NOT NULL | |

Backup copies

In the subsystem parameters load module library, if a member exists with the same name as the name of the new subsystem parameters load module, the stored procedure creates a backup copy of this member before it is replaced with the new subsystem parameters load module. Similarly, in the JCL source library, if a member exists with the same name as the name of the sample JCL that assembles and link-edits the new subsystem parameters load module, the stored procedure creates a backup copy of this member before it is replaced with the sample JCL. The backup copy is created in the same library where the member it replaced resides, and its name has the following format: *ssnmhmmm*, where:

ssnm The *ssid* of the DB2 subsystem where the subsystem parameter changes are implemented.

hh The hour the stored procedure started execution (00-23).

mm The minute the stored procedure started execution (00-59).

When the stored procedure completes successfully, the backup copies are deleted.

When the stored procedure does not complete successfully, the stored procedure restores the replaced members to their state before the stored procedure was run by using their respective backup copies. If the stored procedure is unable to restore a member from the backup, the user must complete this task.

If a member exists with the same name as the backup copy the stored procedure is creating, the stored procedure terminates processing.

Example

The following C language example shows how to invoke ADMIN_UPDATE_SYSPARM.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;
int main( int argc, char *argv[] ) /* Argument count and list */
{
/***** DB2 Host Variables *****/
EXEC SQL BEGIN DECLARE SECTION;
/* SYSPROC.ADMIN_UPDATE_SYSPARM parameters */
char pmember[9]; /* Data sharing group member */
char pmodname[9]; /* Subsystem parameters load */
/* module */
char pmodlib[45]; /* Subsystem parameters load */
/* module library */
char psrclib[45]; /* Sample JCL library */
char pload[2]; /* Perform -SET SYSPARM with */
/* LOAD option */
long int pretcd; /* Return code */
short int ind_pmember; /* Indicator variable */
short int ind_pmodname; /* Indicator variable */
short int ind_pmodlib; /* Indicator variable */
short int ind_psrclib; /* Indicator variable */
short int ind_pload; /* Indicator variable */
short int ind_pretcd; /* Indicator variable */
/* Temporary table SYSIBM.SYSPARM_SETTINGS columns */
long int zrownum; /* Sequence number of the */
/* table row */
char zmacro[9]; /* Macro containing the */
/* subsystem parameter to be */
/* modified */
char zparam[41]; /* Name of the subsystem */
/* parameter to be modified */
char znew_value[2049]; /* New value of the subsystem */
/* parameter to be modified */
/* Result set locators */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;
/* Result set row */
long int rownum; /* Sequence number of the */
/* table row */
char type[13]; /* Type of information found */
/* in corresponding TEXT col */
char text[1332]; /* Message or listing */
}
```

```

EXEC SQL END DECLARE SECTION;
/*****
/* Clear temporary table SYSIBM.SYSPARM_SETTINGS */
/*****
EXEC SQL DELETE FROM SYSIBM.SYSPARM_SETTINGS;
/*****
/* Clear temporary table SYSIBM.UPDSYSPARM_MSG */
/*****
EXEC SQL DELETE FROM SYSIBM.UPDSYSPARM_MSG;
/*****
/* Insert the subsystem parameters to be modified into the
/* created global temporary table SYSIBM.SYSPARM_SETTINGS */
/*****
zrownum = 1;
strcpy(zmacro, "DSN6FAC");
strcpy(zparam, "IDHTOIN");
strcpy(znew_value, "600");
EXEC SQL INSERT INTO SYSIBM.SYSPARM_SETTINGS
      ( ROWNUM, MACRO, PARAMETER, NEW_VALUE)
      VALUES (:zrownum, :zmacro, :zparam, :znew_value);
/*****
/* Set procedure input parameters */
/*****
ind_pmember = -1;
ind_pmodname = -1;
ind_pmodlib = -1;
ind_psrclib = -1;
ind_pload = -1;
ind_pretcd = -1;

/*****
/* Call stored procedure SYSPROC.ADMIN_UPDATE_SYSPARM */
/*****
EXEC SQL CALL SYSPROC.ADMIN_UPDATE_SYSPARM (
      :pmember :ind_pmember,
      :pmodname :ind_pmodname,
      :pmodlib :ind_pmodlib,
      :psrclib :ind_psrclib,
      :pload :ind_pload,
      :pretcd :ind_pretcd);
/*****
/* Retrieve result set when the SQLCODE from the call is +446, */
/* which indicates that result sets were returned */
/*****
if (SQLCODE == +446) /* Result sets were returned */
{
/* Establish a link between the result set and its locator */
EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
      WITH PROCEDURE SYSPROC.ADMIN_UPDATE_SYSPARM;
/* Associate a cursor with the result set */
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
/* Perform fetches using C1 to retrieve all rows from the */
/* result set */
EXEC SQL FETCH C1 INTO :rownum, :type, :text;
while(SQLCODE==0)
{
EXEC SQL FETCH C1 INTO :rownum, :type, :text;
}

EXEC SQL CLOSE C1;
}
return;
}

```

Output

This stored procedure returns the **return-code** output parameter, which is described in “Option descriptions” on page 856.

In addition to the preceding output, the stored procedure returns one result set that contains successful, warning, or error messages that are generated by the stored procedure. The stored procedure also returns (if applicable) the assembler and link-edit listings, and output from the SET SYSPARM with LOAD option command.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.UPDSYSPARM_MSG:

Table 121. Result set row for the ADMIN_UPDATE_SYSPARM result set

| Column name | Data type | Contents |
|-------------|---------------------------|---|
| ROWNUM | INTEGER NOT NULL | Sequence number of the table row, from 1 to <i>n</i> . |
| TYPE | VARCHAR(12) NOT NULL | Type of information that is found in the corresponding TEXT column. Possible values are: <ul style="list-style-type: none">• DSNADMUZ - TEXT is a message that is internally generated by the stored procedure, such as DSNA658I, DSNA666I, DSNA669I, or DSNA685I.• ASSEMBLE - TEXT is a line from the assembler listing.• LINK - TEXT is a line from the link-edit listing.• LOAD - TEXT is a line from the message that is returned by SET SYSPARM with the LOAD option command when this command was issued to load the new subsystem parameters load module into storage.• BACKLINK - TEXT is a line from the link-edit listing which was generated when the linkage editor was executed to back up the subsystem parameters load module that was being replaced.• RESTLINK - TEXT is a line from the link-edit listing which was generated when the linkage editor was executed to restore the subsystem parameters load module which the stored procedure replaced with the new subsystem parameters load module.• LOAD2 - TEXT is a line from the message that is returned by SET SYSPARM with the LOAD option command when this command was issued during restore processing to load the current subsystem parameters load module into storage. |
| TEXT | VARCHAR(1331) NOT NULL | <ul style="list-style-type: none">• A successful, warning, or error message that is generated by the stored procedure. If the message is longer than 1331 characters, the message continues in the next result set row.• Assembler listing• Link-edit listing• Output from SET SYSPARM with the LOAD option command |

ADMIN_UTL_EXECUTE stored procedure

ADMIN_UTL_EXECUTE is a stored procedure that solves alerts stored in the SYSIBM.SYSAUTOALERTS catalog table within the maintenance windows defined by the SYSIBM.SYSAUTOTIMEWINDOWS catalog table. It is required for the use of autonomic statistics.

GUPI

The ADMIN_UTL_EXECUTE stored procedure performs the following tasks:

- Determines the order for resolving alerts.
- Within the maintenance windows that are defined in the SYSIBM.SYSAUTOTIMEWINDOWS catalog table, calls the ADMIN_UTL_SCHEDULE stored procedure to resolve alerts by executing the RUNSTATS utility. For each alert, the options for RUNSTATS are provided in the SYSIBM.SYSAUTOALERTS table.
- Updates the status and output of resolved alerts in the SYSIBM.SYSAUTOALERTS table.
- If the administrative task scheduler is used, reschedules its own execution for the next maintenance window when unsolved alerts remain.

Environment

The ADMIN_UTL_EXECUTE stored procedure runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2. The ADMIN_UTL_EXECUTE stored procedures call ADMIN_UTL_SCHEDULE stored procedures to execute a RUNSTATS operations. The ADMIN_UTL_EXECUTE stored procedure is required and must be installed and executable.

It calls the DSNADM.ADMIN_TASK_LIST and the SYSPROC.ADMIN_TASK_UPDATE routines.

Authorization required

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have DBADM or higher authority.

Syntax

```
▶▶CALL SYSPROC.ADMIN_UTL_EXECUTE(—execute-options—,—history-entry-id—,—  
▶—return-code—,—message—)
```

Option descriptions

The ADMIN_UTL_EXECUTE stored procedure has the following options:

execute-options

A string representation of the configuration parameters for the

ADMIN_UTL_EXECUTE stored procedure, consisting of "NAME=VALUE" pairs separated by commas. Optional parameters include:

STAND-ALONE

NO The ADMIN_UTL_EXECUTE stored procedure interacts with the administrative task scheduler to its own next execution. NO is the default value.

YES The ADMIN_UTL_EXECUTE stored procedure does not interact with the administrative task scheduler.

execute-options is an input parameter of type VARCHAR(30000).

history-entry-id

Provides a unique identifier that can be used to read the execution log written in the SYSIBM.SYSAUTORUNS_HIST table when the SYSPROC.ADMIN_UTL_EXECUTE stored procedure executes. This is an output parameter of type BIGINT.

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

4 The call completed successfully. The message output parameter contains a warning message.

12 The call did not complete successfully. The message output parameter contains messages describing the error.

The *return-code* parameter is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure.

The *message* parameter is an output parameter of type VARCHAR(1331)

Example

The following example shows a Java call to the ADMIN_UTL_EXECUTE stored procedure:

```
long taskid = 7;
CallableStatement callStmt =
con.prepareCall("CALL SYSPROC.ADMIN_UTL_EXECUTE(?, ?, ?, ?)");
callStmt.setString(1, "");
callStmt.registerOutParameter(2,Types.BIGINT);
callStmt.registerOutParameter(3,Types.INTEGER);
callStmt.registerOutParameter(4,Types.LONGVARCHAR);
callStmt.execute();
if ( callStmt.getInt(3) > 0 )
{
    System.err.println("Error: " + callStmt.getString(4));
}
```

External input

The ADMIN_UTL_EXECUTE stored procedure reads additional input from the SYSIBM.SYSAUTOALERTS and SYSIBM.SYSAUTOTIMEWINDOWS catalog tables.

Output

The ADMIN_UTL_EXECUTE stored procedure returns the following output parameters:

- *history-entry-id*
- *return-code*
- *message*

The ADMIN_UTL_EXECUTE stored procedure also updates the following catalog tables:

- In the SYSIBM.SYSAUTOALERTS catalog table, the following columns are updated for each alert that is solved:
 - STARTTS
 - ENDTS
 - STATUS
 - RETURN_CODE
 - MESSAGE
 - OUTPUT
- In the SYSIBM.SYSAUTORUNS_HIST stored procedure, one row of data is added to log the activity.

Related tasks:

-  Automating statistics maintenance (DB2 Performance)
-  Specifying time windows for collecting autonomic statistics (DB2 Performance)

Related reference:

“SYSIBM.SYSAUTOALERTS table” on page 2414

ADMIN_UTL_MONITOR stored procedure

SYSPROC.ADMIN_UTL_MONITOR is an autonomic stored procedure that provides functions that enable analysis of database statistics. These functions include alerts for out-of-date, missing, or conflicting statistics, summary reports and detailed table-level reports that describe generated RUNSTATS statements. It is required for the use of autonomic statistics.

GUPI

The ADMIN_UTL_MONITOR stored procedure enables for the analysis of database statistics, by providing the following functions:

- Issuing RUNSTATS alerts for out-of-date statistics. Counters in the SYSIBM.SYSTABLESPACESTATS table are used to identify out of date statistics. Cloned table spaces, work file table spaces, and directory table spaces are excluded from AUTOSTATS processing.
- Issuing RUNSTATS alerts for missing and conflicting database statistics, including statistics for columns, column groups, and indexes.
- Generating a summary report for the number of tables analyzed and the number of RUNSTATS alerts that were generated.
- Generating detailed table-level reports for RUNSTATS commands, including explanations.
- Scheduling execution of the ADMIN_UTL_EXECUTE stored procedure in the administrative task scheduler to resolve alerts.

Environment

The ADMIN_UTL_MONITOR stored procedure runs in a WLM-established address space and uses the Resource Recovery Services attachment facility to connect to DB2. The ADMIN_UTL_MONITOR stored procedure is required and must be installed and executable.

If the stand-alone option is set to NO, the ADMIN_UTL_MONITOR stored procedure must be defined as a trusted context in RACF and must run in a specific trusted WLM environment to get a RACF PassTicket for the user that called the stored procedure. The ADMIN_UTL_MONITOR stored procedure calls the following interface routines:

- SYSPROC.ADMIN_TASK_ADD
- SYSPROC.ADMIN_TASK_REMOVE
- SYSPROC.ADMIN_TASK_UPDATE
- DSNADM.ADMIN_TASK_LIST
- DSNADM.ADMIN_TASK_STATUS

Authorization required

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have DBADM or higher authority.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking the ADMIN_UTL_MONITOR stored procedure:

```

▶▶—CALL—ADMIN_UTL_MONITOR—(—monitor-options—,—history-entry-id—,—return-code—,——————▶
▶—message—)—————▶▶

```

Option descriptions

The ADMIN_UTL_MONITOR stored procedure has the following options:

monitor-options

A string representation of the configuration parameters for the ADMIN_UTL_MONITOR stored procedure, consisting of "NAME = VALUE" pairs separated by commas. Values, including blanks, equal sign, and comma must be surrounded by single or double quotation marks. For example:

- restrict-ts='partition=1' is valid.
- restrict-ts="partition=1" is valid.
- restrict-ts=partition=1 is not valid.

Any value that contains single or double quotation marks must be surrounded by the opposite kind of quotation marks. For example: restrict-ts="DBNAME='DSNDB06'" is valid because the single quotation marks used in the value are surrounded by double quotation marks.

The following optional parameters are available:

- The following parameters specify general monitoring options:

restrict-ts

Indicates which table spaces require checking. Allowed values are strings that contain valid contents for a WHERE clause on the SYSIBM.SYSTABLESPACESTATS catalog table. For example:

```
DBNAME LIKE 'MYDB%'
```

If no restriction is specified, all table spaces are checked.

stand-alone

Whether alerts trigger the ADMIN_UTL_EXECUTE stored procedure:

NO Alerts are written and the ADMIN_UTL_EXECUTE stored procedure is called to resolve the alerts. NO is the default value.

YES Alerts are written but no call is issued to the ADMIN_UTL_EXECUTE stored procedure.

statistics-scope

Specifies the scope of the statistics for the ADMIN_UTL_MONITOR stored procedure to check:

BASIC

Out-of-date statistics are checked, such as whether RUNSTATS has been run since the last LOAD or REORG operation or whether the number and percentage of changes in a table space are greater than a defined threshold. BASIC is the default value.

PROFILE

Out-of-date statistics and the completeness of statistics are checked, including whether all statistics in the table profile have been collected.

PROFILE-CONSISTENCY

Out-of-date statistics, the completeness of statistics, and the consistency of statistics are checked.

- The following optional parameters specify a threshold and settings for the use of table-sampling by RUNSTATS.

sampling-rate

Indicates the percentage of rows that RUNSTATS samples when collecting statistics on non-indexed columns. You can specify any value from 1 through 100. When sampling-rate is not specified, AUTO is used. When a sampling-rate is not specified, the TABLESAMPLE SYSTEM AUTO option is used for RUNSTATS alerts on single-table table spaces and the SAMPLE 25 option is used for RUNSTATS alerts on multi-table table spaces.

sampling-threshold

Indicates a threshold for the absolute number of rows in a table. When the threshold is exceeded, a sampling option is recorded in the RUNSTATS alert, and that option is used later when RUNSTATS executes to resolve the alert. You can specify a positive integer. A value of 500,000 is used when sampling-threshold is not specified. The specified sampling-rate is used for all tables when you specify sampling-threshold=0.

- The following optional parameters specify thresholds for out-of-date statistics. A RUNSTATS alert might be written when a threshold is exceeded.

Table 122. Parameters for out-of-date statistics

| Option | Description | Allowed values | Default value |
|------------------|--|--|---------------|
| num-changes | Absolute number of inserted, updated, or deleted rows in a table space. A RUNSTATS alert is written when the thresholds for both num-changes and pct-changes are exceeded. | Positive integers, in the range 0 to 2,147,483,647 | 0 |
| num-mass-deletes | Absolute number of massive delete operations. A RUNSTATS alert is written when the num-mass deletes threshold is exceeded. | Positive integers, in the range 0 to 2,147,483,647 | 0 |
| pct-changes | Percentage of inserted, updated, or deleted rows in a table space. A RUNSTATS alert is written when the thresholds for both num-changes and pct-changes are exceeded. | A real number float value greater than 0.0 and less than or equal to 100.0 | 20.0 |

- The following parameters specify thresholds for inconsistent statistics. The thresholds apply only when the value of profile-consistency is specified for **statistics-scope**. A RUNSTATS alert is written when a threshold is exceeded. Each threshold is a percentage difference when related statistics are compared, as described in the following table.

Table 123. Parameters for statistics consistency thresholds

| Option | Description | Allowed values | Default value |
|--|---|---|---------------|
| colgroup-card-greater-than-superset-colgroup-card | The cardinality of a column group is greater than the cardinality of its superset column group. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| different-colgroup-card-from-coldist-and-index | The cardinalities of an index column group and a table column group that contain the same columns do not match. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| different-colgroup-card-from-indexes | The cardinalities of two index column groups that contain the same columns (independent of order) do not match. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| different-single-col-colgroup-card-from-coldist-and-index | An index first key cardinality differs from the corresponding column cardinality | A real number between 0.0 and 100.0 inclusive | 0.1 |
| different-single-col-colgroup-card-from-indexes | An index first key cardinality differs from another index first key cardinality on the same column. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| drf-greater-than-tabcard | The data repetition factor of an index on a table is greater than the cardinality of this table. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| drf-less-than-npages | The data repetition factor of an index on a table is smaller than the number of pages. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| frequency-out-of-range | A column group frequency of a table is greater than 1 or smaller than 0. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| index-fullkeycard-less-than-any-key-card | The full key cardinality of an index is smaller than the cardinality of any column that is involved with the index. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| index-fullkeycard-less-than-firstkeycard | The full key cardinality of an index is smaller than the first key cardinality of the same index | A real number between 0.0 and 100.0 inclusive | 0 |
| maximum-frequency-less-than-reciprocal-of-colgroup-card | The maximal frequency of a column group is smaller than 1 divided by the cardinality of the column group. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| number-of-frequency-records-greater-than-colgroup-card | The number of frequency records of a column group is greater than the cardinality of a column group. | A real number between 0.0 and 100.0 inclusive | 0.1 |

Table 123. Parameters for statistics consistency thresholds (continued)

| Option | Description | Allowed values | Default value |
|--|--|---|---------------|
| product-of-colcard-less-than-colgroup-card | The product of the cardinalities of the columns of a column group is smaller than the cardinality of the column group. | A real number between 0.0 and 100.0 inclusive | 0 |
| quantile-card-greater-than-colcard | The cardinality of a quantile in a column group, on a single column, is greater than the cardinality of the column. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| quantile-card-greater-than-colgroup-card | The cardinality of a quantile in a column of a table is greater than the cardinality of the same column. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| quantile-frequency-out-of-range | The cardinality of a column group quantile is smaller than 0 or greater than 1. | A real number between 0.0 and 100.0 inclusive | 0 |
| single-col-index-fullkeycard-not-equal-firstkeycard | The full key cardinality of an index, on a single column, is different from the first key cardinality. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| sum-of-frequency-greater-than-one | The sum of all frequencies of a column group of a table is greater than one. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| sum-of-histogram-frequency-greater-than-one | The sum of all histogram frequencies of a column group is greater than one. | A real number between 0.0 and 100.0 inclusive | 0 |
| sum-of-histogram-greater-than-colcard | The sum of histogram cardinalities of a column of column group is greater than 1. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| sum-of-histogram-greater-than-colgroup-card | The sum of histogram cardinalities of a column group is greater than the cardinality of the same column group. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| tabcard-less-than-colcard | A table cardinality is smaller than the cardinality of a column in the same table | A real number between 0.0 and 100.0 inclusive | 0.1 |
| tabcard-less-than-colgroup-card | A table cardinality is smaller than the cardinality of a column group for this same table. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| tabcard-less-than-index-keycard | The cardinality of a table is smaller than the cardinality of an index for this table. | A real number between 0.0 and 100.0 inclusive | 0.1 |
| tabcard-not-equal-unique-index-fullkeycard | The cardinality of a table is different from the cardinality of a unique index on that table. | A real number between 0.0 and 100.0 inclusive | 0.1 |

monitor-options is an input parameter of type VARCHAR(30000).

history-entry-id

Returns a unique identifier that can be used to read the execution log in the SYSIBM.SYSAUTORUNS_HIST table and the alerts in the SYSIBM.SYSAUTOALERTS table when the SYSPROC.ADMIN_UTL_MONITOR stored procedure executes. This is an output parameter of type BIGINT.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 4 The call completed successfully. The message output parameter contains a warning message.
- 12 The call did not complete successfully. The message output parameter contains messages describing the error.

The *return-code* parameter is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure.

The *message* parameter is an output parameter of type VARCHAR(1331)

Example

The following example shows a Java call to the ADMIN_UTL_MONITOR stored procedure:

```
CallableStatement callStmt =
con.prepareCall("CALL SYSPROC.ADMIN_UTL_MONITOR(?, ?, ?, ?)");
callStmt.setString(1, "");
callStmt.registerOutParameter(2,Types.INTEGER);
callStmt.registerOutParameter(3,Types.INTEGER);
callStmt.registerOutParameter(4,Types.LONGVARCHAR);
callStmt.execute();
if ( callStmt.getInt(3) > 0 )
{
System.err.println("Error: " + callStmt.getString(4));
}
```

External input

The ADMIN_UTL_MONITOR stored procedure reads additional input from the following catalog tables:

- SYSIBM.SYSTABLESPACESTATS
- SYSIBM.SYSTABLESPACE
- SYSIBM.SYSTABLES
- SYSIBM.SYSCOLUMNS
- SYSIBM.SYSCOLDIST
- SYSIBM.SYSINDEXES
- SYSIBM.SYSKEYS
- SYSIBM.SYSTABLES_PROFILES

Output

The ADMIN_UTL_MONITOR stored procedure returns the following output parameters:

- *history-entry-id*

- *return-code*
- *message*

The ADMIN_UTL_MONITOR stored procedure also inserts rows of data into the following catalog tables:

- In the SYSIBM.SYSAUTOALERTS catalog table, a row of data is inserted for each RUNSTATS alert issued, with values for following columns:
 - HISTORY_ENTRY_ID
 - ACTION
 - TARGET_QUALIFIER
 - TARGET_OBJECT
 - TARGET_PARTITION
 - OPTIONS
 - DURATION
 - STATUS
- In the SYSIBM.SYSTABLES_PROFILES catalog table, a row of data is inserted for each monitored table that doesn't have a profile yet, with values in the following columns:
 - SCHEMA
 - TBNAME
 - PROFILE_TYPE
 - PROFILE_MODE
 - PROFILE_TEXT
 - PROFILE_UPDATE
 - PROFILE_USED
- In the SYSIBM.SYSAUTORUNS_HIST stored procedure, one row of data is added to log the activity.

ADMIN_UTL_MODIFY stored procedure

ADMIN_UTL_MODIFY is an autonomic stored procedure that maintains the SYSIBM.SYSAUTORUNS_HIST and SYSIBM.SYSAUTOALERTS catalog tables.

GUPI

The ADMIN_UTL_MODIFY stored procedure removes all entries in the SYSIBM.SYSAUTORUNS_HIST table that are older than a configurable threshold and removes all entries in the SYSIBM.SYSAUTOALERTS table that are older than the configured threshold and are in COMPLETE state.

Environment

The ADMIN_UTL_MODIFY stored procedure runs in a WLM-established address space and uses the Resource Recovery Services attachment facility to connect to DB2. The ADMIN_UTL_MODIFY stored procedure is required and must be installed and executable.

Authorization required

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have DBADM or higher authority.

Syntax

```
CALL ADMIN_UTL_MODIFY (—modify-options—, —history-entry-id—, —return-code—, —message—)
```

Option descriptions

The ADMIN_UTL_MODIFY stored procedure has the following options:

modify-options

A string representation of the configuration parameters for the ADMIN_UTL_MODIFY stored procedure, consisting of "NAME = VALUE" pairs separated by commas. Optional parameters include:

HISTORY-DAYS

Number of days after that entries in the SYSIBM.SYSAUTORUNS_HIST table and completed alerts in SYSIBM.SYSAUTOALERTS table are deleted. The value be a positive number of days.

modify-options is an input parameter of type VARCHAR(30000)

history-entry-id

Returns a unique identifier that can be used to read the execution log in the SYSIBM.SYSAUTORUNS_HIST table when the SYSPROC.ADMIN_UTL_MODIFY stored procedure executes. This is an output parameter of type BIGINT.

return-code

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 4 The call completed successfully. The message output parameter contains a warning message.
- 12 The call did not complete successfully. The message output parameter contains messages describing the error.

The *return-code* parameter is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure.

The *message* parameter is an output parameter of type VARCHAR(1331)

Example

The following example shows a Java call to the ADMIN_UTL_MODIFY stored procedure:

```
String options = "history-days=90";
CallableStatement callStmt =
con.prepareCall("CALL SYSPROC.ADMIN_UTL_MODIFY(?, ?, ?, ?)");
callStmt.setString(1, options);
callStmt.registerOutParameter(2,Types.INTEGER);
callStmt.registerOutParameter(3,Types.INTEGER);
callStmt.registerOutParameter(4,Types.LONGVARCHAR);
callStmt.execute();
if ( callStmt.getInt(3) > 0 )
{
    System.err.println("Error: " + callStmt.getString(4));
}
```

External input

The AUTO_UTL_MODIFY stored procedure reads additional input from the SYSIBM.SYSAUTORUNS_HIST and SYSIBM.SYSAUTOALERTS catalog tables.

Output

The ADMIN_UTL_MONITOR stored procedure returns the following output parameters:

- *history-entry-id*
- *return-code*
- *message*

The ADMIN_UTL_MODIFY stored procedure also deletes rows from the SYSIBM.SYSAUTORUNS_HIST and SYSIBM.SYSAUTOALERTS tables and inserts a single row in to the SYSIBM.SYSAUTORUNS_HIST table to log its activity.

Related tasks:

Automating statistics maintenance (DB2 Performance)

Scheduling log and alert history cleanup for autonomic statistics (DB2 Performance)

ADMIN_UTL_SCHEDULE stored procedure

The SYSPROC.ADMIN_UTL_SCHEDULE stored procedure executes utilities in parallel.

Environment

ADMIN_UTL_SCHEDULE runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMUM
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_UTL_SCHEDULE stored procedure internally calls the following stored procedures:

- ADMIN_COMMAND_DB2, to execute the DB2 DISPLAY UTILITY command
- ADMIN_INFO_SSID, to obtain the subsystem ID of the connected DB2 subsystem
- ADMIN_UTL_SORT, to sort objects into parallel execution units
- DSNUTILU, to run the requested utilities

The owner of the package or plan that contains the CALL ADMIN_UTL_SCHEDULE statement must also have the authorization required to execute these stored procedures and run the requested utilities.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_UTL_SCHEDULE ( ( max-parallel , optimize-workload , stop-condition , utility-ID-stem , shutdown-duration , number-of-objects , utilities-run , highest-return-code , parallel-tasks , return-code , message ) )
```

The diagram shows the syntax for the CALL statement. It starts with 'CALL SYSPROC.ADMIN_UTL_SCHEDULE' followed by an opening parenthesis. The parameters are grouped into three lines: 1) *max-parallel*, *optimize-workload* (with a NULL placeholder below it), and a comma. 2) *stop-condition* (with a NULL placeholder below it), *utility-ID-stem*, *shutdown-duration* (with a NULL placeholder below it), a comma, and *number-of-objects*. 3) *utilities-run*, a comma, *highest-return-code*, a comma, *parallel-tasks*, a comma, *return-code*, a comma, and *message*. The statement ends with a closing parenthesis.

Option descriptions

max-parallel

Specifies the maximum number of parallel threads that may be started. The actual number may be lower than the requested number based on the optimizing sort result. Possible values are 1 to 99.

This is an input parameter of type SMALLINT and cannot be null.

optimize-workload

Specifies whether the parallel utility executions should be sorted to achieve shortest overall execution time. Possible values are:

NO or null

The workload is not to be sorted.

YES The workload is to be sorted.

This is an input parameter of type VARCHAR(8). The default value is NO.

stop-condition

Specifies the utility execution condition after which ADMIN_UTL_SCHEDULE will not continue starting new utility executions in parallel, but will wait until all currently running utilities have completed and will then return to the caller. Possible values are:

AUTHORIZ or null

No new utility executions will be started after one of the currently running utilities has encountered a return code from DSNUTILU of 12 or higher.

WARNING

No new utility executions will be started after one of the currently running utilities has encountered a return code from DSNUTILU of 4 or higher.

ERROR

No new utility executions will be started after one of the currently running utilities has encountered a return code from DSNUTILU of 8 or higher.

This is an input parameter of type VARCHAR(8). The default value is AUTHORIZ.

utility-ID-stem

Specifies the first part of the utility ID of a utility execution in a parallel thread. The complete utility ID is dynamically created in the form *utility-ID-stem* followed by *TT* followed by *NNNNNN*, where:

TT The zero-padded number of the subtask executing the utility

NNNNNN

A consecutive number of utilities executed in a subtask.

For example, utilityidstem02000005 is the fifth utility execution that has been processed by the second subtask.

This is an input parameter of type VARCHAR(8) and cannot be null.

shutdown-duration

Specifies the elapsed time in seconds that ADMIN_UTL_SCHEDULE will allow utility executions before a shutdown is initiated. When a shutdown is initiated, current utility executions can run to completion, and no new utility will be started. Possible values are:

null A shutdown will not be performed.

1 to 999999999999999

A shutdown will be performed after this many seconds.

This is an input parameter of type FLOAT(8). The default value is null.

number-of-objects

As an input parameter, this specifies the number of utility executions and their sorting objects that were passed in the SYSIBM.UTILITY_OBJECTS table. Possible values are 1 to 999999.

As an output parameter, this specifies the number of objects that were passed in SYSIBM.UTILITY_OBJECTS table that are found in the DB2 catalog.

This is an input and output parameter of type INTEGER and cannot be null.

utilities-run

Indicates the number of actual utility executions.

This is an output parameter of type INTEGER.

highest-return-code

Indicates the highest return code from DSNUTILU for all utility executions.

This is an output parameter of type INTEGER.

parallel-tasks

Indicates the actual number of parallel tasks that were started to execute the utility in parallel.

This is an output parameter of type SMALLINT.

return-code

Provides the return code from the stored procedure. Possible values are:

0 All parallel utility executions ran successfully.

4 The statistics for one or more sorting objects have not been gathered in the catalog.

12 An ADMIN_UTL_SCHEDULE error occurred or all the objects passed in the SYSIBM.UTILITY_OBJECTS table are not found in the DB2 catalog. The *message* parameter contains details.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Additional input

In addition to the input parameters, the stored procedure reads from the created global temporary tables SYSIBM.UTILITY_OBJECTS and SYSIBM.UTILITY_STMT.

The stored procedure reads objects for utility execution from SYSIBM.UTILITY_OBJECTS. The following table shows the format of the created global temporary table SYSIBM.UTILITY_OBJECTS:

Table 124. Format of the input objects

| Column name | Data type | Contents |
|-------------|--------------|--|
| OBJECTID | INTEGER | A unique positive identifier for the object the utility execution is associated with. When you insert multiple rows, increment OBJECTID by 1, starting at 0 for every insert. |
| STMTID | INTEGER | A statement row in SYSIBM.UTILITY_STMT |
| TYPE | VARCHAR(10) | Object type: <ul style="list-style-type: none"> • TABLESPACE • INDEXSPACE • TABLE • INDEX • STOGROUP |
| QUALIFIER | VARCHAR(128) | Qualifier (database or creator) of the object in NAME, empty or null for STOGROUP. If the qualifier is not provided and the type of the object is TABLESPACE or INDEXSPACE, then the default database is DSNDB04. If the object is of the type TABLE or INDEX, the schema is the current SQL authorization ID. |
| NAME | VARCHAR(128) | Unqualified name of the object. NAME cannot be null. If the object no longer exists, it will be ignored and the corresponding utility will not be executed. |
| PART | SMALLINT | Partition number of the object for which the utility will be invoked. Null or 0 if the object is not partitioned. |
| RESTART | VARCHAR(8) | Restart parameter of DSNUUTILU |

Table 124. Format of the input objects (continued)

| Column name | Data type | Contents |
|--------------|-------------|---|
| UTILITY_NAME | VARCHAR(20) | Utility name. UTILITY_NAME cannot be null. Recommendation: Sort objects for the same utility. Possible values are: <ul style="list-style-type: none"> • CHECK DATA • CHECK INDEX • CHECK LOB • COPY • COPYTOCOPY • DIAGNOSE • LOAD • MERGECOPY • MODIFY RECOVERY • MODIFY STATISTICS • QUIESCE • REBUILD INDEX • RECOVER • REORG INDEX • REORG LOB • REORG TABLESPACE • REPAIR • REPORT RECOVERY • REPORT TABLESPACESET • RUNSTATS INDEX • RUNSTATS TABLESPACE • STOSPACE • UNLOAD |

The stored procedure reads the corresponding utility statements from SYSIBM.UTILITY_STMT. The following table shows the format of the created global temporary table SYSIBM.UTILITY_STMT:

Table 125. Format of the utility statements

| Column name | Data type | Contents |
|-------------|-----------|---|
| STMTID | INTEGER | A unique positive identifier for a single utility execution statement |

Table 125. Format of the utility statements (continued)

| Column name | Data type | Contents |
|-------------|---------------|---|
| STMTSEQ | INTEGER | If a utility statement exceeds 4000 characters, it can be split up and inserted into SYSIBM.UTILITY_STMT with the sequence starting at 0, and then being incremented with every insert. During the actual execution, the statement pieces are concatenated without any separation characters or blanks in between. |
| UTSTMT | VARCHAR(4000) | A utility statement or part of a utility statement. A placeholder &OBJECT. can be used to be replaced by the object name passed in SYSIBM.UTILITY_OBJECTS. A placeholder &THDINDEX. can be used to be replaced by the current thread index (01-99) of the utility being executed. You can use this when running REORG with SHRLEVEL CHANGE in parallel, so that you can specify a different mapping table for each thread of the utility execution. |

Example

The following C language sample shows how to invoke ADMIN_UTL_SCHEDULE:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_UTL_SCHEDULE parameters */
    short int maxparallel; /* Max parallel */
    short int ind_maxparallel; /* Indicator variable */
    char optimizeworkload[9]; /* Optimize workload */
    short int ind_optimizeworkload; /* Indicator variable */
    char stoponcond[9]; /* Stop on condition */

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 877:

- *number-of-objects*
- *utilities-run*
- *highest-return-code*
- *parallel-tasks*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns two results sets.

The first result set is returned in the created global temporary table SYSIBM.UTILITY_SYSPRINT and contains the output from the individual utility executions. The following table shows the format of the created global temporary table SYSIBM.UTILITY_SYSPRINT:

Table 126. Result set row for first ADMIN_UTL_SCHEDULE result set

| Column name | Data type | Contents |
|-------------|--------------|---|
| OBJECTID | INTEGER | A unique positive identifier for the object the utility execution is associated with |
| TEXTSEQ | INTEGER | Sequence number of utility execution output statements for the object whose unique identifier is specified in the OBJECTID column |
| TEXT | VARCHAR(254) | A utility execution output statement |

The second result set is returned in the created global temporary table SYSIBM.UTILITY_RETCODE and contains the return code for each of the individual DSNUTILU executions. The following table shows the format of the output created global temporary table SYSIBM.UTILITY_RETCODE:

Table 127. Result set row for second ADMIN_UTL_SCHEDULE result set

| Column name | Data type | Contents |
|-------------|-----------|--|
| OBJECTID | INTEGER | A unique positive identifier for the object the utility execution is associated with |
| RETCODE | INTEGER | Return code from DSNUTILU for this utility execution |

DSNUTILU stored procedure

ADMIN_UTL_SORT stored procedure

The SYSPROC.ADMIN_UTL_SORT stored procedure sorts objects for parallel utility execution using JCL or the ADMIN_UTL_SCHEDULE stored procedure.

Environment

ADMIN_UTL_SORT runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMUS
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have SELECT authority on the following catalog tables:

- SYSIBM.SYSTABLEPART
- SYSIBM.SYSINDEXPART
- SYSIBM.SYSINDEXES
- SYSIBM.SYSTABLES

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_UTL_SORT ( max-parallel, max-per-job, optimize-workload,  
                             NULL, NULL,  
 batch-execution, number-of-objects, parallel-units, max-objects, max-sequences,  
 NULL,  
 return-code, message )
```

Option descriptions

max-parallel

Specifies the maximum number of parallel units. The actual number may be lower than the requested number based on the optimizing sort result. Possible values are: 1 to 99.

This is an input parameter of type SMALLINT and cannot be null.

| **max-per-job**

| Specifies the maximum number of steps per job for batch execution. Possible
| values are:

| **1 to 255**

| Steps per job for batch execution

| **null** Online execution

| This is an input parameter of type SMALLINT. This parameter cannot be null
| if *batch-execution* is YES.

| **optimize-workload**

| Specifies whether the parallel units should be sorted to achieve shortest overall
| execution time. Possible values are:

| **NO or null**

| The workload is not to be sorted.

| **YES** The workload is to be sorted.

| This is an input parameter of type VARCHAR(8). The default value is NO.

| **batch-execution**

| Indicates whether the objects should be sorted for online or batch (JCL)
| execution.

| **NO or null**

| The workload is for online execution.

| **YES** The workload is for batch execution.

| This is an input parameter of type VARCHAR(8). The default value is NO.

| **number-of-objects**

| As an input parameter, this specifies the number of objects that were passed in
| SYSIBM.UTILITY_SORT_OBJ. Possible values are: 1 to 999999.

| As an output parameter, this specifies the number of objects that were passed
| in SYSIBM.UTILITY_SORT_OBJ table that are found in the DB2 catalog.

| This is an input and output parameter of type INTEGER and cannot be null.

| **parallel-units**

| Indicates the number of recommended parallel units.

| This is an output parameter of type SMALLINT.

| **max-objects**

| Indicates the maximum number of objects in any parallel unit.

| This is an output parameter of type INTEGER.

| **max-sequences**

| Indicates the number of jobs in any parallel unit.

| This is an output parameter of type INTEGER.

| **return-code**

| Provides the return code from the stored procedure. Possible values are:

| **0** Sort ran successfully.

| **4** The statistics for one or more sorting objects have not been gathered in
| the catalog or the object no longer exists.

| **12** An ADMIN_UTL_SORT error occurred. The *message* parameter will
| contain details.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Additional input

In addition to the input parameters, this stored procedure reads the objects for sorting and the corresponding utility names from the created global temporary table SYSIBM.UTILITY_SORT_OBJ.

The following table shows the format of the created global temporary table SYSIBM.UTILITY_SORT_OBJ:

Table 128. Input for the ADMIN_UTL_SORT stored procedure

| Column name | Data type | Contents |
|-------------|--------------|--|
| OBJECTID | INTEGER | A unique positive identifier for the object the utility execution is associated with. When you insert multiple rows, increment OBJECTID by 1, starting at 0 for every insert. |
| TYPE | VARCHAR(10) | Object type: <ul style="list-style-type: none">• TABLESPACE• INDEXSPACE• TABLE• INDEX• STOGROUP |
| QUALIFIER | VARCHAR(128) | Qualifier (database or creator) of the object in NAME, empty or null for STOGROUP. If the qualifier is not provided and the type of the object is TABLESPACE or INDEXSPACE, then the default database is DSNDB04. If the object is of the type TABLE or INDEX, the schema is the current SQL authorization ID. If the object no longer exists, it will be ignored. |
| NAME | VARCHAR(128) | Unqualified name of the object. NAME cannot be null. |
| PART | SMALLINT | Partition number of the object for which the utility will be invoked. Null or 0 if the object is not partitioned. |

Table 128. Input for the ADMIN_UTL_SORT stored procedure (continued)

| Column name | Data type | Contents |
|--------------|-------------|---|
| UTILITY_NAME | VARCHAR(20) | <p>Utility name. UTILITY_NAME cannot be null.</p> <p>Recommendation: Sort objects for the same utility.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> • CHECK DATA • CHECK INDEX • CHECK LOB • COPY • COPYTOCOPY • DIAGNOSE • LOAD • MERGECOPY • MODIFY RECOVERY • MODIFY STATISTICS • QUIESCE • REBUILD INDEX • RECOVER • REORG INDEX • REORG LOB • REORG TABLESPACE • REPAIR • REPORT RECOVERY • REPORT TABLESPACESET • RUNSTATS INDEX • RUNSTATS TABLESPACE • STOSPACE • UNLOAD |

Example

The following C language sample shows how to invoke ADMIN_UTL_SORT:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/

}

return(retcd);
}

```

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 886:

- *number-of-objects*
- *parallel-units*
- *max-objects*
- *max-sequences*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the objects sorted into parallel execution units.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.UTILITY_SORT_OUT:

Table 129. Result set row for ADMIN_UTL_SORT result set

| Column name | Data type | Contents |
|--------------|-----------|---|
| OBJECTID | INTEGER | A unique positive identifier for the object |
| UNIT | SMALLINT | Number of parallel execution unit |
| UNIT_SEQ | INTEGER | Job sequence within parallel execution unit |
| UNIT_SEQ_POS | INTEGER | Step within job |
| EXCLUSIVE | CHAR(1) | Requires execution with nothing running in parallel |

DSNACCOR stored procedure (deprecated)

The DB2 real-time statistics stored procedure (DSNACCOR) is a sample stored procedure that makes recommendations to help you maintain your DB2 databases. The DSNACCOR stored procedure is deprecated. It is replaced by the DSNACCOX stored procedure.

PSPI

DSNACCOX provides improved recommendations enhancements, enhanced fields, improved formulas, the ability to select the formula for recommendations, and more. For more information about DSNACCOX, see “DSNACCOX stored procedure” on page 915.

You can continue to use the DSNACCOR stored procedure. However, DSNACCOR does not contain the enhancements that are found in the DSNACCOX stored procedure. DSNACCOR stored procedure is replaced by the DSNACCOX stored procedure.

In particular, DSNACCOR performs the following actions:

- Recommends when you should reorganize, image copy, or update statistics for table spaces or index spaces
- Indicates when a data set has exceeded a specified threshold for the number of extents that it occupies.
- Indicates whether objects are in a restricted state

DSNACCOR uses data from the SYSIBM.SYSTABLESPACESTATS and SYSIBM.SYSSYSINDEXSPACESTATS real-time statistics tables to make its recommendations. DSNACCOR provides its recommendations in a result set.

DSNACCOR uses the set of criteria that are shown in “DSNACCOR formulas for recommending actions” on page 903 to evaluate table spaces and index spaces. By default, DSNACCOR evaluates **all** table spaces and index spaces in the subsystem that have entries in the real-time statistics tables. However, you can override this default through input parameters.

Important information about DSNACCOR recommendations:

- DSNACCOR makes recommendations based on general formulas that require input from the user about the maintenance policies for a subsystem. These recommendations might not be accurate for every installation.
- If the real-time statistics tables contain information for only a small percentage of your DB2 subsystem, the recommendations that DSNACCOR makes might not be accurate for the entire subsystem.
- Before you perform any action that DSNACCOR recommends, ensure that the object for which DSNACCOR makes the recommendation is available, and that the recommended action can be performed on that object. For example, before you can perform an image copy on an index, the index must have the COPY YES attribute.

Environment

DSNACCOR must run in a WLM-established stored procedure address space. The DSNWLM_GENERAL core WLM environment is a suitable environment for this stored procedure.

DSNACCOR is installed and configured by installation job DSNTIJRT, which binds the package for DSNACCOR with isolation UR to avoid lock contention.

Authorization required

To execute the CALL DSNACCOR statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

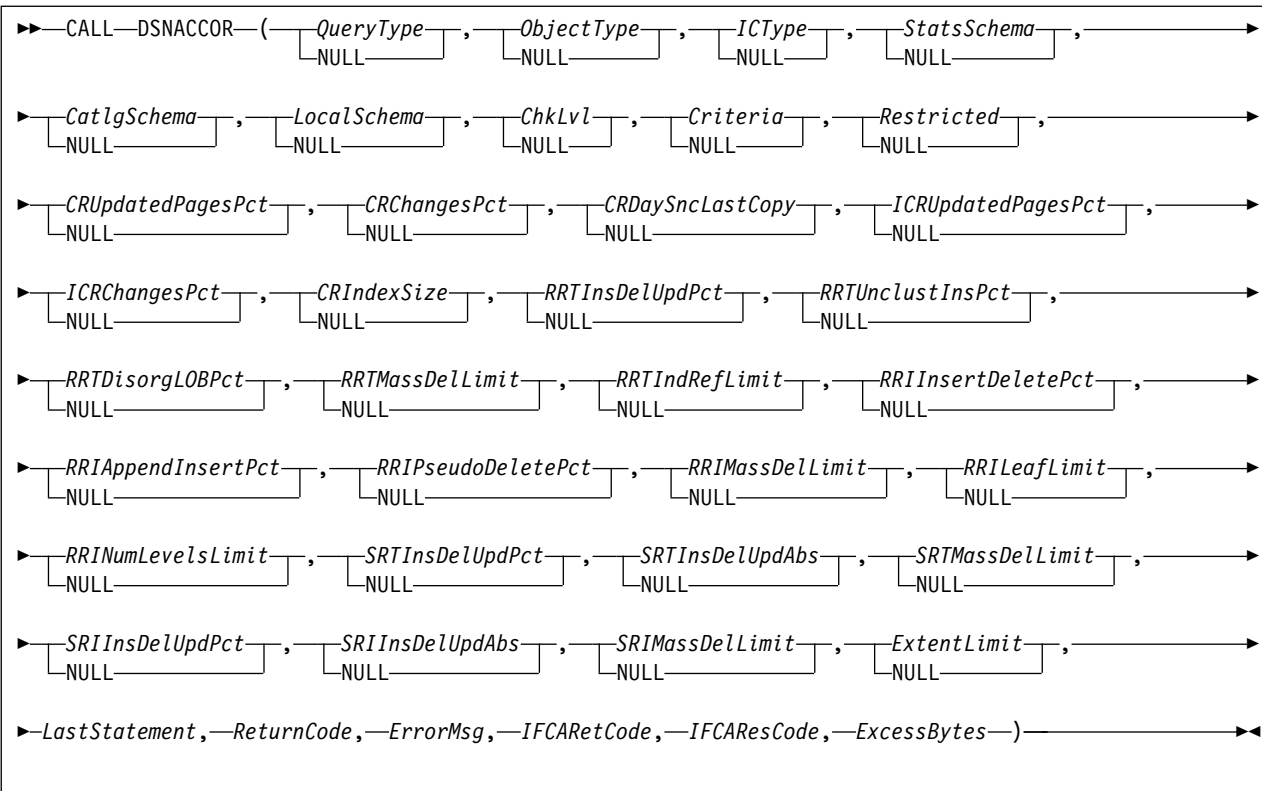

- The EXECUTE privilege on the package for DSNACCOR
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have:

- SELECT authority on the real-time statistics tables
- Select authority on catalog tables
- The DISPLAY system privilege

Syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNACCOR. Because the linkage convention for DSNACCOR is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

Option descriptions

In the following option descriptions, the default value for an input parameter is the value that DSNACCOR uses if you specify a null value.

QueryType

Specifies the types of actions that DSNACCOR recommends. This field contains one or more of the following values. Each value is enclosed in single quotation marks and separated from other values by a space.

ALL Makes recommendations for all of the following actions.

COPY Makes a recommendation on whether to perform an image copy.

RUNSTATS

Makes a recommendation on whether to perform RUNSTATS.

REORG

Makes a recommendation on whether to perform REORG. Choosing this value causes DSNACCOR to process the EXTENTS value also.

EXTENTS

Indicates when data sets have exceeded a user-specified extents limit.

RESTRICT

Indicates which objects are in a restricted state.

QueryType is an input parameter of type VARCHAR(40). The default is **ALL**.

ObjectType

Specifies the types of objects for which DSNACCOR recommends actions:

ALL Table spaces and index spaces.

TS Table spaces only.

IX Index spaces only.

ObjectType is an input parameter of type VARCHAR(3). The default is **ALL**.

ICType

Specifies the types of image copies for which DSNACCOR is to make recommendations:

F Full image copy.

I Incremental image copy. This value is valid for table spaces only.

B Full image copy or incremental image copy.

ICType is an input parameter of type VARCHAR(1). The default is **B**.

StatsSchema

Specifies the qualifier for the real-time statistics table names. *StatsSchema* is an input parameter of type VARCHAR(128). The default is **SYSIBM**.

CatlgSchema

Specifies the qualifier for DB2 catalog table names. *CatlgSchema* is an input parameter of type VARCHAR(128). The default is **SYSIBM**.

LocalSchema

Specifies the qualifier for the names of tables that DSNACCOR creates. *LocalSchema* is an input parameter of type VARCHAR(128). The default is **DSNACC**.

ChkLvl

Specifies the types of checking that DSNACCOR performs, and indicates whether to include objects that fail those checks in the DSNACCOR recommendations result set. This value is the sum of any combination of the following values:

0 DSNACCOR performs none of the following actions.

1 For objects that are listed in the recommendations result set, check the SYSTABLESPACE or SYSINDEXES catalog tables to ensure that those objects have not been deleted. If value 16 is **not** also chosen, exclude rows for the deleted objects from the recommendations result set.

DSNACCOR excludes objects from the recommendations result set if those objects are not in the SYSTABLESPACE or SYSINDEXES catalog tables.

When this setting is specified, DSNACCOR does not use EXTENTS>*ExtentLimit* to determine whether a LOB table space should be reorganized.

2 For index spaces that are listed in the recommendations result set, check the SYSTABLES, SYSTABLESPACE, and SYSINDEXES catalog tables to determine the name of the table space that is associated with each index space.

Choosing this value causes DSNACCOR to also check for rows in the recommendations result set for objects that have been deleted but have entries in the real-time statistics tables (value 1). This means that if value 16 is **not** also chosen, rows for deleted objects are excluded from the recommendations result set.

4 Check whether rows that are in the DSNACCOR recommendations result set refer to objects that are in the exception table. For recommendations result set rows that have corresponding exception

table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set.

- 8 Check whether objects that have rows in the recommendations result set are restricted. Indicate the restricted status in the OBJECTSTATUS column of the result set. A row is added to the result set for each object that has a restricted state, even if a row for the same object is already included in the result set because utility operations are recommended. So, the result set might contain duplicate rows for the same object when you specify this option.
- 16 For objects that are listed in the recommendations result set, check the SYSTABLESPACE or SYSINDEXES catalog tables to ensure that those objects have not been deleted (value 1). In result set rows for deleted objects, specify the word ORPHANED in the OBJECTSTATUS column.
- 32 Exclude rows from the DSNACCOR recommendations result set for index spaces for which the related table spaces have been recommended for REORG. Choosing this value causes DSNACCOR to perform the actions for values 1 and 2.
- 64 For index spaces that are listed in the DSNACCOR recommendations result set, check whether the related table spaces are listed in the exception table. For recommendations result set rows that have corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set.

ChkLvl is an input parameter of type INTEGER. The default is 7 (values 1+2+4).

Criteria

Narrows the set of objects for which DSNACCOR makes recommendations. This value is the search condition of an SQL WHERE clause. *Criteria* is an input parameter of type VARCHAR(4096). The default is that DSNACCOR makes recommendations for all table spaces and index spaces in the subsystem. The search condition can use any column in the result set and wildcards are allowed.

Restricted

A parameter that is reserved for future use. Specify the null value for this parameter. *Restricted* is an input parameter of type VARCHAR(80).

CRUpdatedPagesPct

Specifies a criterion for recommending a full image copy on a table space or index space. If the following condition is true for a table space, DSNACCOR recommends an image copy:

The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.

See item 2 in Figure 18 on page 903. If both of the following conditions are true for an index space, DSNACCOR recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*. See items 2 and 3 in Figure 19 on page 904.

CRUpdatedPagesPct is an input parameter of type INTEGER. The default is 20.

CRChangesPct

Specifies a criterion for recommending a full image copy on a table space or index space. If the following condition is true for a table space, DSNACCOR recommends an image copy:

The total number of insert, update, and delete operations since the last image copy, divided by the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than *CRChangesPct*.

See item 3 in Figure 18 on page 903. If both of the following conditions are true for an index table space, DSNACCOR recommends an image copy:

- The total number of insert and delete operations since the last image copy, divided by the total number of entries in the index space or partition (expressed as a percentage) is greater than *CRChangesPct*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

See items 2 and 4 in Figure 19 on page 904. *CRChangesPct* is an input parameter of type INTEGER. The default is 10.

CRDaySncLastCopy

Specifies a criterion for recommending a full image copy on a table space or index space. If the number of days since the last image copy is greater than this value, DSNACCOR recommends an image copy. (See item 1 in Figure 18 on page 903 and item 1 in Figure 19 on page 904.) *CRDaySncLastCopy* is an input parameter of type INTEGER. The default is 7.

ICRUpdatedPagesPct

Specifies a criterion for recommending an incremental image copy on a table space. If the following condition is true, DSNACCOR recommends an incremental image copy:

The number of distinct pages that were updated since the last image copy, divided by the total number of active pages in the table space or partition (expressed as a percentage) is greater than *ICRUpdatedPagesPct*.

(See item 1 in Figure 20 on page 904.) *ICRUpdatedPagesPct* is an input parameter of type INTEGER. The default is 1.

ICRChangesPct

Specifies a criterion for recommending an incremental image copy on a table space. If the following condition is true, DSNACCOR recommends an incremental image copy:

The ratio of the number of insert, update, or delete operations since the last image copy, to the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than *ICRChangesPct*.

(See item 2 in Figure 20 on page 904.) *ICRChangesPct* is an input parameter of type INTEGER. The default is 1.

CRIndexSize

Specifies, when combined with *CRUpdatedPagesPct* or *CRChangesPct*, a criterion for recommending a full image copy on an index space. (See items 2, 3, and 4 in Figure 19 on page 904.) *CRIndexSize* is an input parameter of type INTEGER. The default is 50.

RRTInsDelUpdPct

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running REORG:

The sum of insert, update, and delete operations since the last REORG, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTInsDelUpdPct*

(See item 1 in Figure 21 on page 904.) *RRTInsDelUpdPct* is an input parameter of type INTEGER. The default is 20.

RRTUnclustInsPct

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running REORG:

The number of unclustered insert operations, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTUnclustInsPct*.

(See item 2 in Figure 21 on page 904.) *RRTUnclustInsPct* is an input parameter of type INTEGER. The default is 10.

RRTDisorgLOBPct

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running REORG:

The number of imperfectly chunked LOBs, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTDisorgLOBPct*.

(See item 3 in Figure 21 on page 904.) *RRTDisorgLOBPct* is an input parameter of type INTEGER. The default is 10.

RRTMassDelLimit

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If one of the following values is greater than *RRTMassDelLimit*, DSNACCOR recommends running REORG:

- The number of mass deletes from a segmented or LOB table space since the last REORG or LOAD REPLACE
- The number of dropped tables from a nonsegmented table space since the last REORG or LOAD REPLACE

(See item 5 in Figure 21 on page 904.) *RRTMassDelLimit* is an input parameter of type INTEGER. The default is 0.

RRTIndRefLimit

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following value is greater than *RRTIndRefLimit*, DSNACCOR recommends running REORG:

The total number of overflow records that were created since the last REORG or LOAD REPLACE, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage)

(See item 4 in Figure 21 on page 904.) *RRTIndRefLimit* is an input parameter of type INTEGER. The default is 10.

RRIInsertDeletePct

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRIInsertDeletePct*, DSNACCOR recommends running REORG:

The sum of the number of index entries that were inserted and deleted since the last REORG, divided by the total number of index entries in the index space or partition (expressed as a percentage)

(See item 1 in Figure 22 on page 905.) This is an input parameter of type INTEGER. The default is 20.

RRIAppendInsertPct

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRIAppendInsertPct*, DSNACCOR recommends running REORG:

The number of index entries that were inserted since the last REORG, REBUILD INDEX, or LOAD REPLACE with a key value greater than the maximum key value in the index space or partition, divided by the number of index entries in the index space or partition (expressed as a percentage)

(See item 2 in Figure 22 on page 905.) *RRIInsertDeletePct* is an input parameter of type INTEGER. The default is 10.

RRIPseudoDeletePct

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRIPseudoDeletePct*, DSNACCOR recommends running REORG:

The number of index entries that were pseudo-deleted since the last REORG, REBUILD INDEX, or LOAD REPLACE, divided by the number of index entries in the index space or partition (expressed as a percentage)

(See item 3 in Figure 22 on page 905.) *RRIPseudoDeletePct* is an input parameter of type INTEGER. The default is 10.

RRIMassDelLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD, or LOAD REPLACE is greater than this value, DSNACCOR recommends running REORG.

(See item 4 in Figure 22 on page 905.) *RRIMassDelLimit* is an input parameter of type INTEGER. The default is 0.

RRILeafLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRILeafLimit*, DSNACCOR recommends running REORG:

The number of index page splits that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE that resulted in a large separation between the parts of the original page, divided by the total number of active pages in the index space or partition (expressed as a percentage)

(See item 5 in Figure 22 on page 905.) *RRILeafLimit* is an input parameter of type INTEGER. The default is 10.

RRINumLevelsLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRINumLevelsLimit*, DSNACCOR recommends running REORG:

The number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE

(See item 6 in Figure 22 on page 905.) *RRINumLevelsLimit* is an input parameter of type INTEGER. The default is 0.

SRTInsDelUpdPct

Specifies, when combined with *SRTInsDelUpdAbs*, a criterion for

recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOR recommends running RUNSTATS:

- The number of insert, update, or delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than *SRTInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRTInsDelUpdAbs*.

(See items 1 and 2 in Figure 23 on page 905.) *SRTInsDelUpdPct* is an input parameter of type INTEGER. The default is 20.

SRTInsDelUpdAbs

Specifies, when combined with *SRTInsDelUpdPct*, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOR recommends running RUNSTATS:

- The number of insert, update, and delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than *SRTInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRTInsDelUpdAbs*.

(See items 1 and 2 in Figure 23 on page 905.) *SRTInsDelUpdAbs* is an input parameter of type INTEGER. The default is 0.

SRTMassDelLimit

Specifies a criterion for recommending that the RUNSTATS utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running RUNSTATS:

- The number of mass deletes from a table space or partition since the last REORG or LOAD REPLACE is greater than *SRTMassDelLimit*.

(See item 3 in Figure 23 on page 905.) *SRTMassDelLimit* is an input parameter of type INTEGER. The default is 0.

SRIInsDelUpdPct

Specifies, when combined with *SRIInsDelUpdAbs*, a criterion for recommending that the RUNSTATS utility is to be run on an index space. If both of the following conditions are true, DSNACCOR recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than *SRIInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRIInsDelUpdAbs*.

(See items 1 and 2 in Figure 24 on page 905.) *SRIInsDelUpdPct* is an input parameter of type INTEGER. The default is 20.

SRIInsDelUpdAbs

Specifies, when combined with *SRIInsDelUpdPct*, a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the following condition is true, DSNACCOR recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than *SRIInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRIInsDelUpdAbs*,

(See items 1 and 2 in Figure 24 on page 905.) *SRIInsDelUpdAbs* is an input parameter of type INTEGER. The default is 0.

SRIMassDelLimit

Specifies a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD INDEX, or LOAD REPLACE is greater than this value, DSNACCOR recommends running RUNSTATS.

(See item 3 in Figure 24 on page 905.) *SRIMassDelLimit* is an input parameter of type INTEGER. The **default** is 0.

ExtentLimit

Specifies a criterion for recommending that the REORG utility is to be run on a table space or index space. Also specifies that DSNACCOR is to warn the user that the table space or index space has used too many extents. DSNACCOR recommends running REORG, and altering data set allocations if the following condition is true:

- The number of physical extents in the index space, table space, or partition is greater than *ExtentLimit*.

(See Figure 25 on page 905.) *ExtentLimit* is an input parameter of type INTEGER. The default is 50.

LastStatement

When DSNACCOR returns a severe error (return code 12), this field contains the SQL statement that was executing when the error occurred. *LastStatement* is an output parameter of type VARCHAR(8012).

ReturnCode

The return code from DSNACCOR execution. Possible values are:

- | | |
|----|--|
| 0 | DSNACCOR executed successfully. The <i>ErrorMsg</i> parameter contains the approximate percentage of the total number of objects in the subsystem that have information in the real-time statistics tables. |
| 4 | DSNACCOR completed, but one or more input parameters might be incompatible. The <i>ErrorMsg</i> parameter contains the input parameters that might be incompatible. |
| 8 | DSNACCOR terminated with errors. The <i>ErrorMsg</i> parameter contains a message that describes the error. |
| 12 | DSNACCOR terminated with severe errors. The <i>ErrorMsg</i> parameter contains a message that describes the error. The <i>LastStatement</i> parameter contains the SQL statement that was executing when the error occurred. |
| 14 | DSNACCOR terminated because it could not access one or more of the real-time statistics tables. The <i>ErrorMsg</i> parameter contains the names of the tables that DSNACCOR could not access. |
| 15 | DSNACCOR terminated because it encountered a problem with one of the declared temporary tables that it defines and uses. |

16 DSNACCOR terminated because it could not define a declared temporary table. No table spaces were defined in the TEMP database.

NULL DSNACCOR terminated but could not set a return code.

ReturnCode is an output parameter of type INTEGER.

ErrorMsg

Contains information about DSNACCOR execution. If DSNACCOR runs successfully (*ReturnCode*=0), this field contains the approximate percentage of objects in the subsystem that are in the real-time statistics tables. Otherwise, this field contains error messages. *ErrorMsg* is an output parameter of type VARCHAR(1331).

IFCARetCode

Contains the return code from an IFI COMMAND call. DSNACCOR issues commands through the IFI interface to determine the status of objects. *IFCARetCode* is an output parameter of type INTEGER.

IFCAREsCode

Contains the reason code from an IFI COMMAND call. *IFCAREsCode* is an output parameter of type INTEGER.

ExcessBytes

Contains the number of bytes of information that did not fit in the IFI return area after an IFI COMMAND call. *ExcessBytes* is an output parameter of type INTEGER.

DSNACCOR formulas for recommending actions

The following formulas specify the criteria that DSNACCOR uses for its recommendations and warnings. The variables in italics are DSNACCOR input parameters. The capitalized variables are columns of the SYSIBM.SYSTABLESPACESTATS or SYSIBM.SYSINDEXSPACESTATS tables. The numbers to the right of selected items are reference numbers for the option descriptions in “Option descriptions” on page 895.

The figure below shows the formula that DSNACCOR uses to recommend a full image copy on a table space.

```
((QueryType='COPY' OR QueryType='ALL') AND
(ObjectType='TS' OR ObjectType='ALL') AND
ICType='F') AND
(COPLYLASTTIME IS NULL OR
REORGLASTTIME>COPLYLASTTIME OR
LOADRLASTTIME>COPLYLASTTIME OR
(CURRENT DATE-COPLYLASTTIME)>CRDaySncLastCopy OR
(COPYUPDATEDPAGES*100)/NACTIVE>CRUpdatedPagesPct OR
(COPYCHANGES*100)/TOTALROWS>CRChangesPct)
```

Figure 18. DSNACCOR formula for recommending a full image copy on a table space

The figure below shows the formula that DSNACCOR uses to recommend a full image copy on an index space.

```

| ((QueryType='COPY' OR QueryType='ALL') AND
| (ObjectType='IX' OR ObjectType='ALL') AND
| (ICType='F' OR ICType='B')) AND
| (COPYLASTTIME IS NULL OR
| REORGLASTTIME>COPYLASTTIME OR
| LOADRLASTTIME>COPYLASTTIME OR
| REBUILDLASTTIME>COPYLASTTIME OR
| (CURRENT DATE-COPYLASTTIME)>CRDaySncLastCopy OR
| (NACTIVE>CRIndexSize AND
| ((COPYUPDATEDPAGES*100)/NACTIVE>CRUpdatedPagesPct OR
| (COPYCHANGES*100)/TOTALENTRIES>CRChangesPct))
|

```

Figure 19. DSNACCOR formula for recommending a full image copy on an index space

The figure below shows the formula that DSNACCOR uses to recommend an incremental image copy on a table space.

```

| ((QueryType='COPY' OR QueryType='ALL') AND
| (ObjectType='TS' OR ObjectType='ALL') AND
| ICType='I' AND
| COPYLASTTIME IS NOT NULL) AND
| (LOADRLASTTIME>COPYLASTTIME OR
| REORGLASTTIME>COPYLASTTIME OR
| (COPYUPDATEDPAGES*100)/NACTIVE>ICRUpdatedPagesPct OR
| (COPYCHANGES*100)/TOTALROWS>ICRChangesPct))
|

```

Figure 20. DSNACCOR formula for recommending an incremental image copy on a table space

The figure below shows the formula that DSNACCOR uses to recommend a REORG on a table space. If the table space is a LOB table space, and CHCKLVL=1, the formula does not include EXTENTS>ExtentLimit.

```

| ((QueryType='REORG' OR QueryType='ALL') AND
| (ObjectType='TS' OR ObjectType='ALL')) AND
| (REORGLASTTIME IS NULL OR
| ((REORGINSERTS+REORGDELETES+REORGUPDATES)*100)/TOTALROWS>RRTInsDelUpdPct OR
| (REORGUNCLUSTINS*100)/TOTALROWS>RRTUnclustInsPct OR
| (REORGDISORGL*100)/TOTALROWS>RRTDisorgLOBPct OR
| ((REORGNearIndRef+REORGFarIndRef)*100)/TOTALROWS>RRTIndRefLimit OR
| REORGMASDELETE>RRTMassDelLimit OR
| EXTENTS>ExtentLimit)
|

```

Figure 21. DSNACCOR formula for recommending a REORG on a table space

The figure below shows the formula that DSNACCOR uses to recommend a REORG on an index space.

```

| ((QueryType='REORG' OR QueryType='ALL') AND
| (ObjectType='IX' OR ObjectType='ALL')) AND
| (REORGLASTTIME IS NULL OR
| ((REORGINSERTS+REORGDELETES)*100)/TOTALENTRIES>RRIInsertDeletePct OR
| (REORGAPPENDINSERT*100)/TOTALENTRIES>RRIAppendInsertPct OR
| (REORGPSEUDODELETES*100)/TOTALENTRIES>RRIPseudoDeletePct OR
| REORGMASDELETE>RRIMassDeleteLimit OR
| (REORGLEAFFAR*100)/NACTIVE>RRILeafLimit OR

The figure below shows the formula that DSNACCOR uses to that too many index space or table space extents have been used.

```

| EXTENTS>ExtentLimit

```

Figure 25. DSNACCOR formula for warning that too many data set extents for a table space or index space are used

Using an exception table

An exception table is an optional, user-created DB2 table that you can use to place information in the INEXCEPTTABLE column of the recommendations result set. You can put any information in the INEXCEPTTABLE column, but the most common use of this column is to filter the recommendations result set. Each row in the exception table represents an object for which you want to provide information for the recommendations result set.

To create the exception table, execute a CREATE TABLE statement similar to the following one. You can include other columns in the exception table, but you must include at least the columns that are shown.

```
CREATE TABLE DSNACC.EXCEPT_TBL
  (DBNAME CHAR(8) NOT NULL,
   NAME CHAR(8) NOT NULL,
   QUERYTYPE CHAR(40))
  CCSID EBCDIC;
```

The meanings of the columns are:

DBNAME

The database name for an object in the exception table.

NAME

The table space name or index space name for an object in the exception table.

QUERYTYPE

The information that you want to place in the INEXCEPTTABLE column of the recommendations result set.

If you put a null value in this column, DSNACCOR puts the value YES in the INEXCEPTTABLE column of the recommendations result set row for the object that matches the DBNAME and NAME values.

Recommendation: If you plan to put many rows in the exception table, create a nonunique index on DBNAME, NAME, and QUERYTYPE.

After you create the exception table, insert a row for each object for which you want to include information in the INEXCEPTTABLE column.

Example: Suppose that you want the INEXCEPTTABLE column to contain the string 'IRRELEVANT' for table space STAFF in database DSNDB04. You also want the INEXCEPTTABLE column to contain 'CURRENT' for table space DSN8S10D in database DSN8D10A. Execute these INSERT statements:

```
INSERT INTO DSNACC.EXCEPT_TBL VALUES('DSNDB04 ', 'STAFF ', 'IRRELEVANT');
INSERT INTO DSNACC.EXCEPT_TBL VALUES('DSN8D10A', 'DSN8S10D', 'CURRENT');
```

To use the contents of INEXCEPTTABLE for filtering, include a condition that involves the INEXCEPTTABLE column in the search condition that you specify in your *Criteria* input parameter.

Example: Suppose that you want to include all rows for database DSNDB04 in the recommendations result set, except for those rows that contain the string 'IRRELEVANT' in the INEXCEPTTABLE column. You might include the following search condition in your *Criteria* input parameter:

```
DBNAME='DSNDB04' AND INEXCEPTTABLE<>'IRRELEVANT'
```

Example

The following COBOL example that shows variable declarations and an SQL CALL for obtaining recommendations for objects in databases DSN8D10A and DSN8D10L. This example also outlines the steps that you need to perform to retrieve the two result sets that DSNACCOR returns.

Figure 26. Example of DSNACCOR invocation

Output

If DSNACCOR executes successfully, in addition to the output parameters described in “Option descriptions” on page 895, DSNACCOR returns two result sets.

The first result set contains the results from IFI COMMAND calls that DSNACCOR makes. The following table shows the format of the first result set.

Table 130. Result set row for first DSNACCOR result set

| Column name | Data type | Contents |
|-------------|-----------|------------------------------------|
| RS_SEQUENCE | INTEGER | Sequence number of the output line |
| RS_DATA | CHAR(80) | A line of command output |

The result set contains rows for table spaces, index spaces, or partitions, if both of the following conditions are true for the object:

- If the *Criteria* input parameter contains a search condition, and the search condition is true for the table space, index space, or partition.
- DSNACCOR recommends at least one action for the table space, index space, or partition.

The result set contains one row for each nonpartitioned table space or nonpartitioning index space. For partitioned table spaces or partitioning indexes, the result set contains one row for each partition. If *ChkLvl* 8 is specified, the result set might contain additional rows, including duplicate rows for the same object.

The following table shows the columns of a result set row.

Table 131. Result set row for second DSNACCOR result set

| Column name | Data type | Description |
|--------------|-----------|---|
| DBNAME | CHAR(8) | Name of the database that contains the object. |
| NAME | CHAR(8) | Table space or index space name. |
| PARTITION | INTEGER | Data set number or partition number. |
| OBJECTTYPE | CHAR(2) | DB2 object type: <ul style="list-style-type: none"> • TS for a table space • IX for an index space |
| OBJECTSTATUS | CHAR(36) | Status of the object: <ul style="list-style-type: none"> • ORPHANED, if the object is an index space with no corresponding table space, or if the object does not exist • If the object is in a restricted state, one of the following values: <ul style="list-style-type: none"> – TS=<i>restricted-state</i>, if OBJECTTYPE is TS – IX=<i>restricted-state</i>, if OBJECTTYPE is IX <i>restricted-state</i> is one of the status codes that appear in DISPLAY DATABASE output. <p>Related information:</p> <ul style="list-style-type: none"> DSNT362I (DB2 Messages) -DISPLAY DATABASE (DB2) (DB2 Commands) • A, if the object is in an advisory state. • L, if the object is a logical partition, but not in an advisory state. • AL, if the object is a logical partition and in an advisory state. |
| IMAGECOPY | CHAR(3) | COPY recommendation: <ul style="list-style-type: none"> • If OBJECTTYPE is TS: FUL (full image copy), INC (incremental image copy), or NO • If OBJECTTYPE is IX: YES or NO |
| RUNSTATS | CHAR(3) | RUNSTATS recommendation: YES or NO. |
| EXTENTS | CHAR(3) | Indicates whether the data sets for the object have exceeded <i>ExtentLimit</i> : YES or NO. |
| REORG | CHAR(3) | REORG recommendation: YES or NO. |
| INEXCEPTABLE | CHAR(40) | A string that contains one of the following values: <ul style="list-style-type: none"> • Text that you specify in the QUERYTYPE column of the exception table. • YES, if you put a row in the exception table for the object that this result set row represents, but you specify NULL in the QUERYTYPE column. • NO, if the exception table exists but does not have a row for the object that this result set row represents. • Null, if the exception table does not exist, or if the <i>ChkLvl</i> input parameter does not include the value 4. |

Table 131. Result set row for second DSNACCOR result set (continued)

| Column name | Data type | Description |
|-----------------|-----------|--|
| ASSOCIATEDTS | CHAR(8) | If OBJECTTYPE is IX and the <i>ChkLvl</i> input parameter includes the value 2, this value is the name of the table space that is associated with the index space. Otherwise null. |
| COPYLASTTIME | TIMESTAMP | Timestamp of the last full or incremental image copy on the object. Null if COPY was never run, or if the last COPY execution was terminated. |
| LOADRLASTTIME | TIMESTAMP | Timestamp of the last LOAD REPLACE on the object. Null if LOAD REPLACE was never run, or if the last LOAD REPLACE execution was terminated. |
| REBUILDLASTTIME | TIMESTAMP | Timestamp of the last REBUILD INDEX on the object. Null if REBUILD INDEX was never run, or if the last REBUILD INDEX execution was terminated. |
| CRUPDPGSPCT | INTEGER | If OBJECTTYPE is TS or IX and IMAGECOPY is YES, the ratio of distinct updated pages to preformatted pages, expressed as a percentage. Otherwise null. |
| CRCPYCHGPCT | INTEGER | If OBJECTTYPE is TS and IMAGECOPY is YES, the ratio of the total number insert, update, and delete operations since the last image copy to the total number of rows or LOBs in the table space or partition, expressed as a percentage. If OBJECTTYPE is IX and IMAGECOPY is YES, the ratio of the total number of insert and delete operations since the last image copy to the total number of entries in the index space or partition, expressed as a percentage. Otherwise null. |
| CRDAYSCELSTCPY | INTEGER | If OBJECTTYPE is TS or IX and IMAGECOPY is YES, the number of days since the last image copy. Otherwise null. |
| CRINDEXSIZE | INTEGER | If OBJECTTYPE is IX and IMAGECOPY is YES, the number of active pages in the index space or partition. Otherwise null. |
| REORGLASTTIME | TIMESTAMP | Timestamp of the last REORG on the object. Null if REORG was never run, or if the last REORG execution was terminated. |
| RRTINSDELUPDPCT | INTEGER | If OBJECTTYPE is TS and REORG is YES, the ratio of the sum of insert, update, and delete operations since the last REORG to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null. |
| RRTUNCINSPECT | INTEGER | If OBJECTTYPE is TS and REORG is YES, the ratio of the number of unclustered insert operations to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null. |
| RRTDISORGLOBPCT | INTEGER | If OBJECTTYPE is TS and REORG is YES, the ratio of the number of imperfectly chunked LOBs to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null. |
| RRTMASSDELETE | INTEGER | If OBJECTTYPE is TS, REORG is YES, and the table space is a segmented table space or LOB table space, the number of mass deletes since the last REORG or LOAD REPLACE. If OBJECTTYPE is TS, REORG is YES, and the table space is nonsegmented, the number of dropped tables since the last REORG or LOAD REPLACE. Otherwise null. |
| RRTINDREF | INTEGER | If OBJECTTYPE is TS, REORG is YES, the ratio of the total number of overflow records that were created since the last REORG or LOAD REPLACE to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null. |

Table 131. Result set row for second DSNACCOR result set (continued)

| Column name | Data type | Description |
|-----------------|-----------|--|
| RRIINSDELPCT | INTEGER | If OBJECTTYPE is IX and REORG is YES, the ratio of the total number of insert and delete operations since the last REORG to the total number of index entries in the index space or partition, expressed as a percentage. Otherwise null. |
| RRIAPPINSPECT | INTEGER | If OBJECTTYPE is IX and REORG is YES, the ratio of the number of index entries that were inserted since the last REORG, REBUILD INDEX, or LOAD REPLACE that had a key value greater than the maximum key value in the index space or partition, to the number of index entries in the index space or partition, expressed as a percentage. Otherwise null. |
| RRIPSDELDPCT | INTEGER | If OBJECTTYPE is IX and REORG is YES, the ratio of the number of index entries that were pseudo-deleted (the RID entry was marked as deleted) since the last REORG, REBUILD INDEX, or LOAD REPLACE to the number of index entries in the index space or partition, expressed as a percentage. Otherwise null. |
| RRIMASSDELETE | INTEGER | If OBJECTTYPE is IX and REORG is YES, the number of mass deletes from the index space or partition since the last REORG, REBUILD, or LOAD REPLACE. Otherwise null. |
| RRILEAF | INTEGER | If OBJECTTYPE is IX and REORG is YES, the ratio of the number of index page splits that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE in which the higher part of the split page was far from the location of the original page, to the total number of active pages in the index space or partition, expressed as a percentage. Otherwise null. |
| RRINUMLEVELS | INTEGER | If OBJECTTYPE is IX and REORG is YES, the number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE. Otherwise null. |
| STATSLASTTIME | TIMESTAMP | Timestamp of the last RUNSTATS on the object. Null if RUNSTATS was never run, or if the last RUNSTATS execution was terminated. |
| SRTINSDELUPDPCT | INTEGER | If OBJECTTYPE is TS and RUNSTATS is YES, the ratio of the total number of insert, update, and delete operations since the last RUNSTATS on a table space or partition, to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null. |
| SRTINSDELUPDABS | INTEGER | If OBJECTTYPE is TS and RUNSTATS is YES, the total number of insert, update, and delete operations since the last RUNSTATS on a table space or partition. Otherwise null. |
| SRTMASSDELETE | INTEGER | If OBJECTTYPE is TS and RUNSTATS is YES, the number of mass deletes from the table space or partition since the last REORG or LOAD REPLACE. Otherwise null. |
| SRIINSDELPCT | INTEGER | If OBJECTTYPE is IX and RUNSTATS is YES, the ratio of the total number of insert and delete operations since the last RUNSTATS on the index space or partition, to the total number of index entries in the index space or partition, expressed as a percentage. Otherwise null. |
| SRIINSDELABS | INTEGER | If OBJECTTYPE is IX and RUNSTATS is YES, the number insert and delete operations since the last RUNSTATS on the index space or partition. Otherwise null. |

| *Table 131. Result set row for second DSNACCOR result set (continued)*

| Column name | Data type | Description |
|---------------|-----------|--|
| SRIMASSDELETE | INTEGER | If OBJECTTYPE is IX and RUNSTATS is YES, the number of mass deletes from the index space or partition since the last REORG, REBUILD INDEX, or LOAD REPLACE. Otherwise, this value is null. |
| TOTALEXTENTS | SMALLINT | If EXTENTS is YES, the number of physical extents in the table space, index space, or partition. Otherwise, this value is null. |

DSNACCOX stored procedure

The DB2 real-time statistics stored procedure (DSNACCOX) is a sample stored procedure that makes recommendations to help you maintain your DB2 databases.

PSPI

The DSNACCOX stored procedure represents an enhancement to the DSNACCOR stored procedure and provides the following improvements:

- Improved recommendations
- New fields
- New formulas
- The option to choose the formula for making recommendations

You can call the DSNACCOX stored procedure to accomplish the following actions:

- Get recommendations for when to reorganize, image copy, or update statistics for table spaces or index spaces
- Identify when a data set has exceeded a specified threshold for the number of extents that it occupies.
- Identify whether objects are in restricted states

DSNACCOX uses data from catalog tables, including real-time statistics tables, to make its recommendations. DSNACCOX provides its recommendations in a result set.

DSNACCOX uses the set of criteria that are shown in “DSNACCOX formulas for recommending actions” on page 928 to evaluate table spaces and index spaces. By default, DSNACCOX evaluates all table spaces and index spaces in the subsystem that have entries in the real-time statistics tables. However, you can override this default through input parameters.

About DSNACCOX recommendations

- DSNACCOX makes recommendations based on general formulas that require input from the user about the maintenance policies for a subsystem. These recommendations might not be accurate for every installation.
- If the real-time statistics tables contain information for only a small percentage of your DB2 subsystem, the recommendations that DSNACCOX makes might not be accurate for the entire subsystem.
- Before you perform any action that DSNACCOX recommends, ensure that the object for which DSNACCOX makes the recommendation is available, and that the recommended action can be performed on that object. For example, REORG might be recommended for an object, but the object might be stopped.

Environment

DSNACCOX must run in a WLM-established stored procedure address space. The DSNWLM_GENERAL core WLM environment is a suitable environment for this stored procedure.

DSNACCOX is installed and configured by installation job DSNTIJRT, which binds the package for DSNACCOX with isolation UR to avoid lock contention.

Authorization required

To execute the CALL DSNACCOX statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNACCOX
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have:

- SELECT authority on catalog tables
- The DISPLAY system privilege

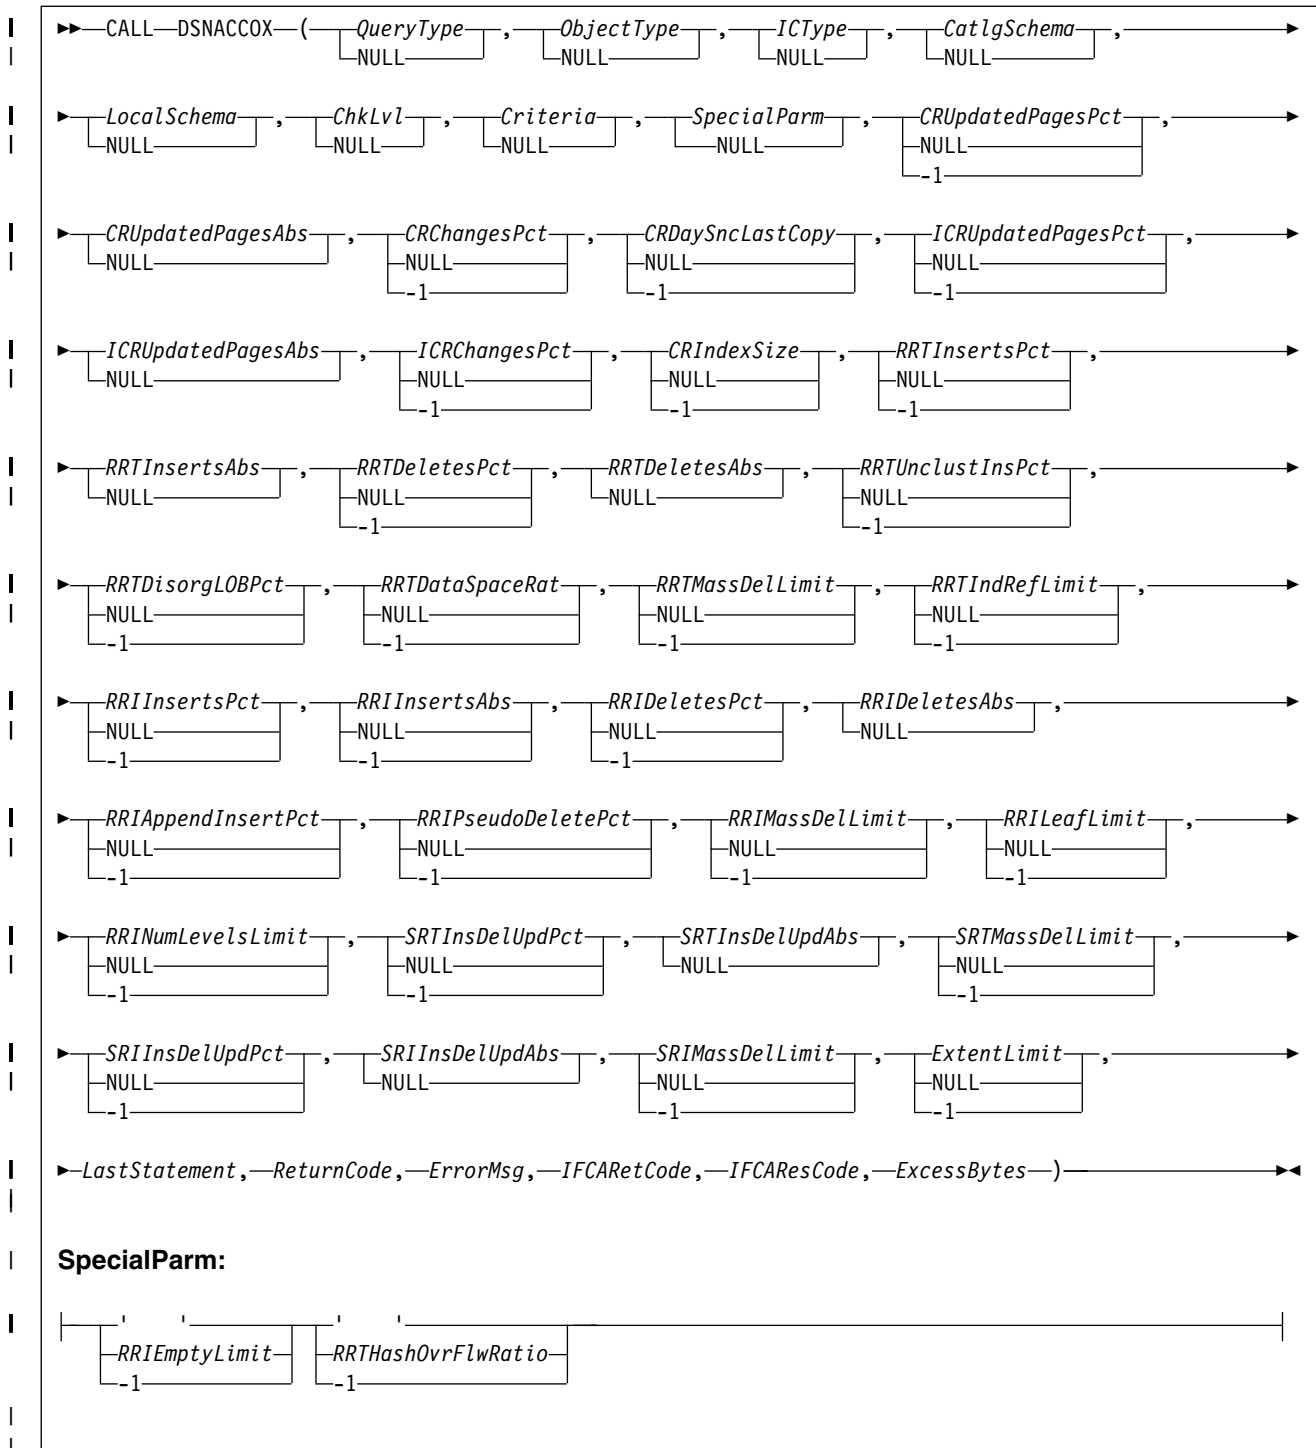

Syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNACCOX. Because the linkage convention for DSNACCOX is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

Related information:

Indicator variables, arrays, and structures (DB2 Application programming and SQL)

Linkage conventions for external stored procedures (DB2 Application programming and SQL)

Option descriptions

In the following option descriptions, the default value for an input parameter is the value that DSNACCOX uses if you specify a null value.

QueryType

Specifies the types of actions that DSNACCOX recommends. This field contains one or more of the following values. Each value is enclosed in single quotation marks and separated from other values by a space.

ALL Makes recommendations for all of the following actions.

COPY Makes a recommendation on whether run an image copy.

RUNSTATS

Makes a recommendation on whether to run RUNSTATS.

REORG

Makes a recommendation on whether to run REORG. Choosing this value causes DSNACCOX to process the EXTENTS value also.

EXTENTS

Indicates when data sets have exceeded a user-specified extents limit.

RESTRICT

Indicates which objects are in a restricted state.

DSNACCOX recommends REORG on the table space when one of the following conditions is true, and REORG (or ALL) is also specified for the value of QUERYTYPE:

- The table space is in REORG-pending status.
- The table space is in advisory REORG-pending status as the result of an ALTER TABLE statement.

DSNACCOX recommends REORG on the index when on the following conditions is true and REORG (or ALL) is also specified for the value of QUERYTYPE::

- The index is in REORG-pending status.
- The index is in advisory REORG-pending as the result of an ALTER TABLE statement.

DSNACCOX recommends FULL COPY on the table space when on the following conditions is true and COPY (or ALL) is also specified for the value of QUERYTYPE::

- The table space is in COPY-pending status.
- The table space is in informational COPY-pending status.

DSNACCOX recommends FULL COPY on the index when on the following conditions is true and COPY (or ALL) is also specified for the value of QUERYTYPE: and SYSINDEX.COPY='Y':

- The index is in COPY-pending status.
- The index is in informational COPY-pending status.

QueryType is an input parameter of type VARCHAR(40). The default value is ALL.

ObjectType

Specifies the types of objects for which DSNACCOX recommends actions:

ALL Table spaces and index spaces.

TS Table spaces only.

IX Index spaces only.

ObjectType is an input parameter of type VARCHAR(3). The default value is ALL.

ICType

Specifies the types of image copies for which DSNACCOX is to make recommendations:

- | F Full image copy.
- | I Incremental image copy. This value is valid for table spaces only.
- | B Full image copy or incremental image copy.

| *ICType* is an input parameter of type VARCHAR(1). The default is B.

| *CatlgSchema*

| Specifies the qualifier for DB2 catalog table names. *CatlgSchema* is an input parameter of type VARCHAR(128). The default value is SYSIBM.

| *LocalSchema*

| Specifies the qualifier for the names of local tables that DSNACCOX references. *LocalSchema* is an input parameter of type VARCHAR(128). The default value is DSNACC.

| *ChkLvl*

| Specifies the types of checking that DSNACCOX performs, and indicates whether to include objects that fail those checks in the DSNACCOX recommendations result set. This value is the sum of any combination of the following values:

- | 0 DSNACCOX performs none of the following actions.
- | 1 Exclude rows from the DSNACCOX recommendations result set for RUNSTATS on:
 - | • Index spaces that are related to tables that are defined as VOLATILE.
 - | • Table spaces for which all of the tables are defined as VOLATILE.
- | 2 Choosing this value causes DSNACCOX to over-ride the default SSDMultiplier when making a REORG recommendation for a table space or table space partition. The default value is 2 times RRTUnclustInsPct. If CHKLVL 2 is specified RRTUnclustInsPct * 5 is used.
- | 4 Check whether rows that are in the DSNACCOX recommendations result set refer to objects that are in the exception table. For recommendations result set rows that have corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set.
- | 8 Check for objects that have restricted states. The value of the *QueryType* option must be ALL or contain RESTRICTED when this value is specified. The OBJECTSTATUS column of the result set indicates the restricted state of the object. A row is added to the result set for each object that has a restricted state. A row is added to the result set for each object that has a restricted state, even if a row for the same object is already included in the result set because utility operations are recommended. So, the result set might contain duplicate rows for the same object when you specify this option.
- | 16 Reserved for future use.
- | 32 Exclude rows from the DSNACCOX recommendations result set for index spaces for which the related table spaces have been recommended for REORG or RUNSTATS.
- | 64 For index spaces that are listed in the DSNACCOX recommendations result set, check whether the related table spaces are listed in the exception table. For recommendations result set rows that have

corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set. Selecting CHKLVL64 also activates CHKLVLs 32 and 4.

ChkLvl is an input parameter of type INTEGER. The default is 5 (values 1+4).

Criteria

Narrows the set of objects for which DSNACCOX makes recommendations. This value is the search condition of an SQL WHERE clause. *Criteria* is an input parameter of type VARCHAR(4096). The default is that DSNACCOX makes recommendations for all table spaces and index spaces in the subsystem. The search condition can use any column in the result set and wildcards are allowed.

SpecialParm

SpecialParm is an input of type CHAR(160), broken into 4 byte sections to accommodate new options. An empty 4 bytes of EBCDIC blanks indicates that the default is used for the option. An EBCDIC character string of '-1', indicates that this option is not used.

RRIEmptyLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than RRIEmptyLimit, DSNACCOX recommends running REORG: The number of pseudo-empty leaf pages that were created since the last CREATE, REORG, REBUILD INDEX, or LOAD REPLACE, divided by the total number of leaf pages in the index space or partition, expressed as a percentage.

RRIEmptyLimit is an input parameter of type CHAR 4. The default value is ' 10'. A plus sign (+) preceding the value indicates that the DSNACCOX stored procedure returns the value in the result set. A negative value turns off this criterion.

The ratio of pseudo-empty pages to the total number of leaf pages is returned in column RRIEMPTYLIMIT of the result set.

RRTHashOvrFlwRatio

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running REORG: The hash access overflow index is being used for access, and the ratio of hash access overflow index entries divided by the total number of rows (expressed as a percentage) is greater than RRTHashOvrFlwRatio.

RRTHashOvrFlwRatio is an input parameter of type CHAR 4. The default value is ' 15'. A plus sign (+) preceding or after the value or by itself indicates that the DSNACCOX stored procedure returns the calculated ratio value in the result set. The value of the *ObjectType* parameter must be ALL, or contain both TS and IX, for this criterion to be used. A negative value turns off this criterion.

The ratio of Hash Access overflow index entries to the total number of rows is returned in the RRTHASHOVRFLWRAT column of the result set.

CRUpdatedPagesPct

Specifies, when combined with *CRUpdatedPagesAbs*, a criterion for recommending a full image copy on a table space or index space. If both of the following conditions are true for a table space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesABS*.

If all of the following conditions are true for an index space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesABS*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

CRUpdatedPagesPct is an input parameter of type DOUBLE. The default is 20.0. A negative value turns off both this criterion and *CRUpdatedPagesABS*.

CRUpdatedPagesABS

Specifies, when combined with *CRUpdatedPagesPct*, a criterion for recommending a full image copy on a table space or index space. If both of the following conditions are true for a table space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updated pages is greater than *CRUpdatedPagesAbs*.

If all of the following conditions are true for an index space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesAbs*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

CRUpdatedPagesAbs is an input parameter of type INTEGER. The default value is 0.

CRChangesPct

Specifies a criterion for recommending a full image copy on a table space or index space. If the following condition is true for a table space, DSNACCOX recommends an image copy:

The total number of insert, update, and delete operations since the last image copy, divided by the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than *CRChangesPct*.

If both of the following conditions are true for an index table space, DSNACCOX recommends an image copy:

- The total number of insert and delete operations since the last image copy, divided by the total number of entries in the index space or partition (expressed as a percentage) is greater than *CRChangesPct*.

- The number of active pages in the index space or partition is greater than *CRIndexSize*.

CRChangesPct is an input parameter of type DOUBLE. The default is 10.0. A negative value turns off this criterion.

CRDaySncLastCopy

Specifies a criterion for recommending a full image copy on a table space or index space. If the number of days since the last image copy is greater than this value, DSNACCOX recommends an image copy.

CRDaySncLastCopy is an input parameter of type INTEGER. The default is 7. A negative value turns off this criterion.

ICRUpdatedPagesPct

Specifies a criterion for recommending an incremental image copy on a table space. If both of the following conditions are true, DSNACCOX recommends an incremental image copy:

- The number of distinct pages that were updated since the last image copy, divided by the total number of active pages in the table space or partition (expressed as a percentage) is greater than *ICRUpdatedPagesPct*.
- The number of distinct pages that were updated since last image copy is greater than *ICRUpdatedPagesAbs*.

ICRUpdatedPagesPct is an input parameter of type DOUBLE. The default value is 1.0. A negative value turns off this criterion and *ICRUpdatedPagesAbs*.

ICRUpdatedPagesAbs

Specifies, when combined with *ICRUpdatedPagesPct*, a criterion for recommending an incremental image copy on a table space. If both of the following conditions are true, DSNACCOX recommends an incremental image copy:

- The number of distinct pages that were updated since the last image copy, divided by the total number of active pages in the table space or partition (expressed as a percentage) is greater than *ICRUpdatedPagesPct*.
- The number of distinct pages that were updated since last image copy is greater than *ICRUpdatedPagesAbs*.

ICRUpdatedPagesAbs is an input parameter of type INTEGER. The default is 0.

ICRChangesPct

Specifies a criterion for recommending an incremental image copy on a table space. If the following condition is true, DSNACCOX recommends an incremental image copy:

The ratio of the number of insert, update, or delete operations since the last image copy, to the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than *ICRChangesPct*.

ICRChangesPct is an input parameter of type DOUBLE. The default is 1.0. A negative value turns off this criterion.

CRIndexSize

Specifies the minimum index size before checking the *CRUpdatedPagesPct* or *CRChangesPct* criteria for recommending a full image copy on an index space.

CRIndexSize is an input parameter of type INTEGER. The default is 50. A negative value turns off this criterion and *ICRChangesPct*.

RRTInsertsPct

Specifies, when combined with *RRTInsertsAbs*, a criterion for recommending

that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of insert, update, and delete operations since the last REORG, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTInsertsPct*
- The sum of insert operations since the last REORG is greater than *RRTInsertsAbs*.

RRTInsertsPct is an input parameter of type DOUBLE. The default value is 25.0. A negative value turns off this criterion and *RRTInsertsAbs*.

RRTInsertsAbs

Specifies, when combined with *RRTInsertsPct*, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of insert operations since the last REORG, divided by the total number of rows or in the table space or partition (expressed as a percentage) is greater than *RRTInsertsPct*
- The sum of insert operations since the last REORG is greater than *RRTInsertsAbs*.

RRTInsertsAbs is an input parameter of type INTEGER. The default value is 0.

RRTDeletesPct

Specifies, when combined with *RRTDeletesAbs*, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of delete operations since the last REORG, divided by the total number of rows or in the table space or partition (expressed as a percentage) is greater than *RRTDeletesPct*
- The sum of delete operations since the last REORG is greater than *RRTDeletesAbs*.

RRTDeletesPct is an input parameter of type DOUBLE. The default value is 25.0. A negative value turns off this criterion and *RRTDeletesAbs*.

RRTDeletesAbs

Specifies, when combined with *RRTDeletesPct*, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of delete operations since the last REORG, divided by the total number of rows or in the table space or partition (expressed as a percentage) is greater than *RRTDeletesPct*
- The sum of delete operations since the last REORG is greater than *RRTDeletesAbs*.

RRTDeletesAbs is an input parameter of type INTEGER. The default value is 0.

RRTUnclustInsPct

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running REORG:

The number of unclustered insert operations, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTUnclustInsPct*.

RRTUnclustInsPct is an input parameter of type DOUBLE. The default is 10.0. A negative value will turn off this criterion.

| *RRTDisorgLOBPct*

| Specifies a criterion for recommending that the REORG utility is to be run on a
| table space. If the following condition is true, DSNACCOX recommends
| running REORG:

| The number of imperfectly chunked LOBs, divided by the total number of
| rows or LOBs in the table space or partition (expressed as a percentage) is
| greater than *RRTDisorgLOBPct*.

| *RRTDisorgLOBPct* is an input parameter of type DOUBLE. The default is 50.0.
| A negative value will turn off this criterion.

| *RRTDataSpaceRat*

| Specifies a criterion for recommending that the REORG utility is to be run on
| table space for space reclamation. If the following condition is true,
| DSNACCOX recommends running REORG:

| The object is not using hash organization.

| The SPACE allocated is greater than *RRTDataSpaceRat* multiplied by the
| actual space used. ($SPACE > RRTDataSpaceRat \times (DATASIZE/1024)$)

| *RRTDataSpaceRat* is an input parameter of type DOUBLE. The default value is
| 2.0. A negative value turns off this criterion.

| *RRTMassDelLimit*

| Specifies a criterion for recommending that the REORG utility is to be run on a
| table space. If one of the following values is greater than *RRTMassDelLimit*,
| DSNACCOX recommends running REORG:

- | • The sum of mass deletes from a segmented or LOB table space since the last
| REORG or LOAD REPLACE
- | • The number of dropped tables from a nonsegmented table space since the
| last REORG or LOAD REPLACE

| *RRTMassDelLimit* is an input parameter of type INTEGER. The default is 0.

| *RRTIndRefLimit*

| Specifies a criterion for recommending that the REORG utility is to be run on a
| table space. If the following value is greater than *RRTIndRefLimit*, DSNACCOX
| recommends running REORG:

| The total number of overflow records that were created since the last
| REORG or LOAD REPLACE, divided by the total number of rows or LOBs
| in the table space or partition (expressed as a percentage)

| *RRTIndRefLimit* is an input parameter of type DOUBLE. The default is 5.0 in
| data sharing environment and 10.0 in a non-data sharing environment.

| *RRIInsertsPct*

| Specifies a criterion for recommending that the REORG utility is to be run on
| an index space. If the both of the following conditions are true, DSNACCOX
| recommends running REORG:

- | • The sum of the number of index entries that were inserted since the last
| REORG, divided by the total number of index entries in the index space or
| partition (expressed as a percentage) is greater than *RRIInsertsPct*.
- | • The sum of the number of index entries that were inserted since the last
| REORG is greater than *RRIInsertsAbs*.

| *RRIInsertsPct* is an input parameter of type DOUBLE. The default is 30.0. A
| negative value turns off this criterion.

| *RRInsertsAbs*

| Specifies a criterion for recommending that the REORG utility is to be run on
| an index space. If both of the following conditions are true, DSNACCOX
| recommends running REORG:

- | • The sum of the number of index entries that were inserted since the last
| REORG, divided by the total number of index entries in the index space or
| partition (expressed as a percentage) is greater than *RRInsertsPct*.
- | • The sum of the number of index entries that were inserted since the last
| REORG is greater than *RRInsertsAbs*.

| *RRInsertsAbs* is an input parameter of type INTEGER. The default is 0. A
| negative value turns off this criterion.

| *RRIDeletesPct*

| Specifies a criterion for recommending that the REORG utility is to be run on
| an index space. If the following value is greater than *RRIDeletesPct*,
| DSNACCOX recommends running REORG:

- | • The sum of the number of index entries that were deleted since the last
| REORG, divided by the total number of index entries in the index space or
| partition (expressed as a percentage) is greater than *RRIDeletesPct*.
- | • The sum of the number of index entries that were deleted since the last
| REORG is greater than *RRIDeletesAbs*.

| *RRIDeletesPct* is an input parameter of type DOUBLE. The default is 30.0. A
| negative value turns off this criterion.

| *RRIDeletesAbs*

| Specifies a criterion for recommending that the REORG utility is to be run on
| an index space. If the following value is greater than *RRIDeletesPct*,
| DSNACCOX recommends running REORG:

- | • The sum of the number of index entries that were deleted since the last
| REORG, divided by the total number of index entries in the index space or
| partition (expressed as a percentage) is greater than *RRIDeletesPct*.
- | • The sum of the number of index entries that were deleted since the last
| REORG is greater than *RRIDeletesAbs*.

| *RRIDeletesAbs* is an input parameter of type INTEGER. The default is 0. A
| negative value turns off this criterion.

| *RRIAppendInsertPct*

| Specifies a criterion for recommending that the REORG utility is to be run on
| an index space. If the following value is greater than *RRIAppendInsertPct*,
| DSNACCOX recommends running REORG:

| The number of index entries that were inserted since the last REORG,
| REBUILD INDEX, or LOAD REPLACE with a key value greater than the
| maximum key value in the index space or partition, divided by the number
| of index entries in the index space or partition (expressed as a percentage)

| *RRIAppendInsertPct* is an input parameter of type DOUBLE. The default is 20.0.
| A negative value turns off this criterion.

| *RRIPseudoDeletePct*

| Specifies a criterion for recommending that the REORG utility is to be run on
| an index space. If the following value is greater than *RRIPseudoDeletePct*,
| DSNACCOX recommends running REORG:

| The number of index entries that were pseudo-deleted since the last
| REORG, REBUILD INDEX, or LOAD REPLACE, divided by the number of
| index entries in the index space or partition (expressed as a percentage)

RRIPseudoDeletePct is an input parameter of type DOUBLE. The default is 5.0 in data sharing and 10.0 in non-data sharing environments. A negative value turns off this criterion.

RRIMassDelLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD, or LOAD REPLACE is greater than this value, DSNACCOX recommends running REORG.

RRIMassDelLimit is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

RRILeafLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRILeafLimit*, DSNACCOX recommends running REORG:

The number of index page splits that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE in which the higher part of the split page was far from the location of the original page, divided by the total number of active pages in the index space or partition (expressed as a percentage)

RRILeafLimit is an input parameter of type DOUBLE. The default is 10.0. A negative value turns off this criterion.

RRINumLevelsLimit

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRINumLevelsLimit*, DSNACCOX recommends running REORG:

The number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE

RRINumLevelsLimit is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

SRTInsDelUpdPct

Specifies, when combined with *SRTInsDelUpdAbs*, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOX recommends running RUNSTATS:

- The number of insert, update, or delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than *SRTInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRTInsDelUpdAbs*.

SRTInsDelUpdPct is an input parameter of type DOUBLE. The default is 20.0. A negative value turns off this criterion.

SRTInsDelUpdAbs

Specifies, when combined with *SRTInsDelUpdPct*, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOX recommends running RUNSTATS:

- The number of insert, update, and delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than *SRTInsDelUpdPct*.

- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRTInsDelUpdAbs*.

SRTInsDelUpdAbs is an input parameter of type INTEGER. The default is 0.

SRTMassDelLimit

Specifies a criterion for recommending that the RUNSTATS utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running RUNSTATS:

- The number of mass deletes from a table space or partition since the last REORG or LOAD REPLACE is greater than *SRTMassDelLimit*.

SRTMassDelLimit is an input parameter of type INTEGER. The default is 0.0. A negative value turns off this criterion.

SRIInsDelPct

Specifies, when combined with *SRIInsDelAbs*, a criterion for recommending that the RUNSTATS utility is to be run on an index space. If both of the following conditions are true, DSNACCOX recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than *SRIInsDelPct*
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRIInsDelAbs*

SRIInsDelPct is an input parameter of type DOUBLE. The default is 20.0. A negative value turns off this criterion.

SRIInsDelAbs

Specifies, when combined with *SRIInsDelPct*, a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the following condition is true, DSNACCOX recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than *SRIInsDelPct*
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRIInsDelAbs*,

SRIInsDelAbs is an input parameter of type INTEGER. The default is 0.

SRIMassDelLimit

Specifies a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD INDEX, or LOAD REPLACE is greater than this value, DSNACCOX recommends running RUNSTATS.

SRIMassDelLimit is an input parameter of type INTEGER. The default value is 0. A negative value turns off this criterion.

ExtentLimit

Specifies a criterion for recommending that the REORG utility is to be run on a table space or index space. Also specifies that DSNACCOX is to warn the user that the table space or index space has used too many extents. DSNACCOX recommends running REORG, and altering data set allocations if the following condition is true:

- The number of physical extents in the index space, table space, or partition is greater than *ExtentLimit*.

ExtentLimit is an input parameter of type INTEGER. The default value is 254. A negative value turns off this criterion.

LastStatement

When DSNACCOX returns a severe error (return code 12), this field contains the SQL statement that was executing when the error occurred. *LastStatement* is an output parameter of type VARCHAR(8012).

ReturnCode

The return code from DSNACCOX execution. Possible values are:

- 0 DSNACCOX executed successfully.
- 4 DSNACCOX completed with a warning. The *ErrorMsg* parameter contains the input parameters that might be incompatible.
- 8 DSNACCOX terminated with errors. The *ErrorMsg* parameter contains a message that describes the error.
- 12 DSNACCOX terminated with severe errors. The *ErrorMsg* parameter contains a message that describes the error. The *LastStatement* parameter contains the SQL statement that was executing when the error occurred.
- 14 DSNACCOX terminated because the real-time statistics table were not yet migrated to the catalog.
- 15 DSNACCOX terminated because it encountered a problem with one of the declared temporary tables that it defines and uses.
- 16 DSNACCOX terminated because it could not define a declared temporary table.
- NULL DSNACCOX terminated but could not set a return code.

ReturnCode is an output parameter of type INTEGER.

ErrorMsg

Contains information about DSNACCOX execution when DSNACCOX terminates with a non-zero value for *ReturnCode*.

IFCARetCode

Contains the return code from an IFI COMMAND call. DSNACCOX issues commands through the IFI interface to determine the status of objects. *IFCARetCode* is an output parameter of type INTEGER.

IFCAResCode

Contains the reason code from an IFI COMMAND call. *IFCAResCode* is an output parameter of type INTEGER.

XsBytes

Contains the number of bytes of information that did not fit in the IFI return area after an IFI COMMAND call. *XsBytes* is an output parameter of type INTEGER.

DSNACCOX formulas for recommending actions

The following formulas specify the criteria that DSNACCOX uses for its recommendations and warnings. The variables in italics are DSNACCOX input parameters. The capitalized variables are columns of the SYSIBM.SYSTABLESPACESTATS or SYSIBM.SYSINDEXSPACESTATS catalog tables.

The following figure shows the formula that DSNACCOX uses to recommend a full image copy on a table space.

```
((QueryType='COPY' OR QueryType='ALL') AND
(ObjectType='TS' OR ObjectType='ALL') AND
(Object is not in Persistent Read Only (PRO) status) AND
(ICType='F' OR ICType='B')) AND
(COPYLASTTIME IS NULL OR
 REORGLASTTIME>COPYLASTTIME OR
 LOADRLASTTIME>COPYLASTTIME OR
 (CURRENT DATE-COPYLASTTIME)>CRDaySncLastCopy OR
 ((COPYUPDATEDPAGES×100)/NACTIVE>CRUpdatedPagesPct AND
 (COPYUPDATEDPAGES>CRUpdatedPagesAbs)) OR
 (COPYCHANGES×100)/TOTALROWS>ICRChangesPct) OR
 ((QueryType='RESTRICT' OR QueryType='ALL' ) AND
 (ObjectType='TS' OR ObjectType='ALL') AND
 The table space is in COPY-pending status or informational COPY-pending status))
```

Figure 27. DSNACCOX formula for recommending a full image copy on a table space

The following figure shows the formula that DSNACCOX uses to recommend a full image copy on an index space.

```
((QueryType='COPY' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL') AND
 (SYSINDEXES.COPY = 'Y')) AND
 (COPYLASTTIME IS NULL OR
 REORGLASTTIME>COPYLASTTIME OR
 LOADRLASTTIME>COPYLASTTIME OR
 REBUILDLASTTIME>COPYLASTTIME OR
 (CURRENT DATE-COPYLASTTIME)>CRDaySncLastCopy OR
 (NACTIVE>CRIndexSize AND
 (((COPYUPDATEDPAGES×100)/NACTIVE>CRUpdatedPagesPct) AND
 (COPYUPDATEDPAGES>CRUpdatedPagesAbs)) OR
 (COPYCHANGES×100)/TOTALENTRIES>CRChangesPct)) OR
 ((QueryType='RESTRICT' OR QueryType='ALL' ) AND
 (ObjectType='IX' OR ObjectType='ALL') AND
 The index space is in COPY-pending status or informational COPY-pending status))
```

Figure 28. DSNACCOX formula for recommending a full image copy on an index space

The following figure shows the formula that DSNACCOX uses to recommend an incremental image copy on a table space.

```

| ((QueryType='COPY' OR QueryType='ALL') AND
| (ObjectType='TS' OR ObjectType='ALL') AND
| (Object is not in Persistent Read Only (PRO) status) AND
| (IcType='F' OR IcType='B')) AND
| (IcType='I') AND
| COPYLASTTIME IS NOT NULL) AND
| (LOADRLASTTIME>COPYLASTTIME OR
| REORGLASTTIME>COPYLASTTIME OR
| ((COPYUPDATEDPAGES×100)/NACTIVE>ICRUpdatedPagesPct) AND
| (COPYUPDATEDPAGES>ICRUpdatedPagesAbs)) OR
| (COPYCHANGES×100)/TOTALROWS>ICRChangesPct)

```

Figure 29. DSNACCOX formula for recommending an incremental image copy on a table space

The following figure shows the formula that DSNACCOX uses to recommend a REORG on a table space. If the table space is a LOB table space, and CHKLVL=1, the formula does not include EXTENTS>ExtentLimit.

```

| (((QueryType='REORG' OR QueryType='ALL') AND
| (ObjectType='TS' OR ObjectType='ALL')) AND
| (Object is not in Persistent Read Only (PRO) status) AND
| ( REORGLASTTIME IS NULL AND LOADRLASTTIME IS NULL) OR
| (NACTIVE IS NULL OR NACTIVE > 5) AND
| (((REORGINSERTS×100)/TOTALROWS>RRTInsertsPct) AND
| REORGINSERTS>RRTInsertsAbs) OR
| (((REORGDELETE×100)/TOTALROWS>RRTDeletesPct) AND
| REORGDELETE>RRTDeletesAbs) OR
| (REORGCLUSTERSENS > 0 AND (REORGUNCLUSTINS×100)/TOTALROWS>RRTUnclustInsPct) OR
| (REORGDISORGLOB×100)/TOTALROWS>RRTDisorgLOBPct OR
| (SPACE×1024)/DATASIZE>RRTDataSpaceRat OR
| ((REORGNEARINDREF+REORGFARINDREF)×100)/TOTALROWS>RRTIndRefLimit OR
| REORGMASDELETE>RRTMassDelLimit OR
| EXTENTS>ExtentLimit)) OR
| ((QueryType='REORG' OR QueryType='ALL') AND
| ObjectType='ALL'1 AND
| overflow index for hash access is used2, and
| (overflow index TOTALENTRY x 100) / TOTALROWS > RRTHashOvrFlwRatio)) OR
| ((QueryType='RESTRICT' OR QueryType='ALL' ) AND
| (ObjectType='TS' OR ObjectType='ALL') AND
| The table space is in advisory or informational reorg pending status)

```

Notes:

1. Both IX and TS must be selected, thus *ObjectType=ALL* must be specified to use this criterion. If only TS or IX is specified, and the value of the special parameter contains a plus sign (+) to indicate that the RRTHASHOVRFLWRAT column is to be included in the result set, an error message is issued. Otherwise, this criterion does not apply when only TS or IX is specified.
2. The overflow index is used when SYSINDEXES.HASH = 'Y' AND SYSINDEXSPACESTATS.REORGINDEXACCESS > 0.

Figure 30. DSNACCOX formula for recommending a REORG on a table space

The following figure shows the formula that DSNACCOX uses to recommend a REORG on an index space.

```

| ((QueryType='REORG' OR QueryType='ALL') AND
| (ObjectType='IX' OR ObjectType='ALL') AND
| (REORGLASTTIME IS NULL AND REBUILDLASTTIME IS NULL) OR
| (NACTIVE IS NULL OR NACTIVE > 5) AND
| (((REORGINSERTS×100)/TOTALENTRIES>RRIInsertsPct) AND
| REORGINSERTS>RRIInsertsAbs) OR
| (((REORGDELETE×100)/TOTALENTRIES>RRIDeletesPct) AND
| REORGDELETE>RRIDeletesAbs) OR
| (REORGAPPENDINSERT×100)/TOTALENTRIES>RRIAppendInsertPct OR
| (REORGSEUDODELETES×100)/TOTALENTRIES>RRIPseudoDeletePct OR
| REORGMASDELETE>RRIMassDeleteLimit OR
| (REORGLAFAFFAR×100)/NACTIVE>RRILeafLimit OR
| REORGNUMLEVELS>RRINumLevelsLimit OR
| (NPAGES>5 AND
| (NPAGES×100)/NLEAF>RRIEmptyLimit) OR
| EXTENTS>ExtentLimit)) OR
| ((QueryType='RESTRICT' OR QueryType='ALL' ) AND
| (ObjectType='IX' OR ObjectType='ALL') AND
| An index is in advisory-REBUILD-pending stats (ARBDP)))

```

Figure 31. DSNACCOX formula for recommending a REORG on an index space

The following figure shows the formula that DSNACCOX uses to recommend RUNSTATS on a table space.

```

| ((QueryType='RUNSTATS' OR QueryType='ALL') AND
| (ObjectType='TS' OR ObjectType='ALL') AND
| Table Space is not cloned) AND
| (STATSLASTTIME IS NULL OR
| STATSLASTTIME<LOADRLASTTIME OR
| STATSLASTTIME<REORGLASTTIME OR
| ((STATSINSERTS+STATSDELETES+STATSUPDATES)×100)/TOTALROWS>SRTInsDelUpdPct AND
| (STATSINSERTS+STATSDELETES+STATSUPDATES)>SRTInsDelUpdAbs) OR
| STATSMASDELETE>SRTMassDeleteLimit)))

```

Figure 32. DSNACCOX formula for recommending RUNSTATS on a table space

The following figure shows the formula that DSNACCOX uses to recommend RUNSTATS on an index space.

```

| ((QueryType='RUNSTATS' OR QueryType='ALL') AND
| (ObjectType='IX' OR ObjectType='ALL')
| Table Space for the index is not cloned ) AND
| (STATSLASTTIME IS NULL OR
| STATSLASTTIME<LOADRLASTTIME OR
| STATSLASTTIME<REORGLASTTIME OR
| ((STATSINSERTS+STATSDELETES)×100)/TOTALENTRIES>SRIInsDelPct AND
| (STATSINSERTS+STATSDELETES)>SRIInsDelAbs) OR
| STATSMASDELETE>SRIInsDelAbs)))

```

Figure 33. DSNACCOX formula for recommending RUNSTATS on an index space

Using an exception table

An exception table is an optional, user-created DB2 table that you can use to place information in the INEXCEPTTABLE column of the recommendations result set. You can put any information in the INEXCEPTTABLE column, but the most

common use of this column is to filter the recommendations result set. Each row in the exception table represents an object for which you want to provide information for the recommendations result set.

To create the exception table, issue a CREATE TABLE statement similar to the following one. You can include other columns in the exception table, but you must include at least the columns that are shown. It is best to create a primary key on the exception table to prevent the duplication of rows in the exception table.

```
CREATE TABLE DSNACC.EXCEPT_TBL
(DBNAME CHAR (8) NOT NULL,
NAME CHAR (8) NOT NULL,
QUERYTYPE CHAR(40),
PRIMARY KEY (DBNAME,NAME))
CCSID EBCDIC;
```

The exception table columns have the following meanings:

DBNAME

The database name for an object in the exception table.

NAME

The table space name or index space name for an object in the exception table.

QUERYTYPE

The information that you want to place in the INEXCEPTTABLE column of the recommendations result set.

If you put a null value in this column, DSNACCOX puts the value YES in the INEXCEPTTABLE column of the recommendations result set row for the object that matches the DBNAME and NAME values.

If you plan to put many rows in the exception table, create a nonunique index on DBNAME, NAME, and QUERYTYPE.

After you create the exception table, insert a row for each object for which you want to include information in the INEXCEPTTABLE column.

Example: Suppose that you want the INEXCEPTTABLE column to contain the string 'IRRELEVANT' for table space STAFF in database DSNDB04. You also want the INEXCEPTTABLE column to contain 'CURRENT' for table space DSN8S10D in database DSN8D10A. Execute these INSERT statements:

```
INSERT INTO DSNACC.EXCEPT_TBL VALUES('DSNDB04 ', 'STAFF ', 'IRRELEVANT');
INSERT INTO DSNACC.EXCEPT_TBL VALUES('DSN8D10A', 'DSN8S10D', 'CURRENT');
```

To use the contents of INEXCEPTTABLE for filtering, include a condition that involves the INEXCEPTTABLE column in the search condition that you specify in your *Criteria* input parameter.

Example: Suppose that you want to include all rows for database DSNDB04 in the recommendations result set, except for those rows that contain the string 'IRRELEVANT' in the INEXCEPTTABLE column. You might include the following search condition in your *Criteria* input parameter:

```
DBNAME='DSNDB04' AND INEXCEPTTABLE<>'IRRELEVANT'
```

Example

The following figure is a COBOL example that shows variable declarations and an SQL CALL for obtaining recommendations for objects in databases DSN8D10A and

DSN8D10L. This example also outlines the steps that you need to perform to retrieve the two result sets that DSNACCOX returns. These result sets are described in "DSNACCOX output" on page 937

```

DSNACCOX output

If DSNACCOX executes successfully, in addition to the output parameters described in “Option descriptions” on page 917, DSNACCOX returns two result sets.

The first result set contains the results from IFI COMMAND calls that DSNACCOX makes. The following table shows the format of the first result set.

Table 132. Result set row for first DSNACCOX result set

| Column name | Data type | Contents |
|-------------|-----------|------------------------------------|
| RS_SEQUENCE | INTEGER | Sequence number of the output line |
| RS_DATA | CHAR(80) | A line of command output |

The second result set contains rows for table spaces, index spaces, or partitions, if both of the following conditions are true for the object:

- If the *Criteria* input parameter contains a search condition, and the search condition is true for the table space, index space, or partition.
- DSNACCOX recommends at least one action for the table space, index space, or partition.

The second result set contains one row for each nonpartitioned table space or nonpartitioning index space. For partitioned table spaces or partitioning indexes, the result set contains one row for each partition. If *ChkLvl 8* is specified, the result set might contain additional rows, including duplicate rows for the same object.

The following table shows the columns of a result set row.

Table 133. Result set row for second DSNACCOX result set

| Column name | Data type ¹ | Description |
|-------------|------------------------|---|
| DBNAME | VARCHAR(24) NOT NULL | Name of the database that contains the object. |
| NAME | VARCHAR(128) NOT NULL | Table space name, index name, or index space name. Index space name is used if the row is added as a result of checking a restricted state and the index name is not available at the time. |
| PARTITION | INTEGER NOT NULL | Data set number or partition number. |
| INSTANCE | SMALLINT NOT NULL | Indicates whether the object is associated with a data set instance. |
| CLONE | CHAR(1) | 'Y' or 'N', 'Y' indicates a cloned object. |
| OBJECTTYPE | CHAR(2) NOT NULL | DB2 object type: <ul style="list-style-type: none"> • 'TS' for a table space • 'IX' for an index space |
| INDEXSPACE | VARCHAR(24) | Index space name. |

Table 133. Result set row for second DSNACCOX result set (continued)

| Column name | Data type ¹ | Description |
|--------------|------------------------|---|
| CREATOR | VARCHAR(128) | Index creator name. |
| OBJECTSTATUS | CHAR(40) | <p>Status of the object:</p> <ul style="list-style-type: none"> • ORPHANED, if the object is an index space with no corresponding table space, or if the object does not exist • If the object is in a restricted state, one of the following values: <ul style="list-style-type: none"> – TS=<i>restricted-state</i>, if OBJECTTYPE is TS – IX=<i>restricted-state</i>, if OBJECTTYPE is IX – LS=<i>restricted-state</i>, if object is LOB TS. – LX=<i>restricted-state</i>, if object is XML TS. <p><i>restricted-state</i> is one of the status codes that appear in the output of the DISPLAY DATABASE command.</p> <p>Related information:</p> <ul style="list-style-type: none"> DSNT362I (DB2 Messages) -DISPLAY DATABASE (DB2) (DB2 Commands) <ul style="list-style-type: none"> • A, if the object is in an advisory state. • L, if the object is a logical partition, but not in an advisory state. • AL, if the object is a logical partition and in an advisory state. |
| IMAGECOPY | CHAR(4) | <p>COPY recommendation:</p> <ul style="list-style-type: none"> • If the object is a table space, one of the following values: <ul style="list-style-type: none"> FULL Full image copy is recommended INC Incremental image copy is recommended NO Image copy is not recommended. • If the object is an index, whether image copy is recommended: YES or NO |
| RUNSTATS | CHAR(3) | <p>RUNSTATS recommendation: YES, NO, or Y**.</p> <p>Y** indicates that the table space contains volatile and non-volatile tables.</p> |
| EXTENTS | CHAR(3) | Indicates whether the data sets for the object have exceeded <i>ExtentLimit</i> : YES or NO. |
| REORG | CHAR(3) | REORG recommendation: YES or NO. |

Table 133. Result set row for second DSNACCOX result set (continued)

| Column name | Data type ¹ | Description |
|-----------------|------------------------|--|
| INEXCEPTTABLE | CHAR(40) | A string that contains one of the following values: <ul style="list-style-type: none"> Text that you specify in the QUERYTYPE column of the exception table. YES, if you put a row in the exception table for the object that this result set row represents, but you specify NULL in the QUERYTYPE column. NO, if the exception table exists but does not have a row for the object that this result set row represents. Null, if the exception table does not exist, or if the <i>ChkLvl</i> input parameter does not include the value 4. |
| ASSOCIATEDTS | VARCHAR(128) | If OBJECTTYPE is IX this value is the name of the table space that is associated with the index space. Otherwise null. |
| COPYLASTTIME | TIMESTAMP | Timestamp of the last full or incremental image copy on the object. Null if COPY was never run, or if the last COPY execution is unknown. |
| LOADRLASTTIME | TIMESTAMP | Timestamp of the last LOAD REPLACE on the object. Null if LOAD REPLACE was never run, or if the last LOAD REPLACE execution is unknown. |
| REBUILDLASTTIME | TIMESTAMP | Timestamp of the last REBUILD INDEX on the object. Null if REBUILD INDEX was never run, or if the last REBUILD INDEX execution is unknown. |
| CRUPDPGSPCT | DOUBLE | If IMAGECOPY contains a value other than NO, the ratio of distinct updated pages to pre-formatted pages, expressed as a percentage. Otherwise null. If the ratio of distinct updated pages to pre-formatted pages, does not exceed the <i>CRUpdatedPagesPct</i> or <i>ICRUpdatedPagesPct</i> (for tables spaces only, when incremental copy is recommended), this value is null. |
| CRUPDPGSABS | INTEGER | If IMAGECOPY contains a value other than NO, the ratio of distinct updated pages to pre-formatted pages. Otherwise null. If the ratio of distinct updated pages to pre-formatted pages, does not exceed the value specified for <i>CRUpdatedPagesAbs</i> or <i>ICRUpdatedPagesAbs</i> (for tables spaces only, when incremental copy is recommended), this value is null. |

Table 133. Result set row for second DSNACCOX result set (continued)

| Column name | Data type ¹ | Description |
|----------------|------------------------|---|
| CRCPYCHGPCT | DOUBLE | <p>If the object is a table space and the value of IMAGECOPY is any value other than NO, the ratio of the total number insert, update, and delete operations since the last image copy to the total number of rows or LOBs in the table space or partition, expressed as a percentage.</p> <p>If the object is an index and IMAGECOPY is YES, the ratio of the total number of insert and delete operations since the last image copy to the total number of entries in the index space or partition, expressed as a percentage. Otherwise null.</p> <p>If the ratio of the total number insert, update, and delete operations since the last image copy to the total number of rows or LOBs in the table space or partition does not exceed the value specified for <i>CRChangesPct</i> or <i>ICRChangesPct</i> (incremental copy is recommended), this value is null.</p> |
| CRDAYSCELSTCPY | INTEGER | <p>If IMAGECOPY is YES, the number of days since the last image copy. Otherwise null.</p> <p>If the number of days since the last image copy does not exceed the value specified for <i>CrDaySncLastCopy</i>, this value is null.</p> |
| CRINDEXSIZE | INTEGER | <p>If IMAGECOPY is YES, the number of active pages in the index space or partition. Otherwise null.</p> <p>If the number of active pages in the index space or partition does not exceed the value specified for <i>CRIndexSize</i>, this value is null.</p> |
| REORGLASTTIME | TIMESTAMP | Timestamp of the last REORG on the object. Null if REORG was never run, or if the last REORG execution was terminated. |
| RRTINSERTSPCT | DOUBLE | <p>If REORG is YES, the ratio of the sum of insert operations since the last REORG to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null.</p> <p>If the ratio of the sum of insert operations since the last REORG to the total number of rows or LOBs in the table space or partition does not exceed the value specified for <i>RRTInsertsPct</i>, this value is null.</p> |

DSNACICS stored procedure

The CICS transaction invocation stored procedure (DSNACICS) invokes CICS server programs.

GUPI DSNACICS gives workstation applications a way to invoke CICS server programs while using TCP/IP as their communication protocol. The workstation applications use TCP/IP and DB2 Connect to connect to a DB2 for z/OS subsystem, and then call DSNACICS to invoke the CICS server programs.

The DSNACICS input parameters require knowledge of various CICS resource definitions with which the workstation programmer might not be familiar. For this reason, DSNACICS invokes the DSNACICX user exit routine. The system programmer can write a version of DSNACICX that checks and overrides the parameters that the DSNACICS caller passes. If no user version of DSNACICX is provided, DSNACICS invokes the default version of DSNACICX, which does not modify any parameters.

Environment

DSNACICS runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2.

If you use CICS Transaction Server for OS/390® Version 1 Release 3 or later, you can register your CICS system as a resource manager with recoverable resource management services (RRMS). When you do that, changes to DB2 databases that are made by the program that calls DSNACICS and the CICS server program that DSNACICS invokes are in the same two-phase commit scope. This means that when the calling program performs an SQL COMMIT or ROLLBACK, DB2 and RRS inform CICS about the COMMIT or ROLLBACK.

If the CICS server program that DSNACICS invokes accesses DB2 resources, the server program runs under a separate unit of work from the original unit of work that calls the stored procedure. This means that the CICS server program might deadlock with locks that the client program acquires.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on stored procedure DSNACICS
- Ownership of the stored procedure
- SYSADM authority

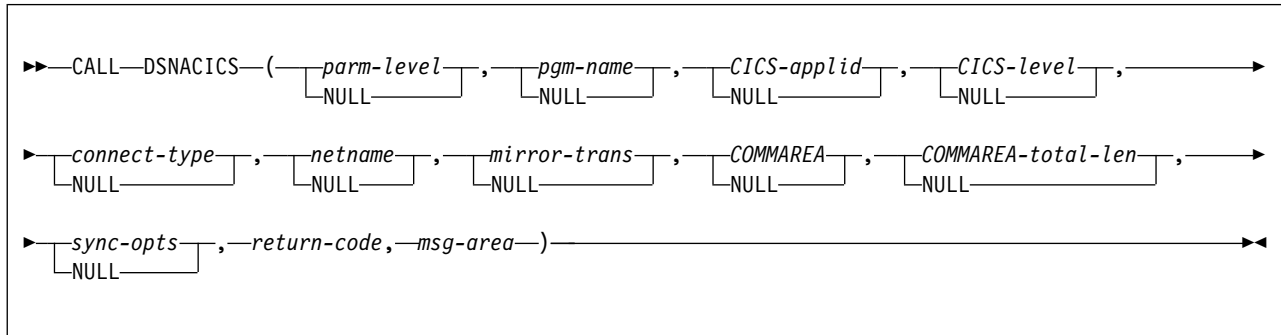

The CICS server program that DSNACICS calls runs under the same user ID as DSNACICS. That user ID depends on the SECURITY parameter that you specify when you define DSNACICS.

The DSNACICS caller also needs authorization from an external security system, such as RACF, to use CICS resources.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure.

Because the linkage convention for DSNACICS is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

Option descriptions

parm-level

Specifies the level of the parameter list that is supplied to the stored procedure. This is an input parameter of type INTEGER. The value must be 1.

pgm-name

Specifies the name of the CICS program that DSNACICS invokes. This is the name of the program that the CICS mirror transaction calls, not the CICS transaction name.

This is an input parameter of type CHAR(8).

CICS-applid

Specifies the applid of the CICS system to which DSNACICS connects.

This is an input parameter of type CHAR(8).

CICS-level

Specifies the level of the target CICS subsystem:

- 1 The CICS subsystem is CICS for MVS/ESA Version 4 Release 1, CICS Transaction Server for OS/390 Version 1 Release 1, or CICS Transaction Server for OS/390 Version 1 Release 2.
- 2 The CICS subsystem is CICS Transaction Server for OS/390 Version 1 Release 3 or later.

This is an input parameter of type INTEGER.

connect-type

Specifies whether the CICS connection is generic or specific. Possible values are GENERIC or SPECIFIC.

This is an input parameter of type CHAR(8).

netname

If the value of *connection-type* is SPECIFIC, specifies the name of the specific connection that is to be used. This value is ignored if the value of *connection-type* is GENERIC.

This is an input parameter of type CHAR(8).

mirror-trans

Specifies the name of the CICS mirror transaction to invoke. This mirror transaction calls the CICS server program that is specified in the *pgm-name*

parameter. *mirror-trans* must be defined to the CICS server region, and the CICS resource definition for *mirror-trans* must specify DFHMIRS as the program that is associated with the transaction.

If this parameter contains blanks, DSNACICS passes a mirror transaction parameter value of null to the CICS EXCI interface. This allows an installation to override the transaction name in various CICS user-replaceable modules. If a CICS user exit routine does not specify a value for the mirror transaction name, CICS invokes CICS-supplied default mirror transaction CSML.

This is an input parameter of type CHAR(4).

COMMAREA

Specifies the communication area (COMMAREA) that is used to pass data between the DSNACICS caller and the CICS server program that DSNACICS calls.

This is an input/output parameter of type VARCHAR(32704). In the length field of this parameter, specify the number of bytes that DSNACICS sends to the CICS server program.

commarea-total-len

Specifies the total length of the COMMAREA that the server program needs.

This is an input parameter of type INTEGER. This length must be greater than or equal to the value that you specify in the length field of the COMMAREA parameter and less than or equal to 32704. When the CICS server program completes, DSNACICS passes the server program's entire COMMAREA, which is *commarea-total-len* bytes in length, to the stored procedure caller.

sync-opts

Specifies whether the calling program controls resource recovery, using two-phase commit protocols that are supported by RRS. Possible values are:

- 1 The client program controls commit processing. The CICS server region does not perform a syncpoint when the server program returns control to CICS. Also, the server program cannot take any explicit syncpoints. Doing so causes the server program to abnormally terminate.
- 2 The target CICS server region takes a syncpoint on successful completion of the server program. If this value is specified, the server program can take explicit syncpoints.

When CICS has been set up to be an RRS resource manager, the client application can control commit processing using SQL COMMIT requests. DB2 for z/OS ensures that CICS is notified to commit any resources that the CICS server program modifies during two-phase commit processing.

When CICS has not been set up to be an RRS resource manager, CICS forces syncpoint processing of all CICS resources at completion of the CICS server program. This commit processing is not coordinated with the commit processing of the client program.

This option is ignored when *CICS-level* is 1. This is an input parameter of type INTEGER.

return-code

Return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The request to run the CICS server program failed. The *msg-area* parameter contains messages that describe the error.

This is an output parameter of type INTEGER.

msg-area

Contains messages if an error occurs during stored procedure execution. The first messages in this area are generated by the stored procedure. Messages that are generated by CICS or the DSNACICX user exit routine might follow the first messages. The messages appear as a series of concatenated, viewable text strings.

This is an output parameter of type VARCHAR(500).

User exit routine

DSNACICS always calls user exit routine DSNACICX. You can use DSNACICX to change the values of DSNACICS input parameters before you pass those parameters to CICS. If you do not supply your own version of DSNACICX, DSNACICS calls the default DSNACICX, which modifies no values and does an immediate return to DSNACICS. The source code for the default version of DSNACICX is in member DSNASCIX in data set *prefix.SDSNSAMP*. The source code for a sample version of DSNACICX that is written in COBOL is in member DSNASCIO in data set *prefix.SDSNSAMP*.

Example

The following PL/I example shows the variable declarations and SQL CALL statement for invoking the CICS transaction that is associated with program CICSPGM1.

```

Output

DSNACICS places the return code from DSNACICS execution in the *return-code* parameter. If the value of the return code is non-zero, DSNACICS puts its own

error messages and any error messages that are generated by CICS and the DSNACICX user exit routine in the *msg-area* parameter.

The *COMMAREA* parameter contains the *COMMAREA* for the CICS server program that DSNACICS calls. The *COMMAREA* parameter has a *VARCHAR* type. Therefore, if the server program puts data other than character data in the *COMMAREA*, that data can become corrupted by code page translation as it is passed to the caller. To avoid code page translation, you can change the *COMMAREA* parameter in the *CREATE PROCEDURE* statement for DSNACICS to *VARCHAR(32704) FOR BIT DATA*. However, if you do so, the client program might need to do code page translation on any character data in the *COMMAREA* to make it readable.

Restrictions

Because DSNACICS uses the distributed program link (DPL) function to invoke CICS server programs, server programs that you invoke through DSNACICS can contain only the CICS API commands that the DPL function supports.

Debugging

If you receive errors when you call DSNACICS, ask your system administrator to add a *DSNDUMP DD* statement in the startup procedure for the address space in which DSNACICS runs. The *DSNDUMP DD* statement causes DB2 to generate an SVC dump whenever DSNACICS issues an error message.

DSNAEXP stored procedure

The DB2 EXPLAIN stored procedure, DSNAEXP, is a sample stored procedure that enables you to execute an EXPLAIN statement for certain simple SQL statements without having the authorization to execute that SQL statement. This stored procedure is deprecated. Starting in DB2 10, use of the EXPLAIN privilege or SQLADM authority is recommended instead.

PSPI

Important: Certain SQL statements might prevent the DSNAEXP stored procedure from parsing the statement correctly, such as:

- Very large SQL statements
- SQL statements that contain complex structures, such as embedded joins, sub-selects, numerous predicates, common table expressions, and unqualified object references.
- SQL statements other than the following basic types:
 - SELECT
 - INSERT
 - DELETE
 - UPDATE
 - MERGE

In certain cases, you might need to provide explicit qualifiers for object references in SQL statements to enable the DSNAEXP stored procedure to explain the statements.

Environment

DSNAEXP must run in a WLM-established stored procedure address space.

Before you can invoke DSNAEXP, table *sqlid*.PLAN_TABLE must exist. *sqlid* is the value that you specify for the *sqlid* input parameter when you call DSNAEXP.

Job DSNTESC in DSN8A10.SDSNSAMP contains a sample CREATE TABLE statement for the PLAN_TABLE.

Authorization required

To execute the CALL SYSPROC.DSNAEXP statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNAEXP
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

In addition:

- The SQL authorization ID of the process in which DSNAEXP is called must have the authority to execute SET CURRENT SQLID=*sqlid*.

- The SQL authorization ID of the process must also have one of the following characteristics:
 - Be the owner of a plan table named PLAN_TABLE
 - Have an alias on a plan table named *owner*.PLAN_TABLE and have SELECT and INSERT privileges on the table

DSNAEXP syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNAEXP. Because the linkage convention for DSNAEXP is GENERAL, you cannot pass null values to the stored procedure.

```

  ►►CALL—DSNAEXP—(—sqlid—,—queryno—,—sql-statement—,—parse—,——————►
  ►—qualifier—,—sqlcode—,—sqlstate—,—error-message—)—————►►

```

DSNAEXP option descriptions

sqlid

Specifies:

- The authorization ID under which the EXPLAIN statement is to be executed
- The qualifier for the table into which EXPLAIN output is written:
sqlid.PLAN_TABLE
- The implicit qualifier for unqualified objects in the SQL statement on which EXPLAIN is executed, if the value of *parse* is 'N'

sqlid is an input parameter of type CHAR(8).

queryno

Specifies a number that is to be used to identify *sql-statement* in the EXPLAIN output. This number appears in the QUERYNO column in the PLAN_TABLE.
queryno is an input parameter of type INTEGER.

sql-statement

Specifies the SQL statement on which EXPLAIN is to be executed. *sql-statement* is an input parameter of type CLOB(2M).

parse

Specifies whether DSNAEXP adds a qualifier for unqualified table or view names in the input SQL statement. Valid values are 'Y' and 'N'. If the value of *parse* is 'Y', *qualifier* must contain a valid SQL qualifier name.

If *sql-statement* is insert-within-select and common table expressions, you need to disable the parsing functionality, and add the qualifier manually.

parse is an input parameter of type CHAR(1).

qualifier

Specifies the qualifier that DSNAEXP adds to unqualified table or view names in the input SQL statement. If the value of *parse* is 'N', *qualifier* is ignored.

If the statement on which EXPLAIN is run contains an INSERT within a SELECT or a common table expression, *parse* must be 'N', and table and view qualifiers must be explicitly specified.

qualifier is an input parameter of type CHAR(8).

sqlcode

Contains the SQLCODE from execution of the EXPLAIN statement. *sqlcode* is an output parameter of type INTEGER.

sqlstate

Contains the SQLSTATE from execution of the EXPLAIN statement. *sqlstate* is an output parameter of type CHAR(5).

error-message

Contains information about DSNAXP execution. If the SQLCODE from execution of the EXPLAIN statement is not 0, *error-message* contains the error message for the SQLCODE. *error-message* is an output parameter of type VARCHAR(960).

Example of DSNAXP invocation

The following C example shows how to call DSNAXP to execute an EXPLAIN statement.

```
EXEC SQL BEGIN DECLARE SECTION;
char      hvsqlid[9];          /* Qualifier for PLAN_TABLE */
long int  hvqueryno;         /* QUERYNO to give the SQL */
struct {
    short int hvsql_stmt_len; /* Input SQL statement length */
    char      hvsql_stmt_txt SQL type is CLOB 2M;
                                /* SQL statement text */
}         hvsql_stmt;        /* SQL statement to EXPLAIN */
char      hvparse[1];        /* Qualify object names */
char      hvqualifier[9];    /* indicator */
char      hvqualifier[9];    /* Qualifier for unqualified */
long int  hvsqlcode;        /* objects */
char      hvsqlstate[6];    /* SQLCODE from CALL DSNAXP */
char      hvsqlstate[6];    /* SQLSTATE from CALL DSNAXP */
struct {
    short int hvmsg_len;     /* Error message length */
    char      hvmsg_text[961]; /* Error message text */
}         hvmsg;           /* Error message from failed */
                                /* CALL DSNAXP */

EXEC SQL END DECLARE SECTION;
short int i;
:
:
/* Set the input parameters */
strcpy(hvsqlid,"ADMFO01 ");
hvqueryno=320;
strcpy(hvsql_stmt.hvsql_stmt_txt,"SELECT CURRENT DATE FROM SYSDUMMY1");
hvsql_stmt.hvsql_stmt_len=strlen(hvsql_stmt.hvsql_stmt_txt);
hvparse[0]='Y';
strcpy(hvqualifier,"SYSIBM");
/* Initialize the output parameters */
hvsqlcode=0;
for (i = 0; i < 5; i++) hvsqlstate[i] = '0';
hvsqlstate[5]='\0';
hvmsg.hvmsg_len=0;
for (i = 0; i < 960; i++) hvmsg.hvmsg_text[i] = ' ';
hvmsg.hvmsg_text[960] = '\0';
/* Call DSNAXP to do EXPLAIN and put output in ADMFO01.PLAN_TABLE */
EXEC SQL
    CALL SYSPROC.DSNAXP(:hvsqlid,
                        :hvqueryno,
                        :hvsql_stmt,
                        :hvparse,
                        :hvqualifier,
                        :hvsqlcode,
                        :hvsqlstate,
                        :hvmsg);
```

DSNAEXP output

If DSNAEXP executes successfully, *sqlid.PLAN_TABLE* contains the EXPLAIN output. A user with SELECT authority on *sqlid.PLAN_TABLE* can obtain the results of the EXPLAIN that was executed by DSNAEXP by executing this query:

```
SELECT * FROM sqlid.PLAN_TABLE WHERE QUERYNO='queryno';
```

If DSNAEXP does not execute successfully, *sqlcode*, *sqlstate*, and *error-message* contain error information.

DSNAIMS stored procedure

DSNAIMS is a stored procedure that allows DB2 applications to invoke IMS transactions and commands easily, without maintaining their own connections to IMS.

GUPI

DSNAIMS uses the IMS Open Transaction Manager Access (OTMA) API to connect to IMS and execute the transactions.

Environment

DSNAIMS runs in a WLM-established stored procedures address space. DSNAIMS requires DB2 with RRSF enabled and IMS version 7 or later with OTMA Callable Interface enabled.

To use a two-phase commit process, you must have IMS Version 8 with UQ70789 or later.

Authorization

To set up and run DSNAIMS, you must be authorized to perform the following steps:

1. Use the job DSNTIJIM to issue the CREATE PROCEDURE statement for DSNAIMS and to grant the execution of DSNAIMS to PUBLIC. DSNTIJIM is provided in the SDSNSAMP data set. You need to customize DSNTIJIM to fit the parameters of your system.
2. Ensure that OTMA C/I is initialized.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.DSNAIMS ( ( dsnaims-function, dsnaims-2pc ) , xcf-group-name ,
                        ( xcf-ims-name , racf-userid , racf-groupid ) , ims-lterm , ims-modname ,
                        ( ims-tran-name , ims-data-in , ims-data-out ) , otma-tpipe-name ,
                        ( otma-dru-name , user-data-in ) , user-data-out , status-message , return-code ) )
```

Option descriptions

dsnaims-function

A string that indicates whether the transaction is send-only, receive-only, or send-and-receive. Possible values are:

SENDRECV

Sends and receives IMS data. SENDRECV invokes an IMS transaction or command and returns the result to the caller. The transaction can be an IMS full function or a fast path. SENDRECV does not support multiple iterations of a conversational transaction

SEND Sends IMS data. SEND invokes an IMS transaction or command, but does not receive IMS data. If result data exists, it can be retrieved with the RECEIVE function. A send-only transaction cannot be an IMS fast path transaction or a conversations transaction.

RECEIVE

Receives IMS data. The data can be the result of a transaction or command initiated by the SEND function or an unsolicited output message from an IMS application. The RECEIVE function does not initiate an IMS transaction or command.

dsnaims-2pc

Specifies whether to use a two-phase commit process to perform the transaction syncpoint service. Possible values are Y or N. For N, commits and rollbacks that are issued by the IMS transaction do not affect commit and rollback processing in the DB2 application that invokes DSNAIMS. Furthermore, IMS resources are not affected by commits and rollbacks that are issued by the calling DB2 application. If you specify Y, you must also specify SENDRECV. To use a two-phase commit process, you must set the IMS control region parameter (RRS) to Y.

This parameter is optional. The default is N.

xcf-group-name

Specifies the XCF group name that the IMS OTMA joins. You can obtain this name by viewing the GRNAME parameter in IMS PROCLIB member DFSPBxxx or by using the IMS command /DISPLAY OTMA.

xcf-ims-name

Specifies the XCF member name that IMS uses for the XCF group. If IMS is not using the XRF or RSR feature, you can obtain the XCF member name from the OTMANM parameter in IMS PROCLIB member DFSPBxxx. If IMS is using the XRF or RSR feature, you can obtain the XCF member name from the USERVAR parameter in IMS PROCLIB member DFSPBxxx.

racf-userid

Specifies the RACF user ID that is used for IMS to perform the transaction or command authorization checking. This parameter is required if DSNAIMS is running APF-authorized. If DSNAIMS is running unauthorized, this parameter is ignored and the EXTERNAL SECURITY setting for the DSNAIMS stored procedure definition determines the user ID that is used by IMS.

racf-groupid

Specifies the RACF group ID that is used for IMS to perform the transaction or command authorization checking. This field is used for stored procedures that are APF-authorized. It is ignored for other stored procedures.

ims-lterm

Specifies an IMS LTERM name that is used to override the LTERM name in the I/O program communication block of the IMS application program.

This field is used as an input and an output field:

- For SENDRECV, the value is sent to IMS on input and can be updated by IMS on output.

- For SEND, the parameter is IN only.
- For RECEIVE, the parameter is OUT only.

An empty or NULL value tells IMS to ignore the parameter.

ims-modname

Specifies the formatting map name that is used by the server to map output data streams, such as 3270 streams. Although this invocation does not have IMS MFS support, the input MODNAME can be used as the map name to define the output data stream. This name is an 8-byte message output descriptor name that is placed in the I/O program communication block. When the message is inserted, IMS places this name in the message prefix with the map name in the program communication block of the IMS application program.

For SENDRECV, the value is sent to IMS on input, and can be updated on output. For SEND, the parameter is IN only. For RECEIVE it is OUT only. IMS ignores the parameter when it is an empty or NULL value.

ims-tran-name

Specifies the name of an IMS transaction or command that is sent to IMS. If the IMS command is longer than eight characters, specify the first eight characters (including the "/" of the command). Specify the remaining characters of the command in the *ims-tran-name* parameter. If you use an empty or NULL value, you must specify the full transaction name or command in the *ims-data-in* parameter.

ims-data-in

Specifies the data that is sent to IMS. This parameter is required in each of the following cases:

- Input data is required for IMS
- No transaction name or command is passed in *ims-tran-name*
- The command is longer than eight characters

This parameter is ignored when for RECEIVE functions.

ims-data-out

Data returned after successful completion of the transaction. This parameter is required for SENDRECV and RECEIVE functions. The parameter is ignored for SEND functions.

The length of *ims-data-out* is 32,000 bytes. If the data that is returned from IMS is greater than the length of *ims-data-out*, the data will be truncated.

otma-tpipe-name

Specifies an 8-byte user-defined communication session name that IMS uses for the input and output data for the transaction or the command in a SEND or a RECEIVE function. If the *otma_tpipe_name* parameter is used for a SEND function to generate an IMS output message, the same *otma_pipe_name* must be used to retrieve output data for the subsequent RECEIVE function.

otma-dru-name

Specifies the name of an IMS user-defined exit routine, OTMA destination resolution user exit routine, if it is used. This IMS exit routine can format part of the output prefix and can determine the output destination for an IMS ALT_PCB output. If an empty or null value is passed, IMS ignores this parameter.

user-data-in

This optional parameter contains any data that is to be included in the IMS

message prefix, so that the data can be accessed by IMS OTMA user exit routines (DFSYIOE0 and DFSYDRU0) and can be tracked by IMS log records. IMS applications that run in dependent regions do not access this data. The specified user data is not included in the output message prefix. You can use this parameter to store input and output correlator tokens or other information. This parameter is ignored for RECEIIVE functions.

user-data-out

On output, this field contains the *user-data-in* in the IMS output prefix. IMS user exit routines (DFSYIOE0 and DFSYDRU0) can also create *user-data-out* for SENDRECV and RECEIVE functions. The parameter is not updated for SEND functions.

The length of *user-data-out* is 1,022 bytes. If the data that is returned from IMS is greater than the length of *user-data-out*, the data will be truncated.

status-message

Indicates any error message that is returned from the transaction or command, OTMA, RRS, or DSNAIMS.

return-code

Indicates the return code that is returned for the transaction or command, OTMA, RRS, or DSNAIMS.

Examples

The following examples show how to call DSNAIMS.

Example 1: Sample parameters for executing an IMS command:

```
CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCLNM", "", "", "", "", "",
                    "/LOG Hello World.", ims_data_out, "", "", "",
                    user_out, error_message, rc)
```

Example 2: Sample parameters for executing an IMS IVTNO transaction:

```
CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCLNM", "", "", "", "", "",
                    "IVTNO    DISPLAY LAST1    ", ims_data_out
                    "", "", "", user_out, error_message, rc)
```

Example 3: Sample parameters for send-only IMS transaction:

```
CALL SYSPROC.DSNAIMS("SEND", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCLNM", "", "", "", "", "",
                    "IVTNO    DISPLAY LAST1    ", ims_data_out,
                    "DSNAPIPE", "", "", user_out, error_message, rc)
```

Example 4: Sample parameters for receive-only IMS transaction:

```
CALL SYSPROC.DSNAIMS("RECEIVE", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCLNM", "", "", "", "", "",
                    "IVTNO    DISPLAY LAST1    ", ims_data_out,
                    "DSNAPIPE", "", "", user_out, error_message, rc)
```

Connecting to multiple IMS subsystems with DSNAIMS

By default DSNAIMS connects to only one IMS subsystem at a time. The first request to DSNAIMS determines to which IMS subsystem the stored procedure connects. DSNAIMS attempts to reconnect to IMS only in the following cases:

- IMS is restarted and the saved connection is no longer valid
- WLM loads another DSNAIMS task

To connect to multiple IMS subsystems simultaneously, perform the following steps:

1. Make a copy of the DB2-supplied job DSNTIJIM and customize it to your environment.
2. Change the procedure name from SYSPROC.DSNAIMS to another name, such as DSNAIMSB.
3. Do not change the EXTERNAL NAME option. Leave it as DSNAIMS.
4. Run the new job to create a second instance of the stored procedure.
5. To ensure that you connect to the intended IMS target, consistently use the XFC group and member names that you associate with each stored procedure instance. For example:

```
CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7TMEM", ...)  
CALL SYSPROC.DSNAIMSB("SENDRECV", "N", "IMS8GRP", "IMS8TMEM", ...)
```

DSNAIMS2 stored procedure

DSNAIMS2 is a stored procedure that allows DB2 applications to invoke IMS transactions and commands easily, without maintaining their own connections to IMS. DSNAIMS2 includes multi-segment input support for IMS transactions.

GUPI DSNAIMS2 uses the IMS Open Transaction Manager Access (OTMA) API to connect to IMS and execute the transactions.

When you define the DSNAIMS2 stored procedure to your DB2 subsystem, you can use the name DSNAIMS in your application if you prefer. Customize DSNTIJI2 to define the stored procedure to your DB2 subsystem as DSNAIMS; however, the EXTERNAL NAME option must still be DSNAIMS2.

Environment

DSNAIMS2 runs in a WLM-established stored procedures address space. DSNAIMS2 requires DB2 with RRSF enabled and IMS version 7 or later with OTMA Callable Interface enabled.

To use a two-phase commit process, you must have IMS Version 8 with UQ70789 or later.

Authorization

To set up and run DSNAIMS2, you must be authorized to perform the following steps:

1. Use the job DSNTIJI2 to issue the CREATE PROCEDURE statement for DSNAIMS2 and to grant the execution of DSNAIMS2 to PUBLIC. DSNTIJI2 is provided in the SDSNSAMP data set. You need to customize DSNTIJI2 to fit the parameters of your system.
2. Ensure that OTMA C/I is initialized.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.DSNAIMS2 (—dsnaims-function, —dsnaims-2pc, —xcf-group-name, —  
NULL, —xcf-ims-name, —racf-userid, —racf-groupid, —ims-lterm, —ims-modname, —  
NULL, —ims-tran-name, —ims-data-in, —ims-data-out, —otma-tpipe-name, —  
NULL, —otma-dru-name, —user-data-in, —user-data-out, —status-message, —otma-data-inseg, —  
NULL, —return-code—)
```

Option descriptions

dsnaims-function

A string that indicates whether the transaction is send-only, receive-only, or send-and-receive. Possible values are:

SENDRECV

Sends and receives IMS data. SENDRECV invokes an IMS transaction or command and returns the result to the caller. The transaction can be an IMS full function or a fast path. SENDRECV does not support multiple iterations of a conversational transaction

SEND Sends IMS data. SEND invokes an IMS transaction or command, but does not receive IMS data. If result data exists, it can be retrieved with the RECEIVE function. A send-only transaction cannot be an IMS fast path transaction or a conversations transaction.

RECEIVE

Receives IMS data. The data can be the result of a transaction or command initiated by the SEND function or an unsolicited output message from an IMS application. The RECEIVE function does not initiate an IMS transaction or command.

dsnaims-2pc

Specifies whether to use a two-phase commit process to perform the transaction syncpoint service. Possible values are Y or N. For N, commits and rollbacks that are issued by the IMS transaction do not affect commit and rollback processing in the DB2 application that invokes DSNAIMS2. Furthermore, IMS resources are not affected by commits and rollbacks that are issued by the calling DB2 application. If you specify Y, you must also specify SENDRECV. To use a two-phase commit process, you must set the IMS control region parameter (RRS) to Y.

This parameter is optional. The default is N.

xcf-group-name

Specifies the XCF group name that the IMS OTMA joins. You can obtain this name by viewing the GRNAME parameter in IMS PROCLIB member DFSPBxxx or by using the IMS command /DISPLAY OTMA.

xcf-ims-name

Specifies the XCF member name that IMS uses for the XCF group. If IMS is not using the XRF or RSR feature, you can obtain the XCF member name from the OTMANM parameter in IMS PROCLIB member DFSPBxxx. If IMS is using the XRF or RSR feature, you can obtain the XCF member name from the USERVAR parameter in IMS PROCLIB member DFSPBxxx.

racf-userid

Specifies the RACF user ID that is used for IMS to perform the transaction or command authorization checking. This parameter is required if DSNAIMS2 is running APF-authorized. If DSNAIMS2 is running unauthorized, this parameter is ignored and the EXTERNAL SECURITY setting for the DSNAIMS2 stored procedure definition determines the user ID that is used by IMS.

racf-groupid

Specifies the RACF group ID that is used for IMS to perform the transaction or command authorization checking. This field is used for stored procedures that are APF-authorized. It is ignored for other stored procedures.

| ***ims-lterm***

| Specifies an IMS LTERM name that is used to override the LTERM name in the
| I/O program communication block of the IMS application program.

| This field is used as an input and an output field:

- | • For SENDRECV, the value is sent to IMS on input and can be updated by
| IMS on output.
- | • For SEND, the parameter is IN only.
- | • For RECEIVE, the parameter is OUT only.

| An empty or NULL value tells IMS to ignore the parameter.

| ***ims-modname***

| Specifies the formatting map name that is used by the server to map output
| data streams, such as 3270 streams. Although this invocation does not have
| IMS MFS support, the input MODNAME can be used as the map name to
| define the output data stream. This name is an 8-byte message output
| descriptor name that is placed in the I/O program communication block.
| When the message is inserted, IMS places this name in the message prefix with
| the map name in the program communication block of the IMS application
| program.

| For SENDRECV, the value is sent to IMS on input, and can be updated on
| output. For SEND, the parameter is IN only. For RECEIVE it is OUT only. IMS
| ignores the parameter when it is an empty or NULL value.

| ***ims-tran-name***

| Specifies the name of an IMS transaction or command that is sent to IMS. If
| the IMS command is longer than eight characters, specify the first eight
| characters (including the "/" of the command). Specify the remaining
| characters of the command in the *ims-tran-name* parameter. If you use an empty
| or NULL value, you must specify the full transaction name or command in the
| *ims-data-in* parameter.

| ***ims-data-in***

| Specifies the data that is sent to IMS. This parameter is required in each of the
| following cases:

- | • Input data is required for IMS
- | • No transaction name or command is passed in *ims-tran-name*
- | • The command is longer than eight characters

| This parameter is ignored when for RECEIVE functions.

| ***ims-data-out***

| Data returned after successful completion of the transaction. This parameter is
| required for SENDRECV and RECEIVE functions. The parameter is ignored for
| SEND functions.

| The length of *ims-data-out* is 32,000 bytes. If the data that is returned from IMS
| is greater than the length of *ims-data-out*, the data will be truncated.

| ***otma-tpipe-name***

| Specifies an 8-byte user-defined communication session name that IMS uses for
| the input and output data for the transaction or the command in a SEND or a
| RECEIVE function. If the *otma_tpipe_name* parameter is used for a SEND
| function to generate an IMS output message, the same *otma_pipe_name* must
| be used to retrieve output data for the subsequent RECEIVE function.

| ***otma-dru-name***

| Specifies the name of an IMS user-defined exit routine, OTMA destination

resolution user exit routine, if it is used. This IMS exit routine can format part of the output prefix and can determine the output destination for an IMS ALT_PCB output. If an empty or null value is passed, IMS ignores this parameter.

user-data-in

This optional parameter contains any data that is to be included in the IMS message prefix, so that the data can be accessed by IMS OTMA user exit routines (DFSYIOE0 and DFSYDRU0) and can be tracked by IMS log records. IMS applications that run in dependent regions do not access this data. The specified user data is not included in the output message prefix. You can use this parameter to store input and output correlator tokens or other information. This parameter is ignored for RECEIVE functions.

user-data-out

On output, this field contains the *user-data-in* in the IMS output prefix. IMS user exit routines (DFSYIOE0 and DFSYDRU0) can also create *user-data-out* for SENDRECV and RECEIVE functions. The parameter is not updated for SEND functions.

The length of *user-data-out* is 1,022 bytes. If the data that is returned from IMS is greater than the length of *user-data-out*, the data will be truncated.

status-message

Indicates any error message that is returned from the transaction or command, OTMA, RRS, or DSNAIMS2.

otma-data-inseg

Specifies the number of segments followed by the lengths of the segments to be sent to IMS. All values should be separated by semicolons. This field is required to send multi-segment input to IMS. For single-segment transactions and commands, set the field to NULL, "0" or "0";".

return-code

Indicates the return code that is returned for the transaction or command, OTMA, RRS, or DSNAIMS2.

Examples

The following examples show how to call DSNAIMS2.

Example 1: Sample parameters for executing a multi-segment IMS transaction:

```
CALL SYSPROC.DSNAIMS2("SEND","N","IMS7GRP","IMS7TMEM",
  "IMSCSNM","","","","","","",
  "PART 1ST SEGMENT FROM CI 2ND SEGMENT FROM CI ",
  ims_data_out,"","","",user_out, error_message,
  "2;25;20",rc)
```

Example 2: Sample parameters for executing a single-segment IMS IVTNO transaction:

```
CALL SYSPROC.DSNAIMS2("SEND","N","IMS7GRP","IMS7TMEM",
  "IMSCSNM","","","","","IVTNO",
  "DISPLAY LAST1",ims_data_out,"","","",
  user_out, error_message,NULL,rc)
```

Connecting to multiple IMS subsystems with DSNAIMS2

By default DSNAIMS2 connects to only one IMS subsystem at a time. The first request to DSNAIMS2 determines to which IMS subsystem the stored procedure connects. DSNAIMS2 attempts to reconnect to IMS only in the following cases:

- IMS is restarted and the saved connection is no longer valid
- WLM loads another DSNAIMS2 task

To connect to multiple IMS subsystems simultaneously, perform the following steps:

1. Make a copy of the DB2-supplied job DSNTIJI2 and customize it to your environment.
2. Change the procedure name from SYSPROC.DSNAIMS2 to another name, such as DSNAIMS2B.
3. Do not change the EXTERNAL NAME option. Leave it as DSNAIMS2.
4. Change the name of the stored procedure in the grant statement in job DSNTIJI2.
5. Run the new job to create a second instance of the stored procedure.
6. To ensure that you connect to the intended IMS target, consistently use the XFC group and member names that you associate with each stored procedure instance. For example:

```
CALL SYSPROC.DSNAIMS2("SENDRECV", "N", "IMS7GRP", "IMS7TMEM", ...)  
CALL SYSPROC.DSNAIMS2B("SENDRECV", "N", "IMS8GRP", "IMS8TMEM", ...)
```

 OTMA C/I initialization

Related information:

 Accessing IMS databases from DB2 stored procedures (DB2 for z/OS Stored Procedures: Through the CALL and Beyond)

DSNLEUSR stored procedure

The DSNLEUSR stored procedure is a sample stored procedure. Use this stored procedure to store encrypted values in the translated authorization ID (NEWAUTHID) and password fields of the SYSIBM.USERNAMES table.

GUPI

You provide all the values for a SYSIBM.USERNAMES row as input to DSNLEUSR. DSNLEUSR encrypts the translated authorization ID and password values before it inserts the row into SYSIBM.USERNAMES.

Environment

DSNLEUSR has the following requirements:

- DSNLEUSR runs in a WLM-established stored procedure address space.
- z/OS Integrated Cryptographic Service Facility (ICSF) must be installed, configured, and active. The services that ICSF calls that are used by this stored procedure are CSNBCKM and CSNBENC.

Authorization

To execute the CALL DSNLEUSR statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the package for DSNLEUSR
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have INSERT authority on SYSIBM.USERNAMES.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL DSNLEUSR ( (Type, AuthID, LinkName, NewAuthID, Password), ReturnCode, MsgArea)
```

Option descriptions

Type

Specifies the value that is to be inserted into the TYPE column of SYSIBM.USERNAMES.

This is an input parameter of type CHAR(1).

|
| **AuthID**

| Specifies the value that is to be inserted into the AUTHID column of
| SYSIBM.USERNAMES.

| This is an input parameter of type VARCHAR(128). If you specify a null value,
| DSNLEUSR does not insert a value for *AuthID* .

|
| **LinkName**

| Specifies the value that is to be inserted into the LINKNAME column of
| SYSIBM.USERNAMES.

| This is an input parameter of type CHAR(8). Although the LINKNAME field
| of SYSIBM.USERNAMES is VARCHAR(24), this value is restricted to a
| maximum of 8 bytes.

| If you specify a null value, DSNLEUSR does not insert a value for *LinkName* .

|
| **NewAuthID**

| Specifies the value that is to be inserted into the NEWAUTHID column of
| SYSIBM.USERNAMES.

| This is an input parameter of type VARCHAR(54). The NEWAUTHID field is
| type VARCHAR(54) to allow for expansion during encryption.

| If you specify a null value, DSNLEUSR does not insert a value for *NewAuthID*.

|
| **Password**

| Specifies the value that is to be inserted into the PASSWORD column of
| SYSIBM.USERNAMES.

| If the input value to *Password* represents a password, the password value is
| restricted to 100 or fewer bytes. This applies even if the PASSWORD column of
| SYSIBM.USERNAMES is VARCHAR(255).

| If you specify a null value, DSNLEUSR does not insert a value for *Password*.

|
| **ReturnCode**

| The return code from DSNLEUSR execution. Possible values are:

- | **0** DSNLEUSR executed successfully.
- | **8** The request to encrypt the translated authorization ID or password
| failed. *MsgArea* contains the following fields:
- An unformatted SQLCA that describes the error.
 - A string that contains a DSNL045I message with the ICSF return
| code, the ICSF reason code, and the ICSF function that failed. The
| string immediately follows the SQLCA field and does not begin with
| a length field.
- | **12** The insert operation for the SYSIBM.USERNAMES row failed. *MsgArea*
| contains an SQLCA that describes the error.
- | **16** DSNLEUSR terminated because the DB2 subsystem is not in
| new-function mode. *MsgArea* contains an SQLCA that describes the
| error.

| This is an output parameter of type INTEGER.

|
| **MsgArea**

| Contains information about DSNLEUSR execution. The information that is
| returned is described in the *ReturnCode* description.

| This is an output parameter of type VARCHAR(500).
|

Example

The following COBOL example shows variable declarations and an SQL CALL for inserting a row into SYSIBM.USERNAMES with an encrypted translated authorization ID and an encrypted password.

DSNUTILS stored procedure (deprecated)

The DSNUTILS stored procedure enables you use the SQL CALL statement to execute DB2 utilities from a DB2 application program that specifies EBCDIC input.

Important: The DSNUTILS stored procedure is deprecated and replaced by DSNUTILU. It is best to convert existing callers of SYSIBM.SYSUTILS to use the SYSIBM.SYSUTILU stored procedure instead.

When called, DSNUTILS performs the following actions:

- Dynamically allocates the specified data sets
- Creates the utility input (SYSIN) stream
- Invokes DB2 utilities (program DSNUTILB)
- Deletes all the rows that are currently in the created temporary table (SYSIBM.SYSPRINT)
- Captures the utility output stream (SYSPRINT) into a created temporary table (SYSIBM.SYSPRINT)
- Declares a cursor to select from SYSPRINT:

```
DECLARE SYSPRINT CURSOR WITH RETURN FOR
  SELECT SEQNO, TEXT FROM SYSPRINT
  ORDER BY SEQNO;
```
- Opens the SYSPRINT cursor and returns.

The calling program then fetches from the returned result set to obtain the captured utility output.

Environment for DSNUTILS

DSNUTILS must run in a WLM environment. The DSNWLM_UTILIS environment is created for DB2 utilities stored procedures only. Stored procedures require special data set allocations.

The WLM core environment DSNWLM_UTILIS. DSNWLM_UTILIS is intended for the following DB2 utilities stored procedures only:

- DSNUTILU
- DSNUTILS (deprecated)

If you plan to run other applications in this environment other than DSNUTILS or DSNUTILU, add the procedure and add the DCB information for SYSIN. For example:

```
//SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND),
// DCB=(RECFM=V,LRECL=32708)
```

Table 134. DSNWLM_UTILIS environment

| Property | Description |
|----------------|-------------|
| NUMTCB | 1 |
| APF authorized | Yes |

Table 134. DSNWLM_UTILS environment (continued)

| | |
|-----------------------------|---|
| Special DDs | <p>These DDs are required:</p> <ul style="list-style-type: none"> • SYSIN Allocates a work file for temporarily storing utility input statements. • SYSPRINT Allocates a work file for temporarily storing utility output messages. • RNPRIN01 Allocates a data set for messages from the sort program. Required only if you plan to invoke RUNSTATS and collect distribution statistics. • UTPRINT Allocates a data set for messages from the sort program. • DSSPRINT Allocates a data set for messages when making concurrent copies. <p>Example:</p> <pre>//UTPRINT DD SYSOUT=* //RNPRIN01 DD SYSOUT=* //DSSPRINT DD SYSOUT=* //SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND) //SYSPRINT DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND)</pre> |
| Other considerations | <p>The STEPLIB needs to include DSN=prefix.SDSNEXIT or other library where the authorization exit modules (DSN3@ATH and DSN3@SGN) reside.</p> |

Installation job DSNTIJMV creates an address space proc called DSNWLMU for DSNWLM_UTILS. When the installation CLIST is customized, the name and library name of this proc are changed according to the DB2 subsystem name you specified on panel DSNTIPM in the field SUBSYSTEM NAME. For example, if you specified a subsystem name of VA1A then this proc will be named VA1AWLMU.

Authorization required for DSNUTILS

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNUTILS
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Then, to execute the utility, you must use a privilege set that includes the authorization to run the specified utility.

Control statement for DSNUTILS

DSNUTILS dynamically allocates the specified data sets. Any utility that requires a sort must include the SORTDEVT keyword in the utility control statement, and optionally, the SORTNUM keyword.

If the DSNUTILS stored procedure invokes a new utility, refer to Table 135 on page 972 for information about the default data dispositions that are specified for dynamically allocated data sets. This table lists the DD name that is used to identify the data set and the default dispositions for the data set by utility.

Table 135. Data dispositions for dynamically allocated data sets

| DD name | CHECK DATA | CHECK INDEX or CHECK LOB | COPY | COPY-TOCOPY | LOAD | MERGE-COPY | REBUILD INDEX | REORG INDEX | REORG TABLE-SPACE | UNLOAD |
|----------|------------------------|--------------------------|------------------------|-----------------------|------------------------|-----------------------|------------------------|-----------------------|------------------------|-----------------------|
| SYSREC | ignored | ignored | ignored | ignored | OLD KEEP KEEP | ignored | ignored | ignored | NEW CATLG CATLG | NEW CATLG CATLG |
| SYSDISC | ignored | ignored | ignored | ignored | NEW CATLG CATLG | ignored | ignored | ignored | NEW CATLG CATLG | ignored |
| SYSPUNCH | ignored | ignored | ignored | ignored | ignored | ignored | ignored | ignored | NEW CATLG CATLG | NEW CATLG CATLG |

DSNUTILS stored procedure syntax diagram

The following syntax diagram shows the SQL CALL statement for invoking utilities as a stored procedure. Because the linkage convention for DSNUTILS is GENERAL, you cannot pass null values for input parameters. For character parameters that you are not using, specify an empty string ('').

```

▶▶—CALL—DSNUTILS—(—utility-id,restart,utstmt,retcode—,—utility-name—————▶
▶,—recdsn,recdevt,recspace—,—discdsn,disdevt,discspace—,—pnchdsn,pnchdevt,pnchspace—————▶

```

DSNUTILS option descriptions

utility-id

Specifies a unique identifier for this utility within DB2.

This is an input parameter of type VARCHAR(16) in EBCDIC.

restart

Specifies whether DB2 is to restart a current utility, and, if so, at what point the utility is to be restarted.

restart is an input parameter of type VARCHAR(8) in Unicode UTF-8, which must be translatable to allowable EBCDIC characters. Specify one of the following values for this parameter:

NO or null

Indicates that the utility job is new, not a restart. No other utility with the same utility identifier (UID) can exist.

The **default** is **null**.

CURRENT

Restarts the utility at the last commit point.

PHASE

Restarts the utility at the beginning of the currently stopped phase. Use the DISPLAY UTILITY to determine the currently stopped phase.

PREVIEW

Executes in PREVIEW mode the utility control statements that follow. While in PREVIEW mode, DB2 parses all utility control statements for syntax errors, but normal utility execution does not take place. If the syntax is valid, DB2 expands all LISTDEF lists and TEMPLATE data set name expressions that appear in SYSIN and prints the results to the SYSPRINT data set. DB2 evaluates and expands all LISTDEF definitions into an actual list of table spaces or index spaces. DB2 also evaluates TEMPLATE data set name expressions into actual data set names through variable substitution. DB2 also expands lists from the SYSLISTD DD and TEMPLATE data set name expressions from the SYSTEMPL DD that is referenced by a utility invocation.

Absence of the PREVIEW keyword turns off preview processing with one exception. The absence of this keyword does not override the PREVIEW JCL parameter which, if specified, remains in effect for the entire job step.

This option is identical to the PREVIEW JCL parameter.

utstmt

Specifies the utility control statements.

This is an input parameter of type VARCHAR(32704) in EBCDIC.

retcode

Specifies the utility highest return code.

This is an output parameter of type INTEGER.

utility-name

Specifies the utility that you want to invoke.

This is an input parameter of type VARCHAR(20) in EBCDIC.

Because DSNUTILS allows only a single utility here, dynamic support of data set allocation is limited. Specify only a single utility that requires data set allocation in the *utstmt* parameter.

Select the utility name from the following list:

- ANY¹
- CHECK DATA
- CHECK INDEX
- CHECK LOB
- COPY
- COPYTOCOPY

| DIAGNOSE
 | LOAD
 | MERGECOPY
 | MODIFY RECOVERY
 | MODIFY STATISTICS
 | QUIESCE
 | REBUILD INDEX
 | RECOVER
 | REORG INDEX
 | REORG LOB
 | REORG TABLESPACE
 | REPAIR
 | REPORT RECOVERY
 | REPORT TABLESPACESET
 | RUNSTATS INDEX
 | RUNSTATS TABLESPACE
 | STOSPACE
 | UNLOAD

1. Use ANY to indicate that TEMPLATE dynamic allocation is to be used. This value suppresses the dynamic allocation that is normally performed by DSNUTILS.

Recommendation: Invoke DSNUTILS with a *utility-name* of ANY and omit all of the *xxdsn*, *xxdevt*, and *xxspace* parameters. Use TEMPLATE statements to allocate the data sets.

When you use TEMPLATE, utilities attempt to close and deallocate data sets when the utilities complete. However, under some circumstances, utilities cannot deallocate data sets. Under those circumstances, take one of the following sets of actions:

- If you want to terminate a utility after a failure:
 1. Use the TERM UTIL command to terminate the failing utility.
 2. Refresh the WLM environment in one of the following ways:
 - Submit the VARY command:
 VARY WLM,APPLENV=xxx,REFRESH
 - Call the WLM_REFRESH stored procedure.

When you terminate the utility, DB2 deletes the data sets that are needed by the utility.

- If you want to restart a utility after a failure:
 1. Specify DISP (NEW,CATLG,CATLG) in your template for data sets that are needed by the utility.
 2. When the utility fails, refresh the WLM environment, but do not terminate the utility.

You need to delete the allocated data sets manually after the utility completes.

recdsn

Specifies the cataloged data set name that is required by LOAD for input, or by REORG TABLESPACE as the unload data set. *recdsn* is required for LOAD.

It is also required for REORG TABLESPACE unless you also specified NOSYSREC or SHRLEVEL CHANGE. If you specify *recdsn*, the data set is allocated to the SYSREC DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specified the INDDN parameter for LOAD, the specified *ddname* value **must** be SYSREC.

If you specify the UNLDDN parameter for REORG TABLESPACE, the specified *ddname* value **must** be SYSREC.

recdevt

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *recdsn* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

recspace

Specifies the number of cylinders to use as the primary space allocation for the *recdsn* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

discdsn

Specifies the cataloged data set name that is used by LOAD as a discard data set to hold records not loaded, and by REORG TABLESPACE as a discard data set to hold records that are not reloaded. If you specify *discdsn*, the data set is allocated to the SYSDISC DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the DISCARDN parameter for LOAD or REORG TABLESPACE, the specified *ddname* value **must** be SYSDISC.

discdevt

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *discdsn* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

discspace

Specifies the number of cylinders to use as the primary space allocation for the *discdsn* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

pnchdsn

Specifies the cataloged data set name that REORG TABLESPACE UNLOAD EXTERNAL or REORG TABLESPACE DISCARD uses to hold the generated LOAD utility control statements. If you specify a value for *pnchdsn*, the data set is allocated to the SYSPUNCH DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the PUNCHN parameter for REORG TABLESPACE, the specified *ddname* value **must** be SYSPUNCH.

pnchdevt

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *pnchdsn* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

| *pchspace*

| Specifies the number of cylinders to use as the primary space allocation for the
| *pchdsn* data set. The secondary space allocation is 10% of the primary space
| allocation.

| This is an input parameter of type SMALLINT.

| *copydsn1*

| Specifies the name of the required target (output) data set, which is needed
| when you specify the COPY, COPYTOCOPY, or MERGECOPY utilities. It is
| optional for LOAD and REORG TABLESPACE. If you specify *copydsn1*, the
| data set is allocated to the SYSCOPY DD name.

| This is an input parameter of type VARCHAR(54) in EBCDIC.

| If you specify the COPYDDN parameter for COPY, COPYTOCOPY,
| MERGECOPY, LOAD, or REORG TABLESPACE, the specified *ddname1* value
| **must** be SYSCOPY.

| *copydevt1*

| Specifies a unit address, a generic device type, or a user-assigned group name
| for a device on which the *copydsn1* data set resides.

| This is an input parameter of type CHAR(8) in EBCDIC.

| *copyspace1*

| Specifies the number of cylinders to use as the primary space allocation for the
| *copydsn1* data set. The secondary space allocation is 10% of the primary space
| allocation.

| This is an input parameter of type SMALLINT.

| *copydsn2*

| Specifies the name of the cataloged data set that is used as a target (output)
| data set for the backup copy. It is optional for COPY, COPYTOCOPY,
| MERGECOPY, LOAD, and REORG TABLESPACE. If you specify *copydsn2*, the
| data set is allocated to the SYSCOPY2 DD name.

| This is an input parameter of type VARCHAR(54) in EBCDIC.

| If you specify the COPYDDN parameter for COPY, COPYTOCOPY,
| MERGECOPY, LOAD, or REORG TABLESPACE, the specified *ddname2* value
| **must** be SYSCOPY2.

| *copydevt2*

| Specifies a unit address, a generic device type, or a user-assigned group name
| for a device on which the *copydsn2* data set resides.

| This is an input parameter of type CHAR(8) in EBCDIC.

| *copyspace2*

| Specifies the number of cylinders to use as the primary space allocation for the
| *copydsn2* data set. The secondary space allocation is 10% of the primary space
| allocation.

| This is an input parameter of type SMALLINT.

| *rcpydsn1*

| Specifies the name of the cataloged data set that is required as a target (output)
| data set for the remote site primary copy. It is optional for COPY,
| COPYTOCOPY, LOAD, and REORG TABLESPACE. If you specify *rcpydsn1*, the
| data set is allocated to the SYSRCPY1 DD name.

| This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specified the RECOVERYDDN parameter for COPY, COPYTOCOPY, MERGECOPY, LOAD, or REORG TABLESPACE, the specified *ddname1* value **must** be SYSRCPY1.

rcpydevt1

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *rcpydsn1* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

rcpyspace1

Specifies the number of cylinders to use as the primary space allocation for the *rcpydsn1* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

rcpydsn2

Specifies the name of the cataloged data set that is required as a target (output) data set for the remote site backup copy. It is optional for COPY, COPYTOCOPY, LOAD, and REORG TABLESPACE. If you specify *rcpydsn2*, the data set is allocated to the **SYSRCPY2** DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the RECOVERYDDN parameter for COPY, COPYTOCOPY, MERGECOPY, LOAD, or REORG TABLESPACE, the specified *ddname2* value **must** be SYSRCPY2.

rcpydevt2

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *rcpydsn2* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

rcpyspace2

Specifies the number of cylinders to use as the primary space allocation for the *rcpydsn2* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

workdsn1

Specifies the name of the cataloged data set that is required as a work data set for sort input and output. It is required for CHECK DATA, CHECK INDEX and REORG INDEX. It is also required for LOAD and REORG TABLESPACE unless you also specify the SORTKEYS keyword. It is optional for REBUILD INDEX. If you specify *workdsn1*, the data set is allocated to the SYSUT1 DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.
