If you specify the WORKDDN parameter for CHECK DATA, CHECK INDEX, LOAD, REORG INDEX, REORG TABLESPACE, or REBUILD INDEX, the specified *ddname* value **must** be SYSUT1.

workdevt1

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *workdsn1* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

| *workspace1*

| Specifies the number of cylinders to use as the primary space allocation for the
| *workdsn1* data set. The secondary space allocation is 10% of the primary space
| allocation.

| This is an input parameter of type SMALLINT.

| *workdsn2*

| Specifies the name of the cataloged data set that is required as a work data set
| for sort input and output. It is required for CHECK DATA. It is also required if
| you use REORG INDEX to reorganize non-unique type 1 indexes. It is required
| for LOAD or REORG TABLESPACE unless you also specify the SORTKEYS
| keyword. If you specify *workdsn2*, the data set is allocated to the SORTOUT
| DD name.

| This is an input parameter of type VARCHAR(54) in EBCDIC.

| If you specify the WORKDDN parameter for CHECK DATA, LOAD, REORG
| INDEX, or REORG TABLESPACE, the specified *ddname* value **must** be
| SORTOUT.

| *workdevt2*

| Specifies a unit address, a generic device type, or a user-assigned group name
| for a device on which the *workdsn2* data set resides.

| This is an input parameter of type CHAR(8) in EBCDIC.

| *workspace2*

| Specifies the number of cylinders to use as the primary space allocation for the
| *workdsn2* data set. The secondary space allocation is 10% of the primary space
| allocation.

| This is an input parameter of type SMALLINT.

| *mapdsn*

| Specifies the name of the cataloged data set that is required as a work data set
| for error processing during LOAD with ENFORCE CONSTRAINTS. It is
| optional for LOAD. If you specify *mapdsn*, the data set is allocated to the
| SYSMAP DD name.

| This is an input parameter of type VARCHAR(54) in EBCDIC.

| If you specify the MAPDDN parameter for LOAD, the specified *ddname* value
| **must** be SYSMAP.

| *mapdevt*

| Specifies a unit address, a generic device type, or a user-assigned group name
| for a device on which the *mapdsn* data set resides.

| This is an input parameter of type CHAR(8).

| *mapspace*

| Specifies the number of cylinders to use as the primary space allocation for the
| *mapdsn* data set. The secondary space allocation is 10% of the primary space
| allocation.

| This is an input parameter of type SMALLINT.

| *errdsn*

| Specifies the name of the cataloged data set that is required as a work data set
| for error processing. It is required for CHECK DATA, and it is optional for
| LOAD. If you specify *errdsn*, the data set is allocated to the SYSERR DD name.

| This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the ERRDDN parameter for CHECK DATA or LOAD, the specified *ddname* value **must** be SYSERR.

errdevt

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *errdsn* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

errspace

Specifies the number of cylinders to use as the primary space allocation for the *errdsn* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

filtrdsn

Specifies the name of the cataloged data set that is required as a work data set for error processing. It is optional for COPY CONCURRENT. If you specify *filtrdsn*, the data set is allocated to the FILTER DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the FILTERDDN parameter for COPY, the specified *ddname* value **must** be FILTER.

filtrdevt

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *filtrdsn* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

filterspace

Specifies the number of cylinders to use as the primary space allocation for the *filtrdsn* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

Modifying the WLM-established address space for DSNUTILS

Add DSSPRINT, SYSIN, and SYSPRINT to the JCL procedure for starting the WLM-established address space in which DSNUTILS runs.

Requirement: You must allocate SYSIN and SYSPRINT in the procedure to temporarily store utility input statements and utility output messages. If you plan to invoke RUNSTATS and collect distribution statistics, you also need to allocate RNPRIN01.

Use JCL similar to the following sample PROC:

```

//*****
//*   JCL FOR RUNNING THE WLM-ESTABLISHED STORED PROCEDURES
//*   ADDRESS SPACE
//*   RGN      -- THE MVS REGION SIZE FOR THE ADDRESS SPACE.
//*   DB2SSN  -- THE DB2 SUBSYSTEM NAME.
//*   APPLENV -- THE MVS WLM APPLICATION ENVIRONMENT
//*           SUPPORTED BY THIS JCL PROCEDURE.
//*
//*   IMPORTANT: You must use the value 1 in this EXEC card:
//*   IEFPROC EXEC PGM=DSNX9WLM,REGION=&RGN,TIME=NOLIMIT,
//*   PARM='&DB2SSN,1,&APPLENV'
//*
//*****
```

```

| //DSNWLM PROC RGN=0K,APPLENV=WLMENV1,DB2SSN=DSN
| //IEFPROC EXEC PGM=DSNX9WLM,REGION=&RGN,TIME=NOLIMIT,
| // PARM='&DB2SSN,1,&APPLENV'
| //STEPLIB DD DISP=SHR,DSN=CEE.V!R!M!.SCEERUN
| // DD DISP=SHR,DSN=DSN! !0.SDSNLOAD
| //UTPRINT DD SYSOUT=*
| //RNPRIN01 DD SYSOUT=*
| //DSSPRINT DD SYSOUT=*
| //SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND)
| //SYSPRINT DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND)

```

Sample program for calling DSNUTILS

Three example programs calling DSNUTILS are shipped in SDSNSAMP.

- DSNTEJ6U: A DSNUTILS caller that uses PL/I. Job DSNTEJ6U compiles, link-edits, binds, and runs sample PL/I program DSN8EPU, which invokes the DSNUTILS stored procedure to execute an utility.
- DSNTEJ6V: A DSNUTILS caller that uses C++. Job DSNTEJ6V compiles, link-edits, binds, and runs sample C++ program DSN8EE1, which invokes the DSNUTILS stored procedure to execute an utility.
- DSNTEJ80: A DSNUTILS caller that uses C and ODBC. You can use this sample to compile, pre-link, link-edit, and execute the sample application DSN8OIVP, which you can use to verify that your DB2 ODBC installation is correct.

DSNUTILS output

DB2 creates the result set according to the DECLARE statement that is shown under Example of declaring a cursor to select from SYSPRINT.

Output from a successful execution of the DSNTEJ6U sample job or an equivalent job lists the specified parameters followed by the messages that are generated by the DB2 DIAGNOSE DISPLAY MEPL utility.

If DSNUTILB abends, the abend codes are returned as DSNUTILS return codes.

[DFSORT Application Programming Guide](#)

DSNUTILU stored procedure

Use the DSNUTILU stored procedure to run DB2 utilities from a DB2 application program.

When called, DSNUTILU performs the following actions:

- Translates the values that are specified for the *utility-id* and *restart* parameters to EBCDIC
- Creates the utility input stream (SYSIN) for utility control statements that are encoded in Unicode
- Invokes DB2 utilities by using DSNUTILB
- Deletes all the rows that are currently in the created temporary table (SYSIBM.SYSPRINT)
- Captures the utility output stream (SYSPRINT) into a created temporary table (SYSIBM.SYSPRINT)
- Declares a cursor to select from SYSPRINT:

```
DECLARE SYSPRINT CURSOR WITH RETURN FOR
  SELECT SEQNO, TEXT FROM SYSPRINT
  ORDER BY SEQNO;
```
- Opens the SYSPRINT cursor

The calling program then fetches rows from the returned result set to obtain the captured utility output.

The character set of the resulting utility SYPRINT output that is placed in the SYSIBM.SYSPRINT table is determined by the BIND PACKAGE statement for the DSNUTILU stored procedure. If the bind option ENCODING(EBCDIC) is specified, the SYSPRINT contents are in EBCDIC. If the bind option ENCODING(UNICODE) is specified, the SYSPRINT contents are in Unicode. The default installation job, DSNTIJRT, contains ENCODING(EBCDIC).

Environment for DSNUTILU

DSNUTILU must run in a WLM environment.

The WLM core environment DSNWLM_UTIL.S. DSNWLM_UTIL.S is intended for the following DB2 utilities stored procedures only:

- DSNUTILU
- DSNUTILS (deprecated)

If you plan to run other applications in this environment, add the procedure and add the DCB information for SYSIN, as shown in the following example:

```
//SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND),
// DCB=(RECFM=V,LRECL=32708)
```

Related information:

Core WLM environments for DB2-supplied routines (DB2 Installation and Migration)

The WLM-established address space for DSNUTILU

The JCL procedure for starting the WLM-established address space in which DSNUTILU runs requires DD statements for DSSPRINT, SYSIN, and SYSPRINT. The SYSIN and SYSPRINT DD statements must allocate workfiles that DSNUTILU

can use to temporarily store utility input statements and utility output messages. If you plan to run RUNSTATS and collect distribution statistics, you also need to allocate a DD statement for RNPRIN01.

DB2 provides an address space procedure for DSNWLM_UTILS, which is the core WLM environment for DSNUTILU. That address space procedure is called DSNWLMU. For detailed information about DSNWLMU, see Core WLM environments for DB2-supplied routines (DB2 Installation and Migration).

Authorization required for DSNUTILU

To call the DSNUTILU stored procedure, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNUTILU
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Then, to execute the utility, you must use a privilege set that includes the authorization to run the specified utility.

Utility control statements that are passed to DSNUTILU

Input data sets for the utility control statements can begin with the following Unicode characters:

- A Unicode UTF-8 blank (X'20')
- A Unicode UTF-8 dash (X'2D')
- Uppercase Unicode UTF-8 "A" through "Z" (X'41' through X'5A')

Any utility that requires a sort must include the SORTDEVT keyword in the utility control statement. Use of the SORTNUM keyword is optional.

Also, DSNUTILU does not dynamically allocate data sets. Use the TEMPLATE utility control statement to dynamically allocate data sets.

DSNUTILU stored procedure syntax diagram

The following syntax diagram shows the SQL CALL statement for invoking utilities as a stored procedure.

►►—CALL—DSNUTILU—(—*utility-id*,*restart*,*utstmt*,*retcode*—)————►►

DSNUTILU option descriptions

utility-id

Specifies a unique identifier for this utility within DB2.

utility-id is an input parameter of type VARCHAR(16) in Unicode UTF-8, which must be translatable to the following allowable EBCDIC characters:

- A - Z (uppercase and lowercase)
- 0 - 9
- #, \$, @, ¢, !, ^, or period (.)

restart

Specifies whether DB2 is to restart a current utility, and, if so, at what point the utility is to be restarted.

restart is an input parameter of type VARCHAR(8) in Unicode UTF-8, which must be translatable to allowable EBCDIC characters. Specify one of the following values for this parameter:

NO or null

Indicates that the utility job is new and is not a restarted job. No other utility with the same utility identifier (UID) can exist.

The default is **null**.

CURRENT

Restarts the utility at the last commit point.

PHASE

Restarts the utility at the beginning of the currently stopped phase. Use the DISPLAY UTILITY command to determine the currently stopped phase.

PREVIEW

Executes the utility control statements that follow in preview mode.

In preview mode, DB2 parses all utility control statements for syntax errors, but normal utility execution does not occur. If the syntax is valid, DB2 expands all LISTDEF lists and TEMPLATE data set name expressions that are included in SYSIN and prints the results to the SYSPRINT data set. DB2 evaluates and expands all LISTDEF statements into a list of table spaces or index spaces. DB2 also evaluates TEMPLATE data set name expressions into data set names through variable substitution. DB2 also expands lists and data set name expressions from any LISTDEF libraries and TEMPLATE libraries that are referenced by a utility invocation.

If the PREVIEW keyword is omitted, preview processing is turned off with one exception. The absence of this keyword does not override the PREVIEW JCL parameter, which, if specified, remains in effect for the entire job step.

This option is identical to the PREVIEW JCL parameter.

Related information:

Restarting an online utility (DB2 Utilities)

-DISPLAY UTILITY (DB2) (DB2 Commands)

Executing statements in preview mode (DB2 Utilities)

utstmt

Specifies the utility control statements.

utstmt is an input parameter of type VARCHAR(32704) in Unicode UTF-8. If the utility statement is not in Unicode UTF-8, DB2 converts it to UTF-8. Therefore, if you pass a utility control statement in another format, consider the Possible consequences of character conversion (DB2 Internationalization Guide).

retcode

Specifies the utility highest return code.

retcode is an output parameter of type INTEGER.

Terminating or restarting a utility with DSNUTILU

If you do not want to restart a utility after a failure, take the following actions:

1. Use the TERM UTIL command to terminate the failing utility.
When you terminate the utility, DB2 deletes the data sets that are needed by the utility.
2. Refresh the WLM environment in one of the following ways:
 - Submit the VARY command:
VARY WLM,APPLENV=xxx,REFRESH
 - Call the WLM_REFRESH stored procedure.

If you want to restart a utility after a failure, take the following actions:

1. When you run the utility, use a TEMPLATE utility control statement, and specify DISP (NEW,CATLG,CATLG) in your template for data sets that are needed by the utility.
2. When the utility fails, refresh the WLM environment, but do not terminate the utility.
3. After the utility completes, delete the allocated data sets manually.

“WLM_REFRESH stored procedure” on page 1067

Sample program for calling DSNUTILU

The following sample program calls DSNUTILU and is included in SDSNSAMP:

Job DSNTEJ6R compiles, link-edits, binds, and runs sample C-language caller program DSN8ED8, which invokes the DSNUTILU stored procedure to execute a utility.

Related information:

Job DSNTEJ6R (DB2 Installation and Migration)

DSNUTILU output

DB2 creates the result set according to the DECLARE statement shown in Example of declaring a cursor to select from SYSPRINT

Output from a successful execution of the DSNTEJ6R sample job or an equivalent job lists the specified parameters, followed by the messages that are generated by the DB2 DIAGNOSE DISPLAY MEPL utility.

Related information:

Syntax and options of the DIAGNOSE control statement (DB2 Utilities)

DSN_WLM_APPLENV stored procedure

This procedure provides a convenient way to define, install, and activate a new WLM application environment for DB2.

Environment

DSN_WLM_APPLENV runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL DSN_WLM_APPLENV statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the DSN_WLM_APPLENV stored procedure
- Ownership of the stored procedure
- SYSADM authority

If the RACF facility class is active and a profile has been defined for the MVSADMIN.WLM.POLICY facility class, then the caller of the stored procedure needs the following access:

- ACCESS(READ) for action WLMINFO:
PERMIT MVSADMIN.WLM.POLICY CLASS(FACILITY) ID(user) ACCESS(READ)
- ACCESS(UPDATE) for action ADD, ADD_ACTIVATE, ACTIVATE:
PERMIT MVSADMIN.WLM.POLICY CLASS(FACILITY) ID(user) ACCESS(UPDATE)

Syntax

```
►►CALL DSN_WLM_APPLENV(—action—, —policyid—, —wlmoptions—, —return-code—, —message—)◄◄
```

Procedure parameters

ACTION

An input parameter of type VARCHAR(20) that identifies the type of action to be performed. This is a required parameter and supports the following values:

ACTIVATE

The stored procedure activates a WLM service policy.

ADD

The stored procedure installs a new WLM application environment to an existing WLM service definition without activating a service policy. The new WLM application environment becomes available only on the next activation of a WLM policy.

ADD_ACTIVATE

The stored procedure installs a new WLM application environment to an existing WLM service definition and automatically activates a WLM service policy to enable the new WLM application environment.

WLMINFO

The stored procedure queries the existing WLM service definition and returns basic information. Examples of the information returned include:

- The service definition name
- The timestamp in the local time the service definition was installed
- The user ID of the service administrator that installed the service definition
- The name of the system on which the service definition was installed from
- The number of application environment currently defined

If the any action other than ACTIVATE or WLMINFO is specified, the WLMOPTIONS input parameter is also required.

POLICYID

An input parameter of type VARCHAR(8) that identifies the WLM service policy to be activated. It can be 1-8 characters long or the word ACTIVE. If the policy specified is ACTIVE, the active service policy is used. This parameter is required if any of the following actions is specified:

- ACTIVATE
- ADD_ACTIVATE

Otherwise, it is ignored and can be set to NULL or an empty string.

WLMOPTIONS

An input parameter of type VARCHAR(4000).

This parameter with the WLMNAME parameter is required if any of the following actions is specified, and other WLM parameters are not valid:

- ADD
- ADD_ACTIVATE

The following WLM options are supported. Separate multiple options by one or more spaces.

WLMNAME (*name*)

WLMNAME is the defined name for an application environment. It can be 1-32 characters long. It cannot begin with the letters SYS. This is a required option.

DESCRIPTION (*description*)

DESCRIPTION is a 32-character area describing the application environment. This option is not required and can be set to an empty value. For example,
DESCRIPTION()

PROCNAME (*procedure-name*)

PROCNAME defines the JCL procedure that WLM uses to start server address spaces for the application environment. It can be 1-8 characters long. This is a required option.

STARTPARM (*start-up-parameters*)

STARTPARM contains the parameters that WLM uses to start the JCL procedure. The parameters can be up to 115 characters. If the parameters include the subsystem name, the symbol &IWMSSNM can be used to cause WLM to substitute the subsystem name instead of typing the

subsystem name directly. This option is useful because multiple instances of the subsystem with different names can use the application environment. For example:

```
STARTPARAM(DB2SSN=&IWMSSNM,APPLENV=WLMENV1,NUMTCB=1)
```

This option is not required and can be set to an empty value.

WLMOPT(WLM_MANAGED|SINGLE_SERVER)

WLMOPT tells WLM to limit the number of server address spaces. For example, if a server address space requires exclusive use of a resource, only a single address space can exist. For DB2 routines, you can set a limit of 1 address space per system if required by the routine. Note that if there are multiple DB2 subsystems on a given system, WLM creates 1 server for each DB2 subsystem that calls the routines. A limit of 1 address space per sysplex does not apply to DB2 routines.

This option is not required and can be set to an empty value. The default is WLM_MANAGED.

Examples

Example: Returning the basic information of the WLM service definition:

```
CALL SYSPROC.DSN_WLM_APPLENV('WLMINFO', NULL, NULL, ?, ?)
```

Here is an example of the output:

```
RETURN_CODE: 0
MESSAGE: DSNT051I DSNTWLMS ACTIVE WLM SERVICE DEFINITION
          SERVICE DEFINITION NAME      WLMAMPL
          INSTALLED ON                  2010-01-25-07.11.57.764052
          INSTALLED BY                   SYSADM
          INSTALLED FROM                  LABEC130
          NUMBER OF APPL ENVIRONMENT     12
DSNT023I DSNTWLMS DISPLAY WLM INFORMATION SUCCESSFUL
```

Example: Identifying the action and WLM options:

```
CALL SYSPROC.DSN_WLM_APPLENV('ADD_ACTIVATE',
                              'ACTIVE',
                              'WLMNAME(DSNWLM_SAMPLE)
                              DESCRIPTION(DB2_SAMPLE WLM ENVIRONMENT)
                              PROCNAME(DSNWLMS)
                              STARTPARAM(DB2SSN=&IWMSSNM,APPLENV=''DSNWLM_SAMPLE'')
                              WLMOPT(WLM_MANAGED)', ?, ?)
```

Here is an example of the output:

```
RETURN_CODE: 0
MESSAGE: DSNT023I DSNTWLMS ADD WLM APPLICATION ENVIRONMENT DSNWLM_SAMPLE SUCCESSFUL

APPLICATION ENVIRONMENT NAME : DSNWLM_SAMPLE
DESCRIPTION                   : DB2_SAMPLE WLM ENVIRONMENT

GET_CONFIG stored procedure

The GET_CONFIG stored procedure retrieves data server configuration information.

This data server configuration information includes:

- Data sharing group information
- DB2 subsystem status information
- DB2 subsystem parameters, DSNHDECP or a user-specified application defaults module, and the IRLM parameters that are found in IFCID 106 section 5
- DB2 distributed access information
- Active log data set information
- The time of the last restart of DB2
- Resource limit facility information
- Connected DB2 subsystems information

Environment

The GET_CONFIG stored procedure runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET_CONFIG stored procedure.

Syntax

```
CALL GET_CONFIG ( major_version , minor_version , requested_locale , xml_input , xml_filter , xml_output , xml_message )
```

The syntax diagram shows the CALL statement for GET_CONFIG. The parameters are: *major_version* (with a NULL placeholder below it), *minor_version* (with a NULL placeholder below it), *requested_locale* (with a NULL placeholder below it), *xml_input* (with a NULL placeholder below it), *xml_filter* (with a NULL placeholder below it), *xml_output*, and *xml_message*. The parameters are enclosed in parentheses and separated by commas.

The schema is SYSPROC.

Option descriptions

major_version

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the procedure. To determine the highest supported document

version, specify NULL for this input parameter and all other required parameters. Currently, the highest major document version that is supported is 2. Major document version 1 is also supported.

If the XML document in the *xml_input* parameter specifies the **Document Type Major Version** key, the value for that key must be equal to the value provided in the *major_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *minor_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

minor_version

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only minor document version that is supported is 0 (zero).

If the XML document in the *xml_input* parameter specifies the **Document Type Minor Version** key, the value for that key must be equal to the value provided in the *minor_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *major_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml_output* and *xml_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested_locale* are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Configuration Input in UTF-8 that contains input values for the stored procedure.

To pass an XML input document to the stored procedure, you must specify the *major_version* parameter as 2 and the *minor_version* parameter as 0 (zero).

For a non-data sharing system, a sample of a Version 2.0 XML input document is as follows:

```

<plist version="1.0">
<?xml version="1.0" encoding="UTF-8" ?>
<dict>
  <key>Document Type Name</key>
  <string>Data Server Configuration Input</string>
  <key>Document Type Major Version</key>
  <integer>2</integer>
  <key>Document Type Minor Version</key>
  <integer>0</integer>
  <key>Document Locale</key>
  <string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>Include</key>
    <dict>
      <key>Value</key>
      <array>
        <string>DB2 Subsystem Status Information</string>
        <string>DB2 Subsystem Parameters</string>
        <string>DB2 Distributed Access Information</string>
        <string>Active Log Data Set Information</string>
        <string>Time of Last DB2 Restart</string>
        <string>Resource Limit Facility Information</string>
        <string>Connected DB2 Subsystem</string>
      </array>
    </dict>
  </dict>
</dict>
</plist>

```

For a data sharing system, a sample of a Version 2.0 XML input document is as follows:

```

<plist version="1.0">
<?xml version="1.0" encoding="UTF-8" ?>
<dict>
  <key>Document Type Name</key>
  <string>Data Server Configuration Input</string>
  <key>Document Type Major Version</key>
  <integer>2</integer>
  <key>Document Type Minor Version</key>
  <integer>0</integer>
  <key>Document Locale</key>
  <string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>Include</key>
    <dict>
      <key>Value</key>
      <array>
        <string>Common Data Sharing Group Information</string>
        <string>DB2 Subsystem Status Information</string>
        <string>DB2 Subsystem Parameters</string>
        <string>DB2 Distributed Access Information</string>
        <string>Active Log Data Set Information</string>
        <string>Time of Last DB2 Restart</string>
        <string>Resource Limit Facility Information</string>
        <string>Connected DB2 Subsystem</string>
      </array>
    </dict>
  <key>DB2 Data Sharing Group Members</key>
  <dict>
    <key>Value</key>
    <array>

      <string>DB2B</string>
    </array>
  </dict>
</dict>
</plist>

```

```

        </array>
      </dict>
    </dict>
  </dict>
</plist>

```

When passing an XML input document to the stored procedure, you must specify the **Document Type Name** key. In a non-data sharing system, you must specify the **Include** parameter. In a data sharing system, you must specify at least one of the following parameters:

- **Include**
- **DB2 Data Sharing Group Members**

If no XML input document is passed to the stored procedure, and you specified the *major_version* parameter as 2 and the *minor_version* parameter as 0 (zero), the stored procedure returns the following parameters for a non-data sharing system in a Version 2.0 XML output document by default:

- **DB2 Subsystem Status Information**
- **DB2 Subsystem Parameters**
- **DB2 Distributed Access Information**
- **Active Log Data Set Information**
- **Time of Last DB2 Restart**
- **Resource Limit Facility Information**
- **Connected DB2 Subsystem**

For a data sharing system, the same information is returned for each member of a data sharing group, plus the **Common Data Sharing Group Information** parameter.

If you passed a Version 2.0 XML input document to the stored procedure, the stored procedure returns the information in a Version 2.0 XML output document. The information returned is dependent on what you specified in the **Include** array and in the **DB2 Data Sharing Group Members** array (if applicable). For a non-data sharing system, the items that are specified in the **Include** array are returned. For a data sharing system, the following information is returned:

- The items that are specified in the **Include** array for each DB2 member that is specified in the **DB2 Data Sharing Group Members** array, if both the **Include** parameter and the **DB2 Data Sharing Group Members** parameter are specified.
- The items that are specified in the **Include** array for every DB2 member in the data sharing group, if only the **Include** parameter is specified.
- The **Common Data Sharing Group Information** and the following items for each member that is specified in the **DB2 Data Sharing Group Members** array, if only the **DB2 Data Sharing Group Members** parameter is specified:
 - **DB2 Subsystem Status Information**
 - **DB2 Subsystem Parameters**
 - **DB2 Distributed Access Information**
 - **Active Log Data Set Information**
 - **Time of Last DB2 Restart**
 - **Resource Limit Facility Information**
 - **Connected DB2 Subsystem**

Note: If the **Common Data Sharing Group Information** item is specified in the **Include** array, this information is returned only once for the data sharing group. This information is not returned repeatedly for every DB2 member that is processed.

Complete mode: For an example of a Version 2.0 XML input document that is returned by the *xml_output* parameter when the stored procedure is running in Complete mode in a non-data sharing system, see Example 4 in the Examples section. For an example of a Version 2.0 XML input document that is returned by the *xml_output* parameter when the stored procedure is running in Complete mode in a data sharing system with two DB2 members, DB2A and DB2B, see Example 5.

xml_filter

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see XPath expressions for filtering output (DB2 Administration Guide).

The following example selects the value for the Data Server Product Version from the XML output document:

```
/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

xml_output

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server Configuration Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

The *xml_output* parameter can return either a Version 1.0 or Version 2.0 XML output document depending on the *major_version* and *minor_version* parameters that you specify. For information about the content of a Version 2.0 XML output document, see the option description for the *xml_input* parameter.

For a sample Version 1.0 XML output document, see Example 1 in the Examples section.

For a sample Version 2.0 XML output document in a non-data sharing system, see Example 6.

For a sample Version 2.0 XML output document in a data sharing system, see Example 7.

xml_message

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about an SQL warning condition. This document is returned when a call to the stored procedure results in an SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

The *xml_message* parameter can return either a Version 1.0 or Version 2.0 XML message document depending on the *major_version* and *minor_version* parameters that you specify.

For an example of an XML message document, see Example 2.

If the GET_CONFIG stored procedure is processing more than one DB2 member in a data sharing system and an error is encountered when processing one of the DB2 members, the stored procedure specifies the name of the DB2 member that is causing the error as the value of the **DB2 Object** key in the XML message document. The value of the **Short Message Text** key applies to the DB2 member that is specified.

The following example shows a fragment of a Version 2.0 XML message document with the **DB2 Object** key specified:

```
<key>Short Message Text</key>
  <dict>
    <key>Display Name</key>
    <string>Short Message Text</string>
    <key>Value</key>
    <string>DSNA6xxI DSNADMGC .....</string>
    <key>DB2 Object</key>
    <string>DB2B</string>
    <key>Hint</key>
    <string />
  </dict>
```

Examples

Example 1: The following example shows a fragment of a Version 1.0 XML output document for the GET_CONFIG stored procedure for a data sharing member. For a non-data sharing member, the following entries in the **DB2 Distributed Access Information** item are not included: **Resynchronization Domain**, **Alias List**, **Member IPv4 Address**, **Member IPv6 Address**, and **Location Server List**.

The two major sections that the XML output document always contains are **Common Data Sharing Group Information** and **DB2 Subsystem Specific Information**. In this example, the ellipsis (. . .) represent a dictionary entry that is comprised of **Display Name**, **Value**, and **Hint**, such as:

```
<dict>
  <key>Display Name</key>
  <string>DDF Status</string>
  <key>Value</key>
  <string>STARTD</string>
  <key>Hint</key>
  <string />
</dict>

Example 2: The following example shows a sample XML message document for the GET_CONFIG stored procedure. Similar to an XML output document, the details about an SQL warning condition are encapsulated in a dictionary entry, which is comprised of **Display Name**, **Value**, and **Hint**.

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>9.1.5</string>
  <key>Data Server Major Version</key><integer>9</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>
  <key>Short Message Text</key>
  <dict>
    <key>Display Name</key><string>Short Message Text</string>
    <key>Value</key>
    <string>DSNA630I DSNADMGC A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND.
      The XML input document must be empty or NULL.</string>
    <key>Hint</key><string />
  </dict>
</dict>
</plist>

```

Example 3: This example shows a simple and static Java program that calls the GET_CONFIG stored procedure with an XPath that queries the value of the data server's IP address. The XPath is statically created as a string object by the program, and then converted to a BLOB to serve as input for the *xml_filter* parameter. After the stored procedure is called, the *xml_output* parameter contains only a single string and no XML document. This output is materialized as a file called *xml_output.xml* that is in the same directory where the *GetConfDriver* class resides.

```

 [Common SQL API stored procedures \(DB2 Administration Guide\)](#)

GET_MESSAGE stored procedure

The GET_MESSAGE stored procedure returns the short message text for an SQLCODE.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET_MESSAGE stored procedure.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

The schema is SYSPROC.

Option descriptions

major_version

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the stored procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only major document version that is supported is 1.

If the XML document in the *xml_input* parameter specifies the **Document Type Major Version** key, the value for that key must be equal to the value provided in the *major_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *minor_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

minor_version

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters

for this stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only minor document version that is supported is 0 (zero).

If the XML document in the *xml_input* parameter specifies the **Document Type Minor Version** key, the value for that key must be equal to the value provided in the *minor_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *major_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml_output* and *xml_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of the XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested_locale* are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Message Input in UTF-8 that contains input values for the stored procedure.

For this stored procedure, the general structure of an XML input document is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <key>Required Parameters</key>
  <dict>
    <key>SQLCODE</key>
    <dict>
      <key>Value</key><integer>sqlcode</integer>
    </dict>
  </dict>
  <key>Optional Parameters</key>
  <dict>
    <key>Message Tokens</key>
    <dict>
      <key>Value</key>
      <array>
        <string>token1 in SQLCA</string>
      </array>
    </dict>
  </dict>
</plist>
```

```

|                                     <string>token2 in SQLCA</string>
|                                     </array>
|                                     </dict>
|                                     </dict>
|                                     </dict>
|                                     </dict>
|                                     </plist>

```

For an example of an XML input document that will not run in Complete mode, see Example 2 in the Examples section.

Complete mode: For an example of an XML input document that is returned by the *xml_output* parameter when the stored procedure is running in Complete mode, see Example 1 in the Examples section.

xml_filter

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see XPath expressions for filtering output (DB2 Administration Guide).

The following example selects the value for the short message text from the XML output document:

```

| /plist/dict/key[.='Short Message Text']/following-sibling::dict[1]/key
| [.='Value']/following-sibling::string[1]

```

If the key is not followed by the specified sibling, an error is returned.

xml_output

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server Message Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

For an example of an XML output document, see Example 3.

xml_message

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about an SQL warning condition. This document is returned when a call to the procedure results in an SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

For an example of an XML message document, see Example 4.

Example

Example 1: The following example shows an XML input document that is returned by the *xml_output* parameter when the stored procedure is running in Complete mode.

```

| <?xml version="1.0" encoding="UTF-8" ?>
| <plist version="1.0">
| <dict>
|   <key>Document Type Name</key>
|   <string>Data Server Message Input</string>
|   <key>Document Type Major Version</key>
|   <integer>1</integer>
|   <key>Document Type Minor Version</key>
|   <integer>0</integer>
|   <key>Document Locale</key>

```

```

<string>en_US</string>
<key>Required Parameters</key>
<dict>
  <key>Display Name</key>
  <string>Required Parameters</string>

    </array>
    <key>Hint</key>
    <string />
  </dict>
  <key>Hint</key>
  <string />
</dict>
</dict>
</plist>

```

Example 2: The following example shows a complete sample of an XML input document for the GET_MESSAGE stored procedure.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key>
  <string>Data Server Message Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Required Parameters</key>
  <dict>
    <key>SQLCODE</key>
    <dict>
      <key>Value</key><integer>-104</integer>
    </dict>
  </dict>
  <key>Optional Parameters</key>
  <dict>
    <key>Message Tokens</key>
    <dict>
      <key>Value</key>
      <array>
        <string>X</string>
        <string>( . LIKE AS</string>
      </array>
    </dict>
  </dict>

```

```

    </dict>
  </dict>
</dict>
</plist>

```

Example 3: The following example shows a complete sample of an XML output document for the GET_MESSAGE stored procedure. The short message text for an SQLCODE will be encapsulated in a dictionary entry, which is comprised of **Display Name**, **Value**, and **Hint**.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key>
  <string>Data Server Message Output</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>9.1.5</string>
  <key>Data Server Major Version</key><integer>9</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>

  <key>Short Message Text</key>
  <dict>
    <key>Display Name</key><string>Short Message Text</string>
    <key>Hint</key><string />
  </dict>
</dict>
</plist>

```

Example 4: The following example shows a sample XML message document for the GET_MESSAGE stored procedure. Similar to an XML output document, the details about an SQL warning condition will be encapsulated in a dictionary entry, which is comprised of **Display Name**, **Value**, and **Hint**.

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>9.1.5</string>
  <key>Data Server Major Version</key><integer>9</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>
  <key>Short Message Text</key>
  <dict>
    <key>Display Name</key><string>Short Message Text</string>
    <key>Value</key>
    <string>DSNA630I DSNADMGM A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND.
      The value for key 'Document Type Minor Version' is '2'. It does
      not match the value '0', which was specified for parameter 2 of
      the stored procedure. Both values must be equal.</string>
    <key>Hint</key><string />
  </dict>
</dict>
</plist>

```

Example 5: This example shows a simple and static Java program that calls the GET_MESSAGE stored procedure with an XML input document and an XPath that queries the short message text of an SQLCODE.

The XML input document is initially saved as a file called `xml_input.xml` that is in the same directory where the `GetMessageDriver` class resides. This sample program uses the following `xml_input.xml` file:

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key>
    <string>Data Server Message Input</string>
    <key>Document Type Major Version</key>
    <integer>1</integer>
    <key>Document Type Minor Version</key>
    <integer>0</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Complete</key>
    <false />
    <key>Required Parameters</key>
    <dict>
      <key>SQLCODE</key>
      <dict>
        <key>Value</key>
        <integer>-204</integer>
      </dict>
    </dict>
    <key>Optional Parameters</key>
    <dict>
      <key>Message Tokens</key>
      <dict>
        <key>Value</key>
        <array>
          <string>SYSIBM.DDF_CONFIG</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```

The XPath is statically created as a string object by the program and then converted to a BLOB to serve as input for the `xml_filter` parameter. After the stored procedure is called, the `xml_output` parameter contains only a single string and no XML document. This output is materialized as a file called `xml_output.xml` that is in the same directory where the `GetMessageDriver` class resides.

Sample invocation of the GET_MESSAGE stored procedure with a valid XML input document and a valid XPath:

```

//*****
// Licensed Materials - Property of IBM

GET_SYSTEM_INFO stored procedure

The GET_SYSTEM_INFO stored procedure returns system information about the data server.

This system information includes:

- Operating system information
- Product information
- DB2 MEPL
- SYSMOD APPLY status
- Workload Manager (WLM) classification rules that apply to DB2 Workload for subsystem types DB2 and DDF

Environment

GUPI

The load module for the GET_SYSTEM_INFO stored procedure, DSNADMGS, must reside in an APF-authorized library. The GET_SYSTEM_INFO stored procedure runs in a WLM-established stored procedures address space, and all of the libraries that are specified in the STEPLIB DD statement must be APF-authorized. TCB=1 is also required.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET_SYSTEM_INFO stored procedure.

In addition, because the GET_SYSTEM_INFO stored procedure queries the SMPCSI data set for the status of the SYSMODs, the authorization ID that is associated with the stored procedure address space where the GET_SYSTEM_INFO stored procedure is running must have at least RACF read authority to the SMPCSI data set.

Syntax

```
CALL GET_SYSTEM_INFO ( [major_version] , [minor_version] ,  
                      [requested_locale] , [xml_input] , [xml_filter] , [xml_output] , [xml_message] )
```

The schema is SYSPROC.

Option descriptions

major_version

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents passed as parameters in the

stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the stored procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and the only major document version that is supported is 1.

If the XML document in the *xml_input* parameter specifies a **Document Type Major Version** key, the value for that key must be equal to the value that is provided in the *major_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *minor_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

minor_version

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents passed as parameters for this stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The highest minor document version that is supported is 1. Minor document version 0 (zero) is also supported.

If the XML document in the *xml_input* parameter specifies a **Document Type Minor Version** key, the value for that key must be equal to the value that is provided in the *minor_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *major_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml_output* and *xml_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of the XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested_locale* are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server System Input in UTF-8 that contains input values for the stored procedure.

This XML input document is optional. If the XML input document is not passed to the stored procedure, the stored procedure returns the following information by default:

- Operating system information
- Product information
- DB2 MEPL
- Workload Manager (WLM) classification rules for DB2 Workload

This stored procedure supports two types of XML input documents, Version 1.0 or Version 1.1.

For Version 1.0, the general structure of an XML input document is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>SMPCSI Data Set</key>
    <dict>
      <key>Value</key><string>SMPCSI data set name</string>
    </dict>
  </dict>
  <key>SYSMOD</key>
  <dict>
    <key>Value</key>
    <array>
      <string>SYSMOD number</string>
      <string>SYSMOD number</string>
    </array>
  </dict>
</dict>
</plist>
```

For Version 1.1, the general structure of an XML input document is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>1</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>Include</key>
    <dict>
      <key>Value</key>
      <array>
        <string>Operating System Information</string>
        <string>Product Information</string>
        <string>DB2 MEPL</string>
        <string>Workload Manager (WLM) Classification Rules for
          DB2 Workload</string>
      </array>
    </dict>
  </dict>
  <key>SMPCSI Data Set</key>
  <dict>
    <key>Value</key><string>SMPCSI data set name</string>
  </dict>
</dict>
```

```

|         <key>SYSMOD</key>
|         <dict>
|           <key>Value</key>
|           <array>
|             <string>SYSMOD number</string>
|             <string>SYSMOD number</string>
|           </array>
|         </dict>
|       </dict>
|     </dict>
| </plist>

```

Version 1.0: When a Version 1.0 XML input document is passed to the stored procedure, the stored procedure returns the following information in a Version 1.0 XML output document:

- Operating system information
- Product information
- DB2 MEPL
- SYSMOD status (APPLY status for the SYSMODs that are listed in the XML input document)
- Workload Manager (WLM) classification rules for DB2 Workload

To use Version 1.0 of the XML input document you must specify the *major_version* parameter as 1 and the *minor_version* parameter as 0 (zero). You must also specify the **Document Type Name** key, the SMPCSI data set, and the list of SYSMODs.

For an example of a Version 1.0 XML input document for the GET_SYSTEM_INFO stored procedure, see Example 3 in the Examples section.

Version 1.1: A Version 1.1 XML input document supports the **Include** parameter, in addition to the **SMPCSI Data Set** and **SYSMOD** parameters that are supported by a Version 1.0 XML input document.

You can use the Version 1.1 XML input document in the following ways:

- To specify which items to include in the XML output document by specifying these items in the **Include** array
- To specify the SMPCSI data set and list of SYSMODs so that the stored procedure returns their APPLY status

To use Version 1.1 of the XML input document, you must specify the *major_version* parameter as 1 and the *minor_version* parameter as 1. You must also specify the **Document Type Name** key, and at least one of the following parameters:

- **Include**
- **SMPCSI Data Set** and **SYSMOD**

If you pass a Version 1.1 XML input document to the stored procedure and specify the **Include**, **SMPCSI Data Set**, and **SYSMOD** parameters, the stored procedure will return the items that you specified in the **Include** array, and the SYSMOD status of the SYSMODs that you specified in the **SYSMOD** array.

If you pass a Version 1.1 XML input document to the stored procedure and specify the **Include** parameter only, the stored procedure will return only the items that you specified in the **Include** array.

If you pass a Version 1.1 XML input document to the stored procedure and specify only the **SMPCSI Data Set** and **SYSMOD** parameters, the stored procedure returns the following information in a Version 1.1 XML output document:

- Operating system information

- Product information
- DB2 MEPL
- SYSMOD status (APPLY status for the SYSMODs that are listed in the XML input document)
- Workload Manager (WLM) classification rules for DB2 Workload

For an example of a complete Version 1.1 XML input document for the GET_SYSTEM_INFO stored procedure, see Example 4.

Complete mode: For examples of Version 1.0 and Version 1.1 XML input documents that are returned by the *xml_output* parameter when the stored procedure is running in Complete mode, see Example 1 and Example 2 respectively.

xml_filter

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see XPath expressions for filtering output (DB2 Administration Guide).

The following example selects the value for the Data Server Product Version from the XML output document:

```
/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

xml_output

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server System Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

The *xml_output* parameter can return either a Version 1.0 or Version 1.1 XML output document depending on the *major_version* and *minor_version* parameters that you specify. For more information about the content differences between the Version 1.0 and Version 1.1 XML output documents, see the option description for the *xml_input* parameter.

A complete XML output document provides the following system information:

- Operating system information
- Product information
- DB2 MEPL
- The APPLY status of SYSMODs
- Workload Manager (WLM) classification rules for DB2 Workload for subsystem types DB2 and DDF

For an example of an XML output document, see Example 5.

xml_message

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about a SQL warning condition. This document is returned when a call to the stored procedure results in a SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

The *xml_message* parameter can return either a Version 1.0 or Version 1.1 XML message document, depending on the *major_version* and *minor_version* parameters that you specify. The format of a Version 1.0 or Version 1.1 XML message document is similar. For an example of an XML message document, see Example 6.

Examples

Example 1: The following example shows a Version 1.0 XML input document that is returned by the *xml_output* parameter when the stored procedure is running in Complete mode.

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Optional Parameters</key>
  <dict>
    <key>Display Name</key><string>Optional Parameters</string>
    <key>SMPCSI Data Set</key>
    <dict>
      <key>Display Name</key><string>SMPCSI Data Set</string>
      <key>Value</key><string />
      <key>Hint</key><string />
    </dict>
    <key>SYSMOD</key>
    <dict>
      <key>Display Name</key><string>SYSMOD</string>
      <key>Value</key>
      <array>
        <string />
      </array>
      <key>Hint</key><string />
    </dict>
    <key>Hint</key><string />
  </dict>
</dict>
</plist>
```

Example 2: The following example shows a Version 1.1 XML input document that is returned by the *xml_output* parameter when the stored procedure is running in Complete mode.

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>1</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Optional Parameters</key>
  <dict>

    <key>Hint</key><string />
</dict>
</dict>
</plist>

```

Example 3: The following example shows a complete sample of a Version 1.0 XML input document for the GET_SYSTEM_INFO stored procedure.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
    <key>Document Type Name</key>
    <string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
        <key>SMPCSI Data Set</key>
        <dict>
            <key>Value</key><string>IXM180.GLOBAL.CSI</string>
        </dict>
        <key>SYSMOD</key>
        <dict>
            <key>Value</key>
            <array>
                <string>UK20028</string>
                <string>UK20030</string>
            </array>
        </dict>
    </dict>
</dict>
</plist>

```

You must specify the SMPCSI data set and one or more SYSMODs. SYSMOD status information will be returned for only the SYSMODs that are listed in the **Optional Parameters** section, provided that the SMPCSI data set that you specify is valid.

Example 4: The following example shows a complete sample of a Version 1.1 XML input document for the GET_SYSTEM_INFO stored procedure.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>

```

```

<key>Document Type Minor Version</key><integer>1</integer>
<key>Document Locale</key><string>en_US</string>
<key>Optional Parameters</key>
<dict>
  <key>Include</key>
  <dict>
    <key>Value</key>
    <array>
      <string>Operating System Information</string>
      <string>Product Information</string>
      <string>DB2 MEPL</string>
      <string>Workload Manager (WLM) Classification Rules for
        DB2 Workload</string>
    </array>
  </dict>
  <key>SMPCSI Data Set</key>
  <dict>
    <key>Value</key><string>IXM180.GLOBAL.CSI</string>
  </dict>
  <key>SYSMOD</key>
  <dict>
    <key>Value</key>
    <array>
      <string>UK24596</string>
      <string>UK24709</string>
    </array>
  </dict>
</dict>
</plist>

```

Example 5: The following example shows a fragment of an XML output document for the GET_SYSTEM_INFO stored procedure. In this example, the ellipsis (. . .) represent a dictionary entry that is comprised of **Display Name**, **Value**, and **Hint**, such as:

```

<dict>

      <key>Value</key>
      <string>DSNA647I DSNADMGS INVOCATION OF GIMAPI FAILED. Error processing
          command: QUERY . RC=12 CC=50504. GIM54701W ALLOCATION FAILED FOR
          SMPCSI - IKJ56228I DATA SET IXM180.GLOBAL.CSI NOT IN CATALOG OR
          CATALOG CAN NOT BE ACCESSED. GIM44232I GIMMPVIA - DYNAMIC
          ALLOCATION FAILED FOR THE GLOBAL ZONE, DATA SET IXM180.GLOBAL.CSI.
          GIM50504S ** OPEN PROCESSING FAILED FOR THE GLOBAL ZONE.</string>
      <key>Hint</key><string />
    </dict>
  </dict>
</plist>

```

Example 7: This example shows a simple and static Java program that calls the GET_SYSTEM_INFO stored procedure with an XML input document and an XPath that queries the value of the operating system name and release.

The XML input document is initially saved as a file called xml_input.xml that is in the same directory where the GetSystemDriver class resides. This sample program uses the following xml_input.xml file:

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key>
    <string>Data Server System Input</string>
    <key>Document Type Major Version</key>
    <integer>1</integer>
    <key>Document Type Minor Version</key>
    <integer>1</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Include</key>
      <dict>
        <key>Value</key>
        <array>
          <string>Operating System Information</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```

The XPath is statically created as a string object by the program and then converted to a BLOB to serve as input for the *xml_filter* parameter. After the stored procedure is called, the *xml_output* parameter contains only a single string and no XML document. This output is materialized as a file called xml_output.xml that is in the same directory where the GetSystemDriver class resides.

Sample invocation of the GET_SYSTEM_INFO stored procedure with a valid XML input document and a valid XPath:

```

//*****
// Licensed Materials - Property of IBM

SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure

The SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure indicates that DB2 is to disable recording of temporal history for a system-period temporal table and allow an application to specify values for row-begin, row-end, and transaction-start-ID columns on subsequent operations.

DB2 continues to generate new values for row-begin, row-end, and transaction-start-ID columns that are not explicitly specified as the target of an assignment clause for a data change statement.

This procedure is not intended for general use. It is intended to be used by products that enable DB2 replication.

 PSPI

Environment

SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY must run in a WLM-established stored procedure address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

Description

The procedure has no parameters.

The result of the procedure is that recording of temporal history for a system-period temporal table is disabled, and an application is allowed to specify values for row-begin, row-end, and transaction-start-ID columns.

 PSPI

SET_PLAN_HINT stored procedure

The SET_PLAN_HINT stored procedure validates, deploys, modifies, or deletes catalog tables rows that influence access path selection for SQL statements.

PSPI

The actions that are taken when you call the SET_PLAN_HINT stored procedure depend on a mode value and the type of hint that you specify. You can specify the following modes: CREATE, DELETE, MODIFY or VALIDATE.

Environment

The SET_PLAN_HINT stored procedure runs in a WLM-established stored procedures address space.

The following staging tables, and related objects, which are created by job DSN8BIJRT, must exist for use by the SET_PLAN_HINT stored procedure:

- DSN8BQRY.PLAN_TABLE
- DSN8BQRY.DSN_USER_QUERY_TABLE

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the SET_PLAN_HINT stored procedure.

Syntax

```
CALL SET_PLAN_HINT ( major_version , minor_version ,  
                   [ NULL ] [ NULL ] ,  
 requested_locale , xml_input , xml_filter , xml_output , xml_message )
```

The schema is SYSPROC.

Option descriptions

major_version

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The only supported value is 1.

If the XML document in the *xml_input* parameter specifies the **Document Type Major Version** key, the value for that key must be equal to the value provided in the *major_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *minor_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

minor_version

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (*xml_input*, *xml_output*, and *xml_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The only minor document version that is supported is 0 (zero).

If the XML document in the *xml_input* parameter specifies the **Document Type Minor Version** key, the value for that key must be equal to the value provided in the *minor_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *major_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml_output* and *xml_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested_locale* are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Hint Management Input in UTF-8 that represents the hint customization. The SET_PLAN_HINT stored procedure does not support Complete mode.

The input document has the following format.

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Hint Management Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>HINT_CUSTOMIZATION</key>
</dict>
```

```
|   hint-customization
| </dict>
| </dict>
| </plist>
```

In the preceding example, *hint-customization* is an XML fragment that describes the customized hint to be generated, validated, or deleted. The following example shows the overview of the format of the hint customization dictionary:

```
| <key>HINT_CUSTOMIZATION</key>
| <dict>
|   <key>DeploymentParameters</key>
|   <dict>
|   </dict>
|   <key>StatementList</key>
|   <array>
|     <dict>
|       <key>DeploymentParameters</key>
|       <dict>
|       </dict>
|       <key>SQLStatement</key>
|       <dict>
|       </dict>
|       <key>ExistingAccessPlanIdentifier</key>
|       <dict>
|       </dict>
|       <key>StatementLevelRules</key>
|       <dict>
|       </dict>
|       <key>PlanLevelRules</key>
|       <dict>
|         <key>TableAccessRules</key>
|         <array></array>
|         <key>JoinSequenceRules</key>
|         <array></array>
|       </dict>
|     </dict>
|   </array>
| </dict>
```

hint-customization is a dictionary that contains the following keys:

DeploymentParameters

The type of hint, the action for the stored procedure, and the deployment parameters for the hint.

Deployment parameters can also be specified at the statement level, within the “StatementList” on page 1043 array. Statement-level deployment parameters override the global deployment parameters for a particular statement.

The DeploymentParameters dictionary can contain the following keys:

MODE

The MODE value is required. It specifies the hint processing mode and controls the actions taken by the SET_PLAN_HINT stored procedure:

CREATE Generates a hint in the deployment table. The following table describes the specific actions and required input parameters for different types of hints:

Table 137. Actions by hint type for the SET_PLAN_HINT stored procedure in CREATE mode

| Hint type | Action | Required Input Parameters |
|---------------------------------|--|---|
| PLAN_TABLE access path hints | <ol style="list-style-type: none"> 1. A check is completed to ensure that the deployment PLAN_TABLE does not contain an existing hint that has matching values for the following parameters that are specified in the DeploymentParameters dictionary: <ul style="list-style-type: none"> • QUERYNO • APPLNAME • PROGNAME • COLLID • VERSION • OPTHINT • BIND_TIME 2. An existing access path is copied from the source PLAN_TABLE to the deployment PLAN_TABLE, and the information specified in the DeploymentParameters, TableAccessRules, and JoinSequenceRules dictionaries are applied to the copied plan. <ul style="list-style-type: none"> • The existing access path is identified by the parameters specified in the ExistingAccessPathIdentifier dictionary. • The source PLAN_TABLE is <i>schema-name</i>.PLAN_TABLE, where <i>schema-name</i> is the PLAN_SCHEMA value that is specified in the ExistingAccessPlanIdentifier dictionary. • The deployment PLAN_TABLE is the <i>schema-name</i>.PLAN_TABLE, where <i>schema-name</i> is the PLAN_SCHEMA value that is specified in the DeploymentParameters dictionary. | <ul style="list-style-type: none"> • DeploymentParameters <ul style="list-style-type: none"> - QUERYNO - APPLNAME - PROGNAME - COLLID - VERSION - OPTHINT - PLAN_SCHEMA (schema of the deployment PLAN_TABLE) • ExistingAccessPlanIdentifier <ul style="list-style-type: none"> - QUERYNO - APPLNAME - PROGNAME - COLLID - VERSION - OPTHINT - PLAN_SCHEMA (schema of the source PLAN_TABLE) |

VALIDATE

Generates a hint and captures EXPLAIN information to validate the hint. The following table shows the actions taken and the required input parameters when VALIDATE mode is used.

Table 140. Actions by hint type for the SET_PLAN_HINT stored procedure in VALIDATE mode

| Hint type | Action | Required Input Parameters |
|-----------|---|--|
| All types | <ol style="list-style-type: none"> 1. A check is completed to ensure that no existing rows the deployment PLAN_TABLE table match the following values that are specified in the DeploymentParameters and ExistingAccessPlanIdentifier dictionaries: <ul style="list-style-type: none"> • QUERYNO • APPLNAME • PROGNAME • COLLID • VERSION • OPTHINT • BIND_TIME 2. If the matching rows do not already exist, the access path identified by the information specified in the ExistingAccessPlanIdentifier dictionary is copied from the source PLAN_TABLE to the deployment PLAN_TABLE. The information specified in the DeploymentParameters, TableAccessRules and JoinSequenceRules dictionaries are applied to the copied plan. <ul style="list-style-type: none"> • The source PLAN_TABLE is <i>schema-name</i>.PLAN_TABLE, where <i>schema-name</i> is the PLAN_SCHEMA value that is specified in the ExistingAccessPlanIdentifier dictionary. • The deployment PLAN_TABLE is the <i>schema-name</i>.PLAN_TABLE, where <i>schema-name</i> is the value of the CURRENT SQLID special register for the process. 3. EXPLAIN information is captured for the resulting access path. The copied access path and the EXPLAIN output are kept or deleted based on the SQLCODE value that is returned for the EXPLAIN operation: <p>SQLCODE +000 The new PLAN_TABLE rows are deleted.</p> <p>SQLCODE +394 The new PLAN_TABLE rows are kept.</p> <p>SQLCODE +395 If the value of the HINT_USED column is blank for all rows, the new PLAN_TABLE rows are deleted.</p> | <ul style="list-style-type: none"> • ExistingAccessPlanIdentifier <ul style="list-style-type: none"> – QUERYNO – APPLNAME – PROGNAME – COLLID – VERSION – PLAN_SCHEMA (the schema of the source PLAN_TABLE) • DeploymentParameters <ul style="list-style-type: none"> – OPTHINT |

Notes:

1. In VALIDATE processing for static statements and dynamic statements that are bound with the DYNAMICRULES(BIND) option, the COLLID,

PROGNAME, and VERSION values for the package that contains the SET_PLAN_HINT stored procedure are used for the BIND QUERY operation. Therefore, the SQL processing options of DSNADM.DSNADMHS are used. Differences between the SQL processing options of the specified package and DSNADMHS might cause the BIND QUERY command to fail. When that happens, the validate operation fails. Option differences that might cause such failures include decimal point representation and others.

Related information:

Options affecting SQL

Decimal point representation

HINT_TYPE

The type of access path hint:

TRADITIONAL

PLAN_TABLE access path hints. This value is used by default.

INSTANCE-LEVEL

Statement-level hints, including:

- Access paths.
- Optimization parameters.

HINT_SCOPE

The scope of the statement-level hint:

SYSTEM-LEVEL

The hint applies at the system level. This value is used by default.

PACKAGE-LEVEL

The hint applies at the package level.

INSTANCE_LEVEL_HINT_TYPE

The action specified by statement-level rows:

ACCESS-PATH

Statement-level access paths. This value is used by default.

OPTIMIZATION-PARAMETERS

Statement-level optimization parameters.

Keys that correspond to the following PLAN_TABLE columns:

- OPTHINT
- PROGNAME¹
- APPLNAME
- VERSION¹
- COLLID¹
- QUERYNO
- BIND_TIME
- QUERYID

For the meanings and accepted values for these keys, see: PLAN_TABLE (DB2 Performance).

PLAN_SCHEMA

The schema of the deployment PLAN_TABLE.

The following example shows the format of the DeploymentParameters dictionary for a PLAN_TABLE access path hint:

```
<key>DeploymentParameters</key>
<dict>
  <key>MODE</key>
  <string>CREATE</string>
  <key>HINT_TYPE</key>
  <string>TRADITIONAL</string>
  <key>HINT_SCOPE</key>
  <string>PACKAGE-LEVEL</string>
  <key>APPLNAME</key>
  <string></string>
  <key>PROGNAME</key>
  <string>DSNTIAD</string>
  <key>COLLID</key>
  <string>DSNTIAB1</string>
  <key>VERSION</key>
  <string>*</string>
  <key>QUERYNO</key>
  <string>200</string>
  <key>PLAN_SCHEMA</key>
  <string>ADMF002</string>
  <key>OPTHINT</key>
  <string>HINT001</string>
</dict>
```

StatementList

A list of SQL statements and the hint definition that is associated with each. Only one SQL statement is supported. Additional SQL statements are ignored. The following example shows the format of the StatementList array:

```
<key>StatementList</key>
<array>
  <dict>
    <key>DeploymentParameters</key>
    <dict>
    </dict>
    <key>SQLStatement</key>
    <dict>
    </dict>
    <key>ExistingAccessPlanIdentifier</key>
    <dict>
    </dict>
    <key>StatementLevelRules</key>
    <dict>
    </dict>
    <key>PlanLevelRules</key>
    <dict>
      <key>TableAccessRules</key>
      <array></array>
      <key>JoinSequenceRules</key>
      <array></array>
    </dict>
  </dict>
</array>
```

DeploymentParameters

Deployment parameters can be specified globally, or specified at the statement level. Statement-level deployment parameters override the global parameters for a particular statement. For a description of the DeploymentParameter dictionary, see “DeploymentParameters” on page 1036.

SQLStatement

The statement text and the default schema for resolving unqualified table names in the statement.

The SQLStatement dictionary can contain the following keys:

SQLText

The text of the SQL statement.

SCHEMA

The default schema for resolving unqualified table names in the statement.

The following example shows the format of the SQLStatement dictionary:

```
<key>SQLStatement</key>
<dict>
  <key>SCHEMA</key>
  <string>USER001</string>
  <key>SQLText</key>
  <string>
    SELECT s_name,
           count(*) as numwait
    FROM supplier,
         lineitem l1,
         order,
         nation
    WHERE s_suppkey = l1.l_suppkey
          AND o_orderkey = l1.l_orderkey
          AND o_orderstatus = 'F'
          AND l1.l_receiptdate > l1.l_commitdate
          AND EXISTS(
            SELECT *
            FROM lineitem l2
            WHERE l2.l_orderkey = l1.l_orderkey
                  AND l2.l_suppkey <> l1.l_suppkey
            )
          AND NOT EXISTS (
            SELECT *
            FROM lineitem l3
            WHERE l3.l_orderkey = l1.l_orderkey
                  AND l3.l_suppkey <> l1.l_suppkey
                  AND l3.l_receiptdate > l3.l_commitdate
            )
          AND s_nationkey = n_nationkey
          AND n_name = 'USA'
    GROUP BY s_name
    ORDER BY numwait desc,s_name
  </string>
</dict>
```

ExistingAccessPlanIdentifier

A list of parameters that identify an access path in a PLAN_TABLE. ExistingAccessPlanIdentifier applies only for hints that specify access paths.

The ExistingAccessPlanIdentifier dictionary can contain the following keys:

Keys that correspond to the following PLAN_TABLE columns

- OPTHINT
- PROGNAME
- APPLNAME

- **VERSION**
- **COLLID**
- **QUERYNO**
- **BIND_TIME**

For the meanings and accepted values for these keys, see: PLAN_TABLE (DB2 Performance).

PLAN_SCHEMA

The schema of the PLAN_TABLE that contains the original access path.

The following example shows the format of the ExistingAccessPlanIdentifier dictionary:

```
<key>ExistingAccessPlanIdentifier</key>
<dict>
  <key>APPLNAME</key>
  <string></string>
  <key>PROGNAME</key>
  <string>DSNADMXX</string>
  <key>COLLID</key>
  <string>DSNADM</string>
  <key>VERSION</key>
  <string>*</string>
  <key>QUERYNO</key>
  <string>200</string>
  <key>PLAN_SCHEMA</key>
  <string>ADMFO02</string>
  <key>OPTHINT</key>
  <string>HINT001</string>
  <key>BIND_TIME</key>
  <string>2012-11-05-07.10.41.700000</string>
</dict>
```

StatementLevelRules

A list of parameters that identify optimization parameter hint properties. StatementLevelRules applies only to hints for optimization parameters.

The StatementLevelRules dictionary can contain the following keys:

Keys that correspond to the following DSN_USERQUERY_TABLE columns:

- **REOPT**
- **STARJOIN**
- **MAX_PAR_DEGREE**
- **DEGREE** (for the DEF_CURR_DEGREE column)
- **SJTABLES**

For meanings and accepted values for these keys, see the column descriptions in DSN_USERQUERY_TABLE (DB2 Performance).

The following example shows the format of the StatementLevelRules dictionary:

```
<key>StatementLevelRules</key>
<dict>
  <key>REOPT</key>
  <dict>
    <key>VALUE</key>
```

```

|   <string>1</string>
| </dict>
|   <key>STARJOIN</key>
| <dict>
|   <key>VALUE</key>
|   <string>N</string>
| </dict>
|   <key>MAX_PAR_DEGREE</key>
| <dict>
|   <key>VALUE</key>
|   <string>2</string>
| </dict>
|   <key>DEGREE</key>
| <dict>
|   <key>VALUE</key>
|   <string>ONE</string>
| </dict>
|   <key>SJTABLES</key>
| <dict>
|   <key>VALUE</key>
|   <string>2</string>
| </dict>
| </dict>

```

PlanLevelRules

A list of parameters that describe the customized access path that is specified by the hint, including separate arrays for table access and join sequence information. PlanLevelRules applies only to hints that specify access paths. The following example shows the format of this PlanLevelRules dictionary:

```

| <key>PlanLevelRules</key>
| <dict>
|   <key>TableAccessRules</key>
|   <array></array>
|   <key>JoinSequenceRules</key>
|   <array></array>
| </dict>

```

TableAccessRules

A list of rules that are related to table access and that describe data access methods, such as table space scans and index scans, for example.

Each table access rule is represented by a TableReferenceIdentifier and its corresponding Settings.

TableReferenceIdentifier

A list of properties that identify the table reference. The properties correspond to PLAN_TABLE columns:

- **QBLOCKNO**
- **TABNO**
- **TABLE_CREATOR** (for the CREATOR column)
- **TABLE_NAME** (for the TNAME column)
- **CORRELATION_NAME**

For the meanings and accepted values for these properties, see: PLAN_TABLE (DB2 Performance).

Settings

A list of access properties. The properties correspond to PLAN_TABLE columns:

- **ACCESS_TYPE** (for the ACCESSTYPE column)

- **ACCESS_CREATOR** (for the ACCESCREATOR column)
- **ACCESS_NAME** (for the ACCESSNAME column)
- **PREFETCH**
- **PAGE_RANGE**
- **SORTN_JOIN**
- **SORTC_JOIN**
- **PARALLELISM_MODE**
- **ACCESS_DEGREE**
- **JOIN_DEGREE**
- **ACCESS_PGROUP_ID**
- **JOIN_PGROUP_ID**
- **PRIMARY_ACCESSTYPE**
- **METHOD**

For the meanings and accepted values for these properties, see: PLAN_TABLE (DB2 Performance).

The following example shows the format of this TableAccessRules array:

```

<key>TableAccessRules</key>
<array>
  <dict>
    <key>TableReferenceIdentifier</key>
    <array>
      <dict>
        <key>NAME</key>
        <string>QBLOCKNO</string>
        <key>VALUE</key>
        <string>1</string>
      </dict>
      ...
    </array>
    <key>Settings</key>
    <array>
      <dict>
        <key>NAME</key>
        <string>ACCESS_TYPE</string>
        <key>VALUE</key>
        <string>IXSCAN</string>
      </dict>
    </array>
  </dict>
</array>

```

JoinSequenceRules

A list of join sequence customization rules. Each join sequence rule is represented by the Settings and Roots (root nodes) for the join sequence. The join sequence rules correspond to the join sequence and join methods, such as merge join and hybrid join, for example.

Settings

A property for the join sequence rule that correspond to the PLAN_TABLE column of the same name: **QBLOCKNO**

Roots

A list of root nodes in the join sequence, where each root node is identified by the node type. Depending on the node type, a

TABLE_REFERENCE_NODE holds the properties to identify the table reference, while an OPERATOR_NODE holds the properties of the operator.

TYPE

The node type:

- TABLE_REFERENCE_NODE
- OPERATOR NODE

TableReferenceIdentifier

A list of properties to identify the table reference if node type is TABLE_REFERENCE_NODE. These properties correspond to PLAN_TABLE columns:

- QBLOCKNO
- TABNO
- TABLE_CREATOR (for the CREATOR column)
- TABLE_NAME (for the TNAME column)
- CORRELATION_NAME

For the meanings and accepted values for these properties, see: PLAN_TABLE (DB2 Performance).

Settings

A list of properties of this operator if node type is OPERATOR_NODE. These properties correspond to PLAN_TABLE columns:

- JOIN_METHOD (for the METHOD column)
- SORTN_JOIN
- SORTC_JOIN
- JOIN_DEGREE
- JOIN_PGROUP_ID

For the meanings and accepted values for these properties, see: PLAN_TABLE (DB2 Performance).

Left

A description of a left-side child node. The data structure is similar to the root node.

Right

A description of a right-side child node. The data structure is similar to the root node.

The following example shows the format of this JoinSequence array:

```
<key>JoinSequenceRules</key>
<array>
  <dict>
    <key>Settings</key>
    <array>
      <dict>
        <key>NAME</key>
        <string>QBLOCKNO</string>
        <key>VALUE</key>
        <string>1</string>
      </dict>
    </array>
  <key>Roots</key>
</array>
```

```

| <array>
|   <dict>
|     <key>TYPE</key>
|     <string>OPERATOR_NODE</string>
|     <key>Settings</key>
|     <array>

xml_filter

An input parameter of type BLOB(4K). Specifies a valid XPath query string to retrieve a single value from an XML output document.

xml_output

An output parameter of type BLOB(2G)

When the mode is VALIDATE, *xml_output* has the following format:

```

| <?xml version="1.0" encoding="UTF-8"?>
| <plist version="1.0">
| <dict>
|   <key>Document Type Name</key><string>Data Server Hint Management Output</string>
|   <key>Document Type Major Version</key><integer>1</integer>
|   <key>Document Type Minor Version</key><integer>0</integer>
|   <key>Data Server Product Name</key><string>DSN</string>
|   <key>Data Server Product Version</key><string>10.1.5</string>
|   <key>Data Server Major Version</key><integer>10</integer>
|   <key>Data Server Minor Version</key><integer>1</integer>
|   <key>Data Server Platform</key><string>z/OS</string>
|   <key>Document Locale</key><string>en_US</string>
|   <key>Hint Validation</key>
|   <dict>
|     <key>Display Name</key><string>Hint Validation</string>
|     <key>EXPLAIN SQLCODE</key>
|     <dict>
|       <key>Display Name</key><string>EXPLAIN SQLCODE</string>

SQLJ.ALTER_JAVA_PATH stored procedure

SQLJ.ALTER_JAVA_PATH modifies the class resolution path of an installed JAR.

SQLJ.ALTER_JAVA_PATH specifies the class resolution path that the JVM uses when a JAR file that is part of a Java stored procedure references a class that is neither contained in that JAR file, found in the CLASSPATH, nor system-supplied.

SQLJ.ALTER_JAVA_PATH authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.ALTER_JAVA_PATH, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.ALTER_JAVA_PATH
- Ownership of SQLJ.ALTER_JAVA_PATH
- SYSADM authority

The privilege set must also include the authority to alter a JAR, which consists of at least one of the following items:

- Ownership of the JAR
- ALTERIN privilege on the schema of the JAR

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

- SYSADM or SYSCTRL authority

For referring to JAR *jar2* in the Java path, the privilege set must include at least one of the following items:

- Ownership of *jar2*
- USAGE privilege on *jar2*
- SYSADM authority

SQLJ.ALTER_JAVA_PATH syntax

```
CALL SQLJ.ALTER_JAVA_PATH (—JAR-name1, 'path'
                             'blanks'
                             '' )
```

path:

```
path-element
```

path-element:

Java-package-name:

class-name:

SQLJ.ALTER_JAVA_PATH parameters

JAR-name1

A VARCHAR(257) input parameter that contains the DB2 name of the JAR whose path is to be altered, in the form *schema.JAR-id* or *JAR-id*. *JAR-name1* is the name that you use when you refer to the JAR in SQL statements. If you omit *schema*, DB2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

path

A VARCHAR(2048) input parameter that specifies the class resolution path that the JVM uses when *JAR-name1* references a class that is neither contained in *JAR-name1*, found in the CLASSPATH, nor system-supplied.

During execution of the Java routine, when DB2 encounters an unresolved class reference, DB2 compares each path element in the path to the class reference. If a path element matches the class reference, DB2 searches for the class in the JAR that is specified by the path element.

- * Indicates that any class reference can be searched for in the JAR that is identified by *JAR-name2*. If an error prevents the class from being found, the search terminates, and a `java.lang.ClassNotFoundException` is thrown to report that error. If the class is not found in the JAR, the search continues with the next path element.

Java-package-name.*

Indicates that class references for classes that are in the package named *Java-package-name* are searched for in the JAR that is identified by *JAR-name2*. If an error prevents a class from being found, the search terminates, and a `java.lang.ClassNotFoundException` is thrown to report that error. If a class is not found in the JAR, the search terminates, and a `java.lang.NoClassDefFoundError` is thrown.

If the class reference is to a class in a different package, the search continues with the next path element.

Java-package-name.class-name or class-name

Indicates that class references for classes whose fully qualified name matches *Java-package-name.class-name* or *class-name* are searched for in the JAR that is identified by *JAR-name2*. Class references for classes that are in packages within the package named *Java-package-name* are not searched for in the JAR

that is identified by *JAR-name2*. If an error prevents a class from being found, the search terminates, and a `java.lang.ClassNotFoundException` is thrown to report that error. If a class is not found in the JAR, the search terminates and a `java.lang.NoClassDefFoundError` is thrown.

If the class reference is to a different class, the search continues with the next path element.

JAR-name2

Specifies the DB2 name of the JAR that is to be searched. The form of *JAR-name2* is *schema.JAR-id* or *JAR-id*. If *schema* is omitted, the JAR name is implicitly qualified with the schema name in the CURRENT SCHEMA special register. JAR *JAR-name2* must exist at the current server. *JAR-name2* must not be the same as *JAR-name1*.

SQLJ.ALTER_JAVA_PATH usage notes

Stored procedures that reference classes in multiple JAR files: A stored procedure that is packaged as a JAR file might reference classes that are in other JAR files, and the referenced JAR files might reference classes in still other JAR files. You need to specify class resolution paths for *all* dependencies among JAR files that the stored procedure uses. For any JAR files that the stored procedure uses that cannot be found in the CLASSPATH, and are not system-supplied, you need to use `SQLJ.ALTER_JAVA_PATH` to define the class resolution path. For example, suppose that stored procedure SP, which is packaged in JAR file JARSP, references classes in JAR files JAR1 and JAR2. Classes in JAR file JAR1 reference classes that are in JAR file JAR2. None of the JAR files are in the CLASSPATH or are system-supplied. You need to call `SQLJ.ALTER_JAVA_PATH` twice, to define the following class resolution paths:

- From JARSP to JAR1 and JAR2
- From JAR1 to JAR2

SQLJ.ALTER_JAVA_PATH example

Suppose that the JAR file that is named `DB2INST3.BUILDPLAN` references classes that are in a previously installed JAR that is named `DB2INST3.BUILDPLAN2`. Those classes are in Java package `buildPlan2`. The following Java program calls `SQLJ.ALTER_JAVA_PATH` to add the classes in the `buildPlan2` package to the resolution path for `DB2INST3.BUILDPLAN`.

```
import java.sql.*; // JDBC classes
import java.io.IOException;
import java.io.File;
import java.io.FileInputStream;
class SimpleInstallJar
{
    public static void main (String argv[])
    {
        String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021";
        String jarname = "DB2INST3.BUILDPLAN";
        String resolutionPath =
            "(buildPlan2.*,DB2INST3.BUILDPLAN2)";
        try
        {
            Class.forName ("com.ibm.db2.jcc.DB2Driver").newInstance ();
            Connection con =
                DriverManager.getConnection(url, "MYID", "MYPW");
            CallableStatement stmt;
            String sql = "Call SQLJ.ALTER_JAVA_PATH(?, ?)";
            stmt = con.prepareCall(sql);
            stmt.setString(1, jarname);
```

```

|
|      stmt.setString(2, resolutionPath);
|      boolean isrs = stmt.execute();
|      stmt.close();
|      System.out.println("Alteration of JAR resolution path succeeded");
|      con.commit();
|      con.close();
|    }
|    catch (Exception e)
|    {
|      System.out.println("Alteration of JAR resolution path failed");
|      e.printStackTrace ();
|    }
|  }
| }

```

Related concepts:

 [Definition of a JAR file for a Java routine to DB2 \(DB2 Application Programming for Java\)](#)

SQLJ.DB2_INSTALL_JAR stored procedure

SQLJ.DB2_INSTALL_JAR creates a new definition of a JAR file in the local DB2 catalog or in a remote DB2 catalog.

To install a JAR file at a remote location, you need to execute a CONNECT statement to connect to that location before you call SQLJ.DB2_INSTALL_JAR.

SQLJ.DB2_INSTALL_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.DB2_INSTALL_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.DB2_INSTALL_JAR
- Ownership of SQLJ.DB2_INSTALL_JAR
- SYSADM authority

The privilege set must also include the authority to install a JAR, which consists of at least one of the following items:

- CREATEIN privilege on the schema of the JAR
The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.
- SYSADM or SYSCTRL authority

SQLJ.DB2_INSTALL_JAR syntax

►►—CALL—SQLJ.DB2_INSTALL_JAR—(—*Jar-locator*,—*JAR-name*,—*deploy*—)—————◄◄

SQLJ.DB2_INSTALL_JAR parameters

JAR-locator

A BLOB locator input parameter that points to the JAR file that is to be installed in the DB2 catalog.

JAR-name

A VARCHAR(257) input parameter that contains the DB2 name of the JAR, in the form *schema.JAR-id* or *JAR-id*. *JAR-name* is the name that you use when you refer to the JAR in SQL statements. If you omit *schema*, DB2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register. The owner of the JAR is the authorization ID in the CURRENT SQLID special register.

deploy

An INTEGER input parameter that indicates whether additional actions are to be performed after the JAR file is installed. Additional actions are not supported, so this value is 0.

SQLJ.DB2_INSTALL_JAR example

Suppose that you want to install the JAR file that is in path /u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar. You want to refer to the JAR file as DB2INST3.BUILDPLAN in SQL statements. The following Java program installs that JAR file.

```
import java.sql.*; // JDBC classes
import java.io.IOException;
import java.io.File;
import java.io.FileInputStream;
class SimpleInstallJar
{
    public static void main (String argv[])
    {
        String url = "jdbc:db2://sysmvs1.st1.ibm.com:5021";
        String jarname = "DB2INST3.BUILDPLAN";
        String jarfile =
            "/u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar";
        try
        {
            Class.forName ("com.ibm.db2.jcc.DB2Driver").newInstance ();
            Connection con =
                DriverManager.getConnection(url, "MYID", "MYPW");
            File aFile = new File(jarfile);
            FileInputStream inputStream = new FileInputStream(aFile);
            CallableStatement stmt;
            String sql = "Call SQLJ.DB2_INSTALL_JAR(?, ?, ?)";
            stmt = con.prepareCall(sql);
            stmt.setBinaryStream(1, inputStream, (int)aFile.length());
            stmt.setString(2, jarname);
            stmt.setInt(3, 0);
            boolean isrs = stmt.execute();
            stmt.close();
            System.out.println("Installation of JAR succeeded");
            con.commit();
            con.close();
        }
        catch (Exception e)
        {
            System.out.println("Installation of JAR failed");
            e.printStackTrace ();
        }
    }
}
```

 Definition of a JAR file for a Java routine to DB2 (DB2 Application Programming for Java)

SQLJ.DB2_REPLACE_JAR stored procedure

SQLJ.DB2_REPLACE_JAR replaces an existing JAR file in the local DB2 catalog or in a remote DB2 catalog.

To replace a JAR file at a remote location, you need to execute a CONNECT statement to connect to that location before you call SQLJ.DB2_REPLACE_JAR.

SQLJ.DB2_REPLACE_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.DB2_REPLACE_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.DB2_REPLACE_JAR
- Ownership of SQLJ.DB2_REPLACE_JAR
- SYSADM authority

The privilege set must also include the authority to replace a JAR, which consists of at least one of the following items:

- Ownership of the JAR
- ALTERIN privilege on the schema of the JAR
The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.
- SYSADM or SYSCTRL authority

SQLJ.DB2_REPLACE_JAR syntax

►►—CALL—SQLJ.DB2_REPLACE_JAR—(—JAR-locator,—JAR-name—)—————►►

SQLJ.DB2_REPLACE_JAR parameters

JAR-locator

A BLOB locator input parameter that points to the JAR file that is to be replaced in the DB2 catalog.

JAR-name

A VARCHAR(257) input parameter that contains the DB2 name of the JAR, in the form *schema.JAR-id* or *JAR-id*. *JAR-name* is the name that you use when you refer to the JAR in SQL statements. If you omit *schema*, DB2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

SQLJ.DB2_REPLACE_JAR example

Suppose that you want to replace a previously installed JAR file that is named DB2INST3.BUILDPLAN with the JAR file that is in path /u/db2inst3/apps/BUILDPLAN2/BUILDPLAN.jar. The following Java program replaces the JAR file.

```
import java.sql.*; // JDBC classes
import java.io.IOException;
import java.io.File;
import java.io.FileInputStream;
class SimpleInstallJar
```

```

{
  public static void main (String argv[])
  {
    String url = "jdbc:db2://sysmvs1.st1.ibm.com:5021";
    String jarname = "DB2INST3.BUILDPLAN";
    String jarfile =
      "/u/db2inst3/apps/BUILDPLAN2/BUILDPLAN.jar";
    try
    {
      Class.forName ("com.ibm.db2.jcc.DB2Driver").newInstance ();
      Connection con =
        DriverManager.getConnection(url, "MYID", "MYPW");
      File aFile = new File(jarfile);
      FileInputStream inputStream = new FileInputStream(aFile);
      CallableStatement stmt;
      String sql = "Call SQLJ.DB2_REPLACE_JAR(?, ?)";
      stmt = con.prepareCall(sql);
      stmt.setBinaryStream(1, inputStream, (int)aFile.length());
      stmt.setString(2, jarname);
      boolean isrs = stmt.execute();
      stmt.close();
      System.out.println("Replacement of JAR succeeded");
      con.commit();
      con.close();
    }
    catch (Exception e)
    {
      System.out.println("Replacement of JAR failed");
      e.printStackTrace ();
    }
  }
}

```

SQLJ.INSTALL_JAR stored procedure

SQLJ.INSTALL_JAR creates a new definition of a JAR file in the local DB2 catalog.

SQLJ.INSTALL_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.INSTALL_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.INSTALL_JAR
- Ownership of SQLJ.INSTALL_JAR
- SYSADM authority

The privilege set must also include the authority to install a JAR, which consists of at least one of the following items:

- CREATEIN privilege on the schema of the JAR
The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.
- SYSADM or SYSCTRL authority

SQLJ.INSTALL_JAR syntax

►►—CALL—SQLJ.INSTALL_JAR—(—url,—JAR-name,—deploy—)—————◄◄

SQLJ.INSTALL_JAR parameters

url

A VARCHAR(1024) input parameter that identifies the z/OS UNIX System Services full path name for the JAR file that is to be installed in the DB2 catalog. The format is `file://path-name` or `file:/path-name`.

JAR-name

A VARCHAR(257) input parameter that contains the DB2 name of the JAR, in the form `schema.JAR-id` or `JAR-id`. *JAR-name* is the name that you use when you refer to the JAR in SQL statements. If you omit *schema*, DB2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register. The owner of the JAR is the authorization ID in the CURRENT SQLID special register.

deploy

An INTEGER input parameter that indicates whether additional actions are to be performed after the JAR file is installed. Additional actions are not supported, so this value is 0.

SQLJ.INSTALL_JAR example

Suppose that you want to install the JAR file that is in path `/u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar`. You want to refer to the JAR file as `DB2INST3.BUILDPLAN` in SQL statements. Use a CALL statement similar to this one.

```
CALL SQLJ.INSTALL_JAR('file:/u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar',  
  'DB2INST3.BUILDPLAN',0)
```

Related concepts:

 Definition of a JAR file for a Java routine to DB2 (DB2 Application Programming for Java)

SQLJ.REMOVE_JAR stored procedure

SQLJ.REMOVE_JAR deletes a JAR file from the local DB2 catalog or from a remote DB2 catalog.

To delete a JAR file at a remote location, you need to execute a CONNECT statement to connect to that location before you call SQLJ.REMOVE_JAR.

The JAR cannot be referenced in the EXTERNAL NAME clause of an existing routine, or in the path of an installed JAR.

SQLJ.REMOVE_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.REMOVE_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.REMOVE_JAR
- Ownership of SQLJ.REMOVE_JAR
- SYSADM authority

The privilege set must also include the authority to remove a JAR, which consists of at least one of the following items:

- Ownership of the JAR
- DROPIN privilege on the schema of the JAR
The authorization ID that matches the schema name implicitly has the DROPIN privilege on the schema.
- SYSADM or SYSCTRL authority

SQLJ.REMOVE_JAR syntax

►►—CALL—SQLJ.REMOVE_JAR—(—JAR-name,—undeploy—)—————◀◀

SQLJ.REMOVE_JAR parameters

JAR-name

A VARCHAR(257) input parameter that contains the DB2 name of the JAR that is to be removed from the catalog, in the form *schema.JAR-id* or *JAR-id*.

JAR-name is the name that you use when you refer to the JAR in SQL statements. If you omit *schema*, DB2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

undeploy

An INTEGER input parameter that indicates whether additional actions should be performed before the JAR file is removed. Additional actions are not supported, so this value is 0.

SQLJ.REMOVE_JAR example

Suppose that you want to remove a previously installed JAR file that is named DB2INST3.BUILDPLAN. Use a CALL statement similar to this one.

```
CALL SQLJ.REMOVE_JAR('DB2INST3.BUILDPLAN',0)
```

Related concepts:

 [Definition of a JAR file for a Java routine to DB2 \(DB2 Application Programming for Java\)](#)

SQLJ.REPLACE_JAR stored procedure

SQLJ.REPLACE_JAR replaces an existing JAR file in the local DB2 catalog.

SQLJ.REPLACE_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.REPLACE_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.REPLACE_JAR
- Ownership of SQLJ.REPLACE_JAR
- SYSADM authority

The privilege set must also include the authority to replace a JAR, which consists of at least one of the following items:

- Ownership of the JAR
- ALTERIN privilege on the schema of the JAR

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

- SYSADM or SYSCTRL authority

SQLJ.REPLACE_JAR syntax

►►—CALL—SQLJ.REPLACE_JAR—(—*url*,—*JAR-name*—)—————►►

SQLJ.REPLACE_JAR parameters

url

A VARCHAR(1024) input parameter that identifies the z/OS UNIX System Services full path name for the JAR file that replaces the existing JAR file in the DB2 catalog. The format is `file://path-name` or `file:/path-name`.

JAR-name

A VARCHAR(257) input parameter that contains the DB2 name of the JAR, in the form `schema.JAR-id` or `JAR-id`. *JAR-name* is the name that you use when you refer to the JAR in SQL statements. If you omit *schema*, DB2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

SQLJ.REPLACE_JAR example

Suppose that you want to replace a previously installed JAR file that is named DB2INST3.BUILDPLAN with the JAR file that is in path `/u/db2inst3/apps/BUILDPLAN2/BUILDPLAN.jar`. Use a CALL statement similar to this one.

```

  'DB2INST3.BUILDPLAN')
```

Related concepts:

 Definition of a JAR file for a Java routine to DB2 (DB2 Application Programming for Java)

WLM_REFRESH stored procedure

The WLM_REFRESH stored procedure refreshes a WLM environment. This stored procedure can recycle the environment in which it runs and in any other WLM environment.

Environment for WLM_REFRESH

The load module for WLM_REFRESH, DSNTWR, must reside in an APF-authorized library.

DSNTWR runs module DSNTWRE as a subtask. DSNTWRE retrieves a copy of the DB2 environment information block (EIB) for the DB2 subsystem. The DSNTWRE module has no APF-authorization requirement, but it must reside in an APF-authorized library to be available to DSNTWR.

Recommendation: Use WLM environment DSNWLM_GENERAL for running WLM_REFRESH. Installation job DSNTIJMV creates an address space procedure called DSNWLMG for this environment.

Authorization required for WLM_REFRESH

To execute the CALL statement, the SQL authorization ID of the process must have READ access or higher to the z/OS Security Server System Authorization Facility (SAF) resource profile *ssid.WLM_REFRESH.WLM-environment-name* in resource class DSNR. This is a different resource profile from the *ssid.WLMENV.WLM-environment-name* resource profile, which DB2 uses to determine whether a stored procedure or user-defined function is authorized to run in the specified WLM environment.

WLM_REFRESH uses an extended MCS console to monitor the operating system response to a WLM environment refresh request. The privilege to create an extended MCS console is controlled by the resource profile MVS.MCSOPER.* in the OPERCMDS class. If the MVS.MCSOPER.* profile exists, or if the specific profile MVS.MCSOPER.DSNTWR exists, the task ID that is associated with the WLM environment in which WLM_REFRESH runs must have READ access to it.

If the MVS.VARY.* profile exists, or if the specific profile MVS.VARY.WLM exists, the task ID that is associated with the WLM environment in which WLM_REFRESH runs must have CONTROL access to it.

WLM_REFRESH syntax diagram

The WLM_REFRESH stored procedure refreshes a WLM environment. WLM_REFRESH can recycle the environment in which it runs, as well as any other WLM environment.

The following syntax diagram shows the SQL CALL statement for invoking WLM_REFRESH. The linkage convention for WLM_REFRESH is GENERAL WITH NULLS.

```

▶▶CALL WLM_REFRESH(—WLM-environment, —ssid, —status-message, —return-code—)▶▶

```

WLM_REFRESH option descriptions

WLM-environment

Specifies the name of the WLM environment that you want to refresh. This is an input parameter of type VARCHAR(32).

ssid

Specifies the subsystem ID of the DB2 subsystem with which the WLM environment is associated. If this parameter is NULL or blank, DB2 uses one of the following values for this parameter:

- In a non-data sharing environment, DB2 uses the subsystem ID of the subsystem on which WLM_REFRESH runs.
- In a data sharing environment, DB2 uses the group attach name for the data sharing group in which WLM_REFRESH runs.

This is an input parameter of type VARCHAR(4).

status-message

Contains an informational message about the execution of the WLM refresh. This is an output parameter of type VARCHAR(120).

return-code

Contains the return code from the WLM_REFRESH call, which is one of the following values:

- | | |
|------------|---|
| 0 | WLM_REFRESH executed successfully. |
| 4 | One of the following conditions exists: <ul style="list-style-type: none"> • The SAF resource profile <i>ssid.WLM_REFRESH.wlm-environment</i> is not defined in resource class DSNR. • The SQL authorization ID of the process (CURRENT SQLID) is not defined to SAF. • The wait time to obtain a response from z/OS was exceeded. |
| 8 | The SQL authorization ID of the process (CURRENT SQLID) is not authorized to refresh the WLM environment. |
| 990 | DSNTWR received an unexpected SQLCODE while determining the current SQLID. |
| 993 | One of the following conditions exists: <ul style="list-style-type: none"> • The <i>WLM-environment</i> parameter value is null, blank, or contains invalid characters. • The <i>ssid</i> value contains invalid characters. |
| 994 | The extended MCS console was not activated within the number of seconds indicated by message DSNT5461. |
| 995 | DSNTWR is not running as an authorized program. |
| 996 | DSNTWR could not activate an extended MCS console. See message DSNT533I for more information. |
| 997 | DSNTWR made an unsuccessful request for a message from its extended MCS console. See message DSNT533I for more information. |

| **998** The extended MCS console for DSNTWR posted an alert. See message
| DSNT534I for more information.

| **999** The operating system denied an authorized WLM_REFRESH request.
| See message DSNT545I for more information.

| *return-code* is an output parameter of type INTEGER.

Example of WLM_REFRESH invocation

| Suppose that you want to refresh WLM environment WLMENV1, which is
| associated with a DB2 subsystem with ID DSN. Assume that you already have
| READ access to the DSN.WLM_REFRESH.WLMENV1 SAF profile. The CALL
| statement for WLM_REFRESH looks like this:

```
|                   strcpy(WLMENV,"WLMENV1");  
|                   strcpy(SSID,"DSN");  
|                   EXEC SQL CALL SYSPROC.WLM_REFRESH(:WLMENV, :SSID, :MSGTEXT, :RC);
```

| For a complete example of setting up access to an SAF profile and calling
| WLM_REFRESH, see job DSNTJ6W, which is in data set *prefix*.SDSNSAMP.

| ➡ Controlling extended MCS consoles using RACF (z/OS MVS Planning:
| Operations)

WLM_SET_CLIENT_INFO stored procedure

This procedure allows the caller to set client information that is associated with the current connection at the DB2 for z/OS server.

The following DB2 for z/OS client special registers can be changed:

- CURRENT CLIENT_ACCTNG
- CURRENT CLIENT_USERID
- CURRENT CLIENT_WRKSTNNAME
- CURRENT CLIENT_APPLNAME

The existing behavior of the CLIENT_ACCTNG register is unchanged. It gets its value from the accounting token for DSN requesters, and from the accounting string for SQL and other requesters.

This procedure is not under transaction control and client information changes made by the procedure are independent of committing or rolling back units of work.

Environment

WLM_SET_CLIENT_INFO runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMSI
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Syntax

```
► WLM_SET_CLIENT_INFO ( client_userid , client_wrkstnname ,  
                          NULL                          NULL  
  
                          client_applname , client_acctstr )  
                          NULL                          NULL
```

The schema is SYSPROC.

Procedure parameters

client_userid

An input argument of type VARCHAR(255) that specifies the user ID for the client. If NULL is specified, the value remains unchanged. If an empty string (") is specified, the user ID for the client is reset to the default value.

If the value specified exceeds 16 bytes, it is truncated to 16 bytes. If the value specified is less than 16 bytes, it is padded on the right with blanks to a length of 16 bytes.

client_wrkstnname

An input argument of type VARCHAR(255) that specifies the workstation name for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the workstation name for the client is reset to the default value.

If the value specified exceeds 18 bytes, it is truncated to 18 bytes. If the value specified is less than 18 bytes, it is padded on the right with blanks to a length of 18 bytes.

client_applname

An input argument of type VARCHAR(255) that specifies the application name for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the application name for the client is reset to the default value.

If the value specified exceeds 32 bytes, it is truncated to 32 bytes. If the value specified is less than 32 bytes, it is padded on the right with blanks to a length of 32 bytes.

client_acctstr

An input argument of type VARCHAR(255) that specifies the accounting string for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the accounting string for the client is reset to the default value.

If the requester is DB2 for z/OS, and the value that is specified exceeds 142 bytes, it is truncated to 142 bytes. Otherwise, if the value specified exceeds 200 bytes, it is truncated to 200 bytes.

Examples

Set the user ID, workstation name, application name, and accounting string for the client.

```
strcpy(user_id, "db2user");
strcpy(wkstn_name, "mywkstn");
strcpy(appl_name, "db2bp.exe");
strcpy(acct_str, "myacctstr");
iuser_id = 0;
iwkstn_name = 0;
iappl_name = 0;
iacct_str = 0;
EXEC SQL CALL SYSPROC.WLM_SET_CLIENT_INFO(:user_id:iuser_id, :wkstn_name:iwkstn_name,
                                           :appl_name:iappl_name, :acct_str:iacct_str);
```

Set the user ID to db2user for the client without setting the other client attributes.

```
strcpy(user_id, "db2user");
iuser_id = 0;
iwkstn_name = -1;
iappl_name = -1;
iacct_str = -1;
EXEC SQL CALL SYSPROC.WLM_SET_CLIENT_INFO(:user_id:iuser_id, :wkstn_name:iwkstn_name,
                                           :appl_name:iappl_name, :acct_str:iacct_str);
```

Reset the user ID for the client to blank without modifying the values of the other client attributes.

```
strcpy(user_id, "");
iuser_id = 0;
iwkstn_name = -1;
iappl_name = -1;
```

```

| iacct_str = -1;
| EXEC SQL CALL SYSPROC.WLM_SET_CLIENT_INFO(:user_id:iuser_id, :wkstn_name:iwkstn_name,
|                                           :appl_name:iappl_name, :acct_str:iacct_str);

```

XSR_ADDSCHEMADOC stored procedure

The XSR_ADDSCHEMADOC stored procedure adds every XML schema, other than the primary XML schema document, to the XSR.

Each XML schema in the XSR can consist of one or more XML schema documents. When an XML schema consists of multiple documents, you need to call XSR_ADDSCHEMADOC for the additional documents.

Environment for XSR_ADDSCHEMADOC

XSR_ADDSCHEMADOC runs in a WLM-established stored procedures address space.

Recommendation: Use WLM environment DSNWLM_XML for running XSR_ADDSCHEMADOC. The startup procedure for this environment, DSNWLMX, can be configured during installation, using installation panel DSNTIPRJ, XML schema processing routines.

Authorization required for XSR_ADDSCHEMADOC

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_ADDSCHEMADOC stored procedure.

XSR_ADDSCHEMADOC syntax diagram

The following syntax diagram shows the CALL statement for invoking XSR_ADDSCHEMADOC.

XSR_ADDSCHEMADOC option descriptions

rschema

An input argument of type VARCHAR(128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name

An input argument of type VARCHAR(128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema is "rschema.name". The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure, and XML schema registration cannot yet be

completed. This argument cannot have a NULL value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schemalocation

An input argument of type VARCHAR(1000), which can have a NULL value, that indicates the schema location of the primary XML schema document to which the XML schema document is being added. This argument is the "external name" of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute. The document that references the schemalocation must use valid a URI format.

content

An input parameter of type BLOB(30M) that contains the content of the XML schema document being added. This argument cannot have a NULL value. An XML schema document must be supplied. The content of the XML schema document must be encoded in Unicode.

docproperty

An input parameter of type BLOB(5M) that indicates the properties for the XML schema document being added. This parameter can have a NULL value; otherwise, the value is an XML document.

Example of XSR_ADDSCHEMADOC

The following example calls the XSR_ADDSCHEMADOC stored procedure:

```
CALL SYSPROC.XSR_ADDSCHEMADOC(  
    'SYSXSR',  
    'POschema',  
    'http://myPOschema/PO.xsd',  
    :schema_content,  
    :schema_properties)
```

In this example, XSR_ADDSCHEMADOC folds the name POschema to uppercase, so the name of the XML schema that is added is POSCHEMA. If you do not want XSR_ADDSCHEMADOC to fold POschema to uppercase, you need to delimit the name with double quotation marks ("), as in the following example.

```
CALL SYSPROC.XSR_ADDSCHEMADOC(  
    'SYSXSR',  
    "POschema",  
    'http://myPOschema/PO.xsd',  
    :schema_content,  
    :schema_properties)
```

Related concepts:

XSR_COMPLETE stored procedure

The XSR_COMPLETE procedure is the final stored procedure to be called as part of the XML schema registration process, which registers XML schemas with the XSR.

An XML schema is not available for validation until the schema registration completes through a call to this stored procedure.

Environment for XSR_COMPLETE

XSR_COMPLETE requires a WLM-established stored procedures address space that is configured for running Java routines.

Recommendation: Use WLM environment DSNWLM_JAVA for running XSR_COMPLETE. The startup procedure for this environment, DSNWLMJ, can be configured during installation, using installation panel DSNTIPRH, XML schema processing routines.

Authorization required for XSR_COMPLETE

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_COMPLETE stored procedure.

XSR_COMPLETE syntax diagram

The following syntax diagram shows the CALL statement for invoking XSR_COMPLETE.

XSR_COMPLETE option descriptions

rschema

An input argument of type VARCHAR(128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name

An input argument of type VARCHAR(128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema, for which a completion check is to be performed, is *rschema.name*. The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure. This argument cannot have a NULL value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schemaproperties

An input argument of type BLOB(5M) that specifies properties, if any, associated with the XML schema. The value for this argument is either NULL, if there are no associated properties, or an XML document representing the properties for the XML schema.

issuedfordecomposition

This value must be zero. XML schema decomposition is not supported.

Example of XSR_COMPLETE

The following example calls the XSR_COMPLETE stored procedure:

```
CALL SYSPROC.XSR_COMPLETE(
  'SYSXSR',
  'POschema',
  :schemaproperty_host_var,
  0)
```

In this example, XSR_COMPLETE folds the name POschema to uppercase, so the name of the XML schema for which registration is completed is POSHEMA. If you do not want XSR_COMPLETE to fold POschema to uppercase, you need to delimit the name with double quotation marks ("), as in the following example.

```
CALL SYSPROC.XSR_COMPLETE(
  'SYSXSR',
  '"POschema"',
  :schemaproperty_host_var,
  0)
```

Related tasks:

[Additional steps for enabling the stored procedures and objects for XML schema support \(DB2 Installation and Migration\)](#)

XSR_REGISTER stored procedure

The XSR_REGISTER procedure is the first stored procedure to be called as part of the XML schema registration process, which registers XML schemas with the XSR.

The user that calls this stored procedure is considered the creator of this XML schema. DB2 obtains the namespace attribute from the schema document when XSR_COMPLETE is invoked.

Environment for XSR_REGISTER

XSR_REGISTER runs in a WLM-established stored procedures address space.

Recommendation: Use WLM environment DSNWLM_XML for running XSR_REGISTER. The startup procedure for this environment, DSNWLMX, can be configured during installation, using installation panel DSNTIPRJ, XML schema processing routines.

Authorization required for XSR_REGISTER

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_REGISTER stored procedure.

XSR_REGISTER syntax diagram

The following syntax diagram shows the CALL statement for invoking XSR_REGISTER.

XSR_REGISTER option descriptions

rschema

An input argument of type VARCHAR(128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name

An input and output argument of type VARCHAR(128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema is "rschema.name" and should be unique among all objects in the XSR. This argument accepts a NULL value. When a NULL value is provided for this argument, a unique value is generated and stored within the XSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schemalocation

An input argument of type VARCHAR(1000), which can have a NULL value, that indicates the schema location of the primary XML schema document. This argument is the "external name" of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute.

content

An input parameter of type BLOB(30M) that contains the content of the primary XML schema document. This argument cannot have a NULL value; an XML schema document must be supplied. The content of the XML schema document must be encoded in Unicode.

docproperty

An input parameter of type BLOB(5M) that indicates the properties for the primary XML schema document. This parameter can have a NULL value; otherwise, the value is an XML document.

Example of XSR_REGISTER

The following example calls the XSR_REGISTER stored procedure:

```

CALL SYSPROC.XSR_REGISTER(
  'SYSXSR',
  'POschema',
  'http://myPOschema/PO.xsd',
  :content_host_var,
  :docproperty_host_var)

```

In this example, XSR_REGISTER folds the name POschema to uppercase, so the registered schema name is POSHEMA. If you do not want XSR_REGISTER to fold POschema to uppercase, you need to delimit the name with double quotation marks ("), as in the following example.

```
CALL SYSPROC.XSR_REGISTER(
  'SYSXSR',
  'POschema',
  'http://myPOschema/PO.xsd',
  :content_host_var,
  :docproperty_host_var)
```

XSR_REMOVE stored procedure

The XSR_REMOVE procedure is used to remove all components of an XML schema. After the XML schema is removed, you can reuse the name of the removed XML schema when you register a new XML schema.

Environment for XSR_REMOVE

XSR_REMOVE runs in a WLM-established stored procedures address space.

Recommendation: Use WLM environment DSNWLM_XML for running XSR_REMOVE. The startup procedure for this environment, DSNWLMX, can be configured during installation, using installation panel DSNTIPRJ, XML schema processing routines.

Authorization required for XSR_REMOVE

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_REMOVE stored procedure.

XSR_REMOVE syntax diagram

The following syntax diagram shows the CALL statement for invoking XSR_REMOVE.

XSR_REMOVE option descriptions

rschema

An input argument of type VARCHAR (128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name

An input argument of type VARCHAR (128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema, for which a completion check is to be performed, is "rschema.name". The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure, and XML schema registration cannot yet be completed. This

| argument cannot have a NULL value. Rules for valid characters and delimiters
| that apply to any SQL identifier also apply to this argument.

| **XSR_REMOVE notes**

| If you run XSR_REMOVE against an XML schema that is part of an XML type
| modifier for a table column, an error occurs.

| **Example of XSR_REMOVE**

| The following example calls the XSR_REMOVE stored procedure:

```
| CALL SYSPROC.XSR_REMOVE(  
| 'SYSXSR',  
| 'POschema')
```

| In this example, XSR_REMOVE folds the name POschema to uppercase, so the
| name of the XML schema that is removed is POSCHEMA. If you do not want
| XSR_REMOVE to fold POschema to uppercase, you need to delimit the name with
| double quotation marks ("), as in the following example.

```
| CALL SYSPROC.XSR_REMOVE(  
| 'SYSXSR',  
| '"POschema"')
```

XML\)](#)

Chapter 6. Queries

A *query* specifies a result table or an intermediate table. A query is a component of certain SQL statements. A query can have one of three forms.

A “subselect” on page 1082

A “fullselect” on page 1123

A “select-statement” on page 1131

A subselect is a subset of a fullselect, and a fullselect is a subset of a *select-statement*.

“Authorization” on page 1080 describes the privilege set that is required to use any form of a query.

Another SQL statement that can be used to retrieve at most a single row is described in “SELECT INTO” on page 2166. SELECT INTO is not a subselect, fullselect, or a *select-statement*.

Related concepts:

 [Types of tables \(Introduction to DB2 for z/OS\)](#)

 [Temporal tables \(DB2 Administration Guide\)](#)

Authorization

For any form of a query, the privilege set that is defined below must include one of the following:

- For each table or view identified in the statement, the privilege set must include one of the following:
 - Ownership of the table or view
 - The SELECT privilege on the table or view
 - DBADM authority for the database (tables only)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

- SYSADM authority
- SYSCTRL authority (catalog tables only)
- DATAACCESS authority

If a query includes a user-defined function, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For each user-defined function that is identified in the statement, one of the following:
 - The EXECUTE privilege on the function
 - Ownership of the function
- SYSADM authority
- DATAACCESS authority

If the *select-statement* is part of a DECLARE CURSOR statement, the privilege set is the privileges that are held by the authorization ID of the owner of the plan or package.

If the *select-statement* contains an SQL data change statement, the privilege set must include the SELECT privilege and the appropriate privileges for the SQL data change statement (insert, update, or delete privileges) on the target table or view.

If the *select-statement* references a table that contain an active row or column access control, and row permissions or column masks are defined for the table, the authorization ID or role of the statement does not need authority to reference objects that are specified in the definitions of those row permissions or column masks.

For dynamically prepared statements, the privilege set depends on the dynamic SQL statement behavior, which is specified by option DYNAMICRULES:

Run behavior

The privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Bind behavior

The privilege set is the privileges that are held by the authorization ID of the owner of the plan or package.

Define behavior

The privilege set is the privileges that are held by the authorization ID of the owner of the stored procedure or user-defined function.

Invoke behavior

The privilege set is the privileges that are held by the authorization ID of the invoker of the stored procedure or user-defined function.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.

When any form of a query is used as a component of another statement, the authorization rules that apply to the query are specified in the description of that statement. For example, see “CREATE VIEW” on page 1838 for the authorization rules that apply to the subselect component of CREATE VIEW.

If your installation uses the access control authorization exit (DSNX@XAC), that exit might be controlling the authorization rules instead of the rules that are listed here.

subselect

The *subselect* is a component of the fullselect. A subselect specifies a result table that is derived from the tables or views that are identified in the FROM clause.

The derivation of the result table can be described as a sequence of operations in which the result of each operation is input for the next. (This is only a way of describing the subselect. The method that is used to perform the derivation might be quite different from this description. If portions of the subselect do not actually need to be executed for the correct result to be obtained, they might not be executed.)

| When a subselect directly or indirectly references a table for which row or column
| access control is enforced, the rules that are defined in the row permissions or
| column masks affect how the rows in the result table are derived. Typically those
| rules are based on the authorization ID or role of the process.

A *scalar-subselect* is a subselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the subselect is no rows, the null value is returned. An error is returned if the result contains more than one row.

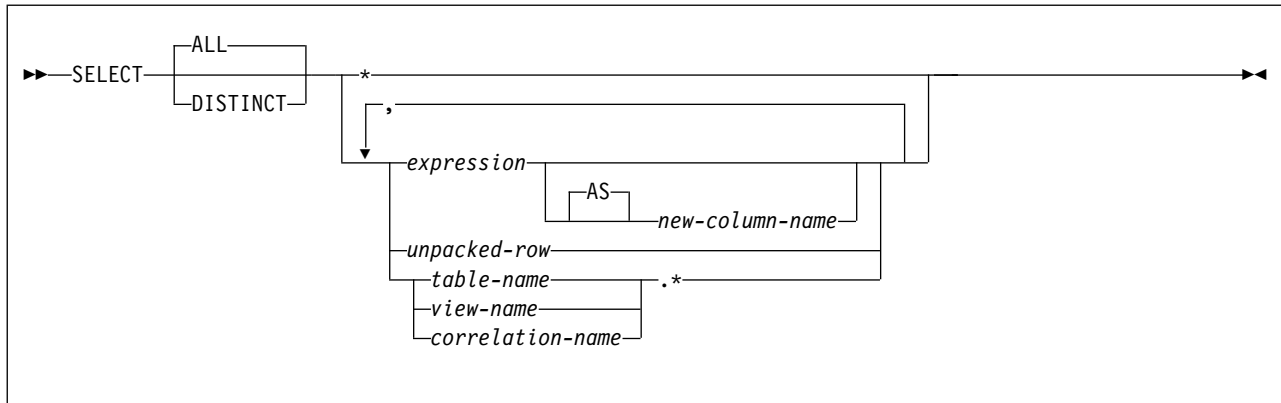

The clauses of the subselect are processed in the following sequence:

1. FROM clause
2. WHERE clause
3. GROUP BY clause
4. HAVING clause
5. SELECT clause
6. ORDER BY clause
7. FETCH FIRST clause

select-clause

The SELECT clause specifies the columns of the final result table. The column values are produced by the application of the *select list* to R. The select list is a list of names and expressions specified in the SELECT clause, and R is the result of the previous operation of the subselect. For example, if SELECT, FROM, and WHERE are the only clauses specified, then R is the result of that WHERE clause.

select-clause

ALL

Retains all rows of the final result table and does not eliminate redundant duplicates. This is the default.

DISTINCT

Eliminates all but one of each set of duplicate rows of the final result table.

Two rows are duplicates of one another only if each value in the first row is equal to the corresponding value in the second row. For determining duplicate rows, two null values are considered equal.

When SELECT DISTINCT is specified, no column or expression in the implicit or explicit list can return a value that is a LOB or XML data type. When a column or expression in the list returns a value that is a DECFLOAT data type and multiple bit representations of the same number exists in the intermediate result, the value that is returned is unpredictable. See "Numeric comparisons" on page 133 for additional information.

Column access controls do not affect the operation of SELECT DISTINCT. The elimination of duplicated rows is based on the original column values, not the masked values. However, after the application of column masks, the masked values in the final result table might not reflect the uniqueness that is enforced by SELECT DISTINCT.

If a column mask is applied to a column that directly or indirectly derives the result of SELECT DISTINCT, SELECT DISTINCT can return a result that is not deterministic. The following conditions are a few examples of when a result that is not deterministic might be returned:

- The definition of the column mask references other columns of the table to which the column mask is applied.
- The column is referenced in the argument of a built-in scalar function, such as COALESCE, IFNULL, NULLIF, MAX, MIN, LOCATE, TOTALORDER, etc.
- The column is referenced in the argument of an aggregation function.

- The column is embedded in an expression and the expression contains a function that is not deterministic or has an external action.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.

Select list notation:

- * Represents a list of columns of table R, excluding any columns that are defined as implicitly hidden. The list of names is established when the statement containing the SELECT clause is prepared. Therefore, * does not identify any columns that have been added to a table after the statement has been prepared.

A column that is defined as implicitly hidden can be explicitly referenced in the select list.

* cannot be used in the definition of a row permission or a column mask.

expression

Specifies the values of a result column. Each *column-name* in the expression must unambiguously identify a column of the intermediate result table.

AS *new-column-name*

Names or renames the result column. The name must not be qualified and does not have to be unique. *new-column-name* is an SQL identifier of 128 UTF-8 bytes or less.

name.*

Represents a list of columns of *name*, excluding any columns that are defined as implicitly hidden, in the order the columns are produced by the FROM clause. *name* can be a table name, view name, or correlation name, and must designate an exposed table, view, or correlation name in the FROM clause that immediately follows the SELECT clause. The first name in the list identifies the first column of the table or view, the second name in the list identifies the second column of the table or view, and so on.

The list of names is established when the statement that contains the SELECT clause is prepared. Therefore, * does not identify any columns that have been added to a table after the statement has been prepared.

*name.** cannot be used in the definition of a row permission or a column mask.

SQL statements can be implicitly or explicitly prepared again. The effect of another prepare on statements that include * or *name.** is that the list of names is re-established. Therefore, the number of columns returned by the statement might change.

The number of columns in the result of SELECT is the same as the number of expressions in the operational form of the select list (that is, the list established at the time the statement is prepared), and cannot exceed 750. The result of a subquery must be a single column unless the subquery is used in an EXISTS predicate.

Notes:

If the FROM clause contains a MERGE statement:

The SELECT list must not implicitly or explicitly refer to a column that has a LOB data type, a ROWID data type (or a distinct type that is based on a LOB, or ROWID), or an XML data type.

Implicitly hidden ROWID columns in the select list:

The result for `SELECT *` does not include any implicitly hidden ROWID columns. To be included in the result, implicitly hidden ROWID columns must be explicitly specified in the select list.

VARBINARY data:

If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To query the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

Applying the select list:

Some of the results of applying the select list to R depend on whether GROUP BY or HAVING is used. The following three lists describe the results.

IF neither GROUP BY nor HAVING is used:

- The select list can include aggregate functions only if it includes other aggregate functions, constants, or expressions that only involve constants.
- If the select list does not include aggregate functions, it is applied to each row of R and the result contains as many rows as there are rows in R.
- If the select list includes aggregate functions, R is the source of the arguments of the functions and the result of applying the select list is one row, even when R has no rows.
- If a column mask is used to mask the values in the final result table, and the select list includes aggregate functions, the definition of the column mask must not reference the following:
 - A scalar fullselect
 - An aggregate function

If HAVING is used and GROUP BY is not used:

Each expression or *column-name* in an expression in the select list must be specified within an aggregate function. Constants or expressions that involve only constants can also be in the select list.

If a column mask is used to mask the values in the final result table, the definition of the column mask must not reference the following:

- A scalar fullselect
- An aggregate function

If GROUP BY is used:

- Each expression in the select list must use one or more grouping expressions. Or, each expression or *column-name* in an expression must:
 - Unambiguously identify a grouping column of R.
 - Be specified within an aggregate function.
 - Be a correlated reference. (A *column-name* is a correlated reference if it identifies a column of a table or view identified in an outer subselect.)
- If an expression in the select list is a scalar fullselect, a correlated reference from the scalar fullselect to a group R must either identify a grouping column or be contained within an aggregate

function. For example, the following query fails because the correlated reference T1.C1 || T1.C2 in the select list of the scalar fullselect does not match a grouping column from the outer subselect. (Matching the grouping expression T1.C1 || T1.C2 is not supported.)

```
SELECT MAX(T1.C2) AS X1,  
       (SELECT T1.C1 || T1.C2 FROM T2 GROUP BY T2.C1) AS Y1  
FROM T1  
GROUP BY T1.C1, T1.C1 || T1.C2;
```

- You cannot use GROUP BY with a name defined using the AS clause unless the name is defined in a nested table expression. Example 6 demonstrates the valid use of AS and GROUP BY in a SELECT statement.

In either case, the *n*th column of the result contains the values specified by applying the *n*th expression in the operational form of the select list.

If a column mask is used to mask the column values in the final result table, a column for which the column mask is applied must satisfy one of the following conditions:

- The column must be specified in an aggregate function and the definition of the column mask must not reference the following:
 - A scalar fullselect
 - An aggregate function
- The column must identify a *column-name* in the GROUP BY clause and the column must not be referenced in an *expression* in the GROUP BY clause. In addition, any columns of the same table as the column for which the column mask is applied and are referenced in the definition of the column mask must be identified with a *column-name* in the GROUP BY clause. These columns must not be referenced in an *expression* in the GROUP BY clause.
- A column of a non-base tables in the select list must be specified in an aggregate function if a column mask is used to mask the column values in the final result table, and the column of a non-base table maps directly or indirectly to a column name or to an expression in a materialized table expression or view to the table where the column mask is applied.

Effect of column masks on result columns:

When column masks are enabled, they determine the values in the final result table of an outermost select list. When a column mask is enabled for a column, if the column appears in the outermost select list (either implicitly or explicitly), the column mask is applied to the column to produce the values for the final result table. If the column itself does not appear in the outermost select list, but is included in the output (for example, it appears in a materialized table expression or a view), the masked value is included in the result table of the table expression or view so that it can be used in the final result table.

The enabled column masks do not interfere with the operations of other clauses within the statement, such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY clauses.

The rows that are returned in the final result table remain the same, except that the values in the result rows might be masked. As such, if a column

with masked values also appears in an ORDER BY clause with a *sort-key* expression, the order is based on the original column values (the masked values in the final result table might not reflect that order). Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression might be different because the column mask is applied to the column before the expression is evaluated. For example, a column mask on column SSN can change the result of the function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values. However, if the expression in the query is the same as the expression that is used to mask the column value in the definition of the column mask, the result of the expression might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression is used in the column mask definition. In this particular example, the expression in the query can be replaced with column SSN to avoid the same expression being evaluated twice.

If a CASE expression appears in the outermost select list, column masks are not applied to the *search-condition* of the WHEN clause.

When the definition of a column mask is applied to an SQL statement to mask column values in the final result table, the semantics of the column mask might conflict with certain SQL semantics in the statement. In these situations, the combination of the statement and the column mask might return an error.

See “ALTER TABLE” on page 1304 for more information about the application of enabled column masks.

Null attributes of result columns:

Result columns allow null values if they are derived from one of the following:

- Any aggregate function except COUNT or COUNT_BIG
- A column that allows null values
- A view column in an outer select list that is derived from an arithmetic expression
- An arithmetic expression in an outer select list
- An arithmetic expression that allows nulls
- A scalar function or string expression that allows null values
- A host variable that has an indicator variable, or in the case of Java, a host variable or expression whose type is able to represent a Java null value
- A result of a set operator if at least one of the corresponding items in the select list is nullable

Names of result columns:

In the following cases a result column is considered a named column:

- If the AS clause is specified, the name of the result column is the name specified on the AS clause.
- If the AS clause is not specified and a column list is specified in the correlation clause, the name of the result column is the corresponding name in the correlation column list.
- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single column (without any functions or operators), the result column name is the unqualified name of that column.

- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single SQL variable or SQL parameter (without any functions or operators), the result column name is the unqualified name of that SQL variable or SQL parameter.

In all other cases, a result column is an unnamed column.

Names of result columns are placed into the SQL descriptor area (SQLDA) when the DESCRIBE statement is executed. This allows an interactive SQL processor such as SPUFI, the command line processor, or DB2 QMF to use the column names when displaying the results. The names in the SQLDA include those specified by the AS clause.

Data types of result columns:

Each column of the result of SELECT acquires a data type from the expression from which it is derived. The following table shows the data types of result columns.

Table 141. Data types of result columns

| When the expression is... | The data type of the result column is... |
|--|--|
| The name of any numeric column | The same as the data type of the column, with the same precision and scale for decimal columns. |
| An integer constant | INTEGER. |
| A decimal or floating-point constant | The same as the data type of the constant, with the same precision and scale for decimal constants. For floating-point constants, the data type is DOUBLE PRECISION. |
| A decimal floating point constant | DECFLOAT(34) |
| The name of any numeric host variable | The same as the data type of the variable, with the same precision and scale for decimal variables. The result is decimal if the data type of the host variable is not an SQL data type; for example, DISPLAY SIGN LEADING SEPARATE in COBOL. |
| An arithmetic or string expression | The same as the data type of the result, with the same precision and scale for decimal results as described in "Expressions" on page 228. |
| Any function | The data type of the result of the function. For a built-in function, see Chapter 4, "Built-in functions," on page 321 to determine the data type of the result. For a user-defined function, the data type of the result is what was defined in the CREATE FUNCTION statement for the function. |
| The name of any string column | The same as the data type of the column, with the same length attribute. |
| The name of any string host variable | The same as the data type of the variable, with a length attribute equal to the length of the variable. The result is a varying-length character string if the data type of the host variable is not an SQL data type; for example, a NUL-terminated string in C. |
| A character string constant of length <i>n</i> | VARCHAR(<i>n</i>). |
| A binary string constant of length <i>n</i> | VARBINARY(<i>n</i>) |
| A graphic string constant of length <i>n</i> | VARGRAPHIC(<i>n</i>). |
| The name of a datetime column | The same as the data type of the column. |
| The name of a ROWID column | Row ID. |
| The name of a distinct type column | The same as the distinct type of the column, with the same length, precision, and scale attributes, if any. |

For information about the CCSID of the result column, see “Rules for result data types” on page 143.

“Examples of subselects” on page 1117

unpacked-row

An *unpacked-row* specifies a row that is the result of an invocation of the UNPACK built-in function.

unpacked-row:

UNPACK-function-invocation

Specifies an invocation of the UNPACK built-in function. The number of specified *field-names* and *field-types* must be the same as the number of fields that are returned by the UNPACK function invocation.

field-name

Names the field that is returned from the UNPACK function. A name must not be qualified, and it does not have to be unique.

data-type

Specifies the built-in data type of the field. The specified data type, length, and CCSID must correspond to the data type, length, and CCSID of the data when the argument was initially encoded with the PACK function.

The following table provides the supported data type mappings from the packed string data:

Table 142. Data type mappings from packed string data

| Data type of an encoded value in the packed string for UNPACK | Data type specified for UNPACK |
|---|---|
| SMALLINT | SMALLINT, INTEGER, BIGINT |
| INTEGER | INTEGER, BIGINT |
| BIGINT | BIGINT |
| decimal (<i>p,s</i>) ¹ | decimal(<i>p'</i> , <i>s'</i>) if <i>s' < s</i> , <i>s-s'</i> digits are truncated. An error occurs if there are more than <i>p'-s'</i> significant digits. |
| real ² or double ³ | double |
| CHAR(<i>n</i>) or VARCHAR(<i>n</i>) | CHAR(<i>m</i>), VARCHAR(<i>m</i>) If <i>m < n</i> and any of the <i>n-m</i> characters is not a blank, an error occurs. Otherwise, the <i>n-m</i> blanks are truncated. If <i>m > n</i> and the specified data type is CHAR, <i>m-n</i> blanks are appended. |
| BINARY(<i>n</i>) or VARBINARY(<i>n</i>) | BINARY(<i>m</i>), VARBINARY(<i>m</i>) If <i>m < n</i> , an error occurs. If <i>m > n</i> and the UNPACK target is BINARY, <i>m-n</i> X'00' bytes are appended. |

Table 142. Data type mappings from packed string data (continued)

| Data type of an encoded value in the packed string for UNPACK | Data type specified for UNPACK |
|---|---|
| DATE | DATE |
| TIME | TIME |
| TIMESTAMP(<i>p</i>) WITHOUT TIME ZONE | TIMESTAMP(<i>p'</i>) WITHOUT TIME ZONE. If $p' > p$, $p'-p$ zeros are appended. If $p' < p$, $p-p'$ digits are truncated. |
| TIMESTAMP(<i>p</i>) WITH TIME ZONE | TIMESTAMP(<i>p'</i>) WITH TIME ZONE. If $p' > p$, $p'-p$ zeros are appended. If $p' < p$, $p-p'$ digits are truncated. |
| <p>Note: The data types in lower case are defined as follows:</p> <ol style="list-style-type: none"> decimal = DECIMAL(<i>p,s</i>) or NUMERIC(<i>p,s</i>) real = REAL or FLOAT(<i>n</i>) where <i>n</i> is the specification for a single precision floating point double = DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(<i>n</i>) where <i>n</i> is the specification for a double precision floating point <p>The synonyms for the data types, in either long or short form, are considered the same as those that are listed.</p> | |

“select-clause” on page 1083

“PACK” on page 533

“UNPACK” on page 730

from-clause

The FROM clause specifies an intermediate result table.

from-clause

If only one *table-reference* is specified, the intermediate result table is simply the result of that *table-reference*. If more than one *table-reference* is specified, the intermediate result table consists of all possible combinations of the rows of the result of each specified *table-reference*.

Each row of the result is a row from the result of the first *table-reference* concatenated with a row from the result of the second *table-reference*, concatenated with a row from the result of the third *table-reference*, and so on. The number of rows in the result is the product of the number of rows in the result of each *table-reference*. Thus, if the result of any *table-reference* is empty, the result is empty.

If *table-reference* has row access controls enforced, *table-reference* has at least one row permission: the default row permission. When there are multiple row permissions defined for a *table-reference*, a row access control search condition is derived by applying the logical OR operator to the search condition in each enabled permission. This derived search condition acts as a filter to the *table-reference* to determine the result table of the *table-reference* that is accessible to the authorization ID or role of the subselect.

If a *table-reference* contains a security label column, DB2 compares the security label of the user to the security label of each row. Results are returned according to the following rules:

- If the security label of the user dominates the security label of the row, DB2 returns the row.
- If the security label of the user does not dominate the security label of the row, DB2 does not return the data from that row, and DB2 does not generate an error report.

Related reference:

“Examples of subselects” on page 1117

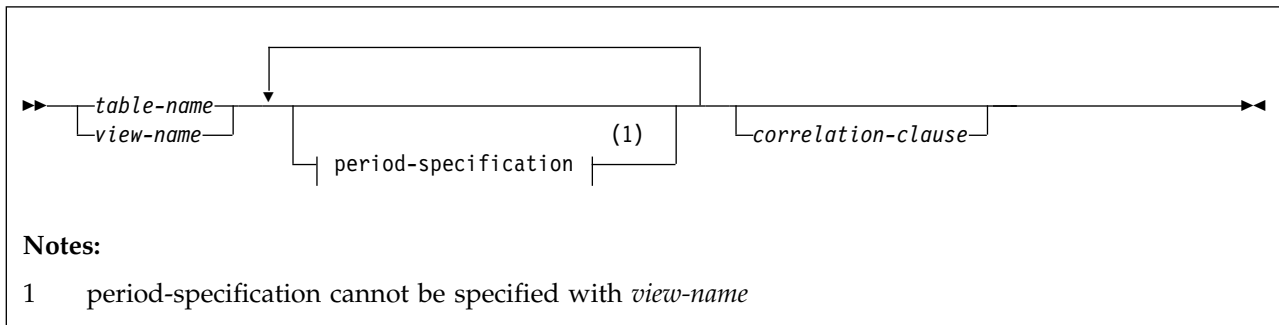

table-reference

A *table-reference* specifies a result table as either a table or view, or an intermediate table.

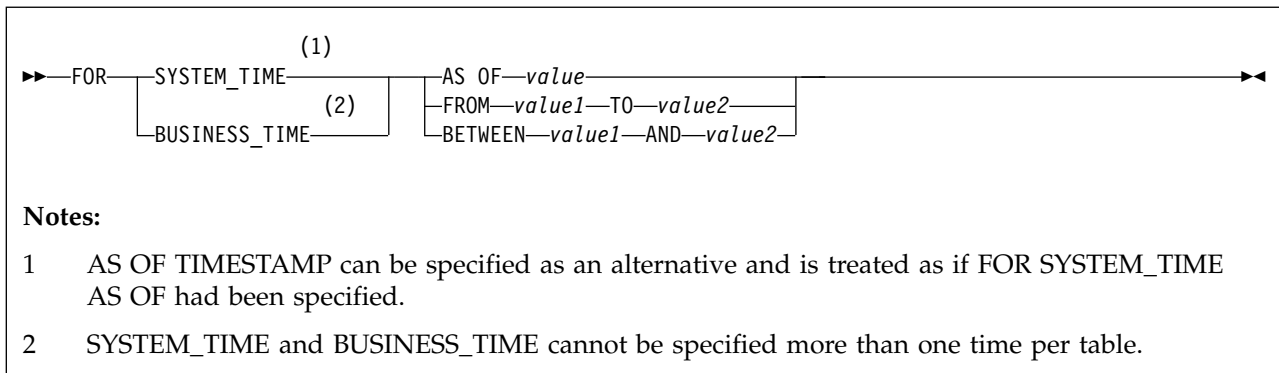

table-reference:

single-table-reference:

| period-specification:

nested-table-expression:

data-change-table-reference:

table-function-reference:

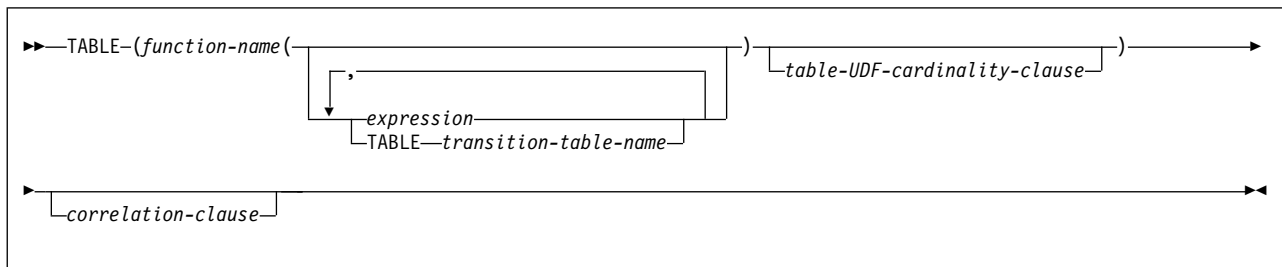

table-UDF-cardinality-clause:

table-locator-reference:

xmltable-expression:

A *table-reference* specifies an intermediate result table.

- If a *single-table-reference* is specified, the intermediate result table is simply that table. If a *period-specification* is specified, the intermediate result table consists of the rows of the temporal table where the period matches the specification.
- If a *nested-table-expression* is specified, the result table is the result of the specified fullselect. The columns of the result do not need unique names, but a column with a non-unique name cannot be explicitly referenced.
- If a *data-change-table-reference* is specified, the intermediate result table is the set of rows that are directly affected by the data change statement.
- If a *table-function-reference* is specified, the intermediate result table is the set of rows that are returned by the table function.

- If a *table-locator-reference* is specified, the host variable represents the intermediate result table. The intermediate result table has the same structure as the table identified in *table-name*.
- If an *xmltable-expression* is specified, the intermediate result table is the set of rows that are returned by the “XMLTABLE” on page 725 function.
- If a *joined-table* is specified, the intermediate result table is the result of one or more join operations. For more information, see “joined-table” on page 1102.

Each *table-name* or *view-name* specified in every **FROM** clause of the same SQL statement must identify a table or view that exists at the same DB2 subsystem. If a **FROM** clause is specified in a subquery of a basic predicate, a view that includes **GROUP BY** or **HAVING** must not be identified.

A *table-reference* must not identify a table that was implicitly created for an XML column.

table-locator-variable

table-locator-variable must specify a variable with a table locator type. The only way to assign a value to a table locator is to pass the old or new transition table of a trigger to a user-defined function or stored procedure. A table locator host variable must not have a null indicator. A table locator variable must not be a parameter marker. In addition, a table locator can be used only in a manipulative SQL statement.

nested-table-expression

A *fullselect* in parentheses is called a *nested table expression*. If a nested table expression is specified, the result table is the result of that *nested-table-expression*. The columns of the result do not need unique names, but a column with a non-unique name cannot be referenced. At any time, the table consists of the rows that would result if the fullselect were executed.

table-function-reference

If a *function-name* is specified, the result table is the set of rows returned by the table function.

expression must not contain a scalar fullselect, a function, or a reference to a column.

Each *function-name*, together with the types of its arguments, must resolve to a table function that exists at the same DB2 subsystem. An algorithm called function resolution, which is described in “Function resolution” on page 221, uses the function name and the arguments to determine the exact function to use. Unless given column names in the *correlation-clause*, the column names for a table function are those specified on the RETURNS clause of the CREATE FUNCTION statement. This is analogous to the column names of a table, which are defined in the CREATE TABLE statement.

If a column mask is used to mask the column values in the final result table, and if the result of the table function is used to derive the final result table, the column mask cannot be applied to a column that is specified in the argument of the table function.

table-UDF-cardinality-clause

The *table-UDF-cardinality-clause* can be specified to each user-defined table function reference within the table spec of the FROM clause in a subselect. This option indicates the expected number of rows to be returned only for the SELECT statement that contains it.

CARDINALITY *integer-constant* specifies an estimate of the expected number of rows returned by the reference to the user-defined function. The value of *integer-constant* must range from 0 to 2147483647.

The value set in the **CARDINALITY** field of SYSIBM.SYSROUTINES for the table function name is used as the reference cardinality value. The product of the specified **CARDINALITY MULTIPLIER** *numeric-constant* and the reference cardinality value are used by DB2 as the expected number of rows returned by the table function reference.

In this case, the *numeric-constant* can be in the integer, decimal, or floating-point format. The value must be greater than or equal to zero. If the decimal number notation is used, the number of digits can be up to 31. An integer value is treated as a decimal number with no fraction. The maximum value allowed for a floating-point number is about $7.237E + 75$. If no value has been set in the **CARDINALITY** field of SYSIBM.SYSROUTINES, its default value is used as the reference cardinality value. If zero is specified or the computed cardinality is less than 1, DB2 assumes that the cardinality of the reference to the user-defined table function is 1.

Only a numeric constant can follow the keyword **CARDINALITY** or **CARDINALITY MULTIPLIER**. No host variable or parameter marker is allowed in a cardinality option. Specifying a cardinality option in a table function reference does not change the corresponding **CARDINALITY** field in SYSIBM.SYSROUTINES. The **CARDINALITY** field value in SYSIBM.SYSROUTINES can be initialized by the **CARDINALITY** option in the CREATE FUNCTION (external table) statement when a user-defined table function is created. It can be changed by the **CARDINALITY** option in the ALTER FUNCTION statement or by a direct update operation to SYSIBM.SYSROUTINES.

data-change-table-reference

A *data-change-table-reference* clause specifies an intermediate result table. This table is based on the rows that are directly changed by the SQL data change statement that is included in the clause. A *data-change-table-reference* can only be specified as the only *table-reference* in the FROM clause of the outer fullselect that is used in a select-statement and that fullselect must be in a subselect, or a SELECT INTO statement. A *data-change-table-reference* in a SELECT statement of a cursor makes the cursor read only. The target table or view of the SQL data change statement is a table or view that is reference in the query. The privileges that are held by the authorization ID of the statement must include the SELECT privilege on that target table or view. The encoding scheme of the result table of the SELECT must be the same as the encoding scheme of the target table or view of the *data-change-table-reference*.

If row access control is enforced for the target of the data change statement, the rows in the intermediate result table already satisfy the rules that are specified in the enabled row permissions. If column access control is enforced for the target of the data change statement, the enabled column masks are applied to the outermost select list. See “*select-clause*” on page 1083 for more information. If an INCLUDE clause is specified as part of the SQL data change statement, and these additional columns appear in the outermost select list, the column values must not be derived from columns for which column masks are defined.

Expressions in the select list of a view in a table reference can only be selected if OLD TABLE is specified or if the expression does not include any of the following objects:

- a function that is defined to read or modify SQL data
- a function that is defined as not deterministic or has an external action
- a NEXT VALUE expression for a sequence

FINAL TABLE

Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement as they appear at the completion of the SQL data change statement. If there are AFTER triggers that result in further operations on the table that is the target of the SQL data change statement, an error is returned. If the target of the SQL data change statement is a view that is defined with an INSTEAD OF trigger for the type of data change, an error is returned.

OLD TABLE

The rows of the intermediate result table represent the set of affected rows as they exist prior to the application of the SQL data change statement.

INSERT statement

Specifies an INSERT statement as described in “INSERT” on page 2038. A fullselect in the INSERT statement cannot contain correlated references to columns that are outside of the fullselect of the INSERT statement. The target of the INSERT statement must be a base table, a view that is defined with the **WITH CASCADED CHECK** clause, or a view where the view definition has no **WHERE** clause. If there are input variables elsewhere in the fullselect, the INSERT statement cannot be a multiple row not atomic insert, or a multiple row atomic insert that specifies the **USING DESCRIPTOR** clause.

MERGE statement

Specifies a MERGE statement as described in “MERGE” on page 2063. The MERGE statement must conform to the following rules:

- A table reference must not contain correlated references to columns that are outside of the table reference in the MERGE statement.
- A referenced view must be defined using the WITH CASCADED CHECK OPTION clause.
- The target table or view of the MERGE statement must not have a column with a ROWID, LOB, or XML data type.
- AFTER triggers that result in further operations on the target table cannot exist on the target table.

searched UPDATE statement

Specifies a searched UPDATE statement as described in “UPDATE” on page 2224. A WHERE clause or a SET clause in the UPDATE statement cannot contain correlated referenced to columns that are outside of the UPDATE statement. The target of the UPDATE statement must be a base table, a symmetric view, or a view where the view definition has no WHERE clause.

If the searched UPDATE statement is used in the SELECT statement and the UPDATE statement references a view, the view must be defined using the WITH CASCADED CHECK OPTION clause.

A searched UPDATE statement in a SELECT statement will not clear the AREO* status of a table.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

searched DELETE statement

Specifies a searched DELETE statement as described in “DELETE” on page 1883. A WHERE clause in the DELETE statement cannot contain correlated references to columns that are outside of the DELETE statement. The target of the DELETE statement must be a base table, a symmetric view, or a view where the view definition has no WHERE clause.

If the searched DELETE statement is used in the SELECT statement and the DELETE statement references a view, the view must be defined using the WITH CASCADED CHECK OPTION clause.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

The content of the intermediate result table for a table reference that contains an SQL data change statement is determined when the cursor is opened. The intermediate result table includes a column for each of the columns of the target table (including implicitly hidden columns) or view. All of the columns of the target table or view of an SQL data change statement are accessible by using the names of the columns from the target table or view unless the columns are renamed by using the correlation clause. If an INCLUDE clause is specified as part of the SQL data change statement, the intermediate result table will contain these additional columns.

correlation-clause

Each *correlation-name* in a *correlation-clause* defines a designator for the immediately preceding result table, which can be used to qualify references to the columns of the table. See “correlation-clause” on page 1101 for more information.

The exposed names of all table references in the FROM clause should be unique. An *exposed name* is considered to be any of the following names:

- A *correlation-name*
- A *table-name* that is not followed by a *correlation-name*
- A *view-name* that is not followed by a *correlation-name*
- A *function-name* that is not followed by a *correlation-name*
- The table name that is specified after LIKE when a *table-locator* is not followed by a *correlation-name*
- The target table or view name for a *data-change-table-reference* that is not followed by a *correlation-name*
- An *alias-name* that is not followed by a *correlation-name*
- A *synonym-name* that is not followed by a *correlation-name*

Any qualified reference to a column must use the exposed name. If the same name is specified twice, at least one specification should be followed by a *correlation-name*. The *correlation-name* is used to qualify references to the columns of the table or view. When a *correlation-name* is specified, column names can also be specified to give names to the columns of the table reference. If the *correlation-clause* does not include column names, the exposed column names are determined as follows:

- Column names of the referenced table or view when the *table-reference* is *table-name*, *view-name*, *alias-name*, or *synonym-name*
- Column names specified in the RETURNS clause of the CREATE FUNCTION statement when the *table-reference* is a *function-name* reference
- Column names of the table referenced after LIKE when the *table-reference* is a *table-locator*

- Column names from the target table of the data change statement, along with any defined INCLUDE columns, when the *table-reference* is a *data-change-table-reference*

Otherwise, there are no exposed names for the columns of that table reference.

xmltable-expression

Specifies an invocation of the built-in XMLTABLE function. See “XMLTABLE” on page 725 for more information.

If a column mask is used to mask the column values in the final result table, and if the result of the XMLTABLE function is used to derive the final result table, the column mask cannot be applied to a column that is specified in the PASSING clause of the XMLTABLE function.

joined-table

If a *joined-table* is specified, the result table is the result of one or more join operations as explained in “joined-table” on page 1102.

period-specification

Specifies that a period specification applies to the *table-reference*. The same period name (SYSTEM_TIME or BUSINESS_TIME) must not be specified more than one time for the same table. The *table-reference* must not be a view.

The rows of the table reference are derived by application of the specified period specification.

If the table is a system-period temporal table and a *period-specification* for the SYSTEM_TIME period is not specified, the table reference includes all current rows of the table and does not include any historical rows of the table.

If the table is an application-period temporal table and a *period-specification* for the BUSINESS_TIME period is not specified, the table reference includes all rows of the table.

If the table is a bitemporal table and a *period-specification* is not specified for either SYSTEM_TIME or BUSINESS_TIME, the table reference includes all current rows of the table and does not include any historical rows of the table.

FOR SYSTEM_TIME

Specifies that the SYSTEM_TIME period is used for the *period-specification*. The table must be a system-period temporal table.

FOR BUSINESS_TIME

Specifies that the BUSINESS_TIME period is used for the *period-specification*. The table must be an application-period temporal table.

AS OF *value*

Specifies that the *table-reference* includes each row for which the begin value for the specified period is less than or equal to *value* and the end value for the period is greater than *value*.

value

Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to the data type of the columns of the specified period according to the comparison rules specified in “Assignment and comparison” on page 119.

The expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as TIMESTAMP WITHOUT TIME ZONE, the expression must not return

a value of a timestamp with a time zone. The expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

FROM *value1* TO *value2*

Specifies that the *table-reference* includes rows that exist for the period that is specified from *value1* up to *value2*.

A row is included in *table-reference* if the start value for the period in the row is less than *value2* and the end value for the period in the row is greater than *value1*. The *table-reference* contains zero rows if *value1* is greater than or equal to *value2*. If *value1* or *value2* is the null value, the *table-reference* is an empty table.

value1* OR *value2

Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to the data type of the columns of the specified period according to the comparison rules specified in “Assignment and comparison” on page 119.

The expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as `TIMESTAMP WITHOUT TIME ZONE`, the expression must not return a value of a timestamp with a time zone. The expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

BETWEEN *value1* AND *value2*

Specifies that the *table-reference* includes rows in which the specified period overlaps at any point in time between *value1* and *value2*.

A row is included in the *table-reference* if the start value for the period in the row is less than or equal to *value2* and the end value for the period in the row is greater than *value1*. The table reference contains zero rows if *value1* is greater than *value2*. If *value1* = *value2*, the expression is equivalent to `AS OF value1`. If *value1* or *value2* is the null value, the table reference is an empty table.

value1* OR *value2

Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to the data type of the columns of the specified period according to the comparison rules specified in “Assignment and comparison” on page 119.

The expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as `TIMESTAMP WITHOUT TIME ZONE`, the expression must not return a value of a timestamp with a time zone. The expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- A built-in scalar function whose arguments are supported operands
- A `CAST` specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

Notes

Correlated references in *table-reference*:

In general, nested table expressions and table functions can be specified in any `FROM` clause. Columns from the nested table expressions and table functions can be referenced in the select list and in the rest of the fullselect using the correlation name. The scope of this correlation name is the same as correlation names for other table or view names in the `FROM` clause. The basic rule that applies for both these cases is that the correlated reference must be from a *table-reference* at a higher level in the hierarchy of subqueries.

Nested table expressions can be used in place of a view to avoid creating a view when general use of the view is not required. They can also be used when the result table is based on host variables.

For table functions, an additional capability exists. A table function can contain one or more correlated references to other tables in the same `FROM` clause if the referenced tables precede the reference in the left-to-right order of the tables in the `FROM` clause. The same capability exists for nested table expressions if the optional keyword `TABLE` is specified; otherwise, only references to higher levels in the hierarchy of subqueries is allowed.

A nested table expression or table function that contains correlated references to other tables in the same `FROM` clause:

- Cannot participate in a `FULL OUTER JOIN` or a `RIGHT OUTER JOIN`
- Can participate in `LEFT OUTER JOIN` or an `INNER JOIN` if the referenced tables precede the reference in the left-to-right order of the tables in the `FROM` clause

The following table shows some examples of valid and invalid correlated references. `TABF1` and `TABF2` represent table functions.

Table 143. Examples of correlated references

| Subselect | Valid | Reason |
|--|-------|--|
| SELECT T.C1, Z.C5 FROM TABLE(TABF1(T.C2)) AS Z, T WHERE T.C3 = Z.C4; | No | T.C2 cannot be resolved because T does not precede TABF1 in FROM |
| SELECT T.C1, Z.C5 FROM T, TABLE(TABF1(T.C2)) AS Z WHERE T.C3 = Z.C4; | Yes | T precedes TABF1 in FROM, making T.C2 known |

Table 143. Examples of correlated references (continued)

| Subselect | Valid | Reason |
|--|-------|--|
| <pre>SELECT A.C1, B.C5 FROM TABLE(TABF2(B.C2)) AS A, TABLE(TABF1(A.C6)) AS B WHERE A.C3 = B.C4;</pre> | No | B in B.C2 cannot be resolved because the table function that would resolve it, TABF1, follows its reference in TABF2 in FROM |
| <pre>SELECT D.DEPTNO, D.DEPTNAME, EMPINFO.AVGSAL, EMPINFO.EMPCOUNT FROM DEPT D, (SELECT AVG(E.SALARY) AS AVGSAL, COUNT(*) AS EMPCOUNT FROM EMP E WHERE E.WORKDEPT = D.DEPTNO) AS EMPINFO;</pre> | No | DEPT precedes nested table expression, but keyword TABLE is not specified, making D.DEPTNO unknown |
| <pre>SELECT D.DEPTNO, D.DEPTNAME, EMPINFO.AVGSAL, EMPINFO.EMPCOUNT FROM DEPT D, TABLE (SELECT AVG(E.SALARY) AS AVGSAL, COUNT(*) AS EMPCOUNT FROM EMP E WHERE E.WORKDEPT = D.DEPTNO) AS EMPINFO;</pre> | Yes | DEPT precedes nested table expression and keyword TABLE is specified, making D.DEPTNO known |

“Examples of subselects” on page 1117

correlation-clause:

Each *correlation-name* in a *correlation-clause* defines a designator for the immediately preceding result table, which can be used to qualify references to the columns of the table.

correlation-clause:

The preceding result table is one of the following objects:

- A table
- A view
- A nested table expression
- A table function
- A data-change table reference

new-column-name is an SQL identifier of 128 UTF-8 bytes or less. Using *new-column-name* to list and rename the columns is optional. A correlation name must be specified for nested table expressions and references to table functions.

If *correlation-name* is not specified for a data-change table reference, the correlation name is the name of the target table or view of the SQL data change statement. Otherwise, the correlation name is *correlation-name*.

If a *new-column-name* list is specified in *correlation-clause*, the number of names must be the same as the number of columns in the corresponding object. Each name must be unique and unqualified. If columns are added to an underlying table of a *table-reference*, the number of columns in the result of the *table-reference* no longer matches the number of names in its *correlation-clause*. Therefore, when a rebind of a package containing the query in question is attempted, DB2 returns an error and the rebind fails. At that point, change the *correlation-clause* of the embedded SQL statement in the application program so that the number of names matches the number of columns. Then prepare the modified program again.

An exposed name is a *correlation-name* or a *table-name* or view name that is not followed by a *correlation-name*. The exposed names in a FROM clause must be unique. Any qualified reference to a column for a table, view, nested table expression, table function, or data-change-table-reference must use the exposed name.

If the same table name or view name is specified twice, at least one specification must be followed by a *correlation-name*. The *correlation-name* is used to qualify references to the columns of the table or view.

When a *correlation-name* is specified, column names can also be specified to give names to the columns of the *table-name*, *view-name*, *nested-table-expression*, *table-function*, or *data-change-table-reference*. If a column list is specified, there must be a name in the column list for each column in the table or view and for each result column in the *nested-table-expression*, *table-function*, or *data-change-table-reference*.

For more information, see “Correlation names” on page 202.

In general, *nested-table-expression*, *table-function*, or *data-change-table-reference* can be specified in any FROM clause. Columns from the *nested-table-expression*, *table-function*, or *data-change-table-reference* can be referenced in the SELECT list and in the rest of the subselect using a correlation name. The scope of this correlation name is the same as correlation names for other table or view names in the FROM clause.

joined-table

A *joined-table* specifies an intermediate result table that is the result of either an inner join, an outer join, or a cross join. The table is derived by applying one of the join operators: INNER, LEFT OUTER, RIGHT OUTER, FULL OUTER, or CROSS to its operands.

joined-table

Cross joins represent the cross product of the tables, where each row of the left table is combined with every row of the right table. Inner joins can be thought of as the cross product of the tables, keeping only the rows where the join condition is true. The result table might be missing rows from either or both of the joined tables. Outer joins include the rows produced by the inner join as well as the missing rows, depending on the type of outer join as follows:

Left outer join

Includes rows from the left table that were missing from the inner join.

Right outer join

Includes rows from the right table that were missing from the inner join.

Full outer join

Includes rows from both the left and right tables that were missing from the inner join.

If a join operator is not specified, INNER is the default. The order in which a LEFT OUTER JOIN or RIGHT OUTER JOIN is performed can affect the result.

A *joined-table* can be used in any context in which any form of the SELECT statement is used. Both a view and a cursor is read-only if its SELECT statement includes a *joined-table*.

If LEFT OUTER JOIN, RIGHT OUTER JOIN, or FULL OUTER JOIN is specified:

- A ROW CHANGE TIMESTAMP expression can only be referenced in a subselect of the outer join if the table designator identifies a base table that includes a row change timestamp column.
- The RID built-in function and the ROW CHANGE TOKEN expression must not be specified in the subselect that contains the FROM clause.

“Examples of subselects” on page 1117

join-condition:

join-condition specifies the conditions of a join that is used in a query.

join-condition

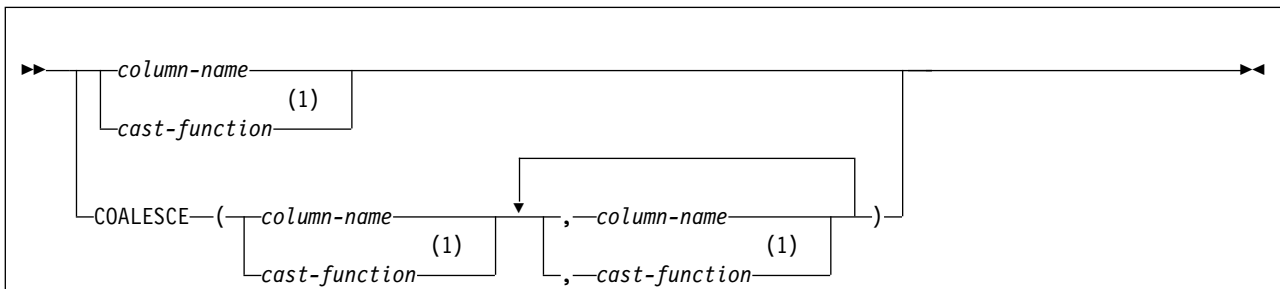

For INNER, LEFT OUTER, and RIGHT OUTER joins:

For FULL OUTER joins:

full-join-expression

Notes:

- 1 *cast-function* must only contain a column and the casting data type must be a distinct type or the data type upon which the distinct type was based.

For INNER, LEFT OUTER, and RIGHT OUTER joins, the *join-condition* is a *search-condition* that must conform to these rules:

- With one exception, It cannot contain any subqueries. If the *join-table* that contains the *join-condition* in the associated FROM clause is composed of only INNER joins, the *join-condition* can contain subqueries.
- Any column that is referenced in an expression of the *join-condition* must be a column of one of the operand tables of the associated join operator (in the scope of the same *joined-table* clause).

For a FULL OUTER (or FULL) join, the *join-condition* is a search condition in which the predicates can only be combined with AND. In addition, each predicate must have the form 'expression = expression', where one expression references only

columns of one of the operand tables of the associated join operator, and the other expression references only columns of the other operand table. The values of the expressions must be comparable. Implicit cast between numeric and string data types is not supported for FULL OUTER join.

Each *full-join-expression* in a FULL OUTER join must include a column name or a cast function that references a column. The COALESCE function is allowed.

For any type of join, column references in an expression of the *join-condition* are resolved using the rules for resolution of column name qualifiers specified in “Resolution of column name qualifiers and column names” on page 206 before any rules about which tables the columns must belong to are applied.

Related reference:

“Examples of subselects” on page 1117

Join operations:

A *join-condition* specifies pairings of T1 and T2, where T1 and T2 are the left and right operand tables of its associated JOIN operator. For all possible combinations of rows T1 and T2, a row of T1 is paired with a row of T2 if the *join-condition* is true.

When a row of T1 is joined with a row of T2, a row in the result consists of the values of that row of T1 concatenated with the values of that row of T2. The execution might involve the generation of a null row. The *null row* of a table consists of a null value for each column of the table, regardless of whether the columns allow null values.

The following summarizes the results of the join operations:

- The result of T1 INNER JOIN T2 consists of their paired rows.
- The result of T1 LEFT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2. All columns derived from T2 allow null values.
- The result of T1 RIGHT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T2, the concatenation of that row with the null row of T1. All columns derived from T1 allow null values.
- The result of T1 FULL OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2, and for each unpaired row of T2, the concatenation of that row with the null row in T1. All columns of the result table allow null values.
- The result of T1 CROSS JOIN T2 consists of each row of T1 paired with each row of T2. CROSS JOIN is also known as Cartesian product.

A join operation is part of a FROM clause. For the purpose of predicting which rows will be returned from a SELECT statement containing a join operation, assume that the join operation is performed before the other clauses in the statement.

A cross join can also be specified without the CROSS JOIN syntax, by listing the two tables in the FROM clause separated by commas without using a WHERE clause to supply join criteria.

“Examples of subselects” on page 1117

where-clause

The WHERE clause specifies a result table that consists of those rows of R for which the search condition is true. R is the result of the FROM clause of the subselect.

where-clause

►—WHERE—*search-condition*—►

The search condition must conform to the following rules:

- Each column name must unambiguously identify a column of R or be a correlated reference. A column name is a correlated reference if it identifies a column of a table, view, *common-table-expression*, or *nested-table-expression* that is identified in an outer subselect.
- An aggregate function must not be specified unless the WHERE clause is specified in a subquery of a HAVING clause and the argument of the function is a correlated reference to a group.

Any subquery in the *search-condition* is effectively executed for each row of R and the results are used in the application of the *search-condition* to the given row of R. A subquery is actually executed for each row of R only if it includes a correlated reference. In fact, a subquery with no correlated references is executed just one time, whereas a subquery with a correlated reference might have to be executed one time for each row.

If row access controls are enabled for a table and no other row permission is defined, the row access control search condition is the default row permission, 1 = 0. If only one row permission is defined, the row access control search condition is the search conditions that are specified by that permission. Otherwise, if multiple row permissions are defined for a table, the row access control search condition is derived by application of the logical OR operator to the search conditions that are specified by each row permission. This row access control search condition, as a whole, is connected by application of the logical AND operator to the search conditions specified by the WHERE clause and has the same precedence level as other search conditions in the WHERE clause. This process is repeated for each *table-reference* in the FROM clause of the subselect for which row access controls are enabled.

The row access control search condition acts as a filter to the *table-reference* to determine the results of the *table-reference* that are accessible to the authorization ID or role of the subselect. Because the order in which operators are evaluated is undefined for operators at the same precedence level, other search conditions in the WHERE clause might be evaluated before the row access control search condition. So, the other search conditions have access to the rows that are restricted by the row permission rules. To ensure that sensitive data is protected, the predicates that reference user-defined functions that are defined with the NOT SECURED option are always evaluated after the row access control search condition.

The column access control does not affect the operation of the WHERE clause.

“Examples of subselects” on page 1117

group-by-clause

The GROUP BY clause specifies a result table that consists of a grouping of the rows of intermediate result table that is the result of the previous clause.

group-by-clause

grouping-expression

A *grouping-expression* is an expression that defines the grouping of R. The following restrictions apply to *grouping-expression*:

- If *grouping-expression* is a single column, the column name must unambiguously identify a column of R.
- The result of *grouping-expression* cannot be a LOB data type (or a distinct type that is based on a LOB) or an XML data type.
- *grouping-expression* cannot include any of the following items:
 - A correlated column
 - A host variable
 - An aggregate function
 - Any function or expression that is not deterministic or that is defined to have an external action
 - A scalar fullselect
 - A CASE expression whose *searched-when-clause* contains a quantified predicate, an IN predicate using a fullselect, or an EXISTS predicate

The result of GROUP BY is a set of groups of rows. In each group of more than one row, all values of each *grouping-expression* are equal, and all rows with the same set of values of the *grouping-expression* are in the same group. For grouping, all null values for a *grouping-expression* are considered equal.

If a *grouping-expression* contains DECFLOAT values, the DECFLOAT values with the same value will be in the same group. But the number of digits returned for each group is unpredictable.

Because every row of a group contains the same value of any *grouping-expression*, a *grouping-expression* can be used in a search condition in a HAVING clause or an expression in a SELECT clause, or in a *sort-key-expression* of an ORDER BY clause. In each case, the reference specifies only one value for each group. For example, if *grouping-expression* is col1+col2, col1+col2+3 would be an allowed expression in the select list. Associative rules for expressions do not allow the similar expression of 3+col1+col2, unless parentheses are used to ensure that the corresponding expression is evaluated in the same order. Thus, 3+(col1+col2) would also be allowed in the select list. If the concatenation operator is used, *grouping-expression* must be used exactly as the expression was specified in the select list.

If a *grouping-expression* contains varying-length strings with trailing blanks, the values in the group can differ in the number of trailing blanks and might not all have the same length. In that case, a reference to *grouping-expression* still specifies

only one value for each group, but the value for a group is chosen arbitrarily from the available set of values. Thus, the actual length of the result value is unpredictable.

| Row access controls do not affect the operation of the GROUP BY clause.

| In certain contexts, the semantics of the column mask can conflict with those in the
| GROUP BY clause. When this occurs, the column mask cannot be applied for the
| statement and an error will be returned at bind time.

having-clause

The HAVING clause specifies a result table that consists of those groups of the intermediate result table for which the search-condition is true. The intermediate result table is the result of the previous clause. If this clause is not GROUP BY, the intermediate result table is considered a single group with no grouping columns of the previous clause of the subselect.

having-clause

▶▶—HAVING—*search-condition*————▶▶

Each *column-name* in *search-condition* must be one of the following:

- Unambiguously identify a grouping column of the intermediate result table
- Be specified within an aggregate function²²
- Be a correlated reference. A *column-name* is a correlated reference if it identifies a column of a table, view, *common-table-expression*, or *nested-table-expression* that is identified in an outer subselect

A group of the intermediate result table to which the search condition is applied supplies the argument for each function in the search condition, except for any function whose argument is a correlated reference.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a group of the intermediate result table, and the results used in applying the search condition. In actuality, the subquery is executed for each group only if it contains a correlated reference. For an illustration of the difference, see Example 4 and Example 5.

A correlated reference to a group of the intermediate result table must either identify a grouping column or be contained within an aggregate function.

When HAVING is used without GROUP BY, any expression or column name in the select list must appear within an aggregate function.

The RID built-in function and the ROW CHANGE expression cannot be specified in a HAVING clause unless they are within an aggregate function.

Row access controls do not affect the operation of the HAVING clause.

In certain contexts, the semantics of the column mask can conflict with those in the HAVING clause. When this occurs, the column mask cannot be applied for the statement and an error will be returned at bind time. See the select-clause for more information about how column access controls affect the HAVING clause.

“Examples of subselects” on page 1117

order-by-clause

The ORDER BY clause specifies an ordering of the rows of the result table.

order-by-clause

sort-key:

A subselect that contains an ORDER BY clause cannot be specified in the outermost fullselect of a view

If the subselect is not enclosed within parentheses and is not the outermost fullselect, the **ORDER BY** clause cannot be specified. The **ORDER BY** clause cannot be used in an outermost fullselect that contains a **FOR UPDATE** clause.

An **ORDER BY** clause that is specified in a subselect only affects the order of the rows that are returned by the query if the subselect is the outermost fullselect, except when a nested subselect includes an **ORDER BY** clause and the outermost fullselect specifies that the ordering of the rows should be retained (by using the **ORDER OF** *table-designator* clause).

Multiple **ORDER BY** clauses can be specified in the same subselect if each clause is separated with parentheses.

INPUT SEQUENCE

Indicates that the result table reflects the input order of the rows specified in the VALUES clause of an INSERT statement. INPUT SEQUENCE ordering can be specified only when an INSERT statement is specified in a *from-clause*.

ORDER OF *table-designator*

Specifies that the same ordering of the rows for the result table that is designated by *table-designator* should be applied to the result table of the subselect (or fullselect) that contains the ORDER OF specification. There must be a table reference in the FROM clause of the subselect (or fullselect) that specifies this clause and matches *table-designator*.

For an ORDER BY clause in an OLAP specification, *table-designator* must not specify a table function, a materialized view, a nested table expression that is materialized, an alias, or a synonym.

sort-key

A *column-name*, *integer*, or *sort-key-expression* that specifies the value that is to be used to order the rows of the result of the subselect.

If a single *sort-key* is identified, the rows are ordered by the values of that *sort-key*. If more than one *sort-key* is identified, the rows are ordered by the values of the first *sort-key*, then by the values of the second *sort-key*, and so on. A *sort-key* cannot be a LOB or XML expression.

The result table can be ordered by a named column in the select list by specifying a *sort-key* that is an integer or the column name. The result table can be ordered by an unnamed column in the select list by specifying a *sort-key* that is an integer or, in some cases, by a *sort-key-expression* that matches the expression in the select list.

column-name

An identifier that usually identifies a column of the result table. In this case, *column-name* must be the name of a named column in the select list. If the *fullselect* includes a set operator, the column name cannot be qualified.

If the query is a *subselect*, the *column-name* can also identify a column name of a table, view, or nested table expression identified in the FROM clause, including a column that is defined as implicitly hidden. The subselect must not include any of the following:

- DISTINCT in the select list
- Aggregate functions in the select list
- GROUP BY clause

integer

An unsigned integer that must be greater than 0 and not greater than the number of columns in the result table. The integer *n* identifies the *n*th column of the result table.

sort-key-expression

An expression that is not simply a *column-name* or unsigned integer constant. The query to which ordering is applied must be a *subselect* to use this form of the *sort-key*.

The *sort-key-expression* cannot include an expression that is not deterministic or a function that is defined to have an external action except for the RID built-in function and the ROW CHANGE expression. Any column name in the expression must conform to the rules described Column names in sort keys. If *sort-key-expression* includes an aggregate function, the input arguments to that function must not reference a named column in the select list that is derived from an aggregate function. An expression cannot be specified if DISTINCT is used in the select list of the *subselect*.

If the *subselect* is grouped, the *sort-key-expression* might or might not be in the select list of the *subselect*. When *sort-key-expression* is not in the select list the following rules apply:

- Each expression in the ORDER BY clause must either:
 - Use one or more grouping expressions
 - Use a column name that either unambiguously identifies a grouping column of R or is specified within a aggregate function.

- Each expression in the ORDER BY clause must not contain a scalar fullselect.

ASC

Uses the values of the *sort-key* in ascending order.

ASC is the default.

DESC

Uses the values of the *sort-key* in descending order.

Ordering is performed in accordance with the comparison rules described in Chapter 2, “Language elements,” on page 55, beginning on page “Numeric comparisons” on page 133. The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified *sort-key* have an arbitrary order. If you do not specify ORDER BY, the rows of the result table have an arbitrary order.

Column access controls do not effect the operation of the ORDER BY clause. The order is based on the original column values. However, after column masks are applied, the masked values in the final result table might not reflect the order of the original column values.

Column names in sort keys: A column name in a *sort-key* must conform to the following rules:

- If the column name is qualified, the query must be a *subselect*. The column name must unambiguously identify a column of a table, view, or nested table expression in the FROM clause of the subselect; its value is used to compute the value of the sort specification.
- If the column name is unqualified and the query is a *subselect*:
 - If the column name is identical to the name of more than one column of the result table, the column name must unambiguously identify a column of some table, view, or nested table expression in the FROM clause of the ordering subselect.
 - If the column name is identical is one column of the result table, its value is used to compute the value of the sort specification.
 - If the column name is not identical to a column in the result table, it must unambiguously identify a column of a table, view, or nested table expression in the FROM clause of the subselect. If the column name is identical to one column of a table, view, or nested table expression in the FROM clause of the subselect, its value is used to compute the value of the sort specification.

fetch-first-clause

The FETCH FIRST clause limits the number of rows that can be fetched. It improves the performance of queries with potentially large result tables when only a limited number of rows are needed.

fetch-first-clause

The FETCH FIRST clause sets a maximum number of rows that can be retrieved. FETCH FIRST specifies that only *integer* rows should be made available to be retrieved, regardless of how many rows there might be in the result table when this clause is not specified. An attempt to fetch beyond *integer* rows is handled the same way as normal end of data. The value of *integer* must be a positive integer (not zero). The default is 1.

The FETCH FIRST clause specifies an ordering of the rows of the result table. A subselect that contains a FETCH FIRST clause cannot be specified in the following objects:

- The outermost fullselect of a view
- The definition of a materialized query table

Limiting the result table to the first *n* rows can improve performance. The DB2 system will cease processing the query when it has determined the first *n* rows. If both the FETCH FIRST clause and the OPTIMIZE FOR clause are specified, the lower of the *integer* values from these clause will be used to influence the buffer size. The values are considered independently for optimization purposes. If the OPTIMIZE FOR clause is not specified, a default of OPTIMIZE FOR *integer* ROWS, where *integer* is the value that is specified in the FETCH FIRST clause, is assumed. The DB2 system uses this value for access path optimization.

Specification of the **FETCH FIRST** clause in an outermost fullselect makes the result table read-only. A read-only result table must not be referenced in an UPDATE, MERGE, or DELETE statement. The **FETCH FIRST** clause cannot be used in an outermost fullselect that contains a **FOR UPDATE** clause.

If both the FETCH FIRST clause and the ORDER BY clause are specified, the ordering is performed on the entire result table prior to returning the first *n* rows.

If the FETCH FIRST clause is specified in the outermost fullselect of a SELECT statement that contains a data change statement (an INSERT, DELETE, UPDATE, or MERGE statement), all rows are processed by the specified data change statement, but only the number of rows that is specified in the FETCH FIRST clause are returned in the final result table.

Row access controls can indirectly affect the FETCH FIRST clause because row access controls affect the rows that are accessible to the authorization ID or role of the subselect. Column access controls do not affect the FETCH FIRST clause.

“Examples of subselects” on page 1117

Examples of subselects

Examples of subselects can illustrate how to use the various clauses of the subselect to construct queries.

Example 1: Show all rows of the table DSN8A10.EMP.

```
SELECT * FROM DSN8A10.EMP;
```

Example 2: Show the job code, maximum salary, and minimum salary for each group of rows of DSN8A10.EMP with the same job code, but only for groups with more than one row and with a maximum salary greater than 50000.

```
SELECT JOB, MAX(SALARY), MIN(SALARY)
FROM DSN8A10.EMP
GROUP BY JOB
HAVING COUNT(*) > 1 AND MAX(SALARY) > 50000;
```

Example 3: For each employee in department E11, get the following information from the table DSN8A10.EMPPROJECT: employee number, activity number, activity start date, and activity end date. Using the CHAR function, convert the start and end dates to their USA formats. Get the needed department information from the table DSN8A10.EMP.

```
SELECT EMPNO, ACTNO, CHAR(EMSTDATE,USA), CHAR(EMENDATE,USA)
FROM DSN8A10.EMPPROJECT
WHERE EMPNO IN (SELECT EMPNO FROM DSN8A10.EMP
                WHERE WORKDEPT = 'E11');
```

Example 4: Show the department number and maximum departmental salary for all departments whose maximum salary is less than the average salary for all employees. (In this example, the subquery would be executed only one time.)

```
SELECT WORKDEPT, MAX(SALARY)
FROM DSN8A10.EMP
GROUP BY WORKDEPT
HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                      FROM DSN8A10.EMP);
```

Example 5: Show the department number and maximum departmental salary for all departments whose maximum salary is less than the average salary for employees in all other departments. (In contrast to Example 4, the subquery in this statement, containing a correlated reference, would need to be executed for each group.)

```
SELECT WORKDEPT, MAX(SALARY)
FROM DSN8A10.EMP Q
GROUP BY WORKDEPT
HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                      FROM DSN8A10.EMP
                      WHERE NOT WORKDEPT = Q.WORKDEPT);
```

Example 6: For each group of employees hired during the same year, show the year-of-hire and current average salary. (This example demonstrates how to use the AS clause in a FROM clause to name a derived column that you want to refer to in a GROUP BY clause.)

```
SELECT HIREYEAR, AVG(SALARY)
FROM (SELECT YEAR(HIREDATE) AS HIREYEAR, SALARY
      FROM DSN8A10.EMP) AS NEWEMP
GROUP BY HIREYEAR;
```

Example 7: For an example of how to group the results of a query by an expression in the SELECT clause without having to retype the expression, see Example 4 for CASE expressions.

Example 8: Get the employee number and employee name for all the employees in DSN8A10.EMP. Order the results by the date of hire.

```
SELECT EMPNO, FIRSTNAME, LASTNAME
FROM DSN8A10.EMP
ORDER BY HIREDATE;
```

Example 9: Select all the rows from tables T1 and T2 and order the rows such that the rows from table T1 are first and are ordered by column C1, followed by the rows from T2, which are ordered by column C2. The rows of T1 are retrieved by one subselect which is connected to the results of another subselect that retrieves the rows from T2. Each subselect specifies the ordering for the rows from the referenced table. Note that both subselects need to be enclosed in parenthesis because each subselect is not the outermost fullselect.

```
(SELECT * FROM T1 ORDER BY C1)
UNION
(SELECT * FROM T2 ORDER BY C2);
```

Example 10: Specify the ORDER BY clause to order the results of a union using the second column of the result table if the union. In this example, the second ORDER BY clause applies to the results of the outermost fullselect (the result of the union) rather than to the second subselect. If the intent is to apply the second ORDER BY clause to the second subselect, the second subselect should be enclosed within parentheses as shown in Example 9.

```
(SELECT * FROM T1 ORDER BY C1)
UNION
SELECT * FROM T2 ORDER BY C2
```

Example 11: Retrieve all rows of table T1 with no specific ordering) and connect the result table to the rows of table T2, which have been ordered by the first column of table T2. The ORDER BY ORDER OF clause in the fullselect specifies that the order of the rows in the result table of the union is to be inherited by the final result.

```
SELECT *
FROM (SELECT * FROM T1
      UNION ALL
      (SELECT * FROM T2 ORDER BY 1)
     ) AS UTABLE
ORDER BY ORDER OF UTABLE;
```

Example 12: The following example uses a query to join data from a table to the result table of a nested table expression. The query uses the ORDER BY ORDER OF clause to order the rows of the result table using the order of the rows of the nested table expression.

```
SELECT T1.C1, T1.C2, TEMP.Cy, TEMP.Cx
FROM T1,
      (SELECT T2.C1, T2.C2 FROM T2 ORDER BY 2) AS TEMP(Cx, Cy)
WHERE Cy = T1.C1
ORDER BY ORDER OF TEMP;
```

Example 13: Using the EMP_ACT table, find the project numbers that have an employee whose salary is in the top three salaries for all employees.

```
SELECT EMP_ACT.EMPNO, PROJNO
FROM EMP_ACT
WHERE EMP_ACT.EMPNO IN
      (SELECT EMPLOYEE.EMPNO
       FROM EMPLOYEE
       ORDER BY SALARY DESC
       FETCH FIRST 3 ROWS ONLY);
```

Example 14: Assume that an external function named ADDYEARS exists. For a given date, the function adds a given number of years and returns a new date. (The data types of the two input parameters to the function are DATE and INTEGER.) Get the employee number and employee name for all employees who have been hired within the last 5 years.

```
SELECT EMPNO, FIRSTNAME, LASTNAME
FROM DSN8A10.EMP
WHERE ADDYEARS(HIREDATE, 5) > CURRENT DATE;
```

To distinguish the different types of joins, to show nested table expressions, and to demonstrate how to combine join columns, the remaining examples use these two tables:

The PARTS table

| PART | PROD# | SUPPLIER |
|---------|-------|--------------|
| WIRE | 10 | ACWF |
| OIL | 160 | WESTERN_CHEM |
| MAGNETS | 10 | BATEMAN |
| PLASTIC | 30 | PLASTIK_CORP |
| BLADES | 205 | ACE_STEEL |

The PRODUCTS table

| PROD# | PRODUCT | PRICE |
|-------|-------------|-------|
| 505 | SCREWDRIVER | 3.70 |
| 30 | RELAY | 7.55 |
| 205 | SAW | 18.90 |
| 10 | GENERATOR | 45.75 |

Example 15: Join the tables on the PROD# column to get a table of parts with their suppliers and the products that use the parts:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS, PRODUCTS
WHERE PARTS.PROD# = PRODUCTS.PROD#;
```

or

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS INNER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;
```

Either one of these two statements give this result:

| PART | SUPPLIER | PROD# | PRODUCT |
|---------|--------------|-------|-----------|
| WIRE | ACWF | 10 | GENERATOR |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |
| BLADES | ACE_STEEL | 205 | SAW |

Notice two things about the example:

- There is a part in the parts table (OIL) whose product (#160) is not listed in the products table. There is a product (SCREWDRIVER, #505) that has no parts listed in the parts table. Neither OIL nor SCREWDRIVER appears in the result of the join.

An outer join, however, includes rows where the values in the joined columns do not match.

- There is explicit syntax to express that this familiar join is not an outer join but an inner join. You can use INNER JOIN in the FROM clause instead of the comma. Use ON when you explicitly join tables in the FROM clause.

You can specify more complicated join conditions to obtain different sets of results. For example, eliminate the suppliers that begin with the letter A from the table of parts, suppliers, product numbers and products:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS INNER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#
AND SUPPLIER NOT LIKE 'A%';
```

The result of the query is all rows that do not have a supplier that begins with A:

| PART | SUPPLIER | PROD# | PRODUCT |
|---------|--------------|-------|-----------|
| ===== | ===== | ===== | ===== |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |

Example 16: Join the tables on the PROD# column to get a table of all parts and products, showing the supplier information, if any.

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS FULL OUTER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

| PART | SUPPLIER | PROD# | PRODUCT |
|---------|--------------|--------|--------------|
| ===== | ===== | ===== | ===== |
| WIRE | ACWF | 10 | GENERATOR |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |
| BLADES | ACE_STEEL | 205 | SAW |
| OIL | WESTERN_CHEM | 160 | (null) |
| (null) | (null) | (null) | SCREWDRIIVER |

The clause FULL OUTER JOIN includes unmatched rows from both tables. Missing values in a row of the result table are filled with nulls.

Example 17: Join the tables on the PROD# column to get a table of all parts, showing what products, if any, the parts are used in:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS LEFT OUTER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

| PART | SUPPLIER | PROD# | PRODUCT |
|---------|--------------|-------|-----------|
| ===== | ===== | ===== | ===== |
| WIRE | ACWF | 10 | GENERATOR |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |
| BLADES | ACE_STEEL | 205 | SAW |
| OIL | WESTERN_CHEM | 160 | (null) |

The clause LEFT OUTER JOIN includes rows from the table identified before it where the values in the joined columns are not matched by values in the joined columns of the table identified after it.

Example 18: Join the tables on the PROD# column to get a table of all products, showing the parts used in that product, if any, and the supplier.

```
SELECT PART, SUPPLIER, PRODUCTS.PROD#, PRODUCT
FROM PARTS RIGHT OUTER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

| PART | SUPPLIER | PROD# | PRODUCT |
|---------|--------------|-------|--------------|
| ===== | ===== | ===== | ===== |
| WIRE | ACWF | 10 | GENERATOR |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |
| BLADES | ACE_STEEL | 205 | SAW |
| (null) | (null) | 505 | SCREWDRIIVER |

The clause RIGHT OUTER JOIN includes rows from the table identified after it where the values in the joined columns are not matched by values in the joined columns of the table identified before it.

Example 19: The result of Example 16 (a full outer join) shows the product number for SCREWDRIVER as null, even though the PRODUCTS table contains a product number for it. This is because PRODUCTS.PROD# was not listed in the SELECT list of the query. Revise the query using COALESCE so that all part numbers from both tables are shown.

```
SELECT PART, SUPPLIER,
       COALESCE(PARTS.PROD#, PRODUCTS.PROD#) AS PRODNUM, PRODUCT
FROM PARTS FULL OUTER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;
```

In the result, notice that the AS clause (AS PRODNUM), provides a name for the result of the COALESCE function:

| PART | SUPPLIER | PRODNUM | PRODUCT |
|---------|--------------|---------|-------------|
| WIRE | ACWF | 10 | GENERATOR |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |
| BLADES | ACE_STEEL | 205 | SAW |
| OIL | WESTERN_CHEM | 160 | (null) |
| (null) | (null) | 505 | SCREWDRIVER |

Example 20: For all parts that are used in product numbers less than 200, show the part, the part supplier, the product number, and the product name. Use a nested table expression.

```
SELECT PART, SUPPLIER, PRODNUM, PRODUCT
FROM (SELECT PART, PROD# AS PRODNUM, SUPPLIER
      FROM PARTS
      WHERE PROD# < 200) AS PARTX
LEFT OUTER JOIN PRODUCTS
ON PRODNUM = PROD#;
```

The result is:

| PART | SUPPLIER | PRODNUM | PRODUCT |
|---------|--------------|---------|-----------|
| WIRE | ACWF | 10 | GENERATOR |
| MAGNETS | BATEMAN | 10 | GENERATOR |
| PLASTIC | PLASTIK_CORP | 30 | RELAY |
| OIL | WESTERN_CHEM | 160 | (null) |

Example 21: Examples of statements with DISTINCT specified more than once in a subselect:

```
SELECT DISTINCT COUNT(DISTINCT A1), COUNT(A2)
FROM T1;

SELECT COUNT(DISTINCT A)
FROM T1
WHERE A3 > 0
HAVING AVG(DISTINCT A4) >1;
```

Example 22: Examples of cross join to combine information for all customers with all states.

Use a cross join to combine information for all customers with all of the states. The cross join combines all rows in both tables and creates a Cartesian product. Assume that the following tables exist:

```
Customer:
-----
ACOL1    | ACOL2
```

| | |
|----|-----|
| A1 | AA1 |
| A2 | AA2 |
| A3 | AA3 |

States:

| | |
|-------|-------|
| BCOL1 | BCOL2 |
| B1 | BB1 |
| B2 | BB2 |

The following two select statements produce identical results:

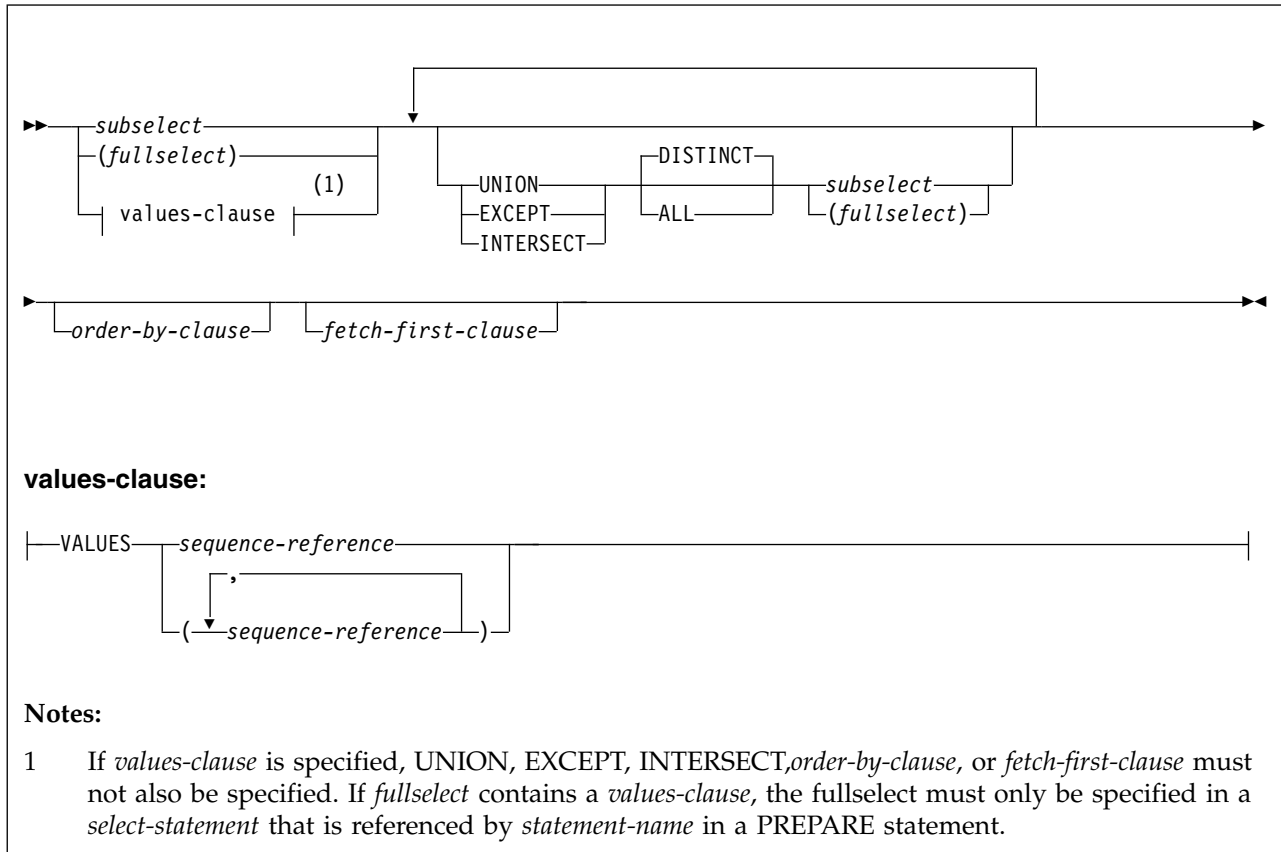

```
SELECT * FROM customer CROSS JOIN states
SELECT * FROM A, B
```

The result table for either of these select statements looks like the following:

| ACOL1 | ACOL2 | BCOL1 | BCOL2 |
|-------|-------|-------|-------|
| A1 | AA1 | B1 | BB1 |
| A1 | AA1 | B2 | BB2 |
| A2 | AA2 | B1 | BB1 |
| A2 | AA2 | B2 | BB2 |
| A3 | AA3 | B1 | BB1 |
| A3 | AA3 | B2 | BB2 |

fullselect

The fullselect is a component of the *select-statement*, ALTER TABLE statement for the definition of a materialized query table, CREATE TABLE statement, CREATE VIEW statement, DECLARE GLOBAL TEMPORARY TABLE statement, INSERT statement, UPDATE statement, and MERGE statement.

A fullselect that is enclosed in parentheses is called a *subquery*. For example, a subquery can be used in a search condition.

A *scalar-fullselect* is a fullselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the fullselect is no rows, then the null value is returned. An error is returned if there is more than one row in the result. For example, a scalar-fullselect can be used in the assignment clause of the DELETE, UPDATE and MERGE statements.

A *row-fullselect* is a fullselect that returns a single row. An error is returned if there is more than one row in the result. For example, a row-fullselect can be used in the assignment clause of the DELETE and UPDATE statements.

UNION, EXCEPT, or INTERSECT

The set operators, UNION, EXCEPT, and INTERSECT, correspond to the relational operators union, difference, and intersection. A *fullselect* specifies a result table. If a set operator is not used, the result of the fullselect is the result of the specified subselect. Otherwise, the result table is derived by combining the two other result tables (R1 and R2) subject to the specified set operator.

UNION DISTINCT or UNION ALL

If UNION ALL is specified, the result consists of all rows in R1 and R2. With UNION DISTINCT, the result is the set of all rows in either R1 or R2 with the redundant duplicate rows eliminated. In either case, each row of the result table of the union is either a row from R1 or a row from R2.

Column masks cannot be applied to the select lists that derive the final result table of set operations if any of the set operators that are used to derive the final result table is UNION ALL or UNION DISTINCT.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.

EXCEPT DISTINCT or EXCEPT ALL

If EXCEPT ALL is specified, the result consists of all rows from only R1, including significant redundant duplicate rows. With EXCEPT DISTINCT, the result consists of all rows that are only in R1, with redundant duplicate rows eliminated. In either case, each row in the result table of the difference is a row from R1 that does not have a matching row in R2.

Column masks cannot be applied to the select lists that derive the final result table of set operations if any of the set operators that are used to derive the final result table is EXCEPT ALL or EXCEPT DISTINCT.

For compatibility with other SQL implementations, MINUS can be specified as a synonym for EXCEPT, and UNIQUE can be specified as a synonym for DISTINCT.

INTERSECT DISTINCT or INTERSECT ALL

If INTERSECT ALL is specified, the result consists of all rows that are both in R1 and R2, including significant redundant duplicate rows. With INTERSECT DISTINCT, the result consists of all rows that are in both R1 and R2, with redundant duplicate rows eliminated. In either case each row of the result table of the intersection is a row that exists in both R1 and R2.

Column masks cannot be applied to the select lists that derive the final result table of set operations if any of the set operators that are used to derive the final result table is INTERSECT ALL or INTERSECT DISTINCT.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.

values-clause

Derives a result table by specifying the actual values, using sequence expressions, for each column of a row in the result table.

A *values-clause* is specified by:

- A single sequence expression for a single-column result table.
- *n* sequence expressions, separated by commas and enclosed in parentheses. *n* is the number of columns in the result table.

All result columns in a *values-clause* are unnamed.

Rules for columns:

- R1 and R2 must have the same number of columns, and the data type of the *n*th column of R1 must be compatible with the data type of the *n*th column of R2.
- The *n*th column of the result of a set operator is derived from the *n*th columns of R1 and R2. The attributes of the result columns are determined using the rules for result columns.

- R1 and R2 must not include columns having a data type of CLOB, BLOB, DBCLOB, XML, or a distinct type that is based on any of these types. However, this rule is not applicable when UNION ALL is used with the set operator.
- If the *n*th column of R1 and the *n*th column of R2 have the same result column name, the *n*th column of the result table of the set operation has the same result column name. Otherwise, the *n*th column of the result table of the set operation is unnamed.
- Qualified column names cannot be used in the ORDER BY clause when the set operators are specified.

For information on the valid combinations of operand columns and the data type of the result column, see “Rules for result data types” on page 143.

Duplicate rows: Two rows are duplicates if the value in each column in the first row is equal to the corresponding value of the second row. For determining duplicates, two null values are considered equal.

The DECFLOAT data type allows for multiple bit representations of the same number. For example 2.00 and 2.0 are two numbers with the same coefficient, but different exponent values. See “Numeric comparisons” on page 133 section for more information. So if the result table of UNION contains a DECFLOAT column and multiple bit representations of the same number exist, the one returned is unpredictable.

Operator precedence: When multiple set operations are combined in an expression, set operations within parentheses are performed first. If the order is not specified by parentheses, set operations are performed from left to right with the exception that all INTERSECT operations are performed before any UNION or any EXCEPT operations.

Results of set operators: The following table illustrates the results of all set operations, with rows from result table R1 and R2 as the first two columns and the result of each operation on R1 and R2 under the corresponding column heading.

Table 144. Example of UNION, EXCEPT, and INTERSECT set operations on result tables R1 and R2.

| Rows in R1 | Rows in R2 | Result of UNION ALL | Result of UNION DISTINCT | Result of EXCEPT ALL | Result of EXCEPT DISTINCT | Result of INTERSECT ALL | Result of INTERSECT DISTINCT |
|------------|------------|---------------------|--------------------------|----------------------|---------------------------|-------------------------|------------------------------|

Table 144. Example of UNION, EXCEPT, and INTERSECT set operations on result tables R1 and R2. (continued)

| Rows in R1 | Rows in R2 | Result of UNION ALL | Result of UNION DISTINCT | Result of EXCEPT ALL | Result of EXCEPT DISTINCT | Result of INTERSECT ALL | Result of INTERSECT DISTINCT |
|------------|------------|---------------------|--------------------------|----------------------|---------------------------|-------------------------|------------------------------|
| | | 4 | | | | | |
| | | 4 | | | | | |
| | | 4 | | | | | |
| | | 5 | | | | | |

Examples of fullselects

Example 1: A query specifies the union of result tables R1 and R2. A column in R1 has the data type CHAR(10) and the subtype BIT. The corresponding column in R2 has the data type CHAR(15) and the subtype SBCS. Hence, the column in the union has the data type CHAR(15) and the subtype BIT. Values from the first column are converted to CHAR(15) by adding five trailing blanks.

Example 2: Show all the rows from DSN8A10.EMP.

```
SELECT * FROM DSN8A10.EMP;
```

Example 3: Using sample tables DSN8A10.EMP and DSN8A10.EMPPROJECT, list the employee numbers of all employees for which either of the following statements are true:

- Their department numbers begin with 'D'.
- They are assigned to projects whose project numbers begin with 'AD'.

```
SELECT EMPNO FROM DSN8A10.EMP
WHERE WORKDEPT LIKE 'D%'
UNION
SELECT EMPNO FROM DSN8A10.EMPPROJECT
WHERE PROJNO LIKE 'AD%';
```

The result is the union of two result tables, one formed from the sample table DSN8A10.EMP, the other formed from the sample table DSN8A10.EMPPROJECT. The result—a one-column table—is a list of employee numbers. Because UNION, rather than UNION ALL, was used, the entries in the list are distinct. If instead UNION ALL were used, certain employee numbers would appear in the list more than once. These would be the numbers for employees in departments that begin with 'D' while their projects begin with 'AD'.

Example 4: Specify a series of unions and order the results by the first column of the final result table.

```
SELECT * FROM T1
UNION
SELECT * FROM T2
UNION
SELECT * FROM T3
ORDER BY 1;
```

Example 5: Specify a series of unions and order the results by the first column of the final result table. The first ORDER BY clause order the rows of the result of the first union by the first column of that result table. The second ORDER BY clause is applied as part of the outer fullselect and it causes the rows of the final result table to be ordered by the first column of the final result table.

```
(SELECT * FROM T1
 UNION
 SELECT * FROM T2
 ORDER BY 1)
 UNION
 SELECT * FROM T3
 ORDER BY 1;
```

Example 6: Assume that tables T1 and T2 exist and each contain the same number of columns named C1, C2, and so on. This example of the EXCEPT operator produces all rows that are in T1 but not in T2, with duplicate rows removed:

```
(SELECT * FROM T1)
 EXCEPT DISTINCT
 (SELECT * FROM T2);
```

Example 7: Assume that tables T1 and T2 exist and each contain the same number of columns named C1, C2, and so on. This example of the INTERSECT operator produces all rows that are in both table T1 and table T2, with duplicate rows removed:

```
(SELECT * FROM T1)
 INTERSECT DISTINCT
 (SELECT * FROM T2);
```

|
|
|
|
|

Example 8: Retrieve the most recently generated value for the sequence MYSEQ1:
VALUES PREVIOUS VALUE FOR MYSEQ1;

Example 9: Retrieve the next value for the sequence MYSEQ1:
VALUES NEXT VALUE FOR MYSEQ1;

Character conversion in set operations and concatenations

The SQL operations that combine strings include concatenation, set operators, and the IN list of an IN predicate. Within an SQL statement, concatenation combines two or more strings into a new string. Within a fullselect, set operation, or the IN list of an IN predicate combine two or more string columns resulting from the subselects into results column.

All such operations have the following in common:

- The choice of a result CCSID for the string or column
- The possible conversion of one or more of the component strings or columns to the result CCSID

For all such operations, the rules for those two actions are the same, as described in “Selecting the result CCSID” on page 1129. These rules also apply to the COALESCE scalar function.

Selecting the result CCSID

The result CCSID is selected at package prepare time. The result CCSID is the CCSID of one of the operands.

Two operands: When two operands are used, the result CCSID is determined by the operand types, their CCSIDs, and their relative positions in the operation. When a CCSID is X'FFFF', the result CCSID is always X'FFFF', and no character conversions take place. When neither CCSID is X'FFFF', the rules for selecting the result CCSID are identical to the ones for string comparison. See "Conversion rules for comparisons" on page 137.

Three or more operands:

If all the operands have the same CCSID, the result CCSID is the common CCSID.

If at least one of the CCSIDs has the value X'FFFF', the result CCSID also has the value X'FFFF'.

Otherwise, selection proceeds as follows:

1. The rules for a pair of operands are applied to the first two operands. This picks a "candidate" for the second step. The candidate is the operand that would furnish the result CCSID if just the first two operands were involved in the operation.
2. The rules are applied to the Step 1 candidate and the third operand, thereby selecting a second candidate.
3. If a fourth operand is involved, the rules are applied to the second candidate and fourth operand, to select a third candidate, and so on.

The process continues until all operands have been used. The remaining candidate is the one that furnishes the result CCSID. Whenever the rules for a pair are applied to a candidate and an operand, the candidate is considered to be the first operand.

Consider, for example, the following concatenation:

```
A CONCAT B CONCAT C
```

Here, the rules are first applied to the strings A and B. Suppose that the string selected as candidate is A. Then the rules are applied to A and C. If the string selected is again A, then A furnishes the result CCSID. Otherwise, C furnishes the result CCSID.

Character conversion of components: An operand of concatenation or the selected argument of the COALESCE scalar function is converted, if necessary, to the coded character set of the result string. Each string of an operand of a set operation is converted, if necessary, to the coded character set of the result column. In either case, the coded character set is the one identified by the result CCSID. Character conversion is necessary only if all of the following are true:

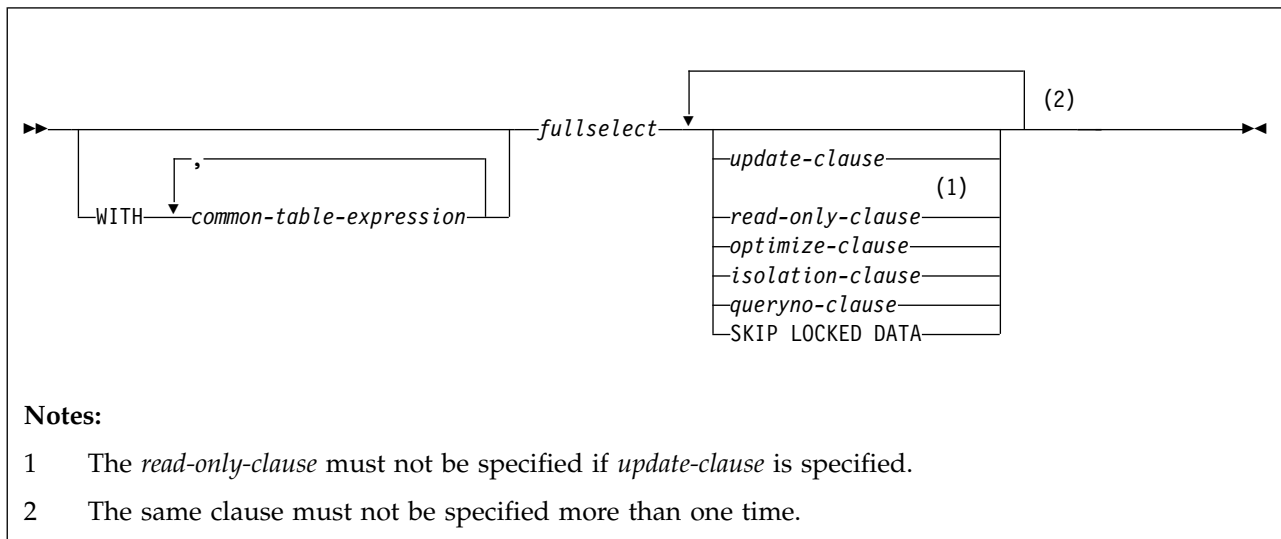

- The result and operand CCSIDs are different.
- Neither CCSID is X'FFFF' (neither string is defined as BIT data).
- The string is neither null nor empty.
- The SYSSTRINGS catalog table indicates that conversion is necessary.

An error occurs if a character of a string cannot be converted, SYSSTRINGS is used but contains no information about the CCSID pair, or DB2 cannot do the

conversion through z/OS support for Unicode. A warning occurs if a character of a string is converted to the substitution character.

select-statement

The *select-statement* is the form of a query that can be directly specified in a DECLARE CURSOR statement or FOR statement, prepared and then referenced in a DECLARE CURSOR statement, or directly specified in an SQLJ assignment clause. It can also be issued using SPUFI or the command line processor which causes a result table to be displayed at your terminal. In any case, the result table specified by a *select-statement* is the result of the *fullselect*.

The tables and view identified in a select statement can be at the current server or any DB2 subsystem with which the current server can establish a connection.

For local queries on DB2 for z/OS or remote queries in which the server and requester are DB2 for z/OS, if a table is encoded as ASCII or Unicode, the retrieved data is encoded in EBCDIC. For information on retrieving data encoded in ASCII or Unicode, see *DB2 Application Programming and SQL Guide*.

A select statement can implicitly or explicitly invoke user-defined functions or implicitly invoke stored procedures. This technique is known as *nesting* of SQL statements. A function or procedure is implicitly invoked in a select statement when it is invoked at a lower level. For instance, if you invoke a user-defined function from a select statement and the user-defined function invokes a stored procedure, you are implicitly invoking the stored procedure. When a SELECT statement refers to a table, any SQL statements that are implicitly invoked (as a result of nested functions or procedures) must not result in an SQL data change statement that modifies the same table.

For example, suppose that you execute this SQL statement at level 1 of nesting:
SELECT UDF1(C1) FROM T1;

You cannot execute this SQL statement at a lower level of nesting:
INSERT INTO T1 VALUES(...);

common-table-expression

A *common table expression* defines a result table with *table-identifier* that can be referenced in any FROM clause of the *fullselect* that follows.

Multiple common table expressions can be specified following the single WITH keyword. Each specified common table expression can also be referenced by name in the FROM clause of subsequent common table expressions.

common-table-expression

If a list of columns is specified, it must consist of as many names as there are columns in the result table of the *fullselect*. Each *column-name* must be unique and unqualified. If these column names are not specified, the names are derived from the select list of the *fullselect* used to define the common table expression.

table-identifier must be an unqualified SQL identifier, and it must be different from any other *table-identifier* in the same statement. If the common table expression is specified in an INSERT statement, the *table-identifier* must not be the same as the table or view name that is the object of the insert. If the common table expression is specified in a CREATE VIEW statement, the *table-identifier* must not be the same as the view name that is created. A common table expression *table-identifier* can be specified as a table name in any FROM clause throughout the *fullselect*.

If more than one common table expression is defined in the same statement, cyclic references between the common table expressions are not permitted. A *cyclic reference* occurs when two common table expressions *dt1* and *dt2* are created such that *dt1* refers to *dt2* and *dt2* refers to *dt1*. Furthermore, a common table expression defined before cannot refer to subsequent common table expressions.

A common table expression name can only be referenced in the *select-statement*, SELECT INTO statement, INSERT statement, CREATE VIEW statement, or RETURN statement that defines it.

If a *select-statement*, SELECT INTO statement, INSERT statement, or CREATE VIEW statement that is not contained in a trigger definition refers to an unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the *select-statement*, the name identifies the common table expression that is in the innermost scope.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

If a *select-statement*, SELECT INTO statement, INSERT statement, or CREATE VIEW statement that is contained in a trigger definition refers to a unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the *select-statement*, the name identifies the common table expression that is in the innermost scope.
- If the unqualified name corresponds to a transition table name, the name identifies that transition table.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

The common table expression is also optional prior to the *fullselect* in the CREATE VIEW and INSERT statements. However, the use of common table expressions is not allowed in a INSERT within SELECT statement.

A common table expression can be used:

- In place of a view to avoid creating the view (when general use of the view is not required and positioned updates or deletes are not used)
- When the result table that you want is based on host variables
- When the same result table needs to be shared in a *fullselect*
- When the result needs to be derived using recursion

If a *fullselect* of a common table expression contains a reference to itself in a FROM clause, the common table expression is a *recursive common table expression*. Queries using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The following must be true of a recursive common table expression:

- Each *fullselect* that is part of the recursion cycle must start with SELECT or SELECT ALL. Use of SELECT DISTINCT is not allowed. Furthermore, the set operators must use the ALL keyword.
- The column names must be specified following the *table-name* of the common table expression.
- The first *fullselect* of the first set operator (the initialization *fullselect*) must not include a reference to the common table expression itself in any FROM clause).
- If a column name of the common table expression is referred to in the iterative *fullselect*, the data type, length, and CCSID for the column are determined based on the initialization *fullselect*. The corresponding column in the iterative *fullselect* must have the same data type and length as the data type and length determined based on the initialization *fullselect* and the CCSID must match. However, for character string types, the length of the two data types can differ. In this case, the column in the iterative *fullselect* must have a length that would always be assignable to the length determined from the initialization *fullselect*. If a column of a recursive common table expression is not used recursively in its definition, the data type, length, and CCSID for the column are determined by applying rules associated with non-recursive queries.
- Each *fullselect* that is part of the recursion cycle must not include any aggregate functions, GROUP BY clauses, HAVING clauses, ORDER BY clauses, or FETCH FIRST clauses. The FROM clauses of these *fullselects* can include at most one reference to a common table expression that is part of a recursion cycle.
- Subqueries (scalar or quantified) must not be part of any recursion cycles.

- Outer join must not be part of any recursion cycles.

| All columns referenced in a recursive common table expression are nullable for the
| query, even if they are defined as NOT NULL.

When developing recursive common table expressions, remember that an infinite recursion cycle (loop) can be created. Check that recursion cycles will terminate. This is especially important if the data involved is cyclic. A recursive common table expression is expected to include a predicate that will prevent an infinite loop. The recursive common table expression is expected to include:

- In the iterative *fullselect*, an integer column incremented by a constant.
- A predicate in the WHERE clause of the iterative *fullselect* in the form of "*counter_col* < *constant*" or "*counter_col* < *:hostvar*". A warning is issued if this syntax is not found.

| If the result of a recursive common table expression is used to derive the final
| result table, and if a column mask is used to mask the column values in the final
| result table, the column mask cannot be applied to a column that is specified in the
| *fullselect* of the recursive common table expression.

update-clause

The optional FOR UPDATE clause identifies the columns that can appear as targets in an assignment clause in a later positioned UPDATE statement.

update-clause

Each column name must be unqualified and must identify a column of the table or view identified in the first **FROM** clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only.

If **FOR UPDATE** clause is specified with a *column-name* list *column-name* must be an updatable column.

If the **FOR UPDATE** clause is specified without a *column-name* list, the implicit list of column names consists of all updatable columns of the table or view that is identified in the first **FROM** clause of the fullselect.

If a dynamically prepared select-statement does not contain a **FOR UPDATE** clause, the cursor that is associated with the select statement cannot be referenced in a positioned **UPDATE** statement.

If a statically prepared *select-statement* does not contain a **FOR UPDATE** clause and its result table is not read-only, an implicit **UPDATE** clause will result. The implicit list of column names consists of all updatable columns of the table or view that is identified in the first **FROM** clause of the fullselect.

The declaration of a cursor referenced in a positioned **UPDATE** statement need not include an **UPDATE** clause if the STDSQL(YES) or NOFOR SQL processing option is specified when the program is prepared. For more on the subject, see “Positioned updates of columns” on page 314.

When **FOR UPDATE** is used, **FETCH** operations referencing the cursor acquire U or X locks rather than S locks when:

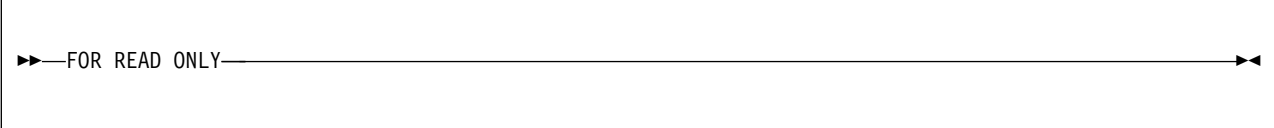

- The isolation level of the statement is cursor stability.
- The isolation level of the statement is repeatable read or read stability and field U LOCK FOR RR/RS on installation panel DSNTIPI is set to get U locks.
- The isolation level of the statement is repeatable read or read stability and **USE AND KEEP EXCLUSIVE LOCKS** or **USE AND KEEP UPDATE LOCKS** is specified in the SQL statement, an X lock or a U lock, respectively, is acquired at fetch time.

No locks are acquired on declared temporary tables. For a discussion of U locks and S locks, see *DB2 Performance Monitoring and Tuning Guide*.

read-only-clause

The read-only clause specifies that the result table is read-only. Therefore, the cursor cannot be referred to in positioned UPDATE or DELETE statements.

read-only-clause

Some result tables are read-only by nature (for example, a table based on a read-only view.) FOR READ ONLY can still be specified for such tables, but the specification has no effect.

For tables in which updates and deletes are allowed, specifying FOR READ ONLY can possibly improve the performance of FETCH operations as DB2 can do blocking and avoid exclusive locks. For example, in programs that contain dynamic SQL statements without the FOR READ ONLY or ORDER BY clause, DB2 might open cursors as if the UPDATE clause was specified.

A read-only result table must not be referred to in an UPDATE or DELETE statement, whether it is read-only by nature or specified as FOR READ ONLY.

To take advantage of the possibly improved performance of FETCH operations while guaranteeing that selected data is not modified and preventing some types of deadlocks, you can specify FOR READ ONLY in combination with the optional syntax of USE AND KEEP ... LOCKS on the *isolation-clause*.

Alternative syntax and synonyms: FOR FETCH ONLY can be specified as a synonym for FOR READ ONLY.

- ["DELETE" on page 1883](#)
- ["isolation-clause" on page 1138](#)

optimize-clause

The OPTIMIZE clause requests special optimization of the *select-statement*.

optimize-clause

The *optimize-clause* tells DB2 to assume that the program does not intend to retrieve more than *integer* rows from the result table. Without this clause, DB2 assumes that all rows of the result table will be retrieved, unless the FETCH FIRST clause is specified. Optimizing for *integer* rows can improve performance. If this clause is omitted and the FETCH FIRST is specified, OPTIMIZE FOR *integer* ROWS is assumed, where *integer* is the value that is specified in the FETCH FIRST clause. DB2 will optimize the query based on the specified number of rows.

The clause does not limit the number of rows that can be fetched, change the result table, or change the order in which the rows are fetched. Any number of rows can be fetched, but performance can possibly degrade after *integer* fetches. In general, if you are retrieving only a few rows, specify OPTIMIZE FOR 1 ROW to influence the access path that DB2 selects.

The value of *integer* must be a positive integer (not zero).

Row access controls indirectly affects the OPTIMIZE FOR clause because row access controls affect the rows that are accessible to the authorization ID or role of the subselect.

Column access controls do not affect the OPTIMIZE FOR clause.

Related concepts:

➡ The effect of the OPTIMIZE FOR n ROWS clause in distributed applications (DB2 Performance)

Related tasks:

➡ Minimizing the cost of retrieving few rows (DB2 Performance)

➡ Optimizing retrieval for a small set of rows (DB2 Application programming and SQL)

isolation-clause

The *isolation-clause* specifies the isolation level at which the statement is executed. (Isolation level does not apply to declared temporary tables because no locks are acquired.)

isolation-clause

RR Repeatable read

RR *lock-clause*

Repeatable read, using and keeping the type of lock that is specified in *lock-clause* on all accessed pages and rows

RS Read stability

RS *lock-clause*

Read stability, using and keeping the type of lock that is specified in *lock-clause* on all accessed pages and rows

CS Cursor stability

UR Uncommitted read

lock-clause

Specifies the type of lock.

USE AND KEEP EXCLUSIVE LOCKS

USE AND KEEP UPDATE LOCKS

USE AND KEEP SHARE LOCKS

Specifies that DB2 is to acquire and hold X, U, or S locks, respectively.

WITH UR can be specified only if the result table of the fullselect or the SELECT INTO statement is read-only.

In an ODBC application, the SQLSetStmtAttr function can be used to set statement attributes that interact with the *lock-clause*. If SQLSetStmtAttr is invoked with a cursor's statement handle and specifying that its SQL_ATTR_CLOSE_BEHAVIOR is SQL_CC_RELEASE (locks are to be released when the cursor is closed), then irrespective of any *lock-clause*, lock used by the cursor that are not needed to protect the integrity of changed data are released..

Although requesting an UPDATE or EXCLUSIVE LOCK can reduce concurrency, it can prevent some types of deadlocks.

The **default** isolation level of the statement depends on:

- The isolation of the package or plan that the statement is bound in
- Whether the result table is read-only

Table 145 shows the default isolation level of the statement.

Table 145. Default isolation level based on the isolation level of the package or plan and whether the result table is read-only

| If package isolation is: | And plan isolation is: | And the result table is: | Then the default isolation is: |
|--------------------------|------------------------|--------------------------|--------------------------------|
| RR | Any | Any | RR |
| RS | Any | Any | RS |
| CS | Any | Any | CS |
| UR | Any | Read-only | UR |
| | | Not read-only | CS |
| Not specified | Not specified | Any | RR |
| | | RR | RR |
| | | RS | RS |
| | | CS | CS |
| | | UR | UR |
| | | UR | CS |

A simple way to ensure that a result table is read-only is to specify FOR READ ONLY in the SQL statement.

Alternative syntax and synonyms: KEEP UPDATE LOCKS can be specified as a synonym for USE AND KEEP EXCLUSIVE LOCKS. However, KEEP UPDATE LOCKS can be specified only if FOR UPDATE OF is specified, and it is not supported in the SELECT INTO statement.

 SQLSetStmtAttr() - Set statement attributes (DB2 Programming for ODBC)

queryno-clause

The QUERYNO clause specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO columns of the plan tables for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

queryno-clause

►►—QUERYNO—*integer*—►►

integer is the value to be used to identify this SQL statement in EXPLAIN output and trace records.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

SKIP LOCKED DATA

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks that would block the progress of the statement are held on the rows by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only with isolation CS or RS and applies only to row level or page level locks.

▶—SKIP LOCKED DATA—◀

Important: The recommendation is to not rely on the SKIP LOCKED DATA option to remove rows from results returned by a query. The SKIP LOCKED DATA option is meant only to prevent possibly incompatible locks from impeding the progress of queries that can tolerate possibly incomplete results. However, DB2 might use lock avoidance techniques to avoid taking certain locks.

SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, and whether the result table is read-only.

Examples of SELECT statements

Examples of SELECT statements.

Introductory concepts:

How a SELECT statement works (Introduction to DB2 for z/OS)

Example 1: Select all the rows from DSN8A10.EMP.

```
SELECT * FROM DSN8A10.EMP;
```

Example 2: Select all the rows from DSN8A10.EMP, arranging the result table in chronological order by date of hiring.

```
SELECT * FROM DSN8A10.EMP  
ORDER BY HIREDATE;
```

Example 3: Select the department number (WORKDEPT) and average departmental salary (SALARY) for all departments in the table DSN8A10.EMP. Arrange the result table in ascending order by average departmental salary.

```
SELECT WORKDEPT, AVG(SALARY)  
FROM DSN8A10.EMP  
GROUP BY WORKDEPT  
ORDER BY 2;
```

Example 4: Change various salaries, bonuses, and commissions in the table DSN8A10.EMP. Confine the changes to employees in departments D11 and D21. Use positioned updates to do this with a cursor named UP_CUR. Use a FOR UPDATE clause in the cursor declaration to indicate that all updatable columns are updated. Below is the declaration for a PL/I program.

```
EXEC SQL DECLARE UP_CUR CURSOR FOR  
SELECT WORKDEPT, EMPNO, SALARY, BONUS, COMM  
FROM DSN8A10.EMP  
WHERE WORKDEPT IN ('D11', 'D21')  
FOR UPDATE;
```

Beginning where the cursor is declared, all updatable columns would be updated. If only specific columns needed to be updated, such as only the salary column, the FOR UPDATE clause could be used to specify the salary column (FOR UPDATE OF SALARY).

Example 5: Find the maximum, minimum, and average bonus in the table DSN8A10.EMP. Execute the statement with uncommitted read isolation, regardless of the value of ISOLATION with which the plan or package containing the statement is bound. Assign 13 as the query number for the SELECT statement.

```
EXEC SQL  
SELECT MAX(BONUS), MIN(BONUS), AVG(BONUS)  
INTO :MAX, :MIN, :AVG  
FROM DSN8A10.EMP  
WITH UR  
QUERYNO 13;
```

If bind option EXPLAIN(YES) is specified, rows are inserted into the plan table. The value used for the QUERYNO column for these rows is 13.

Example 6: The cursor declaration shown below is in a PL/I program. In the query within the declaration, X.RMT_TAB is an alias for a table at some other DB2. Hence, when the query is used, it is processed using DRDA access. See "Distributed data" on page 38.

The declaration indicates that no positioned updates or deletes will be done with the query's cursor. It also specifies that the access path for the query be optimized for the retrieval of at most 50 rows. Even so, the program can retrieve more than 50 rows from the result table, which consists of the entire table identified by the alias. However, when more than 50 rows are retrieved, performance could possibly degrade.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT * FROM X.RMT_TAB
  OPTIMIZE FOR 50 ROWS
  FOR READ ONLY;
```

The `FETCH FIRST` clause could be used instead of the `OPTIMIZE FOR` clause to ensure that only 50 rows are retrieved as in the following example:

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT * FROM X.RMT_TAB
  FETCH FIRST 50 ROWS ONLY;
```

Example 7: Assume that table `DSN8A10.EMP` has 1000 rows and you want to see the first five `EMP_ROWID` values that were inserted into `DSN8A10.EMP_PHOTO_RESUME`.

```
EXEC SQL DECLARE CS1 CURSOR FOR
  SELECT EMP_ROWID
  FROM FINAL TABLE (INSERT INTO DSN8A10.EMP_PHOTO_RESUME (EMPNO)
                     SELECT EMPNO FROM DSN8A10.EMP)
  FETCH FIRST 5 ROWS ONLY;
```

All 1000 rows are inserted into `DSN8A10.EMP_PHOTO_RESUME`, but only the first five are returned.

Chapter 7. Statements

This section contains syntax diagrams, semantic descriptions, rules, and examples of the use of the SQL statements.

Table 146. SQL statements

| SQL statement | Function | Topic |
|----------------------------------|--|---|
| ALLOCATE CURSOR | Defines and associates a cursor with a result set locator variable | "ALLOCATE CURSOR" on page 1159 |
| ALTER DATABASE | Changes the description of a database | "ALTER DATABASE" on page 1161 |
| ALTER FUNCTION (external) | Changes the description of a user-defined external scalar or table function | "ALTER FUNCTION (external)" on page 1164 |
| ALTER FUNCTION (SQL scalar) | Changes the description of an SQL scalar function | "ALTER FUNCTION (compiled SQL scalar)" on page 1183 |
| ALTER FUNCTION (SQL table) | Changes the description of an SQL table function | "ALTER FUNCTION (SQL table)" on page 1219 |
| ALTER INDEX | Changes the description of an index | "ALTER INDEX" on page 1227 |
| ALTER MASK | Changes the description of a column mask | "ALTER MASK" on page 1246 |
| ALTER PERMISSION | Changes the description of a row permission. | "ALTER PERMISSION" on page 1248 |
| ALTER PROCEDURE (external) | Changes the description of an external procedure | "ALTER PROCEDURE (external)" on page 1250 |
| ALTER PROCEDURE (SQL - external) | Changes the description of an external SQL procedure | "ALTER PROCEDURE (SQL - external)" on page 1261 |
| ALTER PROCEDURE (SQL - native) | Changes the description of or defines additional versions for a native SQL procedure | "ALTER PROCEDURE (SQL - native)" on page 1267 |
| ALTER SEQUENCE | Changes the description of a sequence | "ALTER SEQUENCE" on page 1295 |
| ALTER STOGROUP | Changes the description of a storage group | "ALTER STOGROUP" on page 1301 |
| ALTER TABLE | Changes the description of a table | "ALTER TABLE" on page 1304 |
| ALTER TABLESPACE | Changes the description of a table space | "ALTER TABLESPACE" on page 1389 |
| ALTER TRUSTED CONTEXT | Changes the description of a trusted context | "ALTER TRUSTED CONTEXT" on page 1412 |
| ALTER TRIGGER | Changes the description of a trigger. | "ALTER TRIGGER" on page 1409 |
| ALTER VIEW | Regenerates a view | "ALTER VIEW" on page 1424 |
| ASSOCIATE LOCATORS | Gets the result set locator value for each result set returned by a stored procedure | "ASSOCIATE LOCATORS" on page 1426 |
| BEGIN DECLARE SECTION | Marks the beginning of a host variable declaration section | "BEGIN DECLARE SECTION" on page 1430 |
| CALL | Calls a stored procedure | "CALL" on page 1432 |

Table 146. SQL statements (continued)

| SQL statement | Function | Topic |
|-----------------------------------|---|--|
| CLOSE | Closes a cursor | "CLOSE" on page 1444 |
| COMMENT | Replaces or adds a comment to the description of an object | "COMMENT" on page 1446 |
| COMMIT | Ends a unit of recovery and commits the database changes made by that unit of recovery | "COMMIT" on page 1456 |
| CONNECT | Connects the process to a server | "CONNECT" on page 1459 |
| CREATE ALIAS | Defines an alias | "CREATE ALIAS" on page 1466 |
| CREATE AUXILIARY TABLE | Defines an auxiliary table for storing LOB data | "CREATE AUXILIARY TABLE" on page 1469 |
| CREATE DATABASE | Defines a database | "CREATE DATABASE" on page 1473 |
| CREATE FUNCTION (external scalar) | Defines a user-defined external scalar function | "CREATE FUNCTION (external scalar)" on page 1501 |
| CREATE FUNCTION (external table) | Defines a user-defined external table function | "CREATE FUNCTION (external table)" on page 1526 |
| CREATE FUNCTION (sourced) | Defines a user-defined function that is based on an existing scalar or aggregate function | "CREATE FUNCTION (sourced)" on page 1555 |
| CREATE FUNCTION (SQL scalar) | Defines a user-defined SQL scalar function | "CREATE FUNCTION (compiled SQL scalar)" on page 1477 |
| CREATE FUNCTION (SQL table) | Defines a user-defined SQL table function | "CREATE FUNCTION (SQL table)" on page 1569 |
| CREATE GLOBAL TEMPORARY TABLE | Defines a created temporary table | "CREATE GLOBAL TEMPORARY TABLE" on page 1579 |
| CREATE INDEX | Defines an index on a table | "CREATE INDEX" on page 1585 |
| CREATE MASK | Defines a column mask | "CREATE MASK" on page 1617 |
| CREATE PERMISSION | Defines a row permission. | "CREATE PERMISSION" on page 1628 |
| CREATE PROCEDURE (external) | Defines an external stored procedure | "CREATE PROCEDURE (external)" on page 1637 |
| CREATE PROCEDURE (SQL - external) | Defines an external SQL procedure | "CREATE PROCEDURE (SQL - external)" on page 1656 |
| CREATE PROCEDURE (SQL - native) | Defines a native SQL procedure | "CREATE PROCEDURE (SQL - native)" on page 1668 |
| CREATE ROLE | Defines a role | "CREATE ROLE" on page 1692 |
| CREATE SEQUENCE | Defines a sequence | "CREATE SEQUENCE" on page 1693 |
| CREATE STOGROUP | Defines a storage group | "CREATE STOGROUP" on page 1701 |
| CREATE SYNONYM | Defines an alternate name for a table or view | "CREATE SYNONYM" on page 1704 |

Table 146. SQL statements (continued)

| SQL statement | Function | Topic |
|--------------------------------|--|---|
| CREATE TABLE | Defines a table | "CREATE TABLE" on page 1706 |
| CREATE TABLESPACE | Defines a table space, which includes allocating and formatting the table space | "CREATE TABLESPACE" on page 1775 |
| CREATE TRIGGER | Defines a trigger | "CREATE TRIGGER" on page 1802 |
| CREATE TRUSTED CONTEXT | Defines a trusted context | "CREATE TRUSTED CONTEXT" on page 1820 |
| CREATE TYPE | Defines a type (user-defined data type) | "CREATE TYPE (distinct)" on page 1830 |
| CREATE VIEW | Defines a view of one or more tables or views | "CREATE VIEW" on page 1838 |
| DECLARE CURSOR | Defines an SQL cursor | "DECLARE CURSOR" on page 1846 |
| DECLARE GLOBAL TEMPORARY TABLE | Defines a declared temporary table | "DECLARE GLOBAL TEMPORARY TABLE" on page 1858 |
| DECLARE STATEMENT | Declares names used to identify prepared SQL statements | "DECLARE STATEMENT" on page 1872 |
| DECLARE TABLE | Provides the programmer and the precompiler with a description of a table or view | "DECLARE TABLE" on page 1873 |
| DECLARE VARIABLE | Defines a CCSID for a host variable | "DECLARE VARIABLE" on page 1880 |
| DELETE | Deletes one or more rows from a table | "DELETE" on page 1883 |
| DESCRIBE CURSOR | Puts information about the result set associated with a cursor into a descriptor | "DESCRIBE CURSOR" on page 1900 |
| DESCRIBE INPUT | Puts information about the input parameter markers of a prepared statement into a descriptor | "DESCRIBE INPUT" on page 1902 |
| DESCRIBE OUTPUT | Describes the result columns of a prepared statement | "DESCRIBE OUTPUT" on page 1905 |
| DESCRIBE PROCEDURE | Puts information about the result sets returned by a stored procedure into a descriptor | "DESCRIBE PROCEDURE" on page 1912 |
| DESCRIBE TABLE | Describes the columns of a table or view | "DESCRIBE TABLE" on page 1915 |
| DROP | Deletes objects | "DROP" on page 1918 |
| END DECLARE SECTION | Marks the end of a host variable declaration section | "END DECLARE SECTION" on page 1938 |
| EXCHANGE | Exchanges data between the specified base table and an associated clone table | "EXCHANGE" on page 1939 |
| EXECUTE | Executes a prepared SQL statement | the EXECUTE statement |
| EXECUTE IMMEDIATE | Prepares and executes an SQL statement | "EXECUTE IMMEDIATE" on page 1945 |
| EXPLAIN | Obtains information about how an SQL statement would be executed | "EXPLAIN" on page 1948 |
| FETCH | Positions the cursor, returns data, or both positions the cursor and returns data | "FETCH" on page 1957 |

Table 146. SQL statements (continued)

| SQL statement | Function | Topic |
|--|---|---|
| FREE LOCATOR | Removes the association between a LOB locator variable and its value | "FREE LOCATOR" on page 1983 |
| GET DIAGNOSTICS | Provides diagnostic information about the last SQL statement that was executed | "GET DIAGNOSTICS" on page 1984 |
| GRANT | The GRANT statement grants privileges to authorization IDs. There is a separate form of the statement for each of the classes of privilege. | "GRANT" on page 2000 |
| GRANT (collection privileges) | Grants authority to create a package in a collection | "GRANT (collection privileges)" on page 2004 |
| GRANT (database privileges) | Grants privileges on a database | "GRANT (database privileges)" on page 2005 |
| GRANT (type or JAR file privileges) | Grants the usage privilege on a type (user-defined data type) or a JAR file | "GRANT (type or JAR file privileges)" on page 2030 |
| GRANT (function or procedure privileges) | Grants privileges on a user-defined function or a stored procedure | "GRANT (function or procedure privileges)" on page 2008 |
| GRANT (package privileges) | Grants authority to bind, execute, or copy a package | "GRANT (package privileges)" on page 2013 |
| GRANT (plan privileges) | Grants authority to bind or execute an application plan | "GRANT (plan privileges)" on page 2016 |
| GRANT (schema privileges) | Grants privileges on a schema | "GRANT (schema privileges)" on page 2017 |
| GRANT (sequence privileges) | Grants privileges on a user-defined sequence | "GRANT (sequence privileges)" on page 2019 |
| GRANT (system privileges) | Grants system privileges | "GRANT (system privileges)" on page 2020 |
| GRANT (table or view privileges) | Grants privileges on a table or view | "GRANT (table or view privileges)" on page 2026 |
| GRANT (use privileges) | Grants authority to use specified buffer pools, storage groups, or table spaces | "GRANT (use privileges)" on page 2032 |
| HOLD LOCATOR | Allows a LOB locator variable to retain its association with its value beyond a unit of work | "HOLD LOCATOR" on page 2034 |
| INCLUDE | Inserts declarations into a source program | "INCLUDE" on page 2036 |
| INSERT | Inserts one or more rows into a table | "INSERT" on page 2038 |
| LABEL | Replaces or adds a label on the description of a table, view, alias, or column | "LABEL" on page 2058 |
| LOCK TABLE | Locks a table or table space partition in shared or exclusive mode | "LOCK TABLE" on page 2060 |
| MERGE | Updates and/or inserts one or more rows of a table | "MERGE" on page 2063 |
| OPEN | Opens a cursor | "OPEN" on page 2077 |
| PREPARE | Prepares an SQL statement (with optional parameters) for execution | "PREPARE" on page 2083 |
| REFRESH TABLE | Refreshes the data in a materialized query table | "REFRESH TABLE" on page 2105 |
| RELEASE (connection) | Places one or more connections in the release pending status | "RELEASE (connection)" on page 2107 |

Table 146. SQL statements (continued)

| SQL statement | Function | Topic |
|---|---|--|
| RELEASE SAVEPOINT | Releases a savepoint and any subsequently set savepoints within a unit of recovery | "RELEASE SAVEPOINT" on page 2109 |
| RENAME | Renames an existing table or index | "RENAME" on page 2110 |
| REVOKE | Revokes privileges from authorization IDs. There is a separate form of the statement for each of the classes of privilege | "REVOKE" on page 2115 |
| REVOKE (collection privileges) | Revokes authority to create a package in a collection | "REVOKE (collection privileges)" on page 2122 |
| REVOKE (database privileges) | Revokes privileges on a database | "REVOKE (database privileges)" on page 2124 |
| REVOKE (type or JAR file privileges) | Revokes the usage privilege on a type (user-defined data type) or a JAR file | "REVOKE (type or JAR file privileges)" on page 2154 |
| REVOKE (function or procedure privileges) | Revokes privileges on a user-defined function or a stored procedure | "REVOKE (function or procedure privileges)" on page 2127 |
| REVOKE (package privileges) | Revokes authority to bind, execute, or copy a package | "REVOKE (package privileges)" on page 2134 |
| REVOKE (plan privileges) | Revokes authority to bind or execute an application plan | "REVOKE (plan privileges)" on page 2137 |
| REVOKE (schema privileges) | Revokes privileges on a schema | "REVOKE (schema privileges)" on page 2139 |
| REVOKE (sequence privileges) | Revokes privileges on a user-defined sequence | "REVOKE (sequence privileges)" on page 2142 |
| REVOKE (system privileges) | Revokes system privileges | "REVOKE (system privileges)" on page 2144 |
| REVOKE (table or view privileges) | Revokes privileges on a table or view | "REVOKE (table or view privileges)" on page 2150 |
| REVOKE (use privileges) | Revokes authority to use specified buffer pools, storage groups, or table spaces | "REVOKE (use privileges)" on page 2157 |
| ROLLBACK | Ends a unit of recovery and backs out the changes to the database made by that unit of recovery, or partially rolls back the changes to a savepoint within the unit of recovery | "ROLLBACK" on page 2160 |
| SAVEPOINT | Sets a savepoint within a unit of recovery | "SAVEPOINT" on page 2163 |
| SELECT | Specifies the SELECT statement of the cursor | "SELECT" on page 2165 |
| SELECT INTO | Specifies a result table of no more than one row and assigns the values to host variables | "SELECT INTO" on page 2166 |
| SET CONNECTION | Establishes the database server of the process by identifying one of its existing connections | "SET CONNECTION" on page 2170 |
| SET CURRENT APPLICATION ENCODING SCHEME | Assigns a value to the CURRENT APPLICATION ENCODING SCHEME special register | "SET CURRENT APPLICATION ENCODING SCHEME" on page 2173 |
| SET CURRENT DEBUG MODE | Assigns a value to the CURRENT DEBUG MODE special register | "SET CURRENT DEBUG MODE" on page 2174 |
| SET CURRENT DECFLOAT ROUNDING MODE | Assigns a value to the CURRENT DECFLOAT ROUNDING MODE special register | "SET CURRENT DECFLOAT ROUNDING MODE" on page 2176 |

Table 146. SQL statements (continued)

| SQL statement | Function | Topic |
|---|---|--|
| SET CURRENT DEGREE | Assigns a value to the CURRENT DEGREE special register | "SET CURRENT DEGREE" on page 2178 |
| SET CURRENT EXPLAIN MODE | Assigns a value to the CURRENT EXPLAIN MODE special register | "SET CURRENT EXPLAIN MODE" on page 2180 |
| SET CURRENT LOCALE LC_CTYPE | Assigns a value to the CURRENT LOCALE LC_CTYPE special register | "SET CURRENT LOCALE LC_CTYPE" on page 2183 |
| SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION | Assigns a value to the CURRENT MAINTAINED TABLE TYPES FOR MAINTAINED TABLE TYPES special register | "SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION" on page 2185 |
| SET CURRENT OPTIMIZATION HINT | Assigns a value to the CURRENT OPTIMIZATION HINT special register | "SET CURRENT OPTIMIZATION HINT" on page 2187 |
| SET CURRENT PACKAGE PATH | Assigns a value to the CURRENT PACKAGE PATH special register | "SET CURRENT PACKAGE PATH" on page 2188 |
| SET CURRENT PACKAGESET | Assigns a value to the CURRENT PACKAGESET special register | "SET CURRENT PACKAGESET" on page 2192 |
| SET CURRENT PRECISION | Assigns a value to the CURRENT PRECISION special register | "SET CURRENT PRECISION" on page 2194 |
| SET CURRENT REFRESH AGE | Assigns a value to the CURRENT REFRESH AGE special register | "SET CURRENT REFRESH AGE" on page 2197 |
| SET CURRENT ROUTINE VERSION | Assigns a value to the CURRENT ROUTINE VERSION special register | "SET CURRENT ROUTINE VERSION" on page 2199 |
| SET CURRENT RULES | Assigns a value to the CURRENT RULES special register | "SET CURRENT RULES" on page 2201 |
| SET CURRENT SQLID | Assigns a value to the CURRENT SQLID special register | "SET CURRENT SQLID" on page 2202 |
| SET ENCRYPTION PASSWORD | Assign a value for the ENCRYPTION PASSWORD and an optional hint for the password | "SET ENCRYPTION PASSWORD" on page 2204 |
| SET host-variable Assignment | Assigns values to host variables | "SET host-variable assignment" on page 2206 |
| SET PATH | Assigns a value to the CURRENT PATH special register | "SET PATH" on page 2209 |
| SET SCHEMA | Assigns a value to the CURRENT SCHEMA special register | "SET SCHEMA" on page 2212 |
| SET transition-variable Assignment | Assigns values to transition variables | "SET transition-variable assignment" on page 2216 |
| SIGNAL | Signals an error or warning condition and optionally returns the specified message text | "SIGNAL statement" on page 2294 |
| TRUNCATE | Deletes all rows from a table | "TRUNCATE" on page 2220 |
| UPDATE | Updates the values of one or more columns in one or more rows of a table | "UPDATE" on page 2224 |
| VALUES | Provides a way to invoke a user-defined function from a trigger | "VALUES" on page 2244 |
| VALUES INTO | Assigns values to host variables | "VALUES INTO" on page 2245 |
| WHENEVER | Defines actions to be taken on the basis of SQL return codes | "WHENEVER" on page 2248 |

How SQL statements are invoked

SQL statements are invoked in different ways depending on whether the statement is an executable or nonexecutable statement or the *select-statement*.

The SQL statements are classified as *executable* or *nonexecutable*. The description of each statement includes a heading on invocation that indicates whether or not the statement is executable.

Executable statements can be invoked in the following ways:

- Embedded in an application program
- Dynamically prepared and executed
- Dynamically prepared and executed using DB2 ODBC function calls
- Issued interactively

Depending on the statement, you can use some or all of these methods. The section on invocation in the description of each statement tells you which methods can be used.

A *nonexecutable statement* can only be embedded in an application program.

The *select-statement* is an additional SQL statement construct. (See “select-statement” on page 1131.) It is used in a different way from other statements.

A *select-statement* can be invoked in the following ways:

- Included in DECLARE CURSOR and implicitly executed by OPEN
- Dynamically prepared, referred to in DECLARE CURSOR, and implicitly executed by OPEN
- Dynamically executed (no PREPARE required) using a DB2 ODBC function call
- Issued interactively

The first two methods are called, respectively, the *static* and the *dynamic* invocation of *select-statement*.

 Overview of programming applications that access DB2 for z/OS data (DB2 Application programming and SQL)

Embedding a statement in an application program

You can include SQL statements in a source program that will be submitted to the DB2 precompiler or coprocessor. Such statements are said to be *embedded* in the application program. An embedded statement can be placed anywhere in the application program where a host language statement is allowed. Each embedded statement must be preceded by a keyword (or keywords) to indicate that the statement is an SQL statement.

- In C and COBOL, each embedded statement must be preceded by the keywords EXEC SQL.
- In Java, each embedded statement must be preceded by the keywords #sql.
- In REXX, each embedded statement must be preceded by the keyword EXECSQL.

Executable statements: An executable statement embedded in an application program is executed every time a statement of the host language would be executed if specified in the same place. (Thus, for example, a statement within a loop is executed every time the loop is executed, and a statement within a conditional construct is executed only when the condition is satisfied.)

An embedded statement can contain references to host variables. A host variable referred to in this way can be used in one of two ways:

As input

The current value of the host variable is used in the execution of the statement.

As output

The variable is assigned a new value as a result of executing the statement.

In particular, all references to host variables in expressions and predicates are effectively replaced by current values of the variables; that is, the variables are used as input. The treatment of other references is described individually for each statement.

The successful or unsuccessful execution of the statement is indicated by setting the SQLCODE and SQLSTATE fields in the SQLCA.²³ You must therefore follow all executable statements by a test of SQLCODE or SQLSTATE. Alternatively, you can use the WHENEVER statement (which is itself nonexecutable) to change the flow of control immediately after the execution of an embedded statement.

Nonexecutable statements: An embedded nonexecutable statement is processed only by the precompiler or coprocessor. The precompiler or coprocessor reports any errors encountered in the statement. The statement is never executed, and acts as a no-operation if placed among executable statements of the application program. Therefore, do not follow such statements with a test of an SQL return code.

Dynamic preparation and execution

Your application program can dynamically build an SQL statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, input from a workstation).

In non-Java languages, the statement so constructed can be prepared for execution by means of the (embedded) statement PREPARE and executed by means of the (embedded) statement EXECUTE, as described in *DB2 Application Programming and SQL Guide*. Alternatively, you can use the (embedded) statement EXECUTE IMMEDIATE to prepare and execute a statement in one step. In Java, the statement

23. SQLCODE and SQLSTATE cannot be in the SQLCA when the SQL processing option STDSQL(YES) is in effect. See "SQL standard language" on page 313.

can be prepared for execution by means of the Statement, PreparedStatement, and CallableStatement classes, and executed by means of their respective execute() methods.

The statement can also be prepared by calling the DB2 ODBC SQLPrepare function and then executed by calling the DB2 ODBC SQLExecute function. In both cases, the application does not contain an embedded PREPARE or EXECUTE statement. You can execute the statement, without preparation, by passing the statement to the DB2 ODBC SQLExecDirect function. *DB2 ODBC Guide and Reference* describes the APIs supported with this interface.

A statement that is going to be prepared must not contain references to host variables. It can instead contain parameter markers. (See Parameter markers in the description of the PREPARE statement for rules concerning parameter markers.) When the prepared statement is executed, the parameter markers are effectively replaced by current values of the host variables specified in the EXECUTE statement. (See the EXECUTE statement for rules concerning this replacement.) After it is prepared, a statement can be executed several times with different values of host variables. Parameter markers are not allowed in the SQL statement prepared and executed using EXECUTE IMMEDIATE.

In non-Java languages, the successful or unsuccessful execution of the statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the EXECUTE (or EXECUTE IMMEDIATE) statement. You should check the fields as described above for embedded statements. In Java, the successful or unsuccessful execution of the statement is handled by Java Exceptions.

As explained in “Authorization IDs and dynamic SQL” on page 75, the DYNAMICRULES behavior in effect determines the privilege set that is used for authorization checking when dynamic SQL statements are processed. The following table summarizes those privilege sets. (See Table 6 on page 75 for a list of the DYNAMICRULES bind option values that determine which behavior is in effect).

Table 147. DYNAMICRULES behaviors and authorization checking

| DYNAMICRULES behavior | Privilege set |
|------------------------------|---|
| Run behavior | The union of the set of privileges held by each authorization ID of the process if the dynamically prepared statement is other than an ALTER, CREATE, DROP, GRANT, RENAME, or REVOKE statement. The privileges that are held by the SQL authorization ID of the process or the role of the primary authorization ID (if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER clause), if the dynamic SQL statement is a CREATE, GRANT, or REVOKE statement. |
| Bind behavior | The privileges that are held by the primary authorization ID of the owner of the package or plan. |
| Define behavior | The privileges that are held by the authorization ID of the stored procedure or user-defined function owner (definer). |

Table 147. DYNAMICRULES behaviors and authorization checking (continued)

| DYNAMICRULES behavior | Privilege set |
|-----------------------|--|
| Invoke behavior | The privileges that are held by the authorization ID of the stored procedure or user-defined function invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked if they are needed for the required authorization. Therefore, in that case, the privilege set is the union of the set of privileges that are held by each authorization ID or role (if running in a trusted context). |

Static invocation of a SELECT statement

A SELECT statement can be invoked statically in different ways.

You can include a SELECT statement as a part of the (nonexecutable) statement DECLARE CURSOR. Such a statement is executed every time you open the cursor by means of the (embedded) statement OPEN. After the cursor is open, you can retrieve the result table a row at a time by successive executions of the (embedded) SQL FETCH statement.

If the application is using DB2 ODBC, the SELECT statement is first prepared with the SQLPrepare function call. It is then executed with the SQLExecute function call. Data is then fetched with the SQLFetch function call. The application does not explicitly open the cursor.

The SELECT statement used in this way can contain references to host variables. These references are effectively replaced by the values that the variables have at the moment of executing OPEN.

The successful or unsuccessful execution of the SELECT statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the OPEN. You should check the fields as described above for embedded statements.

If the application is using DB2 ODBC, the successful execution of the SELECT statement is indicated by the return code from the SQLExecute function call. If necessary, the application can retrieve the SQLCA by calling the SQLGetSQLCA function.

Dynamic invocation of a SELECT statement

Your application program can dynamically build a SELECT statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, a query obtained from a terminal).

The statement so constructed can be prepared for execution by means of the (embedded) statement PREPARE, and referred to by a (nonexecutable) statement DECLARE CURSOR. The statement is then executed every time you open the cursor by means of the (embedded) statement OPEN. After the cursor is open, you can retrieve the result table a row at a time by successive executions of the (embedded) SQL FETCH statement.

The SELECT statement used in that way must not contain references to host variables. It can instead contain parameter markers. (See "Notes" in "PREPARE" on page 2083 for rules concerning parameter markers.) The parameter markers are

effectively replaced by the values of the host variables specified in the OPEN statement. (See “OPEN” on page 2077 for rules concerning this replacement.)

The successful or unsuccessful execution of the SELECT statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the OPEN. You should check the fields as described above for embedded statements.

Interactive invocation

An SQL statement submitted to DB2 from a terminal is said to be issued interactively.

IBM relational database management systems allow you to enter SQL statements from a terminal. DB2 for z/OS provides SPUFI to prepare and execute SQL statements. Other products are also available. A statement entered in this way is said to be issued interactively.

A statement issued interactively must not contain parameter markers or references to host variables, because these make sense only in the context of an application program. For the same reason, there is no SQLCA involved.

SQL diagnostics information

DB2 uses a diagnostics area to store status information and diagnostics information about the execution of an executable SQL statement.

When an SQL statement other than GET DIAGNOSTICS or *compound-statement* is processed, the current diagnostics area is cleared before processing the SQL statement. As each SQL statement is processed, information about the execution of that SQL statement is recorded in the current diagnostics area as one or more completion conditions or exception conditions.

A completion condition indicates that the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the statement was not successful. The GET DIAGNOSTICS statement can be executed in most languages to return conditions and other information about the previously executed SQL statement from the diagnostics area. Additionally, the condition information is provided through language specific mechanisms for SQL procedures, and host language applications.

Related concepts:

“Detecting and processing error and warning conditions in host language applications” on page 1156

Related reference:

“GET DIAGNOSTICS” on page 1984

“SQL-procedure-statement” on page 2256

Detecting and processing error and warning conditions in host language applications

Errors and warnings conditions in host language applications can be checked by using the `SQLCODE` or `SQLSTATE` host variables or by using the `SQLCA`.

Each host language provides a mechanism for handling diagnostic information.

- In Assembler, C, COBOL, Fortran, and PL/I, an application program that contains executable SQL statements must provide at least one of the following:
 - A structure named `SQLCA`, which can be provided by using the `INCLUDE SQLCA` statement
 - A stand-alone `CHAR(5)` (`CHAR(6)` in C) variable named `SQLSTATE` (`SQLSTT` in Fortran)
 - A stand-alone integer variable named `SQLCODE` (`SQLCOD` in Fortran)
- In Java, for error conditions, the `getSQLState` method of the JDBC `SQLException` class can be used to get the `SQLSTATE` and the `getErrorCode` method can be used to get the `SQLCODE`.
- In REXX, an `SQLCA` is provided automatically.

Whether you define stand-alone `SQLCODE` and `SQLSTATE` host variables or an `SQLCA` in your program depends on the DB2 precompiler option you choose.

If the application is using DB2 ODBC and it calls the `SQLGetSQLCA` function, it need only include an `SQLCA`. Otherwise, all notification of success or errors is specified with return codes for the various function calls.

When you specify `STDSQL(YES)`, which indicates conformance to the SQL standard, you should not define an `SQLCA`. The stand-alone variable for `SQLCODE` must be a valid host variable in the `DECLARE SECTION` of a program. It can also be declared outside of the `DECLARE SECTION` when no variable is defined for `SQLSTATE`. The stand-alone variable for `SQLSTATE` must be declared in the `DECLARE SECTION`. It must not be declared as an element of a structure.

Use a stand-alone `SQLSTATE` to conform with the SQL 2003 Core standard. When you specify `STDSQL(NO)`, which indicates conformance to DB2 rules, you must include an `SQLCA` explicitly to have access to the `SQLSTATE` and `SQLCODE` information.

SQLSTATE

DB2 sets `SQLSTATE` after each SQL statement (other than `GET DIAGNOSTICS` or a compound statement) is executed. DB2 returns values that conform to the error specification in the SQL standard. Thus, application programs can check the execution of SQL statements by testing `SQLSTATE` instead of `SQLCODE`.

`SQLSTATE` provides application programs with common codes for common error conditions (the values of `SQLSTATE` are product-specific if the error or warning is product-specific). Furthermore, `SQLSTATE` is designed so that application programs can test for specific errors or classes of errors. The coding scheme is the same for all IBM implementations of SQL. The `SQLSTATE` values are based on the `SQLSTATE` specifications contained in the SQL standard. Error messages and the tokens that are substituted for variables in error messages are associated with `SQLCODE` values, not `SQLSTATE` values.

In the case of a LOOP statement, the SQLSTATE is set after the END LOOP portion of the LOOP statement completes. With the REPEAT statement, the SQLSTATE is set after the UNTIL and END REPEAT portions of the REPEAT statement completes.

If the application is using DB2 ODBC, the SQLSTATE returned conforms to the ODBC Version 2.0 specification.

SQLCODE

The SQLCODE is also set by DB2 after each SQL statement is executed as follows:

DB2 conforms to the SQL standard as follows:

- If SQLCODE = 0 and SQLWARN0 is blank, execution was successful.
- If SQLCODE = 100, "no data" was found. For example, a FETCH statement returned no data because the cursor was positioned after the last row of the result table.
- If SQLCODE > 0 and not = 100, execution was successful with a warning.
- If SQLCODE = 0 and SQLWARN0 = 'W', execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.

In the case of a LOOP statement, the SQLSTATE is set after the END LOOP portion of the LOOP statement completes. With the REPEAT statement, the SQLSTATE is set after the UNTIL and END REPEAT portions of the REPEAT statement completes.

The SQL standard does not define the meaning of any other specific positive or negative values of SQLCODE, and the meaning of these values is not the same in all implementations of SQL.

If the application is using DB2 ODBC, an SQLCODE is only returned if the application issues the SQLGetSQLCA function.

SQL comments

Static SQL statements can include host language or SQL comments. Dynamic SQL statements can include SQL comments. There are two types of SQL comments, simple comments and bracketed comments.

simple comments

Simple comments are introduced with two consecutive hyphens (--) and end with the end of a line. The following rules apply to the use of simple comments:

- The two hyphens must be on the same line and must not be separated by a space.
- Simple comments can be started whenever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Simple comments cannot be continued to the next line.
- In COBOL, the hyphen must be preceded by a space.

bracketed comments

Bracketed comments are introduced with /* and end with */. The following rules apply to the use of bracketed comments:

- The /* must be on the same line and not separated by a space.
- The */ must be on the same line and not separated by a space.
- Bracketed comments can be started wherever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Bracketed comments can be continued to the next line.
- Bracketed comments can be nested within other bracketed comments. However, nested bracketed comments are not supported by DSNTEP2, DSNTEP4, SPUFI, or the command line processor.
- Bracketed comments are not allowed in static SQL statements in a COBOL, Fortran, or Assembler program.

Example: This example shows how to include comments in an SQL statement within a C program. The example uses both simple and bracketed comments:

```
EXEC SQL
  CREATE VIEW PRJ_MAXPER          --projects with most support personnel
  /*
   * Returns number and name of the project
   */
  AS SELECT PROJNO, PROJNAME     -- number and name of project
     FROM DSN8910.PROJ
  /*
   * E21 is the systems support dept code
   */
  WHERE DEPTNO = 'E21'          -- systems support dept code
  AND PRSTAFF > 1;
```

For information about host language comments, refer to *DB2 Application Programming and SQL Guide*.

ALLOCATE CURSOR

The `ALLOCATE CURSOR` statement defines a cursor and associates it with a result set locator variable.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

Authorization

None required.

Syntax

```
▶▶—ALLOCATE—cursor-name—CURSOR FOR RESULT SET—rs-locator-variable—▶▶
```

Description

cursor-name

Names the cursor. The name must not identify a cursor that has already been declared in the source program.

CURSOR FOR RESULT SET *rs-locator-variable*

Specifies a result set locator variable that has been declared in the application program according to the rules for declaring result set locator variables.

The result set locator variable must contain a valid result set locator value, as returned by the `ASSOCIATE LOCATORS` or `DESCRIBE PROCEDURE SQL` statement. The value of the result set locator variable is used at the time the cursor is allocated. Subsequent changes to the value of the result set locator have no affect on the allocated cursor. The result set locator value must not be the same as a value used for another cursor allocated in the source program.

Notes

Dynamically prepared ALLOCATE CURSOR statements: The `EXECUTE` statement with the `USING` clause must be used to execute a dynamically prepared `ALLOCATE CURSOR` statement. In a dynamically prepared statement, references to host variables are represented by parameter markers (question marks). In the `ALLOCATE CURSOR` statement, *rs-locator-variable* is always a host variable. Thus, for a dynamically prepared `ALLOCATE CURSOR` statement, the `USING` clause of the `EXECUTE` statement must identify the host variable whose value is to be substituted for the parameter marker that represents *rs-locator-variable*.

You cannot prepare an `ALLOCATE CURSOR` statement with a statement identifier that has already been used in a `DECLARE CURSOR` statement. For example, the following SQL statements are invalid because the `PREPARE` statement uses `STMT1` as an identifier for the `ALLOCATE CURSOR` statement and `STMT1` has already been used for a `DECLARE CURSOR` statement.

```
DECLARE CURSOR C1 FOR STMT1;  
PREPARE STMT1 FROM          INVALID  
  'ALLOCATE C2 CURSOR FOR RESULT SET ?';
```

Rules for using an allocated cursor: The following rules apply when you use an allocated cursor:

- You cannot open an allocated cursor with the OPEN statement.
- You can close an allocated cursor with the CLOSE statement. Closing an allocated cursor closes the associated cursor defined in the stored procedure.
- You can allocate only one cursor to each result set.

The life of an allocated cursor: A rollback operation, an implicit close, or an explicit close destroy allocated cursors. A commit operation destroys allocated cursors that are not defined WITH HOLD by the stored procedure. Destroying an allocated cursor closes the associated cursor defined in the stored procedure.

Considerations for scrollable cursors: Following an ALLOCATE CURSOR statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see “GET DIAGNOSTICS” on page 1984):

- DB2_SQL_ATTR_CURSOR_HOLD. Whether the cursor was defined with the WITH HOLD attribute.
- DB2_SQL_ATTR_CURSOR_SCROLLABLE. Scrollability of the cursor.
- DB2_SQL_ATTR_CURSOR_SENSITIVITY. Effective sensitivity of the cursor. The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.
- DB2_SQL_ATTR_CURSOR_ROWSET. Whether the cursor can be used to access rowsets.
- DB2_SQL_ATTR_CURSOR_TYPE. Whether a cursor type is forward-only, static, or dynamic.

In addition, if subsystem parameter DISABSCL is set to NO, a subset of the above information is returned in the SQLCA:

- The scrollability of the cursor is in SQLWARN1.
- The sensitivity of the cursor is in SQLWARN4.
- The effective capability of the cursor is in SQLWARN5.

Example

The statement in the following example is assumed to be in a PL/I program.

Define and associate cursor C1 with the result set locator variable *LOC1* and the related result set returned by the stored procedure:

```
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :LOC1;
```

ALTER DATABASE

The ALTER DATABASE statement changes the description of a database at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

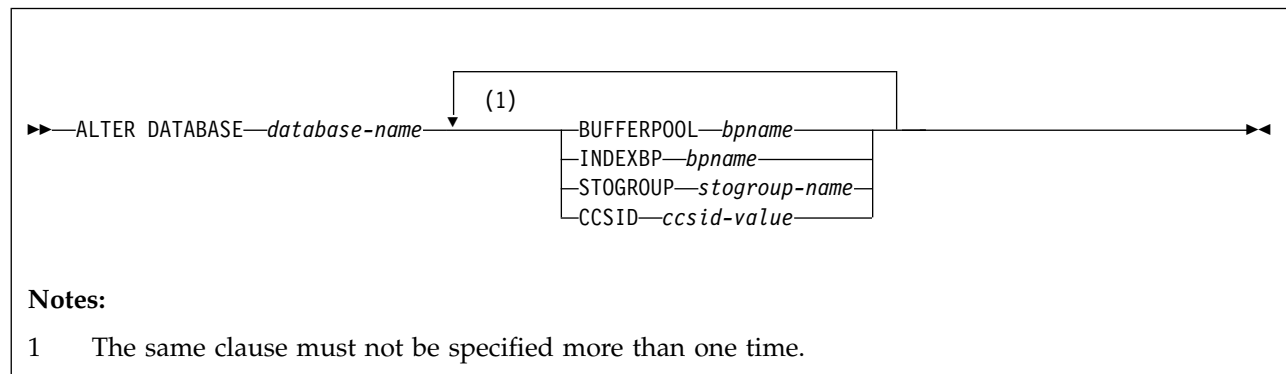

The privilege set that is defined below must include at least one of the following:

- The DROP privilege on the database
- Ownership of the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

Description

DATABASE *database-name*

Identifies the database that is to be altered. The name must identify a database that exists at the current server and must not identify an implicitly created system database.

BUFFERPOOL *bpname*

Identifies the default buffer pool for the table spaces within the database. It does not apply to table spaces that already exist within the database.

If the database is a work file database, 8 KB and 16 KB buffer pools cannot be specified.

See “Naming conventions” on page 59 for more details about *bpname*.

INDEXBP *bpname*

Identifies the default buffer pool for the indexes within the database. It does not apply to indexes that already exist within the database. The name can identify a 4 KB, 8 KB, 16 KB, or 32 KB buffer pool. See “Naming conventions” on page 59 for more details about *bpname*.

STOGROUP *stogroup-name*

Identifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. It does not apply to table spaces and indexes that already exist within the database.

CCSID *ccsid-value*

Identifies the default CCSID for table spaces within the database. It does not apply to existing table spaces in the database. *ccsid-value* must identify a CCSID value that is compatible with the current value of the CCSID for the database. “Notes” contains a list that shows the CCSID to which a given CCSID can be altered.

CCSID cannot be specified for a work file database.

Notes

Altering the CCSID: The ability to alter the default CCSID enables you to change to a CCSID that supports the Euro symbol. You can only convert between specific CCSIDs that do and do not define the Euro symbol. In most cases, the code point that supports the Euro symbol replaces an existing code point, such as the International Currency Symbol (ICS).

Changing a CCSID can be disruptive to the system and requires several steps. For each encoding scheme of a system (ASCII, EBCDIC, and Unicode), DB2 supports SBCS, DBCS, and mixed CCSIDs. Therefore, the CCSIDs for all databases and all table spaces within an encoding scheme should be altered at the same time. Otherwise, unpredictable results might occur.

The recommended method for changing the CCSID requires that the data be unloaded and reloaded. See *DB2 Installation Guide* for the steps needed to change the CCSID, such as running an installation CLIST to modify the CCSID data in DSNHDECP, when to drop and re-create views, and when to rebind invalidated packages.

The following lists show the CCSIDs that can be converted. The second CCSID in each pair is the CCSID with the Euro symbol. The CCSID can be changed from the CCSID that does not support the Euro symbol to the CCSID that does, and vice versa. For example, if the current CCSID is 500, it can be changed to 1148.

EBCDIC CCSIDs

| | |
|-----|------|
| 37 | 1140 |
| 273 | 1141 |
| 277 | 1142 |
| 278 | 1143 |
| 280 | 1144 |
| 284 | 1145 |
| 285 | 1146 |
| 297 | 1147 |
| 500 | 1148 |
| 871 | 1149 |

ASCII CCSIDs

| | |
|------|------|
| 850 | 858 |
| 874 | 4970 |
| 1250 | 5346 |
| 1251 | 5347 |
| 1252 | 5348 |
| 1253 | 5349 |
| 1254 | 5350 |
| 1255 | 5351 |
| 1256 | 5352 |
| 1257 | 5353 |

Example

Change the default buffer pool for both table spaces and indexes within database ABCDE to BP2.

```
ALTER DATABASE ABCDE
  BUFFERPOOL BP2
  INDEXBP BP2;
```

ALTER FUNCTION (external)

The ALTER FUNCTION statement changes the description of a user-defined external scalar function or external table function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has installation SYSADM authority, the function is identified as system-defined function when the function definition is reevaluated.

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

For *external scalar functions*, when LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

If the environment in which the function is to be run is being changed, the authorization ID must have authority to use the WLM environment specified. The required authorization is obtained from an external security product, such as RACF.

Syntax

parameter-type:

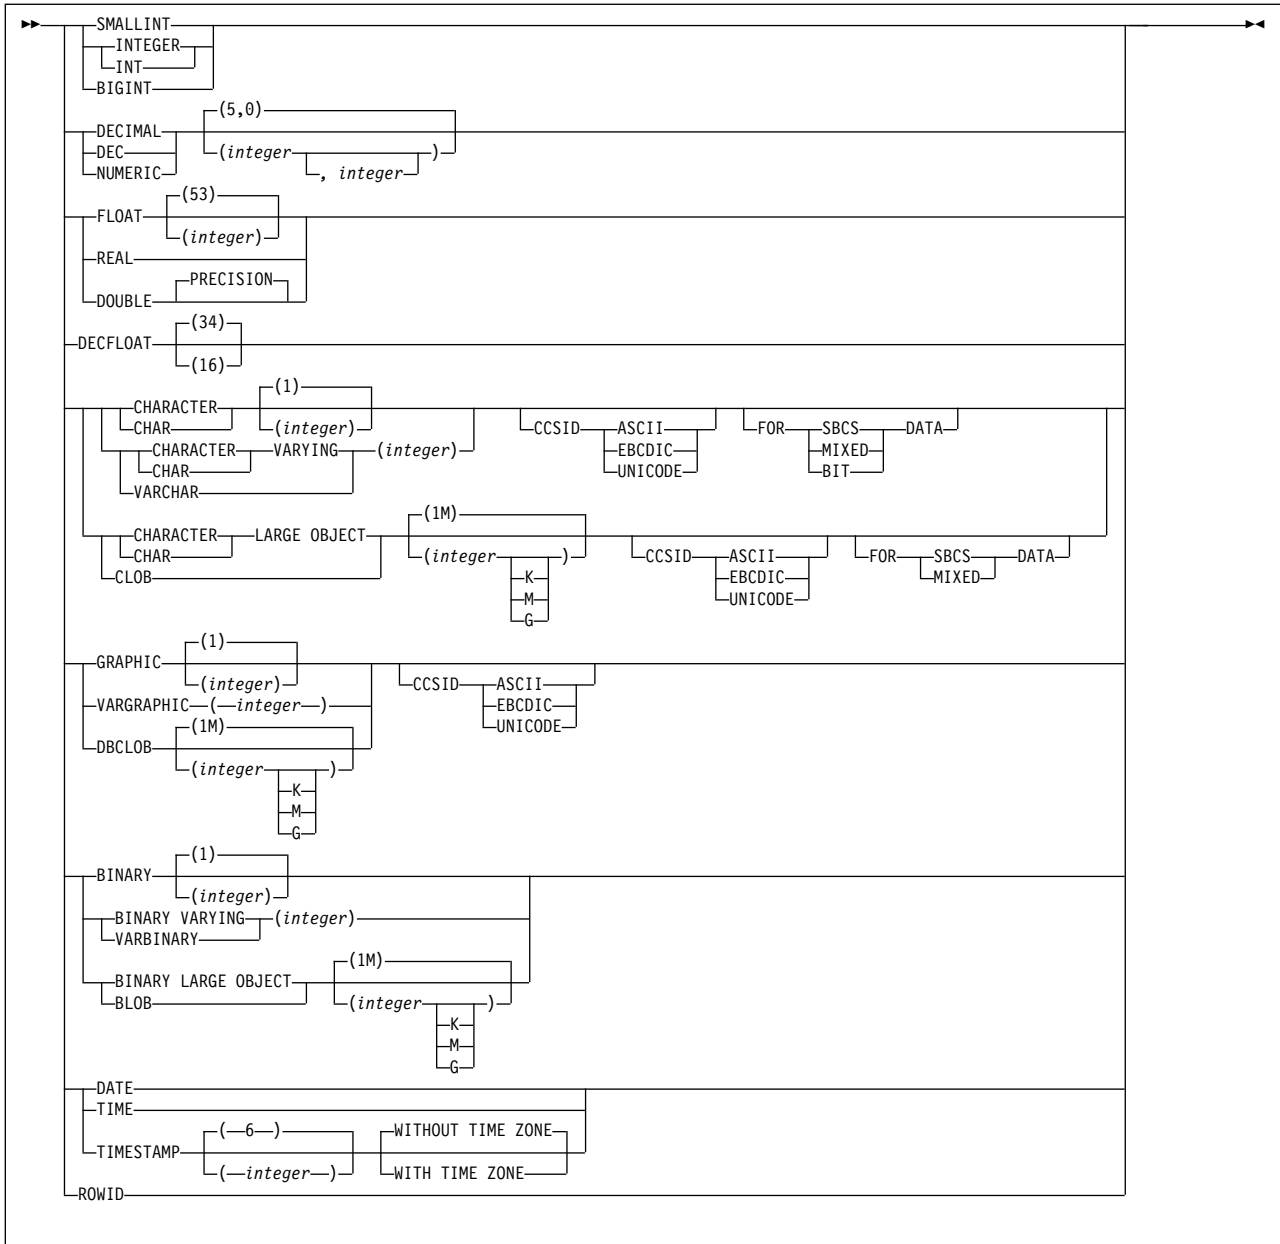

Notes:

- 1 **AS LOCATOR** can be specified only for a LOB data type or a distinct type based on a LOB data type.

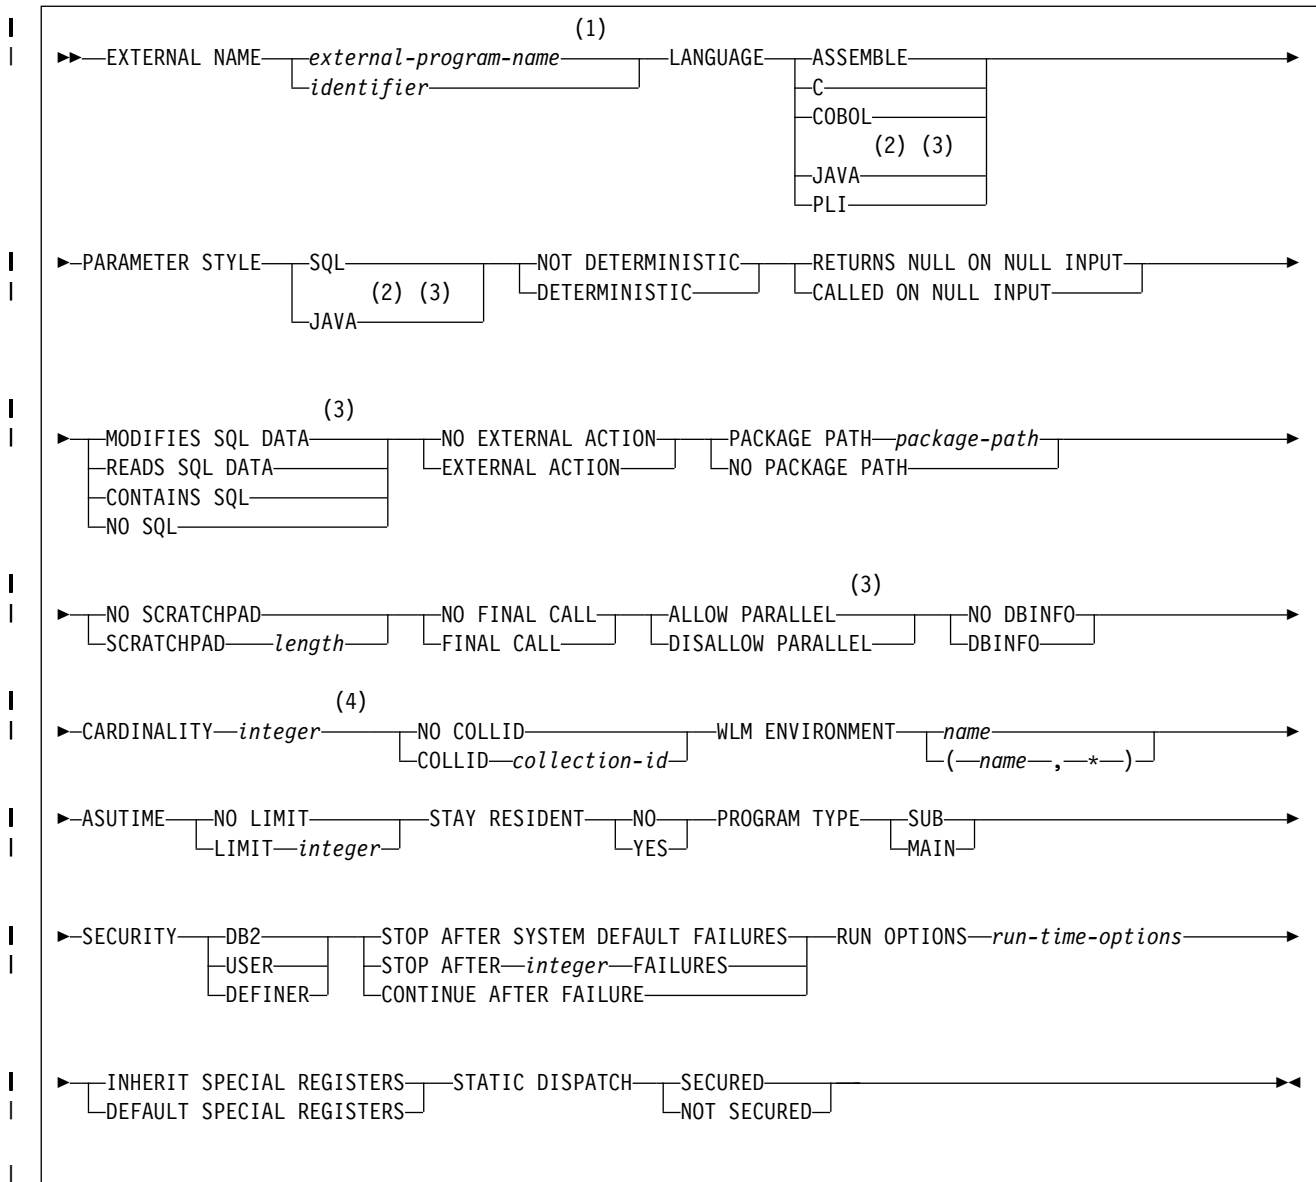

data-type:

built-in-type:

option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

Notes:

- 1 If **LANGUAGE** is **JAVA**, **EXTERNAL NAME** must be specified with a valid *external-java-routine-name*.
- 2 When **LANGUAGE JAVA** is specified, **PARAMETER STYLE JAVA** must also be specified. When **PARAMETER STYLE JAVA** is specified, **LANGUAGE JAVA** must also be specified.
- 3 **LANGUAGE JAVA**, **PARAMETER STYLE JAVA**, **MODIFIES SQL DATA**, and **ALLOW PARALLEL** are not supported for *external table functions*.
- 4 **CARDINALITY** is not supported for *external scalar functions*.

external-java-routine-name:

jar-name:

method-name:

method-signature:

Notes:

- 1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

Description

One of the following three clauses identifies the function to be changed.

FUNCTION *function-name*

Identifies the external function by its function name. *function-name* must identify a function that exists at the current server. The function must be a user-defined external function, and there must be exactly one function with *function-name* in the schema.

The function can have any number of input parameters. If the schema does not contain a function with *function-name* or contains more than one function with this name, an error occurs.

FUNCTION *function-name* (*parameter-type*,...)

Identifies the external function by its function signature, which uniquely identifies the function.

function-name

Identifies the function by its name.

If *function-name()* is specified, the function that is identified must have zero parameters.

(parameter-type,...)

Identifies the number of input parameters of the function and their data types.

The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

If the function was defined with a table parameter (the **LIKE TABLE name AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.

For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

The specific value for FLOAT(*n*) does not have to exactly match the defined value of the source function because $1 \leq n \leq 21$ indicates REAL and $22 \leq n \leq 53$ indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the **FOR subtype DATA** clause or the **CCSID** clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See “CREATE FUNCTION” on page 1476 for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

SPECIFIC FUNCTION *specific-name*

Identifies the external function by its specific name. A function with the specific name must exist in the schema.

The following clauses change the description of the function that has been identified to be changed.

EXTERNAL NAME *external-program-name* **or** *identifier*

Identifies the user-written code (program) that runs when the function is invoked.

If **LANGUAGE** is **JAVA**, *external-program-name* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *external-program-name* values are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a Java function for which **NO SQL** is in effect.

An *external-java-routine-name* contains the following parts:

jar-name

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the **QUALIFIER** option of the **BIND** subcommand for a package or plan when the package or plan was created or last changed. The schema name can also be the authorization ID in the **QUALIFIER** option of the **CREATE PROCEDURE** or **ALTER PROCEDURE** statement for a native SQL procedure when the procedure was created or last changed. If the **QUALIFIER** is not specified, the schema name is the owner of the package, plan, or native SQL procedure.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the **CURRENT SCHEMA** special register.

If *jar-name* is specified, it must exist when the **ALTER FUNCTION** statement is processed.

If *jar-name* is not specified, the function is loaded from the class file directly. DB2 searches the directories in the **CLASSPATH** associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a **JAVAENV** DD card on the JCL used to start the address space for a WLM-managed function.

method-name

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method IDs are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what method IDs can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

class-id

Identifies the class identifier of the Java object.

method-id

Identifies the method identifier with the Java class to be invoked.

method-signature

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the user-defined function involves any input or output parameters that can be NULL. When the function that is being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements that are specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER FUNCTION statement.

For other values of **LANGUAGE**, the value must conform to the naming conventions for load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

LANGUAGE

Specifies the application programming language in which the function is written. All programs must be designed to run in IBM's Language Environment environment.

ASSEMBLE

The function is written in Assembler.

C The function is written in C or C++.

COBOL

The function is written in COBOL, including the object-oriented language extensions.

JAVA

The user-defined function is written in Java and is executed in the Java virtual machine. If the ALTER FUNCTION statement results in changing **LANGUAGE** to **JAVA**, **PARAMETER STYLE JAVA** and an **EXTERNAL NAME** clause must be specified to provide the appropriate values. When **LANGUAGE JAVA** is specified, the **EXTERNAL NAME** clause must also be specified with a valid *external-java-routine-name* and **PARAMETER STYLE** must be specified with **JAVA**.

Do not specify **LANGUAGE JAVA** when **SCRATCHPAD**, **FINAL CALL**, **DBINFO**, **PROGRAM TYPE MAIN**, or **RUN OPTIONS** is specified. Do not specify **LANGUAGE JAVA** for a table function.

PLI

The function is written in PL/I.

PARAMETER STYLE

Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

SQL

Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- Input parameters. The first n parameters are the input parameters that are specified for the function.
- Result parameters. For an external scalar function, a parameter for the result of the function. For an external table function, the next m parameters that are specified on the RETURNS TABLE clause of the CREATE statement that defined the function.
- Input parameter indicator variables. n parameters for the indicator variables for the input parameters.
- Result parameter indicator variables. For an external scalar function, a parameter for the indicator variable for the result of the function that is specified on the RETURNS clause of the CREATE statement that defined the function. For an external table function, m parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause of the CREATE statement that defined the function.
- The SQLSTATE to be returned to DB2.
- The qualified name of the function.
- The specific name of the function.
- The SQL diagnostic string to be returned to DB2.
- The scratchpad, if **SCRATCHPAD** is specified.
- The call type. For an external scalar function, the call type is passed only if **FINAL CALL** is specified. The call type is always passed for an external table function.
- The DBINFO structure, if **DBINFO** is specified.

JAVA

Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications. If the ALTER FUNCTION statement results in changing **LANGUAGE** to **JAVA**, **PARAMETER STYLE JAVA** and an **EXTERNAL NAME** clause must be specified to provide the appropriate values. **PARAMETER STYLE JAVA** can be specified only if **LANGUAGE** is **JAVA**. **JAVA** must be specified for **PARAMETER STYLE** when **LANGUAGE** is **JAVA**.

Do not specify **PARAMETER STYLE JAVA** for a table function.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

Some SQL functions that invoke functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the **DISALLOW PARALLEL** clause for these functions.

If a view or a materialized query table definition refers to the function, the function cannot be changed to **NOT DETERMINISTIC**. To change the function, drop any views or materialized query tables that refer to the function first.

DETERMINISTIC

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON NULL INPUT

The function is not called if any of the input arguments is null. For an external scalar function, the result is the null value. For an external table function, the result is an empty table, which is a table with no rows.

CALLED ON NULL INPUT

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. For an external scalar function, the function can return a null or nonnull value. For an external table function, the function can return an empty table, depending on its logic.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function.

MODIFIES SQL DATA

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify **MODIFIES SQL DATA** when **ALLOW PARALLEL** is in effect.

READS SQL DATA

Specifies that the function can execute statements with a data access indication of **READS SQL DATA**, **CONTAINS SQL**, or **NO SQL**. The function cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data classification of **CONTAINS SQL** or **NO SQL**. SQL statements that neither read nor modify SQL data can be executed by the function. Statements that are not supported in any function return a different error.

NO SQL

Specifies that the function can execute only SQL statements with a data access classification of **NO SQL**. Do not specify **NO SQL** for a Java function that uses a JAR file.

NO EXTERNAL ACTION or EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for external functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **NO EXTERNAL ACTION** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the **DISALLOW PARALLEL** clause for functions that do not work correctly with parallelism.

If you specify **EXTERNAL ACTION**, DB2:

- Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify **EXTERNAL ACTION** if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared **WITH HOLD**.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

If a view or a materialized query table definition refers to the function, the function cannot be changed to **EXTERNAL ACTION**. To change the function, drop any views or materialized query tables that refer to the function first.

DB2 does not verify that the function program is consistent with the specification of **EXTERNAL ACTION** or **NO EXTERNAL ACTION**.

NO PACKAGE PATH or PACKAGE PATH *package-path*

Identifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM that is associated with the function is bound.

NO PACKAGE PATH

Specifies that the list of package collections for the function is the same as

the list of package collections for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as used in the SET CURRENT PACKAGE PATH statement.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The *package-path* value that is associated with the function definition is checked when the function is invoked. If *package-path* contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

NO SCRATCHPAD or SCRATCHPAD

Specifies whether DB2 is to provide a scratchpad for the function. Using reentrant external functions and a scratchpad (which provides an area for the function to save information from one invocation to the next) is strongly recommended.

NO SCRATCHPAD

A scratchpad is not allocated and passed to the function.

SCRATCHPAD *length*

When the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- *length* must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00').
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad.

For example, assuming that user-defined function UDFX is a scalar function that is defined with the SCRATCHPAD option, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```
SELECT A, UDFX(A) FROM TABLEB
WHERE UDFX(A) > 103 OR UDFX(A) < 19;
```

For another example, assume that UDFX is a user-defined table function that is defined with the SCRATCHPAD option. Two scratchpads are allocated for the two references to function UDFX in the following SQL statement:

```
SELECT *
FROM TABLE (UDFX(A)), TABLE (UDFX(B));
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2

initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.

- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify **FINAL CALL** to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time that the function is invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify **SCRATCHPAD**, DB2:

- Does not move the function from one TCB or address space to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

Do not specify **SCRATCHPAD** when **LANGUAGE JAVA** is specified.

NO FINAL CALL or FINAL CALL

Specifies whether a final call is made to the function. A *final call* enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the **SCRATCHPAD** keyword and the function acquires system resource and anchors them in the scratchpad.

The effect of **NO FINAL CALL** or **FINAL CALL** depends on whether the external function is a scalar function or a table function.

For an external scalar function:

NO FINAL CALL

A final call is not made to the external scalar function. The function does not receive an additional argument that specifies the type of call.

FINAL CALL

A final call is made to the external scalar function. See the following description of call types for the characteristics of a final call. When **FINAL CALL** is specified, the function receives an additional argument that specifies the type of call to enable the function to differentiate between a final call and another type of call. Do not specify **FINAL CALL** when **LANGUAGE JAVA** is specified.

For more information on **NO FINAL CALL** and **FINAL CALL** for external scalar functions, including the types of calls, see the description of the option for "CREATE FUNCTION (external scalar)" on page 1501.

For an external table function:

NO FINAL CALL

A first and final call are not made to the external table function.

FINAL CALL

A first call and final call are made to the external table function in addition to one or more other types of calls.

For both **NO FINAL CALL** and **FINAL CALL**, the function receives an additional argument that specifies the type of call. For more information on

NO FINAL CALL and FINAL CALL for external table functions, including the types of calls, see the description of the option for “CREATE FUNCTION (external table)” on page 1526.

ALLOW or DISALLOW PARALLEL

Specifies whether, for a single reference to the function, the function can be executed in parallel. If the function is defined with **MODIFIES SQL DATA**, specify **DISALLOW PARALLEL**, not **ALLOW PARALLEL**.

ALLOW PARALLEL

Specifies that DB2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.

See **SCRATCHPAD**, **EXTERNAL ACTION**, and **FINAL CALL** for considerations when specifying **ALLOW PARALLEL**.

DISALLOW PARALLEL

Specifies that DB2 does not consider parallelism for the function.

NO DBINFO or DBINFO

Specifies whether additional status information is passed to the function when it is invoked.

NO DBINFO

Additional information is not passed.

DBINFO

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

Do not specify **DBINFO** when **LANGUAGE JAVA** is specified.

CARDINALITY *integer*

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of *integer* must range from 0 to 2147483647.

If a function has an infinite cardinality (which means that the function never returns the “end-of-table” condition and always returns a row), a query that requires the end-of-table condition to work correctly needs to be interrupted. Thus, avoid using such functions in queries that involve **GROUP BY** and **ORDER BY**.

Do not specify **CARDINALITY** for external scalar functions.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function is bound.

NO COLLID

Specifies the package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the **CURRENT PACKAGE PATH** special register, the **CURRENT PACKAGESET**

special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

COLLID *collection-id*

Specifies the name of the package collection that is to be used when the function is executed.

WLM ENVIRONMENT

An SQL identifier that identifies the *name* of the WLM (workload manager) application environment in which the function is to run.

name

The WLM environment in which the function must run. If the user-defined function is nested and if the calling stored procedure or invoking user-defined function is not running in an address space associated with the specified WLM environment, DB2 routes the function request to a different address space.

(name,)*

When an SQL application program calls the function, *name* specifies the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in the same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

The *name* of the WLM environment is an SQL identifier.

To change the environment in which the function is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the service units.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the load module for the function is to remain resident in memory when the function ends.

NO The load module is deleted from memory after the function ends. Use **NO** for non-reentrant functions.

YES

The load module remains resident in memory after the function ends. Use **YES** for reentrant functions.

PROGRAM TYPE

Specifies whether the function program runs as a main routine or a subroutine.

SUB

The function runs as a subroutine.

MAIN

The function runs as a main routine.

Do not specify **PROGRAM TYPE MAIN** when **LANGUAGE JAVA** is in effect.

SECURITY

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID associated with the WLM-established stored procedure address space.

USER

An external security environment should be used with the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

DEFINER

An external security environment should be used with the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures. The following options must not be specified for SQL functions or sourced functions.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS *run-time-options*

Specifies the Language Environment run time options to be used for the function. You must specify *run-time-options* as a character string that is no longer than 254 bytes. To replace any existing run time options with no options, specify an empty string with **RUN OPTIONS**. When you specify an

empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see *z/OS Language Environment Programming Reference*.

Do not specify **RUN OPTIONS** when **LANGUAGE JAVA** is specified.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in "Special registers in a user-defined function or a stored procedure" on page 199.

DEFAULT SPECIAL REGISTERS

Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in "Special registers in a user-defined function or a stored procedure" on page 199.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters.

SECURED or NOT SECURED

Specifies whether the function is considered secure.

SECURED

Specifies that the function is considered secure.

NOT SECURED

Specifies that the function is considered not secure. **NOT SECURED** must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

Notes

Invalidation of packages:

When an external function is altered, all the packages that refer to that function are marked invalid.

LANGUAGE C and the PARAMETER VARCHAR clause:

The **ALTER** statement does not allow you to alter the value of the **PARAMETER VARCHAR** or **PARAMETER CCSID** clauses that are associated with the function definition. However, you can alter the **LANGUAGE** clause for the function. If the **PARAMETER VARCHAR** clause is specified for the creation of a **LANGUAGE C** function, the catalog information for that option is not affected by a subsequent **ALTER** function statement. The function might be changed to a language other than **C**, in which case the **PARAMETER VARCHAR** setting is ignored. If the function is later changed back to **LANGUAGE C**, the setting of the **PARAMETER VARCHAR** option that was specified during the **CREATE FUNCTION** statement will be used.

Altering a function from NOT SECURED to SECURED:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function.

The function is considered secure after the ALTER FUNCTION statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

Altering a function from SECURED to NOT SECURED:

Packages and statements in the dynamic statement cache that reference the function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

Invoking other user-defined functions in a secure function:

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**
- NOT NULL CALL as a synonym for **RETURNS NULL ON NULL INPUT**
- NULL CALL as a synonym for **CALLED ON NULL INPUT**
- PARAMETER STYLE DB2SQL as a synonym for **PARAMETER STYLE SQL**
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Assume that two functions CENTER are in the PELLOW schema. The first function has two input parameters with INTEGER and FLOAT data types,

respectively. The specific name for the first function is FOCUS1. The second function has three parameters with CHAR(25), DEC(5,2), and INTEGER data types.

Using the specific name to identify the function, change the WLM environment in which the first function runs from WLMENVNAME1 to WLMENVNAME2:

```
ALTER SPECIFIC FUNCTION ENGLES.FOCUS1 WLM ENVIRONMENT WLMENVNAME2;
```

Example 2: Change the second function that is described in *Example 1* so that it is not invoked when any of the arguments are null. Use the function signature to identify the function:

```
ALTER FUNCTION ENGLES.CENTER (CHAR(25), DEC(5,2), INTEGER)  
  RETURNS NULL ON NULL INPUT;
```

You can also code the ALTER FUNCTION statement without the exact values for the CHAR and DEC data types:

```
ALTER FUNCTION ENGLES.CENTER (CHAR(), DEC(), INTEGER)  
  RETURNS NULL ON NULL INPUT;
```

If you use empty parentheses, DB2 is to ignore the length, precision, and scale attributes when looking for matching data types to find the function.

ALTER FUNCTION (compiled SQL scalar)

The ALTER FUNCTION (compiled SQL scalar) statement changes the description of a user-defined compiled SQL scalar function at the current server. The function options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER FUNCTION statement.

Invocation

This statement can only be dynamically prepared and the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has installation SYSADM authority, the function is identified as system-defined function when the function definition is reevaluated.

Additional privileges might be required in the following situations:

- If *SQL-routine-body* is specified, the privilege set must include the privileges that are required to execute the statements in *SQL-routine-body*.
- If a user-defined type is referenced (i.e. as the data type of an SQL variable in the body of the function), the privilege set must include at least one of the following:
 - Ownership of the distinct type
 - The USAGE privilege on the user-defined type
 - SYSADM authority
- If the function uses a table as a parameter, the privilege set must also include at least one of the following:
 - Ownership of the table
 - The SELECT privilege on the table
 - SYSADM authority
- If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, the privilege set must include the authority to define programs that run in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.
- When replacing an SQL scalar function, the privilege set must include the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL authority.

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

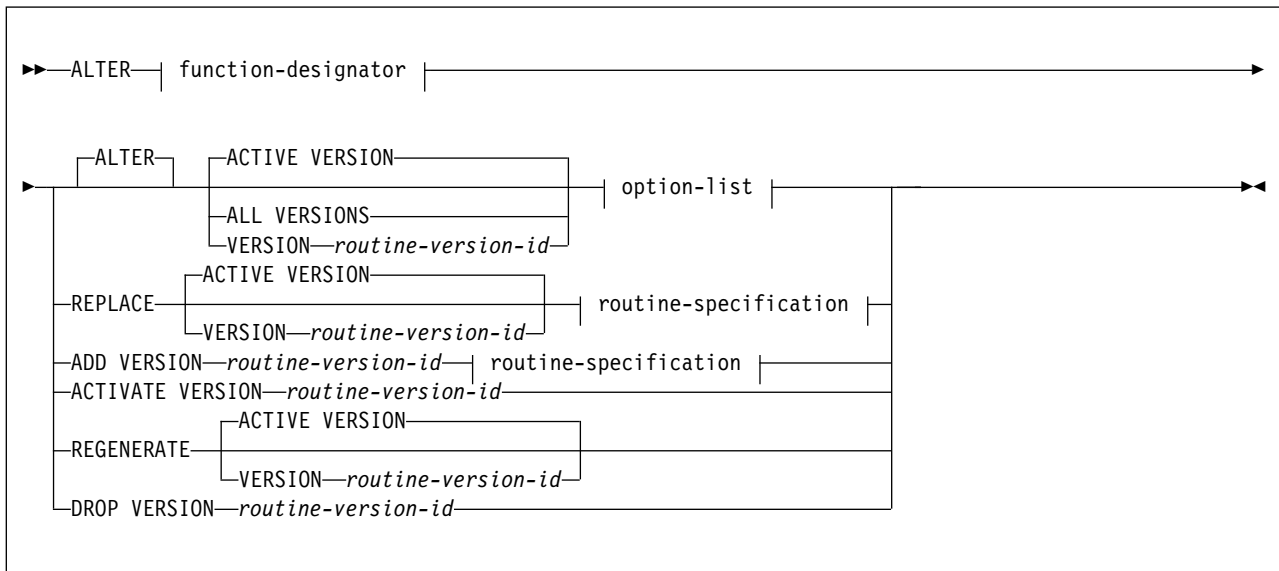

At least one of those privileges is also required if the function is currently secure and the ALTER ACTIVE VERSION, ALTER VERSION *routine-version-id*, ADD VERSION, or REPLACE clause is specified.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

Syntax

function-designator:

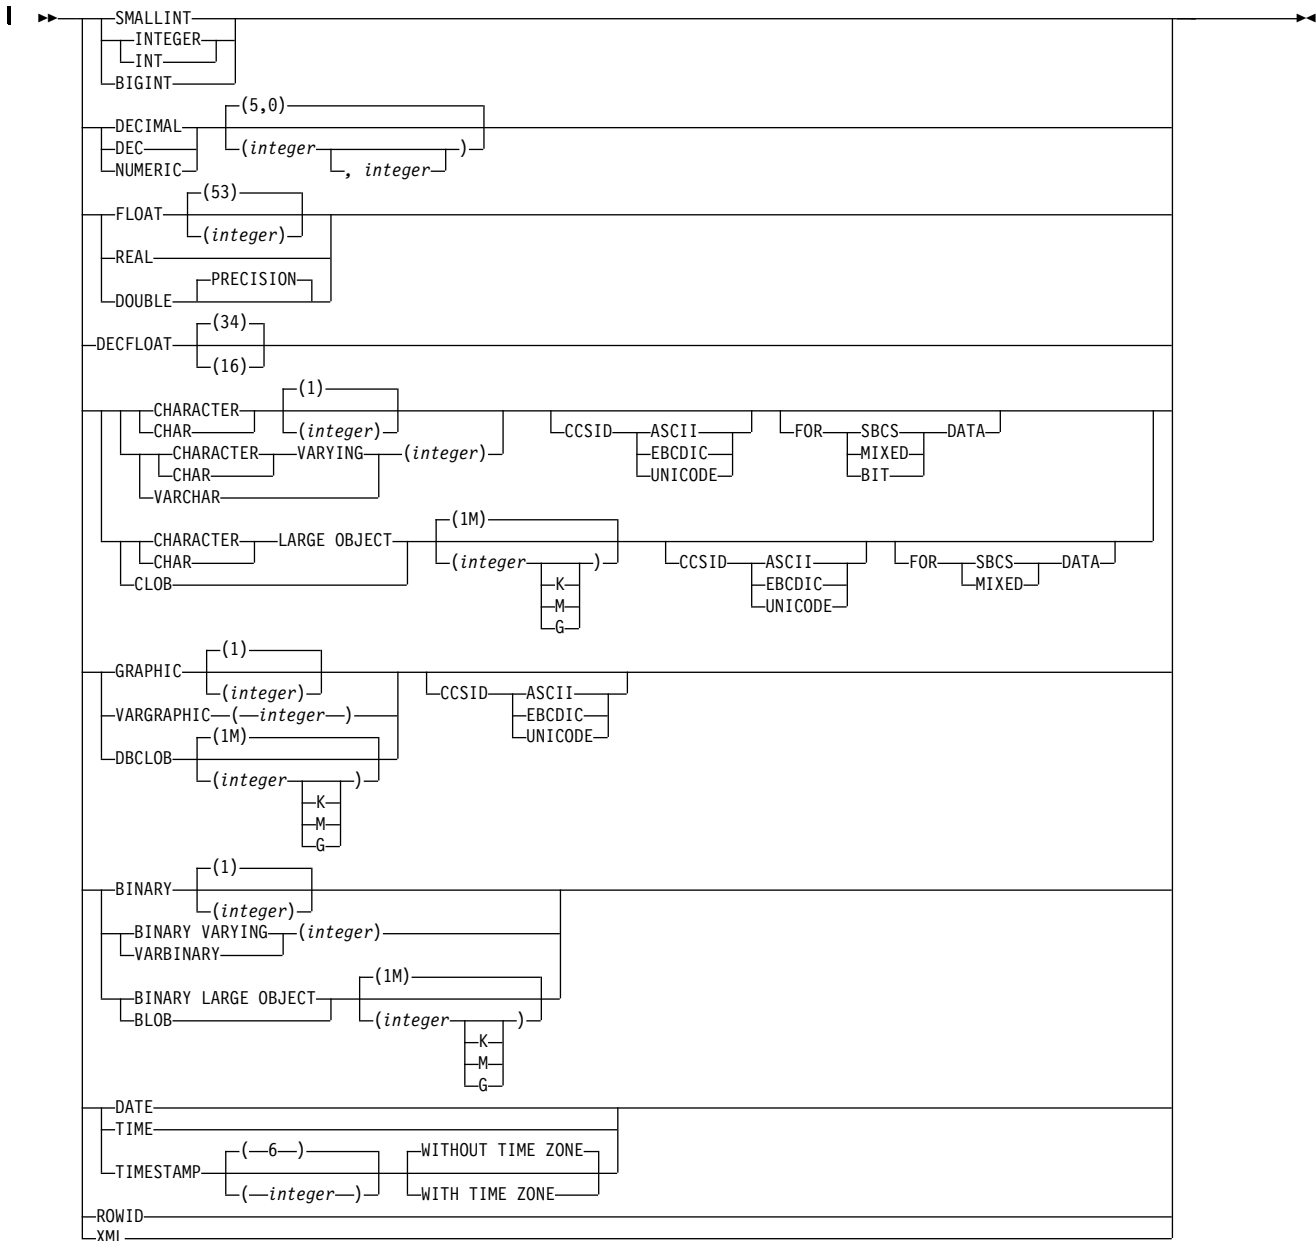

routine-specification:

data-type, data-type2:

built-in-type:

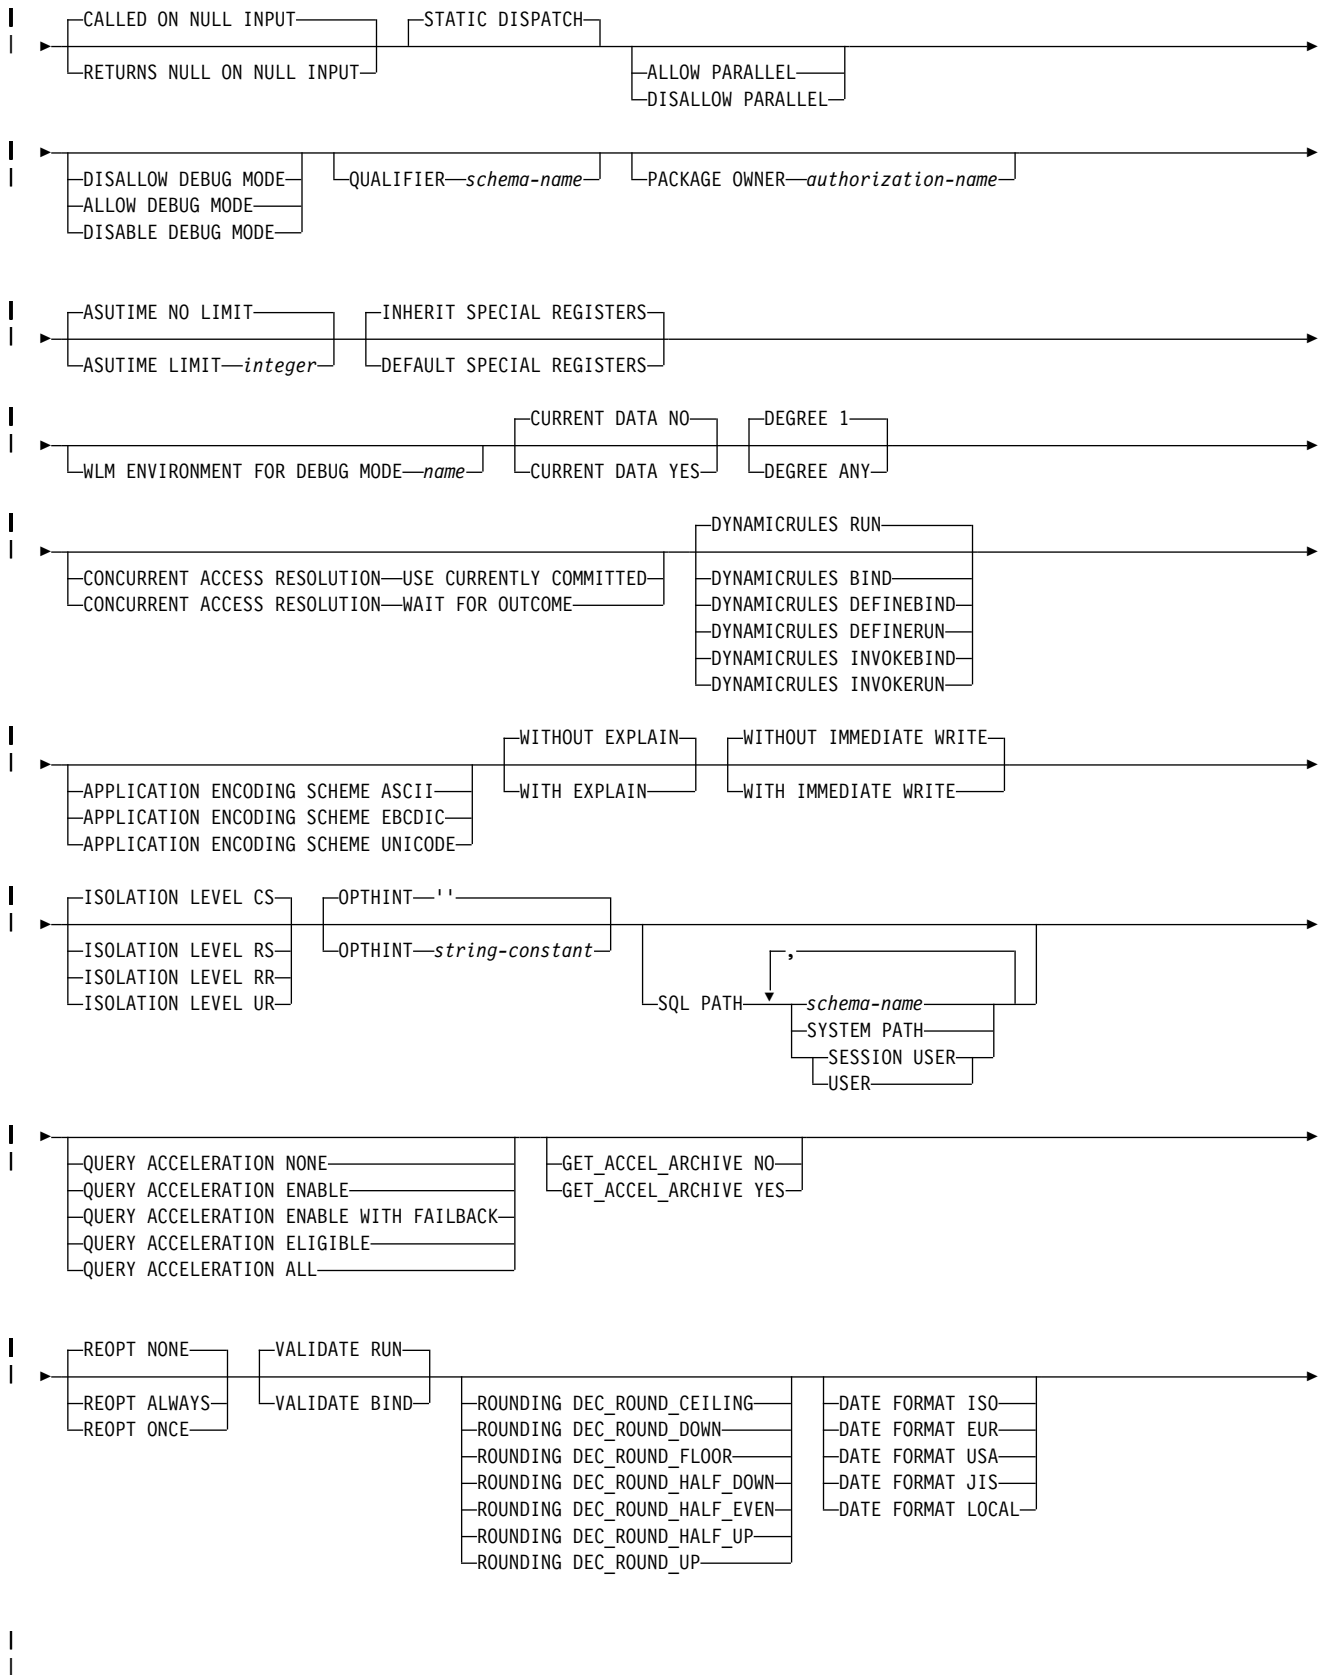

SQL-routine-body:

option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than one time.)

Notes:

- 1 Only LANGUAGE SQL, NOT DETERMINISTIC, DETERMINISTIC, EXTERNAL ACTION, NO EXTERNAL ACTION, CONTAINS SQL, READS SQL DATA, STATIC DISPATCH, and CALLED ON NULL INPUT can be specified for an inline SQL scalar function.

Description

One of the following three clauses identifies the function to be changed.

FUNCTION *function-name*

Identifies the SQL function by its function name.

The identified function must be an SQL scalar function. There must be exactly one function with *function-name* in the schema. The function can have any number of input parameters.²⁴ If the schema does not contain a function with *function-name* or contains more than one function with this name, an error occurs.

FUNCTION *function-name* (*parameter-type*,...)

Identifies the SQL function by its function signature, which uniquely identifies the function.

function-name

Gives the function name of the SQL function.

If *function-name*() is specified, the function that is identified must have zero parameters.

(*parameter-type*,...)

Specifies the number of input parameters of the function and the name and data type of each parameter.

If the function was defined with a table parameter (the **LIKE TABLE** *name* **AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

(*data-type*,...)

Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

24. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.

For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

The specific value for FLOAT(*n*) does not have to exactly match the defined value of the source function because 1<=*n*<= 21 indicates REAL and 22<=*n*<=53 indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the **FOR subtype DATA** clause or the **CCSID** clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See “CREATE FUNCTION” on page 1476 for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

SPECIFIC FUNCTION *specific-name*

Identifies a particular user-defined function by its specific name. The name is implicitly or explicitly qualified with a schema name. A compiled SQL scalar function with the specific name must exist in the schema. If the specific name is not qualified, it is implicitly qualified with a schema name as described in the description for **FUNCTION** *function-name*.

ALTER ACTIVE VERSION, ALL VERSIONS, or VERSION *routine-version-id*

Specifies that a version of the function is to be changed. When you change a function using **ALTER** option-list, any option that is not explicitly specified will use the existing value from the version of the function that is being changed.

ACTIVE VERSION, ALL VERSION or, VERSION *routine-version-id*

Identifies the version of the function that is to be changed.

ACTIVE VERSION

Specifies that the currently active version of the function is to be changed, replaced, or regenerated. If the function is secure, the changed, replaced, or regenerated version remains secure.

ACTIVE VERSION is the default.

ALL VERSIONS

Specifies that all of the versions of the function are to be changed. SECURED and NOT SECURED are the only options that can be changed when ALL VERSIONS is specified.

| **VERSION** *routine-version-id*

| Identifies the version of the function that is to be changed, replaced, or
| regenerated. *routine-version-id* is the version identifier that is assigned
| when the version of the function is defined. *routine-version-id* must
| identify a version of the specified function that exists at the current
| server. If the function is secure, the changed, replaced, or regenerated
| version remains secure.

| **REPLACE ACTIVE VERSION or VERSION** *routine-version-id*

| Specifies that a version of the function is to be replaced.

| Binding the replaced version of the function might result in a new access path
| even if the routine body is not being changed.

| When you replace a function, the data types, CCSID specifications, and
| character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters
| must be the same as the attributes of the corresponding parameters for the
| currently active version of the function. For options that are not explicitly
| specified, the system default values for those options are used, even if those
| options were explicitly specified for the version of the function that is being
| replaced. This is not the case for versions of the function that specified
| DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a
| version of a function, it cannot be changed by using the REPLACE clause.
| When a function definition is replaced, any existing comments in the catalog
| for that definition of the function are removed.

| **ACTIVE VERSION or VERSION** *routine-version-id*

| Identifies the version of the function that is to be replaced.

| **ACTIVE VERSION**

| Specifies that the currently active version of the function is to be
| changed, replaced, or regenerated. If the function is secure, the
| changed, replaced, or regenerated version remains secure.

| **ACTIVE VERSION** is the default.

| **VERSION** *routine-version-id*

| Identifies the version of the function that is to be changed, replaced, or
| regenerated. *routine-version-id* is the version identifier that is assigned
| when the version of the function is defined. *routine-version-id* must
| identify a version of the specified function that exists at the current
| server. If the function is secure, the changed, replaced, or regenerated
| version remains secure.

| **ADD VERSION** *routine-version-id*

| Specifies that a new version of the function is to be created. *routine-version-id* is
| the version identifier for the new version of the function. *routine-version-id*
| must not identify a version of the specified function that already exists at the
| current server.

| When a new version of a function is created, the comment that is recorded in
| the catalog for the new version will be the same as the comment that is in the
| catalog for the currently active version.

| When you add a new version of a function, the data types, CCSID
| specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of
| the parameters must be the same as the attributes of the corresponding
| parameters for the currently active version of the function. The parameter
| names can differ from the other versions of the function. For options that are
| not explicitly specified, the system default values will be used.

If the function is secure, the new version is considered secure.

ACTIVATE VERSION *routine-version-id*

Specifies the version of the function that is to be the currently active version. *routine-version-id* is the version identifier that is assigned when the version of the function is defined. The version that is specified with *routine-version-id* is the version that will be invoked by a function invocation. *routine-version-id* must identify a version of the function that exists at the current server.

REGENERATE ACTIVE VERSION or VERSION *routine-version-id*

Specifies that a version of the function is to be regenerated. When DB2 maintenance is applied that changes how an SQL function is generated, the function might need to be regenerated to process the changes from applying the maintenance.

REGENERATE automatically rebinds, at the current server, the package for the SQL control statements for the function and rebinds the package for the SQL statements that are included in the body of the function.

REGENERATE is different than the REBIND PACKAGE command. REBIND PACKAGE rebinds the SQL statements (usually to generate better access paths for those statement) but the SQL control statements in the function definition are not rebound.

When a function definition is regenerated, any existing comments in the catalog for that definition of the function are not removed.

ACTIVE VERSION or VERSION *routine-version-id*

Identifies the version of the function that is to be regenerated.

ACTIVE VERSION

Specifies that the currently active version of the function is to be changed, replaced, or regenerated. If the function is secure, the changed, replaced, or regenerated version remains secure.

ACTIVE VERSION is the default.

VERSION *routine-version-id*

Identifies the version of the function that is to be changed, replaced, or regenerated. *routine-version-id* is the version identifier that is assigned when the version of the function is defined. *routine-version-id* must identify a version of the specified function that exists at the current server. If the function is secure, the changed, replaced, or regenerated version remains secure.

DROP VERSION *routine-version-id*

Drops the version of the function that is identified with *routine-version-id*. *routine-version-id* is the version identifier that is assigned when the version is defined. *routine-version-id* must identify a version of the function that exists at the current server and must not identify the currently active version of the function. Only the identified version of the function is dropped.

When only a single version of the function exists at the current server, use the DROP FUNCTION statement to drop the function.

RETURNS

Identifies the output of the function.

data-type2

Specifies the data type of the output. The data type must match the data type that was specified in the RETURNS clause of the CREATE FUNCTION statement.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic.

DETERMINISTIC

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function.

If you specify **EXTERNAL ACTION**, DB2:

- Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify **EXTERNAL ACTION** if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with **EXTERNAL ACTION**.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **NO EXTERNAL ACTION** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **EXTERNAL ACTION** or **NO EXTERNAL ACTION**.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function.

MODIFIES SQL DATA

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify **MODIFIES SQL DATA** when **ALLOW PARALLEL** is in effect.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of **READS SQL DATA**, **CONTAINS SQL**, or **NO SQL**. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of **CONTAINS SQL** or **NO SQL**. The function cannot execute SQL statements the read or modify data.

CALLED ON NULL INPUT or RETURNS NULL ON NULL INPUT

Specifies whether the function is invoked if any of the input arguments is null at execution time.

CALLED ON NULL INPUT

Specifies that the function is to be invoked, if any, or all, argument values are null. This specification means that the body of the function must be coded to test for null argument values.

CALLED ON NULL INPUT is the default.

RETURNS NULL ON NULL INPUT

Specifies that the function is not invoked and returns the null value if any of the input arguments is null.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters.

STATIC DISPATCH is the default.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies if the function can be run in parallel. The default is **DISALLOW PARALLEL**, if you specify one or more of the following clauses:

- NOT DETERMINISTIC
- EXTERNAL ACTION

- MODIFIES SQL DATA

Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that the function can be run in parallel.

DISALLOW PARALLEL

Specifies that the function cannot be run in parallel.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE

Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

DISALLOW DEBUG MODE

Specifies that this version of the routine cannot be run in debugging mode.

You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

DISABLE DEBUG MODE

Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

QUALIFIER *schema-name*

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the procedure body. See “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67 for information about how the default for this option is determined.

PACKAGE OWNER *authorization-name*

Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

The authorization ID must have the privileges that are required to execute the SQL statements that are contained in the routine body and must contain the necessary bind privileges. The value of PACKAGE OWNER is subject to translation when it is sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process or the authorization ID of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID that contains the necessary bind privileges.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

Specifies that there is no limit on the service units.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 43 on page 199.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 43 on page 199.

WLM ENVIRONMENT FOR DEBUG MODE *name*

Specifies the WLM (workload manager) application environment that is used by DB2 when debugging the routine. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

CURRENT DATA YES or CURRENT DATA NO

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

CURRENT DATA YES

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquires page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

CURRENT DATA NO

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of **CURRENT DATA NO** is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

CURRENT DATA NO is the default.

DEGREE

Specifies whether to attempt to run a query using parallel processing to maximize performance.

1 Specifies that parallel processing should not be used.

1 is the default.

ANY

Specifies that parallel processing can be used.

CONCURRENT ACCESS RESOLUTION

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

WAIT FOR OUTCOME

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

DYNAMICRULES

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

RUN

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND

Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

DEFINERUN

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

INVOKEBIND

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

INVOKERUN

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See "Authorization IDs and dynamic SQL" on page 75 for information on the effects of these options.

APPLICATION ENCODING SCHEME

Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

ASCII

Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN

Specifies whether information will be provided about how SQL statements in the routine will execute.

WITHOUT EXPLAIN

Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN

Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table *owner.PLAN_TABLE*. *owner* is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as *owner.PLAN_TABLE* that points to the base table, *PLAN_TABLE*. *owner* must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. *PLAN_TABLE* must have a base table and can have multiple aliases with the same table name, *PLAN_TABLE*, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to *owner.PLAN_TABLE*, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables if they exist: *DSN_STATEMNT_TABLE* and *DSN_FUNCTION_TABLE*. *DSN_STATEMNT_TABLE* contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. *DSN_FUNCTION_TABLE* contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1948.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDIATEWRITE subsystem parameter has no effect of this option. *DB2 Command Reference* shows the implied hierarchy of the IMMEDIATEWRITE bind option (which is similar to this routine option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.

| **ISOLATION LEVEL RR, RS, CS, or UR**

| Specifies how far to isolate the routine from the effects of other running
| applications. For information about isolation levels, see *DB2 Performance*
| *Monitoring and Tuning Guide*.

| **RR** Specifies repeatable read.

| **RS** Specifies read stability.

| **CS** Specifies cursor stability. **CS** is the default.

| **UR** Specifies uncommitted read.

| **OPTHINT** *string-constant*

| Specifies whether query optimization hints are used for static SQL statements
| that are contained within the body of the routine.

| *string-constant* is a character string of up to 128 bytes in length, which is used
| by the DB2 subsystem when searching the PLAN_TABLE for rows to use as
| input. The default value is an empty string, which indicates that the DB2
| subsystem does not use optimization hints for static SQL statements.

| Optimization hints are only used if optimization hints are enabled for your
| system. See *DB2 Installation Guide* for information about enabling optimization
| hints.

| **SQL PATH**

| Specifies the SQL path that the DB2 subsystem uses to resolve unqualified
| user-defined types, functions, and procedure names (in CALL statements) in
| the body of the routine. The default value is "SYSIBM", "SYSFUN", "SYSPROC",
| and the value of the QUALIFIER option, which is the qualifier for the trigger
| that is the target of the statement. The maximum length of the SQL path is
| 2048 bytes. DB2 calculates the length by taking each *schema-name* that is
| specified and removing any trailing blanks from it, adding two delimiters
| around it, and adding one comma after each schema name except for the last
| name. The length of the resulting string cannot exceed 2048 bytes.

| *schema-name*

| Identifies a schema. DB2 does not verify that the schema exists when the
| ALTER statement is processed. The same schema name should not appear
| more than one time in the list of schema names.

| **SYSTEM PATH**

| Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC".

| **SESSION_USER or USER**

| Specifies the value of the SESSION_USER (or USER) special register. At the
| time the ALTER statement is processed, the actual length is included in the
| total length of the list of schema names that is specified for the SQL PATH
| option.

| **REOPT**

| Specifies if DB2 will determine the access path at run time by using the values
| of SQL variables or SQL parameters, parameter markers, and special registers.

| **NONE**

| Specifies that DB2 does not determine the access path at run time by using
| the values of SQL variables or SQL parameters, parameter markers, and
| special registers.

| **NONE** is the default.

|
| **ALWAYS**

| Specifies that DB2 always determines the access path at run time each time
| an SQL statement is run. Do not specify REOPT ALWAYS with the WITH
| KEEP DYNAMIC or NODEFER PREPARE clauses.

|
| **ONCE**

| Specifies that DB2 determine the access path for any dynamic SQL
| statements only once, at the first time the statement is opened. This access
| path is used until the prepared statement is invalidated or removed from
| the dynamic statement cache and need to be prepared again.

| **QUERY ACCELERATION**

| Specifies whether a static SQL query is bound for acceleration, and if so, with
| what behavior.

| **NONE**

| Specifies that no static SQL query in the application is bound for
| acceleration or will be accelerated when the application is run.

| **ENABLE**

| Specifies that a static SQL query is bound for acceleration if it satisfies the
| acceleration criteria, including the cost and heuristics criteria. The query is
| routed to an accelerator when the application runs. Otherwise, if the static
| query does not satisfy the acceleration criteria, the query is bound for
| execution in DB2.

| If an error condition, such as one of the following examples, occurs while
| executing the accelerated static query when the application is run, DB2
| fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and DB2 cannot route the static query to the accelerator for execution.

| **ENABLE WITH FAILBACK**

| Results in the same behavior as ENABLE, except if one of the error
| conditions occurs on the first OPEN of the accelerated static query when
| the application is run. In this case, instead of failing the static query and
| returning a negative SQL code to the application, DB2 performs a
| temporary *statement-level* incremental bind of the query and runs the query
| in DB2. The application does not see the acceleration failure. Failback to
| DB2 is not possible after the application does a successful OPEN for the
| query on the accelerator.

| **ELIGIBLE**

| Specifies that a static SQL query is bound for acceleration if the query
| meets the basic acceleration criteria, regardless of the cost or heuristics
| criteria. The query is routed to the accelerator when the application runs.

| Like the behavior for ENABLE, if an error condition occurs while executing
| the accelerated static query when the application is run, DB2 fails the static
| query and returns a negative SQL code to the application.

| **ALL**

| Specifies that all of the static SQL queries in the application are to be
| bound for acceleration and routed to the accelerator when the application
| runs. If DB2 determines that a static query cannot be bound to run on the
| accelerator and the query references a user base table or view, the BIND or
| REBIND PACKAGE operation fails with an error message for that query.

(A failure exception is made for declared global temporary tables (DGTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a *fullselect* or WITH *common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

NO Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in DB2.

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

YES

Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The QUERYACCELERATION bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a *fullselect* or WITH *common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

VALIDATE RUN or VALIDATE BIND

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN

Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

VALIDATE RUN is the default.

|
| **VALIDATE BIND**

| Specifies that if needed objects or privileges do not exist at the time the
| CREATE statement is processed, an error is issued and the CREATE
| statement fails.

|
| **ROUNDING**

| Specifies the rounding mode for manipulation of DECFLOAT data. The default
| value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING
| MODE in DECP.

| **DEC_ROUND_CEILING**

| Specifies numbers are rounded towards positive infinity.

| **DEC_ROUND_DOWN**

| Specifies numbers are rounded towards 0 (truncation).

| **DEC_ROUND_FLOOR**

| Specifies numbers are rounded towards negative infinity.

| **DEC_ROUND_HALF_DOWN**

| Specifies numbers are rounded to nearest; if equidistant, round down.

| **DEC_ROUND_HALF_EVEN**

| Specifies numbers are rounded to nearest; if equidistant, round so that the
| final digit is even.

| **DEC_ROUND_HALF_UP**

| Specifies numbers are rounded to nearest; if equidistant, round up.

| **DEC_ROUND_UP**

| Specifies numbers are rounded away from 0.

| **DATE FORMAT ISO, EUR, USA, JIS, or LOCAL**

| Specifies the date format for result values that are string representations of
| date or time values. See "String representations of datetime values" on page
| 101 for more information.

| The default format is specified in the DATE FORMAT field of installation panel
| DSNTIP4 of the system where the routine is defined. You cannot use the
| LOCAL option unless you have a date exit routine.

| **DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)**

| Specifies the maximum precision that is to be used for decimal arithmetic
| operations. See "Arithmetic with two decimal operands" on page 231 for more
| information. The default format is specified in the DECIMAL ARITHMETIC
| field of installation panel DSNTIPF of the system where the routine is defined.
| If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents
| the minimum scale that is to be used for division.

| **FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED**

| Specifies whether the FOR UPDATE clause is required for a DECLARE
| CURSOR statement if the cursor is to be used to perform positioned updates.

| **FOR UPDATE CLAUSE REQUIRED**

| Specifies that a FOR UPDATE clause must be specified as part of the
| cursor definition if the cursor will be used to make positioned updates.

| **FOR UPDATE CLAUSE REQUIRED** is the default.

| **FOR UPDATE CLAUSE OPTIONAL**

| Specifies that the FOR UPDATE clause does not need to be specified in

order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 101 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

SECURED or NOT SECURED

Specifies if the function is considered secure. When the option is specified with the **ALL VERSIONS** clause, it applies to all existing versions and to any future versions of the function. When it is specified with other clauses such as **ADD VERSION**, or **REPLACE**, the value must be the same as the value that is in effect for the function that is being changed.

SECURED

Specifies that the function is considered secure.

NOT SECURED

Specifies that the function is considered not secure. NOT SECURED must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SQL-routine-body

Specifies a single SQL control statement, including a compound-statement. See Chapter 8, “SQL control statements for SQL routines,” on page 2251 for more information about defining SQL functions.

A call to a procedure that issues a COMMIT, ROLLBACK, CONNECT, RELEASE, or SET CONNECTION statement is not allowed in a function.

If the *SQL-routine-body* is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.

An ALTER FUNCTION (compiled SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION or REPLACE clause is not allowed in an *SQL-routine-body*.

Notes

The order of options and the RETURNS clause

The RETURNS clause must precede the *options-list*. If the body of the function contains only a *RETURN-statement*, *RETURN-statement* must be specified after the RETURNS clause and the *options-list* in the routine body.

ALTER FUNCTION for in use functions:

ALTER FUNCTION will be locked out from making changes if the function is in use. For example, if a query that is currently running is referencing an SQL scalar function named 'fn1' (*routine-version-id* is 'v1'), an ALTER FUNCTION fn1 ACTIVATE VERSION v2 statement will wait for the query that is currently running to complete before making 'v2' the active version for function 'fn1'. This wait for completion behavior happens even if the query invokes the function multiple times for processing multiple rows or if the query contains multiple references to the function that is being changed.

Considerations for changing a version of a function:

To change a version of a function, the environment settings that are in effect when the ALTER FUNCTION statement is issued must be the same as the environment settings that are in effect when the version of the function is first created using the CREATE FUNCTION or ALTER FUNCTION statement if one of the following options is specified:

- QUALIFIER
- PACKAGE OWNER
- WLM ENVIRONMENT FOR DEBUG MODE
- OPTHINT
- SQL PATH
- DECIMAL (if the value includes a comma)

Considerations for catalog comments for a routine definition:

When a function definition is replaced, any existing comment in the catalog for the definition is removed. However, when a function definition is regenerated, any existing comment in the catalog for the definition is retained.

Identifier resolution:

See Chapter 8, "SQL control statements for SQL routines," on page 2251 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, and the label name for SQL variables.

Characteristics of the package that is generated for a function:

The package that is associated with a version of a function is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the function
- *package-id* is the same as the specific name of the function
- *version-id* is the same as the version identifier for the version of the function

The package is generated using the bind options that correspond to the implicitly or explicitly specified function options. In addition to the corresponding bind options, the package is generated using the following bind options:

- FLAG(I)
- SQLERROR(NOPACKAGE)

- ENABLE(*)

Correspondence of function options to bind command options:

The following table lists options for CREATE FUNCTION and ALTER FUNCTION and the corresponding bind command option. See BIND and REBIND options for packages and plans (DB2 Commands) for information about the BIND command options.

Table 148. Correspondence of function options to bind options

| CREATE FUNCTION or ALTER FUNCTION option | bind command option |
|---|--|
| APPLICATION ENCODING SCHEME | ENCODING(ASCII), ENCODING(EBCDIC), ENCODING(UNICODE) |
| CURRENT DATA NO | CURRENTDATA(NO) |
| CURRENT DATA YES | CURRENTDATA(YES) |
| DYNAMICRULES | DYNAMICRULES(RUN), DYNAMICRULES(BIND), DYNAMICRULES(DEFINEBIND), DYNAMICRULES(DEFINERUN), DYNAMICRULES(INVOKEBIND), DYNAMICRULES(INVOKERUN) |
| ISOLATION LEVEL | ISOLATION(RR), ISOLATION(RS), ISOLATION(CS), ISOLATION(UR) |
| OPTHINT | OPTHINT |
| PACKAGE OWNER | OWNER |
| QUALIFIER | QUALIFIER |
| REOPT ALWAYS | REOPT(ALWAYS) |
| REOPT NONE | REOPT(NONE) |
| REOPT ONCE | REOPT(ONCE) |
| ROUNDING DEC_ROUND_CEILING | ROUNDING(CEILING) |
| ROUNDING DEC_ROUND_DOWN | ROUNDING(DOWN) |
| ROUNDING DEC_ROUND_FLOOR | ROUNDING(FLOOR) |
| ROUNDING DEC_ROUND_HALF_DOWN | ROUNDING(HALFDOWN) |
| ROUNDING DEC_ROUND_HALF_EVEN | ROUNDING(HALFEVEN) |
| ROUNDING DEC_ROUND_HALF_UP | ROUNDING(HALFUP) |
| ROUNDING DEC_ROUND_UP | ROUNDING(UP) |
| SQL PATH | PATH |
| VALIDATE BIND | VALIDATE(BIND) |
| VALIDATE RUN | VALIDATE(RUN) |
| WITH EXPLAIN | EXPLAIN(YES) |
| WITHOUT EXPLAIN | EXPLAIN(NO) |
| WITH IMMEDIATE WRITE | IMMEDWRITE(YES) |
| WITHOUT IMMEDIATE WRITE | IMMEDWRITE(NO) |

Invalidation of packages:

When a version of an SQL function is altered to change any option that is specified for the active version, all packages that refer to that function are marked invalid. In addition, when certain attributes of an SQL function are

changed, the body of the function might be rebound or regenerated. The following table summarizes when implicit rebind and regeneration occurs when specific options are changed. A value of 'Y' in a row indicates that a rebind or regeneration occurs if the option is changed for a version of the function. A value of 'N' in a row indicates that a rebind or regeneration does not occur.

Table 149. CREATE FUNCTION and ALTER FUNCTION options that result in rebind or regeneration of the function when changed

| CREATE FUNCTION or ALTER FUNCTION option | Change requires rebind of invoking application | Change results in implicit rebind of non-control statements in the body of the function | Change results in implicit regeneration of the entire body of the function |
|--|--|---|--|
| ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE | Y 1 2 | Y 1 | Y |
| APPLICATION ENCODING SCHEME | Y | Y | Y |
| ASUTIME | Y | N | N |
| CURRENT DATA | N | Y | N |
| DATE FORMAT | Y | Y | Y |
| DECIMAL | Y | Y | Y |
| DYNAMICRULES | N | Y | N |
| FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED | Y | Y | Y |
| INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS | Y | N | N |
| ISOLATION LEVEL | N | Y | N |
| MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL | Y | Y | Y |
| NOT DETERMINISTIC or DETERMINISTIC | N | N | N |
| OPTHINT | N | Y | N |
| PACKAGE OWNER | N | Y | N |
| QUALIFIER | N | Y | N |
| REOPT | N | Y | N |
| ROUNDING | Y | Y | Y |
| SQL PATH | N | Y | N |
| TIME FORMAT | Y | Y | Y |

Table 149. CREATE FUNCTION and ALTER FUNCTION options that result in rebind or regeneration of the function when changed (continued)

| CREATE FUNCTION or ALTER FUNCTION option | Change requires rebind of invoking application | Change results in implicit rebind of non-control statements in the body of the function | Change results in implicit regeneration of the entire body of the function |
|---|--|---|--|
| VALIDATE RUN or VALIDATE BIND | N | Y | N |
| WITH EXPLAIN or WITHOUT EXPLAIN | N | Y | N |
| WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE | N | Y | N |
| WLM ENVIRONMENT FOR DEBUG MODE | Y | N | N |
| Note: <ol style="list-style-type: none"> 1 The function package is rebound or regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE 2 Invoking applications are invalidated if a value of DISALLOW DEBUG MODE is changed to DISABLE DEBUG MODE | | | |

Considerations for SQL processor programs:

SQL processor programs (such as SPUFI, the command line processor, and DSNTEP2) might not correctly parse SQL statements in the routine body that are ended with semicolons. These processor programs accept multiple SQL statements as input when each statement is separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator might truncate an ALTER FUNCTION statement with embedded semicolons and pass only a portion of the statement to DB2. Therefore, you might need to change to SQL terminator character for these processor programs.

Considerations for the SYSENVIRONMENTS catalog table:

An ALTER statement that specifies new environment settings will result in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the statement. Thus, a new SYSENVIRONMENT row might be added to the table even for an ALTER statement that fails.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Altering a function from NOT SECURED to SECURED:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function.

The function is considered secure after the ALTER FUNCTION statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all

changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

Altering a function from SECURED to NOT SECURED:

Packages and statements in the dynamic statement cache that reference the function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

Invoking other user-defined functions in a secure function:

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Deploying a compiled SQL function:

When a BIND DEPLOY command is issued to deploy a compiled SQL function to a target location, the SECURED and NOT SECURED options are included in the deployment process.

When deploying a compiled SQL function, if a function with the same target name does not exist at the target location, the deployed function is created as a new function at the target location with the same SECURED or NOT SECURED option that is specified (or the default of NOT SECURED is used) in the source function of the deployment.

When deploying a compiled SQL function, if a function with the same target name already exists at the target location, the deployed function is either added as a new version of the function or is used to replace an existing version of the function. The SECURED or NOT SECURED option of the deployed function must be the same as that of the existing function at the target location

Compatibilities:

For compatibility with the CREATE FUNCTION (SQL scalar) statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

Optional syntax:

To provide compatibility with the syntax of the CREATE FUNCTION statement, the following options can also be specified:

- SPECIFIC
- PARAMETER CCSID

However, if these options are specified, the value for the option must be the same as the value that is already in effect for the function.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**
- NULL CALL as a synonym for **CALLED ON NULL INPUT**
- NOT NULL CALL as a synonym for **RETURNS NULL ON NULL INPUT**
- TIMEZONE can be specified as an alternative to **TIME ZONE**

Examples

Example 1: Modify the definition for an SQL function to indicate that the function is deterministic.

```
ALTER FUNCTION MY_UDF1
DETERMINISTIC;
```

Example 2: The following statement changes the existing function options for the active version of the REVERSE SQL function. If you need to change a different version of the function, you would specify **VERSION** *routine-version-id* in place of **ACTIVE VERSION**. Note, the **ALTER** clause that precedes the version specification can be omitted:

```
ALTER FUNCTION REVERSE
ALTER ACTIVE VERSION
NOT DETERMINISTIC
ALLOW DEBUG MODE;
```

Example 3: To change the function body of any existing version of a function, you need to use the **REPLACE** clause. The following statement changes both the function body and the existing SQL data access option for the version V2 of the REVERSE function. The list of parameters is specified even though no changes are made to the list. To replace an existing version of the function, you must specify the list of parameters, **RETURNS** clause, any options that are to have non-default values (even if those options are already specified in the version of the function that you are replacing), and the body of the function, as in the following statement:

```
ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))
REPLACE VERSION V2 (INSTR VARCHAR(4000))
RETURNS VARCHAR(4000)
DETERMINISTIC
NO EXTERNAL ACTION
CONTAINS SQL
BEGIN
DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
DECLARE LEN INT;
IF INSTR IS NULL THEN
RETURN NULL;
END IF;
SET RESTSTR = INSTR;
SET LEN = LENGTH(INSTR);
WHILE LEN > 0 DO
SET (REVSTR, RESTSTR, LEN) = (SUBSTR(RESTSTR, 1, 1) CONCAT
RESTSTR, SUBSTR(RESTSTR, 2, LEN - 1), LEN - 1);
END WHILE;
RETURN REVSTR;
END
```

| *Example 4:* To add a new version of an existing function, use the ADD VERSION
| clause. The following statement adds a new version of the REVERSE function to
| combine two SET statements into one SET statement. The list of parameters is
| specified even though the new version of the function uses the same parameters as
| the existing version of the function. To add a new version of the function, you
| must specify the list of parameters, RETURNS clause, any options that will have
| non-default values, and the body of the function, as in the following statement,
| which creates version V3 of the REVERSE function:

```
| ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))  
| ADD VERSION V3 (INSTR VARCHAR(4000))  
| RETURNS VARCHAR(4000)  
| DETERMINISTIC  
| NO EXTERNAL ACTION  
| CONTAINS SQL  
| BEGIN  
| DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';  
| DECLARE LEN INT;  
| IF INSTR IS NULL THEN  
|     RETURN NULL;  
| END IF;  
| SET (RESRSTR, LEN) = (INSTR, LENGTH(INSTR));  
| WHILE LEN > 0 DO  
|     SET (REVSTR, RESTSTR, LEN) = (SUBSTR(RESTSTR, 1, 1) CONCAT  
|         REVSTR, SUBSTR(RESTSTR, 2, LEN - 1), LEN - 1);  
| END WHILE;  
| RETURN REVSTR;  
| END
```

| *Example 5:* To change the currently active version of the function, you must specify
| the ACTIVATE VERSION clause on the ALTER FUNCTION statement, even if the
| version you want to be the active version has just been defined. The following
| statement causes version V3 of the REVERSE SQL function to be the currently
| active version:

```
| ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))  
| ACTIVATE VERSION V3;
```

| *Example 6:* To regenerate the currently active version of the function, you must
| specify the REGENERATE clause, as in the following statement:

```
| ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))  
| REGENERATE ACTIVE VERSION;
```

ALTER FUNCTION (inlined SQL scalar)

The ALTER FUNCTION (inlined SQL scalar) statement changes the description of a user-defined inlined SQL scalar function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has installation SYSADM authority, the function is identified as system-defined function when the function definition is reevaluated.

Additional privileges might be required in the following situations:

- If *SQL-routine-body* is specified, the privilege set must include the privileges that are required to execute the statements in *SQL-routine-body*.
- If a user-defined type is referenced (for example, as the data type of a parameter), the privilege set must include at least one of the following:
 - Ownership of the user-defined type
 - The USAGE privilege on the user-defined type
 - SYSADM authority

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

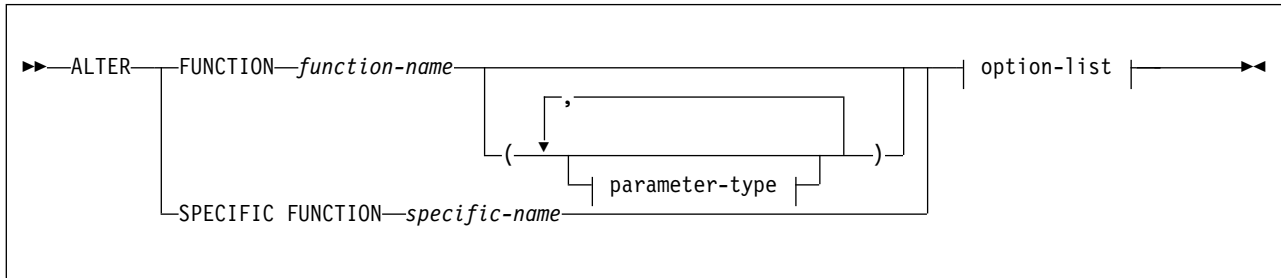

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority

- The SQL authorization ID of the process has the ALTERIN privilege on the schema

Syntax

parameter-type:

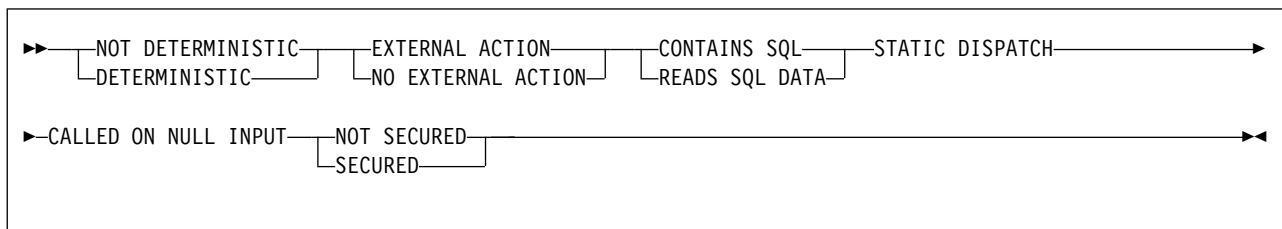

data-type:

built-in-type:

option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than one time.)

Description

One of the following three clauses identifies the function to be changed.

| **FUNCTION** *function-name*

| Identifies the SQL function by its function name.

| The identified function must be an inlined SQL scalar function. There must be
| exactly one function with *function-name* in the schema. The function can have
| any number of input parameters.²⁵ If the schema does not contain a function
| with *function-name* or contains more than one function with this name, an error
| occurs.

| **FUNCTION** *function-name (parameter-type,...)*

| Identifies the SQL function by its function signature, which uniquely identifies
| the function.

| *function-name*

| Gives the function name of the inlined SQL scalar function.

| If *function-name()* is specified, the function that is identified must have zero
| parameters.

| *(parameter-type,...)*

| Specifies the number of input parameters of the function and the name and
| data type of each parameter.

| *(data-type,...)*

| Identifies the number of input parameters of the function and the data
| type of each parameter. The data type of each parameter must match the
| data type that was specified in the CREATE FUNCTION statement for the
| parameter in the corresponding position. The number of data types and
| the logical concatenation of the data types are used to uniquely identify the
| function. Therefore, you cannot change the number of parameters or the
| data types of the parameters.

| For data types that have a length, precision, or scale attribute, you can use
| a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that DB2 is to ignore the attribute when
determining whether the data types match.

| For example, DEC() will be considered a match for a parameter of a
| function defined with a data type of DEC(7,2). Similarly DECFLOAT()
| will be considered a match for DECFLOAT(16) or DECFLOAT(34).

| FLOAT cannot be specified with empty parentheses because its
| parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the
value must exactly match the value that was specified (implicitly or
explicitly) in the CREATE FUNCTION statement.

| The specific value for FLOAT(*n*) does not have to exactly match the
| defined value of the source function because 1<=*n*<= 21 indicates REAL
| and 22<=*n*<=53 indicates DOUBLE. Matching is based on whether the
| data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty
parentheses are not specified, the default length of the data type is
implied. The implicit length must exactly match the value that was
specified (implicitly or explicitly) in the CREATE FUNCTION statement.

| For data types with a subtype or encoding scheme attribute, specifying the
| **FOR** *subtype* **DATA** clause or the **CCSID** clause is optional. Omission of
| either clause indicates that DB2 is to ignore the attribute when determining

25. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See “CREATE FUNCTION” on page 1476 for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

SPECIFIC FUNCTION *specific-name*

Identifies a particular user-defined function by its specific name. The name is implicitly or explicitly qualified with a schema name. An inlined SQL scalar function with the specific name must exist in the schema. If the specific name is not qualified, it is implicitly qualified with a schema name as described in the description for FUNCTION *function-name*.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic.

DETERMINISTIC

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function.

If you specify **EXTERNAL ACTION**, DB2:

- Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements

that refer to this function. Do not specify **EXTERNAL ACTION** if the function does not have an external action.

- Does not move the function from one task control block (TCB) to another between **FETCH** operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared **WITH HOLD**.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under **RRS** control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the **SQL** routine body invokes a function that is defined with **EXTERNAL ACTION**.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for **SELECT** or **SQL** data change statements that refer to this function. If applicable, specify **NO EXTERNAL ACTION** to prevent non-optimal access paths from being chosen for **SQL** statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **EXTERNAL ACTION** or **NO EXTERNAL ACTION**.

READS SQL DATA or CONTAINS SQL

Specifies which **SQL** statements, if any, can be executed in the function or any routine that is called from this function.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of **READS SQL DATA**, **CONTAINS SQL**, or **NO SQL**. The function cannot execute **SQL** statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL

Specifies that the function can execute only **SQL** statements with a data access classification of **CONTAINS SQL** or **NO SQL**. The function cannot execute **SQL** statements the read or modify data.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters.

CALLED ON NULL INPUT

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null arguments. The function can return null.

SECURED or NOT SECURED

Specifies if the function is considered secure.

SECURED

Specifies that the function is considered secure.

NOT SECURED

Specifies that the function is considered not secure. NOT SECURED must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

Notes

ALTER FUNCTION for in use functions:

ALTER FUNCTION will be locked out from making changes if the function is in use. This wait for completion behavior happens even if the query invokes the function multiple times for processing multiple rows or if the query contains multiple references to the function that is being changed.

Invalidation of plans and packages:

When an inlined SQL function is altered, all the plans and packages that refer to that function are marked invalid.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Altering a function from NOT SECURED to SECURED:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function.

The function is considered secure after the ALTER FUNCTION statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

Altering a function from SECURED to NOT SECURED:

Packages and statements in the dynamic statement cache that reference the function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

Invoking other user-defined functions in a secure function:

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security

administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Compatibilities:

For compatibility with the CREATE FUNCTION (SQL scalar) statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

Optional syntax:

To provide compatibility with the syntax of the CREATE FUNCTION statement, the following options can also be specified:

- SPECIFIC
- PARAMETER CCSID

However, if these options are specified, the value for the option must be the same as the value that is already in effect for the function.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**
- NULL CALL as a synonym for **CALLED ON NULL INPUT**

Examples

Example 1: Modify the definition for an SQL function to indicate that the function is deterministic.

```
ALTER FUNCTION MY_UDF1
DETERMINISTIC;
```

ALTER FUNCTION (SQL table)

The ALTER FUNCTION (SQL table) statement changes the description of a user-defined SQL table function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following privileges or authorities:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has installation SYSADM authority, the function is identified as system-defined function when the function definition is reevaluated.

If a distinct type is referenced (i.e. as the data type of an SQL variable in the body of the function), the privilege set must also include at least one of the following:

- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

▶▶ SPECIFIC FUNCTION *specific-name* ▶▶

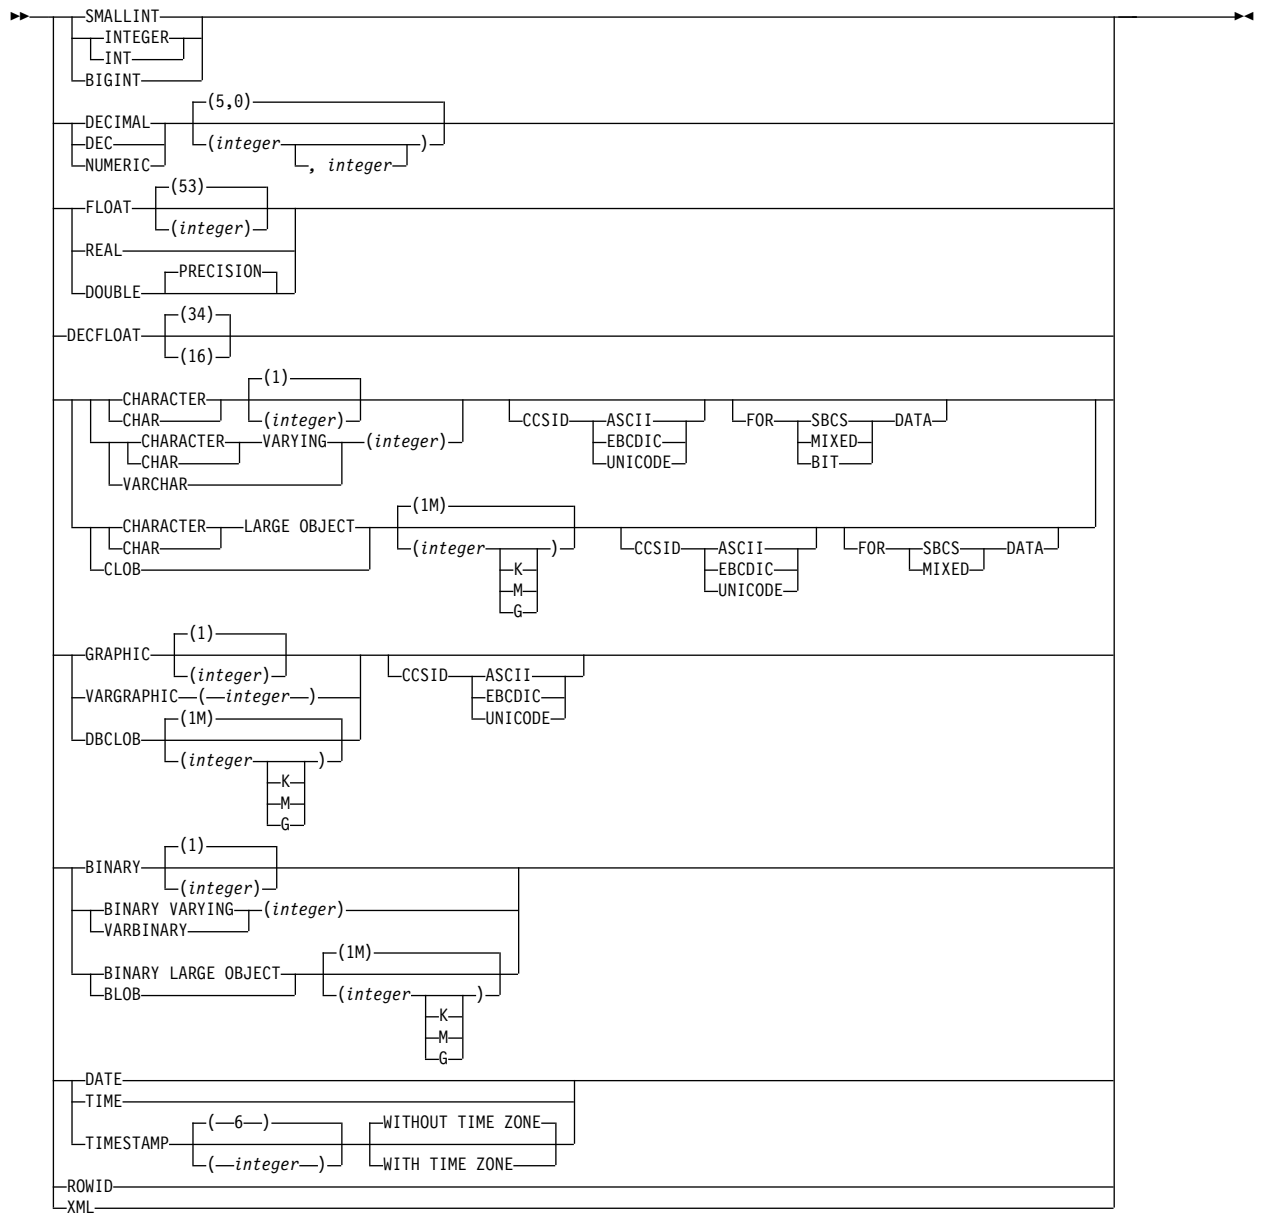

parameter-type:

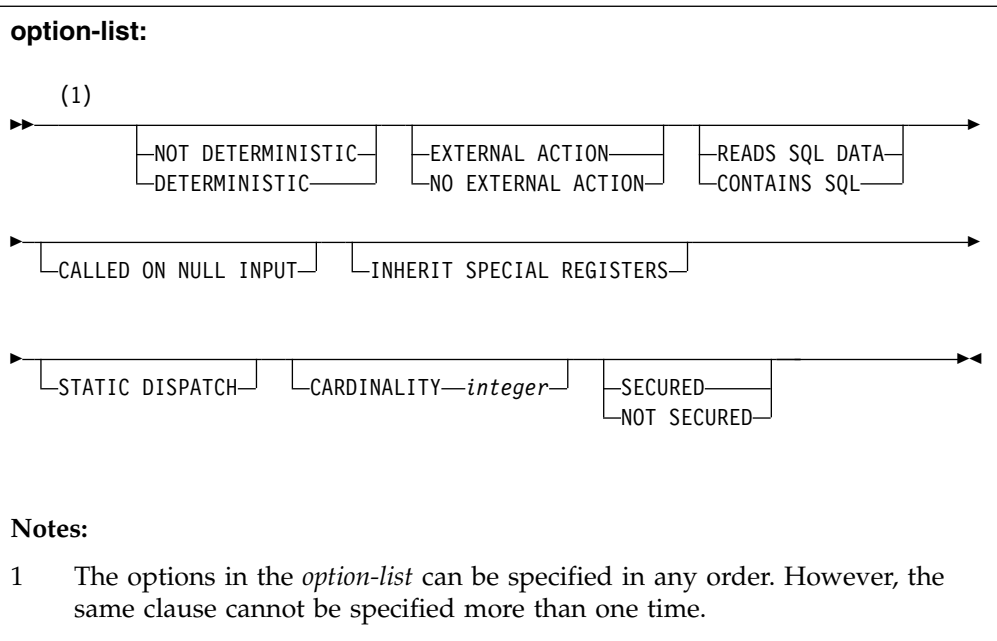

▶▶ data-type ▶▶

data-type:

▶▶ built-in-type | *distinct-type-name* ▶▶

built-in-type:

Description

FUNCTION *function-name*

Identifies the SQL table function by its function name. The identified function must be an SQL table function.

There must be exactly one function with *function-name* in the schema. The function can have any number of input parameters. If the schema does not contain a function with *function-name*, or contains more than one function with this name, an error is returned.

FUNCTION *function-name* (*parameter-type*, ...)

Identifies the SQL function by its function signature, which uniquely identifies the function.

A function with the function signature must exist in the explicitly or implicitly specified schema.

function-name

Identifies the function name of the SQL function. If the function was defined with a table parameter (the **LIKE TABLE** *name* **AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specified parameters.

If *function-name()* is specified, the function that is identified must have zero parameters.

parameter-type

Identifies the number of parameters of the function.

data-type

Identifies the data type of each input parameter of the function. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the

data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.

For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

The specific value for FLOAT(*n*) does not have to exactly match the defined value of the source function because 1<=*n*<= 21 indicates REAL and 22<=*n*<=53 indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the **FOR *subtype* DATA** clause or the **CCSID** clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See “CREATE FUNCTION” on page 1476 for more information on the specification of the parameter list.

RESTRICT

Indicates that the function will not be altered or replaced if it is referenced by any dependent package, function, materialized query table, or view.

Exception: When the ALTER statement specifies only DETERMINISTIC or NOT DETERMINISTIC, the function is altered, and all dependent packages are invalidated.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. DB2 does not verify that the function program is consistent with the specification of NOT DETERMINISTIC or DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result table each time that the function is invoked with the same input arguments, even when the referenced data in the database has not changed. The function depends on some state values that might affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a table function that is not deterministic is one

which references special registers, other functions that are not deterministic, or a sequence in a way that affects the table function's result table.

DETERMINISTIC

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments (provided that the referenced data in the database has not changed). DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function.

If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function contains an external action. DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

EXTERNAL ACTION

The function performs some external action (outside the scope of the function program). Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION must be specified if the function invokes another function that has external actions.

NO EXTERNAL ACTION

The function does not perform any external action. It need not be called with each successive function invocation. Functions that are defined with NO EXTERNAL ACTION might perform better than functions that are defined with EXTERNAL ACTION because the function might not be invoked for each successive function invocation.

READS SQL DATA or CONTAINS SQL

Specifies the classification of SQL statements that the function (any routine that is invoked from this function) can execute. DB2 verifies that the SQL statements that the function issues are consistent with this specification.

READS SQL DATA

Specifies that the function can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The function cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access indication of CONTAINS SQL. The function cannot execute statements that read or modify data.

CALLED ON NULL INPUT

Specifies that the function is called regardless of whether any of the input argument values are null, making the function responsible for testing for null argument values. The function might return an empty table, depending on the logic in the body of the function.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH

Specifies that at function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters.

| **CARDINALITY** *integer*

| Specifies an estimate of the expected number of rows that the function returns.
| The number is used for optimization purposes. The value of *integer* must be
| between 0 and 2147483647.

| If a function has an infinite cardinality (the function never returns the
| end-of-table condition and always returns a row), a query that requires the
| end-of-table condition to work correctly will need to be interrupted.

| **SECURED or NOT SECURED**

| Specifies whether the function is considered secure.

| **SECURED**

| Specifies that the function is considered secure.

| **NOT SECURED**

| Specifies that the function is considered not secure. NOT SECURED must
| not be specified when a row permission or a column mask depends on the
| function.

| When the function is invoked, the arguments of the function must not
| reference a column for which a column mask is enabled when the table is
| using active column access control.

| **Notes**

| **Invalidation of packages:**

| When an SQL function is changed, all the packages that refer to that
| function are marked invalid.

| **Dependent objects:**

| An SQL routine is dependent on objects that are referenced in the routine
| body.

| **Altering a function from NOT SECURED to SECURED:**

| Typically, the security administrator will examine the data that is accessed
| by a function, ensure that it is secure, and grant the
| CREATE_SECURE_OBJECT privilege to the user that requires privileges to
| change the user-defined function to be secured. After the function is
| changed to SECURED, the security administrator will revoke the
| CREATE_SECURE_OBJECT privilege from the owner of the function.

| The function is considered secure after the ALTER FUNCTION statement is
| executed. DB2 treats the SECURED attribute as an assertion that declares
| that the security administrator has established an audit procedure for all
| changes to the user-defined function. DB2 assumes that such a control
| audit procedure is in place for all subsequent ALTER FUNCTION
| statements or changes to external packages.

| Packages and statements in the dynamic statement cache that reference the
| function are invalidated.

| **Altering a function from SECURED to NOT SECURED:**

| Packages and statements in the dynamic statement cache that reference the
| function are invalidated when the function is changed from SECURED to
| NOT SECURED. An function that is not secured might negatively impact
| performance if that function accesses data in a table that is using row
| access control or column access control. To minimize the performance
| impact, either change the function to use the SECURED option or
| deactivate row access control or column access control for the table that the
| function is accessing.

| **Invoking other user-defined functions in a secure function:**

| When a secure user-defined function is referenced in an SQL data change
| statement that references a table that is using row access control or column
| access control, and if the secure user-defined function invokes other
| user-defined functions, the nested user-defined functions are not validated
| as secure. If those nested functions can access sensitive data, the security
| administrator needs to ensure that those functions are allowed to access
| sensitive data and should ensure that a change control audit procedure has
| been established for all changes to those functions.

| **The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:**

| The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table
| indicates if a user-defined function is considered secure.

| **Compatibilities:**

| For compatibility with the CREATE FUNCTION (SQL table) statement, the
| following clause can be specified, but will be ignored:

- LANGUAGE SQL

| **Alternative syntax and synonyms:**

| To provide compatibility with previously releases of DB2 or other products
| in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

| **Examples**

| *Example 1:* The following statement modifies the definition of an SQL table function
| to set the estimated cardinality to 10,000.

| ALTER FUNCTION GET_TABLE
| RESTRICT CARDINALITY 10000;

ALTER INDEX

The ALTER INDEX statement changes the description of an index at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include one of the following:

- Ownership of the index
- Ownership of the table on which the index is defined
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM

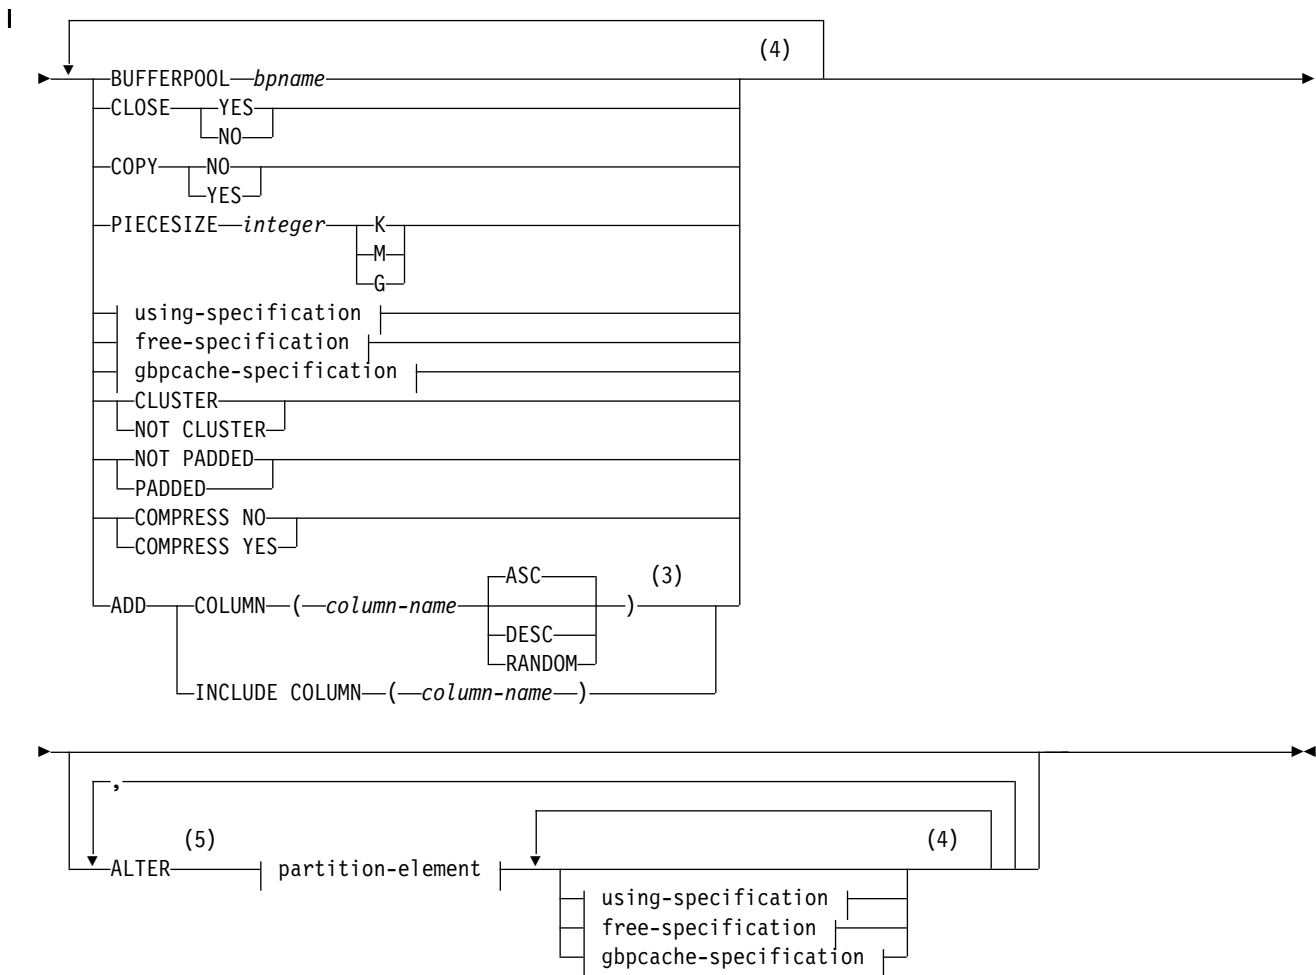

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If **BUFFERPOOL** or **USING STOGROUP** is specified, additional privileges could be needed, as explained in the description of those clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

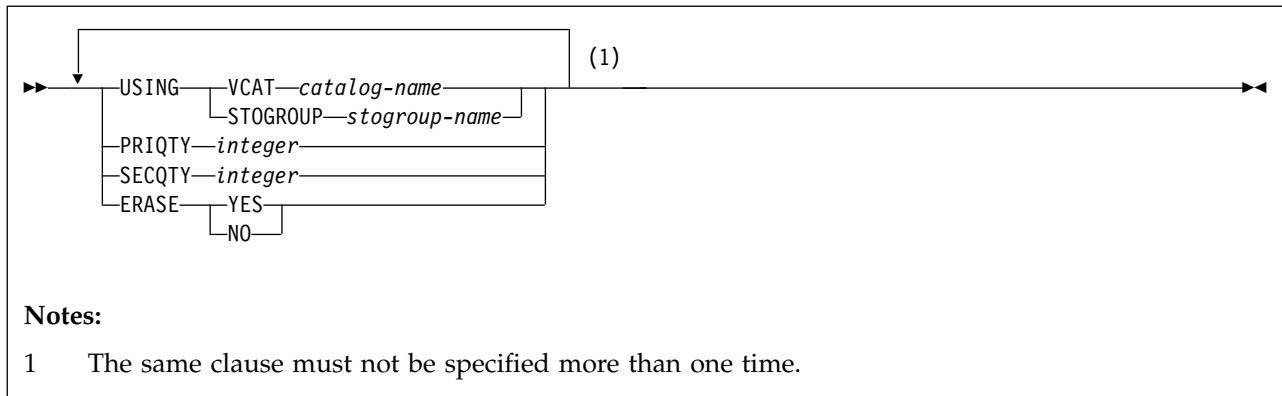

▶▶—ALTER INDEX—*index-name*—⁽¹⁾——REGENERATE—⁽²⁾—▶▶

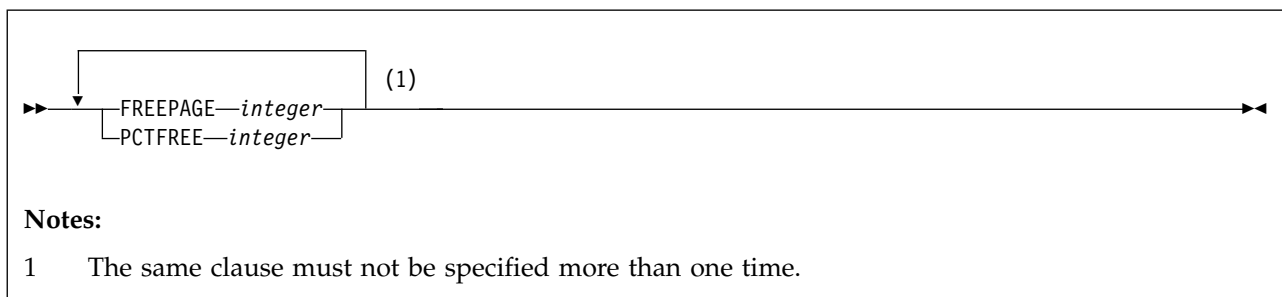

Notes:

- 1 At least one clause must be specified after *index-name*. It can be from the optional list or it can be **ALTER PARTITION**.
- 2 If **REGENERATE** is specified, it must be the only clause specified on the ALTER INDEX statement.
- 3 If **ADD COLUMN** and **PADDED** or **NOT PADDED** are specified, **ADD COLUMN** must be specified before **PADDED** or **NOT PADDED**.
- 4 The same clause must not be specified more than one time.
- 5 The **ALTER** clause can only be specified for partitioned indexes. The **ALTER** clause must be specified last.

using-specification:

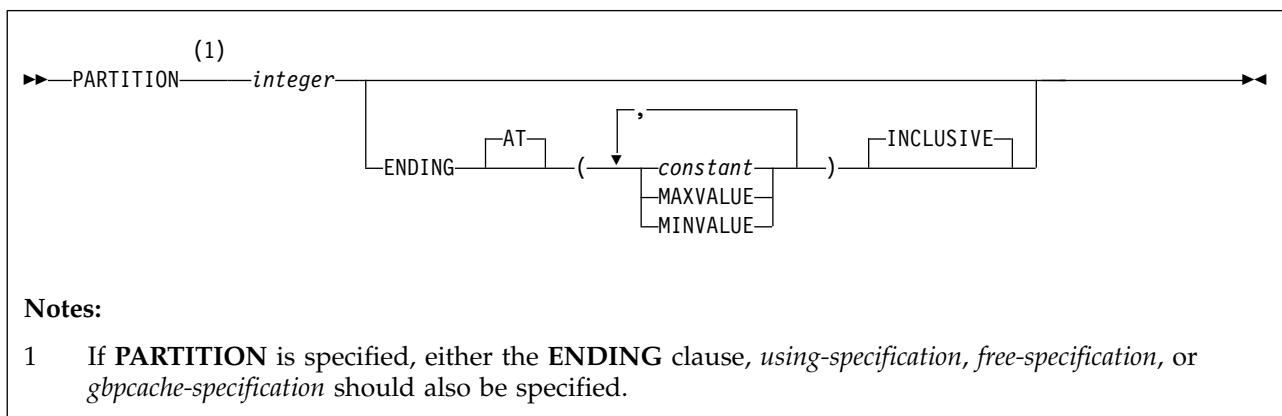

free-specification:

gbpcache-specification:

partition-element:

Description

index-name

Identifies the index to be changed or regenerated. The name must identify a

user-created index that exists at the current server. The name must not identify an index that is defined on a declared temporary table.

REGENERATE

Specifies that the index will be regenerated. The structure that represents the index definition is regenerated. The index definition will be composed from the catalog. Existing authorities and dependencies, if any, are retained. The catalog is updated with the regenerated index definition. The index is put into rebuild-pending state, all packages that depend on the index are invalidated, and catalog entries for the index statistics are deleted.

If the index cannot be successfully regenerated, an error is returned. In this case, the index must be dropped and re-created.

BUFFERPOOL *bpname*

Identifies the buffer pool that is to be used for the index. *bpname* must identify an activated 4K, 8 KB, 16 KB, or 32 KB buffer pool, and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the buffer pool.

A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

If the index is changed to use index compression (the **COMPRESS YES** clause), the buffer pool must be 8 KB, 16 KB, or 32 KB in size.

The change is a pending definition change if all of the following conditions are true:

- The data sets of the index are created
- The index is defined on one of the following:
 - A table that is in a universal table space
 - An XML table that is associated with a base table that is in a universal table space
 - An auxiliary table that is associated with a base table that is in a universal table space
- There are pending definition changes for the index or the table space
- The buffer pool is changed to a buffer pool with a different size

If any of the previous conditions are not true, the change is an immediate change.

If the change is an immediate change, the change to the description of the index takes effect the next time the data sets of the index space are opened. The data sets can be closed and reopened by a **STOP DATABASE** command to stop the index followed by a **START DATABASE** command to start the index.

If the buffer pool is changed to a buffer pool with a different page size, and the change is an immediate change, the index is placed into REBUILD-pending status.

If the change is a pending definition change, the change is not reflected in the current definition or data at the time of the alter. Instead, the index is placed in an advisory REORG-pending (AREOR) state. A subsequent reorganization of the entire index with an appropriate utility will materialize the changes and apply the pending definition changes to the catalog and data.

CLOSE

Specifies whether the data set is eligible to be closed when the index is not

being used and the limit on the number of open data sets is reached. The change to the close rule takes effect the next time the data sets of the index space are opened.

YES

Eligible for closing.

NO Not eligible for closing.

If DSMAX is reached and there are no CLOSE YES page sets to close, CLOSE NO page sets will be closed.

COPY

Indicates whether the COPY utility is allowed for the index.

NO Does not allow full image or concurrent copies or the use of the RECOVER utility on the index.

YES

Allows full image or concurrent copies and the use the RECOVER utility on the index. For data sharing, changing **COPY** to **YES** causes additional SCA (Shared Communications Area) storage to be used until the next full or incremental image copy is taken or until **COPY** is set back to **NO**.

PIECESIZE *integer*

Specifies the maximum addressability of each data set for a non-partitioned index. The **PIECESIZE** clause can only be specified for non-partitioned indexes.

Be aware that when you alter the **PIECESIZE** value, the index is placed into page set REBUILD-pending (PSRBD) status. The entire index space becomes inaccessible. You must run the REBUILD INDEX or the REORG TABLESPACE utility to remove that status.

The subsequent keyword **K**, **M**, or **G**, indicates the units of the value that is specified in *integer*.

K Indicates that the *integer* value is to be multiplied by 1024 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 268435456.

M Indicates that the *integer* value is to be multiplied by 1048576 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 262144.

G Indicates that the *integer* value is to be multiplied by 1073741824 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 256.

Table 150 shows the valid values for data set size, which depend on the size of the table space.

Table 150. Valid values of **PIECESIZE** clause

| K units | M units | G units | Size attribute of table space |
|----------------|----------------|----------------|--------------------------------------|
| 256K | | | |
| 512K | | | |
| 1024K | 1M | | |
| 2048K | 2M | | |
| 4096K | 4M | | |
| 8192K | 8M | | |

Table 150. Valid values of *PIECESIZE* clause (continued)

| K units | M units | G units | Size attribute of table space |
|------------|---------|---------|-------------------------------|
| 16384K | 16M | | |
| 32768K | 32M | | |
| 65536K | 64M | | |
| 131072K | 128M | | |
| 262144K | 256M | | |
| 524288K | 512M | | |
| 1048576K | 1024M | 1G | |
| 2097152K | 2048M | 2G | |
| 4194304K | 4096M | 4G | LARGE, DSSIZE 4G (or greater) |
| 8388608K | 8192M | 8G | DSSIZE 8G (or greater) |
| 16777216K | 16384M | 16G | DSSIZE 16G (or greater) |
| 33554432K | 32768M | 32G | DSSIZE 32G (or greater) |
| 67108864K | 65536M | 64G | DSSIZE 64G (or greater) |
| 134217728K | 131072M | 128G | DSSIZE 128G (or greater) |
| 268435456K | 262144M | 256G | DSSIZE 256G |

The data set size limit for partitioned table spaces with more than 256 partitions is 4096.

begin using-specification block

The components of the *using-specification* are discussed below, first for non-partitioned indexes and then for partitioned indexes.

USING (specification for nonpartitioned indexes)

For nonpartitioned indexes, the **USING** clause specifies whether the data sets for the index are to be managed by the user or managed by DB2. The **USING** clause applies to every data set that can be used for the index.

If you specify **USING**, the index must be in the stopped state when the ALTER INDEX statement is executed. See Altering storage attributes to determine how and when changes take effect.

VCAT *catalog-name*

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify the catalog name in the form of an SQL identifier. Thus, you must specify an alias if the name of the integrated catalog facility catalog is longer than eight characters. When the new description of the index is applied, the integrated catalog facility catalog must contain an entry for the data set that conforms to the DB2 naming conventions described in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

STOGRUP *stogroup-name*

Specifies using a DB2-managed data set that resides on a volume of the specified storage group. *stogroup-name* must identify a storage group that

exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. When the new description of the index is applied, the description of the storage group must include at least one volume serial number. Each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

If you specify **USING STOGROUP** and the current data set is DB2-managed, omission of the **PRIQTY**, **SECQTY**, or **ERASE** clause is an implicit specification of the current value of the omitted clause.

If you specify **USING STOGROUP** to convert from user-managed data sets to DB2-managed data sets:

- Omission of the **PRIQTY** clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the **SECQTY** clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the **ERASE** clause is an implicit specification of **ERASE NO**.

PRIQTY *integer*

Specifies the minimum primary space allocation for a DB2-managed data set. *integer* must be a positive integer, or -1. This clause can be specified only if the data set is currently managed by DB2 and **USING VCAT** is not specified.

When you specify **PRIQTY** with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is:

12 If *integer* is less than 12

integer

If *integer* is between 12 and 4194304

2097152

If both of the following conditions are true:

- *integer* is greater than 2097152.
- The index is a non-partitioned index on a table space that is not defined with the **LARGE** or **DSSIZE** attribute.

4194304

If *integer* is greater than 4194304

If you specify **PRIQTY** with a value of -1, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value for primary space allocation, see Rules for primary and secondary space allocation.

If **USING STOGROUP** is specified and **PRIQTY** is omitted, the value of **PRIQTY** is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of **USING STOGROUP**.)

If you specify **PRIQTY** and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of 4 KB not less than *n*, where *n* is defined as in the **PRIQTY** description. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see **DEFINE CLUSTER** command (DFSMS Access Method Services for Catalogs).

When determining a suitable value for **PRIQTY**, be aware that two of the pages of the primary space could be used by DB2 for purposes other than storing index entries.

SECQTY *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set. *integer* must be a positive integer, 0, or -1. This clause can be specified only if the data set is currently managed by DB2 and **USING VCAT** is not specified.

If you specify **SECQTY** with a value of -1, DB2 uses a default value for the secondary space allocation.

If **USING STOGROUP** is specified and **SECQTY** is omitted, the value of **SECQTY** is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of **USING STOGROUP**.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or DB2 uses a default value, see Rules for primary and secondary space allocation.

If you specify **SECQTY**, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of 4 KB not less than *integer*. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see **DEFINE CLUSTER** command (DFSMS Access Method Services for Catalogs).

ERASE

Indicates whether the DB2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index.

NO Does not erase the data sets. Operations involving data set deletion will perform better than **ERASE YES**. However, the data is still accessible, though not through DB2.

YES

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

This clause can be specified only if the data set is currently managed by DB2 and **USING VCAT** is not specified. If you specify **ERASE**, the index must be in the stopped state when the **ALTER INDEX** statement is executed. See Altering storage attributes to determine how and when changes take effect.

USING (specification for partitioned indexes:)

For a partitioned index, there is an optional **PARTITION** clause for each partition. A *using-specification* can be specified at the global level or at the partition level. A *using-specification* within a **PARTITION** clause applies only to that partition. A *using-specification* specified before any **PARTITION** clauses applies to every partition except those with a **PARTITION** clause with a *using-specification*.

For DB2-managed data sets, the values of **PRIQTY**, **SECQTY**, and **ERASE** for each partition are given by the first of these choices that applies:

- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in the *using-specification* within the **PARTITION** clause for the partition. Do not use more than one *using-specification* in any **PARTITION** clause.

- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in the *using-specification* before any **PARTITION** clause
- The current values of **PRIQTY**, **SECQTY**, and **ERASE**

For data sets that are being changed from user-managed to DB2-managed, the values of **PRIQTY**, **SECQTY**, and **ERASE** for each partition are given by the first of these choices that applies:

- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in the *using-specification* within the **PARTITION** clause for the partition. Do not use more than one *using-specification* in any **PARTITION** clause.
- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in a *using-specification* before any **PARTITION** clauses
- The default values of **PRIQTY**, **SECQTY**, and **ERASE**, which are:
 - **PRIQTY** 12
 - **SECQTY** 12, if **PRIQTY** is not specified in either *using-specification*, or 10% of **PRIQTY** or 3 times the index page size (whichever is larger) when **PRIQTY** is specified
 - **ERASE** NO

Any partition for which **USING** or **ERASE** is specified (either explicitly at the partition level or implicitly at the global level) must be in the stopped state when the **ALTER INDEX** statement is executed. See *Altering storage attributes* to determine how and when changes take effect.

VCAT *catalog-name*

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify the catalog name in the form of an SQL identifier. Thus, you must specify an alias if the name of the integrated catalog facility catalog is longer than eight characters.

If *n* is the number of the partition, the identified integrated catalog facility catalog must already contain an entry for the *v*th data set of the index, conforming to the DB2 naming convention for data sets described in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

STOGROUP *stogroup-name*

If **USING STOGROUP** is used, *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group.

DB2 assumes one and only one data set for each partition.

For information on the **PRIQTY**, **SECQTY**, and **ERASE** clauses, see the description of those clauses in the *using-specification* for secondary indexes.

end using-specification block

begin free-specification block

FREEPAGE *integer*

Specifies how often to leave a page of free space when index entries are created as the result of executing a DB2 utility. One free page is left for every *integer* pages. The value of *integer* can range from 0 to 255. The change to the description of the index or partition has no effect until it is loaded or reorganized using a DB2 utility. Do not specify **FREEPAGE** for an implicitly created XML index.

PCTFREE *integer*

Determines the percentage of free space to leave in each nonleaf page and leaf page when entries are added to the index or partition as the result of executing a DB2 utility. The first entry in a page is loaded without restriction. When additional entries are placed in a nonleaf or leaf page, the percentage of free space is at least as great as *integer*.

The value of *integer* can range from 0 to 99, however, if a value greater than 10 is specified, only 10 percent of free space will be left in nonleaf pages. The change to the description of the index or partition has no effect until it is loaded or reorganized using a DB2 utility. Do not specify **PCTFREE** for an implicitly created XML index.

If the index is partitioned, the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that applies:

- The values of **FREEPAGE** and **PCTFREE** given in the **PARTITION** clause for that partition. Do not use more than one *free-specification* in any **PARTITION** clause.
- The values given in a *free-specification* before any **PARTITION** clauses.
- The current values of **FREEPAGE** and **PCTFREE** for that partition.

end free-specification block

begin gbpcache-specification block

GBPCACHE

Specifies what index pages are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify this option, but it is ignored.

CHANGED

When there is inter-DB2 read-write interest on the index or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 read-write interest, the group buffer pool is not used. Inter-DB2 read-write interest exists when more than one member in the data sharing group has the index or partition open, and at least one member has it open for update.

If the index is in a group buffer pool that is defined as **GBPCACHE(NO)**, **CHANGED** is ignored and no pages are cached to the group buffer pool.

ALL

Indicates that pages are to be cached to the group buffer pool as they are read in from DASD, with one exception. When the page set is not GBP-dependent and one DB2 data sharing member has exclusive read-write interest in that page set (no other group members have any interest in the page set), no pages are cached in the group buffer pool.

If the index is in a group buffer pool that is defined as **GBPCACHE(NO)**, **ALL** is ignored and no pages are cached to the group buffer pool.

NONE

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-invalidation.

If you specify **NONE**, the index or partition must not be in group buffer pool recover-pending (GRECP) status.

If the index is partitioned, the value of **GBPCACHE** for a particular partition is given by the first of these choices that applies:

1. The value of **GBPCACHE** given in the **PARTITION** clause for that partition. Do not use more than one *gbpcache-specification* in any **PARTITION** clause.
2. The value given in a *gbpcache-specification* before any **PARTITION** clauses.
3. The current value of **GBPCACHE** for that partition.

If you specify **GBPCACHE** in a data sharing environment, the index or partition must be in the stopped state when the ALTER INDEX statement is executed. You cannot alter the **GBPCACHE** value for certain indexes on DB2 catalog tables; for more information, see "SQL statements allowed on the catalog" on page 2697.

end gbpcache-specification block

CLUSTER or NOT CLUSTER

Specifies whether the index is the clustering index for the table.

CLUSTER

The index is used as the clustering index for the table. This change takes effect immediately. Any subsequent insert operations will use the new clustering index. Existing data remains clustered by the previous clustering index until the table space is reorganized.

The implicit or explicit clustering index is ignored when data is inserted into a table space that is defined with **MEMBER CLUSTER**. Instead of using cluster order, DB2 chooses where to locate the data based on available space. The **MEMBER CLUSTER** attribute affects only data that is inserted with an insert operation; data is always loaded and reorganized in cluster order.

Do not specify **CLUSTER** in the following cases:

- The index is for an auxiliary table.
- **CLUSTER** was used already for a different index on the table.
- The index is an XML index.
- The index includes expressions.
- The index is for a table that uses hash organization.
- The index is the hash overflow index for a table.

NOT CLUSTER

The index is not used as the clustering index of the table. If the index is already defined as the clustering index, it continues to be used as the clustering index by DB2 and the REORG utility until clustering is explicitly changed by specifying **CLUSTER** for a different index.

Specifying **NOT CLUSTER** for an index that is not a clustering index is ignored.

If the index is the partitioning index for a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning. The

high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

COMPRESS NO or COMPRESS YES

Specifies whether the index data will be compressed. If the index is partitioned, this option will apply to all partitions.

When an index is changed from one compression option to another (either from COMPRESS YES to COMPRESS NO, or from COMPRESS NO to COMPRESS YES), the index is marked as rebuild pending. For a non-partitioned index, the index will be placed in a page set rebuilding state. For a partitioned index, the index will be placed in rebuilding state.

COMPRESS NO

Specifies that index compression will be turned off.

COMPRESS YES

Specifies that the index will use index compression. **COMPRESS YES** can be specified for user-managed data sets only if the control interval size is 4K.

NOT PADDED or PADDED

Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned.

NOT PADDED

Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key.

NOT PADDED is ignored and has no effect if the index is on an auxiliary table. Indexes on auxiliary tables are always padded.

When **PADDED** is changed to **NOT PADDED**, the maximum key length is recalculated with the varying-length formula ($2000 - n - 2m$, where n is the number of columns that can contain null values and m is the number of varying-length columns in the key). If it is possible that the index key length might exceed the maximum length (because when it was padded, the formula $2000 - n$ was used), an error occurs.

PADDED

Specifies that varying-length string columns within the index are always padded with the default pad character to their maximum length.

When an index with at least one varying-length column is changed from **PADDED** to **NOT PADDED**, or vice versa, the index is placed in restricted rebuild-pending status (RBDP). The index cannot be accessed until it is rebuilt from the table (using the REBUILD INDEX, REORG TABLESPACE, or LOAD REPLACE utility). For nonpartitioned secondary indexes (NPSIs), the index is placed in page set rebuild-pending status (PSRBD), and the entire index must be rebuilt. In addition, packages that are dependent on the table are quiesced, and dynamically cached statements that are dependent on the index are invalidated.

Do not specify **PADDED** if the index is an XML index.

ADD COLUMN *column-name*

Adds *column-name* to the index.

column-name must be unqualified, must identify a column of the table, must not be one of the existing columns of the index, and must not be a LOB column, a DECFLOAT column, or a distinct-type column that is based on a LOB or DECFLOAT data type.

The column cannot be:

- A VARBINARY column or a distinct-type column that is based on a VARBINARY data type, if the column is defined with the DESC attribute or if the index is defined with the PADDED attribute

The column cannot be a timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) when the PARTITION or PARTITION BY RANGE clause is also specified.

The index must not already be defined with the BUSINESS_TIME WITHOUT OVERLAPS specification.

The total number of columns for the index cannot exceed 64.

For PADDED indexes, the sum of the length attributes of the columns must not be greater than $2000 - n$, where n is the number of columns that can contain null values. For NOT PADDED indexes, the sum of the length attributes of the columns must not be greater than $2000 - n - 2m$, where n is the number of nullable columns and m is the number of varying-length columns.

The index cannot be any of the following types of indexes:

- A system-defined catalog index
- An index that enforces a primary key, unique key, or referential constraint, or matches a foreign key
- A partitioning index when index-controlled partitioning is being used
- A unique index required for a ROWID column defined as GENERATED BY DEFAULT
- An auxiliary index
- An XML index
- An index that includes expressions
- The hash overflow index for a table.

The index is put into rebuild-pending (RBDP) status in the following cases:

- *column-name* specifies is a ROWID column
- a column is added to a table, rows are inserted into the table, and the same column is added to an associated index all within the same commit scope
- a column is added to a table and then is added to an associated index in a separate commit scope

Otherwise, the index is put into an advisory reorg-pending (AREO*) state.

ASC

Index entries are put in ascending order by the column.

DESC

Index entries are put in descending order by the column.

RANDOM

Index entries are put in a random order by the column. **RANDOM** cannot be specified in the following cases:

- A varying length column is part of the index key and the index is defined with the NOT PADDED option.

- A column of the index key is defined as `TIMESTAMP WITH TIME ZONE`.
- The index is part of a partitioning key.

ADD INCLUDE (*column-name*)

Specifies an additional column to append to the set of index key columns of a unique index. Any column that is specified using **INCLUDE** *column-name*, is not used to enforce uniqueness. The included column might improve performance for some queries using index only access.

Columns that are specified in the **ADD INCLUDE** clause count towards the limits for the number of columns and the limits on the sum of the length attributes of the columns that are specified in the index. The total number of columns for the index cannot exceed 64.

column-name must be unqualified, must identify a column of the specified table, and must not be one of the existing columns of the index. *column-name* must not identify a LOB or DECFLOAT column (or a distinct type that is based on one of those types).

The **INCLUDE** clause cannot be specified for the following types of indexes:

- A system defined catalog index
- A non-unique index
- A partitioning index when index-controlled partitioning is used
- An auxiliary index
- An index on a foreign key
- An XML index
- An extended index
- An index that includes expressions

If a column is added to both a table and an associated index within the same commit scope and the column is not a ROWID column, the index is placed in an advisory reorg-pending state (AREO*). Otherwise, the index is placed in a rebuild-pending state (RBDP).

Columns in the **INCLUDE** list that are defined as character or graphic string data types must be defined with the same encoding scheme as other key columns with character or graphic string data types.

ALTER PARTITION *integer*

Identifies the partition of the index to be altered. For an index that has *n* partitions, you must specify an integer in the range 1 to *n*. You must not use this clause under the following conditions:

- If the index is nonpartitioned
- If the index is defined on a table that contains an XML column and uses index-controlled partitioning

You must use this clause if the index is partitioned and you specify the **ENDING AT** clause.

ENDING AT(*constant*), **MAXVALUE**, or **MINVALUE**

Specifies the highest value of the index key for the identified partition of the partitioning index. In this context, highest means highest in the sorting sequence of the index columns. In a column defined as ascending (ASC), highest and lowest have the usual meanings. In a column defined as descending (DESC), the lowest actual value is highest in the sorting sequence.

You must use at least one value (*constant*, **MAXVALUE**, or **MINVALUE**) after **ENDING AT** in each **PARTITION** clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index. The length of each highest key value (also called the limit key) is the same as the length of the partitioning index

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is 'X'FF'. If the column is descending, the padding character is 'X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all 'X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the **MINVALUE** clause cannot be specified following **MAXVALUE**. After **MAXVALUE** is specified, all subsequent columns must be **MAXVALUE**.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all 'X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the **MAXVALUE** clause cannot be specified following **MAXVALUE**. After **MINVALUE** is specified, all subsequent columns must be **MINVALUE**.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on.
- If a key includes a ROWID column (or a column with a distinct type that is based on a ROWID data type), the values of the ROWID column are assumed to be in the range of 'X'000...00' to 'X'FFF...FF'. Only the first 17 bytes of the value that is specified for the corresponding ROWID column are considered.
- Using fewer values than there are columns in the key has the same effect as using the highest possible values for all omitted columns for an ascending index.
- If the key exceeds 255 bytes, only the first 255 bytes are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- The highest value of the key in the last partition depends on how the table space was defined. For table spaces created without the **LARGE** or **DSSIZE** option, the constants you specify after **ENDING AT** are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

For table spaces created with the **LARGE** or **DSSIZE** options, the constants you specify after **ENDING AT** are enforced. The value specified for the last partition is the highest value of the key that can be

placed in the table. Any keys that are made invalid after the ALTER TABLE statement is executed are placed in a discard data set when you run the REORG utility. If the last partition is in reorg-pending status, regardless of whether you changed its limiting key values, you must specify a discard data set when you run the REORG utility.

ENDING AT must not be specified for any indexes defined on a table that uses table-controlled partitioning. Use ALTER TABLE ALTER PARTITION to modify the partitioning boundaries for a table that uses table-controlled partitioning.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

Notes

Pending definition changes:

The following ALTER INDEX options can cause pending changes to the definition of the specified index under certain conditions:

- BUFFERPOOL
- COMPRESS

ALTER INDEX BUFFERPOOL results in an immediate definition change except when all of the following conditions are true:

- The data sets of the index are created
- The index is defined on one of the following:
 - A table that is in a universal table space
 - An XML table that is associated with a base table this is in a universal table space
 - An auxiliary table that is associated with a base table that is in a universal table space
- There are pending definition changes for the index or the table space, or the buffer pool is changed to a buffer pool with a different size.

When ALTER INDEX causes a pending definition change, semantic validation and authorization checking are performed for the statement. However, the current definition of the index is not changed, and the index is placed in advisory REORG-pending (AREOR) state. If there are no pending definition changes for the table space, you can run the REORG INDEX utility with SHRLEVEL CHANGE or the REORG TABLESPACE utility with SHRLEVEL CHANGE or REFERENCE to enable the changes to the definition of the index. If pending definition changes also exist for the table space, you must run the REORG TABLESPACE utility with SHRLEVEL CHANGE or REFERENCE to enable the changes to the definition of the index (and the pending table space definition). When the pending definition changes are applied to the index, dependent packages might be invalidated.

Restrictions involving pending definition changes:

ALTER INDEX statements that result in a pending definition change are not allowed in the following cases:

- On the catalog, system objects, or objects in a workfile database
- If the definition of the table space is incomplete
- If the definition of the table on which the index is defined is incomplete

- If the ALTER INDEX statement also specifies options that will cause an immediate definition change
- If there are already pending definition changes to the index, ALTER INDEX to change from COMPRESS NO to COMPRESS YES is not allowed
- If there are already pending definition changes to the index or the table space that contains the index, the following are not allowed:
 - ALTER INDEX (with or without ALTER PARTITION) to change from a DB2-managed data set to a user-managed data set
 - ALTER INDEX REGENERATE to regenerate the index
 - ALTER INDEX ADD COLUMN to add a column to the index
 - ALTER INDEX to change the value of PIECESIZE

Altering storage attributes:

The **USING**, **PRIQTY**, **SECQTY**, and **ERASE** clauses define the storage attributes of the index or partition. If you specify the **USING** or **ERASE** clause when altering storage attributes, the index or partition must be in the stopped state when the ALTER INDEX statement is executed. A **STOP DATABASE...SPACENAM...** command can be used to stop the index or partition.

If the catalog name changes, the changes take effect after you move the data and start the index or partition using the **START DATABASE...SPACENAM...** command. The catalog name can be implicitly or explicitly changed by the ALTER INDEX statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in *DB2 Administration Guide*.

Changes to the secondary space allocation (**SECQTY**) take effect the next time DB2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the REORG, RECOVER, or LOAD REPLACE utility on the index or partition. Changes to the other storage attributes take effect the next time you use the REORG, RECOVER, or LOAD REPLACE utility on the index or partition. If you change the primary space allocation parameters or erase rule, you can have the changes take effect earlier if you move the data before you start the index or partition.

Altering indexes on DB2 catalog tables:

For details on altering options on catalog tables, see “SQL statements allowed on the catalog” on page 2697.

Size restriction for the object descriptor of an index in the SYSIBM.SYSOBDS catalog table:

The following case might result in an error being returned if the ALTER INDEX statement results in a versioned object descriptor that is larger than 30,000 bytes being added (or updated) in the SYSIBM.SYSOBDS catalog table:

- An ALTER INDEX statement that results in the first version of the object descriptor being generated for the index

You might need to drop and re-create the index if the object descriptor for the index exceeds 30,000 bytes.

Altering limit keys:

If you specify **ALTER PARTITION *integer* ENDING AT** to change the

limit key values of a partitioning index, the packages that are dependent on that index are marked invalid and go through automatic rebind the next time they are run.

Invalidation of packages:

When an index is altered, all the packages that refer to that index are marked invalid if one of the following conditions is true:

- A column is added to the index.
- The index is altered to be **PADDED** or **NOT PADDED**.
- The index is a partitioning index on a table that uses index-controlled partitioning, and one or more limit key values is altered.
- The index is altered to **REGENERATE**.

Restrictions on SQL data change statements in the same commit scope as ALTER INDEX:

SQL data change statements that affect an index cannot be performed in the same commit scope as ALTER INDEX statements that affect that index.

Altering indexes for tables that are involved in a clone relationship:

You cannot change any index for a table that is involved in a clone relationship (base table or clone table). If a change to an index is required, the clone table must be dropped before the index can be changed. After the index is changed, the clone table can be created again.

Adding a varying length column to a key for a system with NOT PADDED as the default:

If the system default is NOT PADDED (the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE is NO), no varying length columns are in the key, and the PADDED or NOT PADDED option is not explicitly specified when the index is created, the PADDED column of the SYSIBM.SYSINDEXES catalog table is populated with a blank value. If a varying length column is later added to the key, the value of the PADDED column in SYSIBM.SYSINDEXES is changed to 'Y' to indicate that the index is now a PADDED index.

Running utilities:

You cannot execute the ALTER INDEX statement while a DB2 utility has control of the index or its associated table space.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords when altering the partitions of a partitioned index:

- PART can be specified as a synonym for **PARTITION**. In addition, the **ALTER** keyword that precedes **PARTITION** is optional. In addition, if you alter more than one partition, specifying a comma between each **ALTER PARTITION integer** clause is optional.
- VALUES can be specified as a synonym for **ENDING AT**.

Although these keywords are supported as alternatives, they are not the preferred syntax.

Examples

Example 1: Alter the index DSN8A10.XEMP1. Indicate that DB2 is not to close the data sets that support the index when there are no current users of the index.

```
ALTER INDEX DSN8A10.XEMP1
CLOSE NO;
```

Example 2: Alter the index DSN8A10.XPROJ1. Use BP1 as the buffer pool that is to be associated with the index, indicate that full image or concurrent copies on the index are allowed, and change the maximum size of each data set to 8 megabytes.

```
ALTER INDEX DSN8A10.XPROJ1
BUFFERPOOL BP1
COPY YES
PIECESIZE 8M;
```

Example 3: Assume that index X1 contains a least one varying-length column and is a padded index. Alter the index to an index that is not padded.

```
ALTER INDEX X1
NOT PADDED;
```

The index is placed in restricted rebuild-pending status (RBDP) and cannot be accessed until it is rebuilt from the table

Example 4: Alter partitioned index DSN8A10.DEPT1. For partition 3, leave one page of free space for every 13 pages and 13 percent of free space per page. For partition 5, leave one page for every 25 pages and 25 percent of free space. For all the other partitions, leave one page of free space for every 6 pages and 11 percent of free space. Ensure that index pages are cached to the group buffer pool for all partitions except partition 4. For partition 4, write pages only when there is inter-DB2 read-write interest on the partition.

```
ALTER INDEX DSN8A10.XDEPT1
BUFFERPOOL BP1
CLOSE YES
COPY YES
USING VCAT CATLGG
FREEPAGE 6
PCTFREE 11
GBPCACHE ALL
ALTER PARTITION 3
USING VCAT CATLGG
FREEPAGE 13
PCTFREE 13,
ALTER PARTITION 4
USING VCAT CATLGG
GBPCACHE CHANGED,
ALTER PARTITION 5
USING VCAT CATLGG
FREEPAGE 25
PCTFREE 25;
```

ALTER MASK

The ALTER MASK statement changes a column mask that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER MASK mask-name { ENABLE | DISABLE | REGENERATE }
```

The diagram shows the syntax for the ALTER MASK statement. It starts with the keyword ALTER MASK, followed by a hyphenated placeholder mask-name. A bracketed list of three options follows: ENABLE, DISABLE, and REGENERATE. The entire statement is enclosed in a box with arrows at both ends, indicating it is a complete statement.

Description

mask-name

Identifies the column mask to be altered. The name must identify a mask that exists at the current server.

ENABLE

Specifies that the column mask is to be enabled for column access control. If column access control is not currently activated for the table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

A column mask with a regeneration error cannot be enabled. To clear the status of the column mask, the column mask must be dropped and re-created with a modified definition.

ENABLE is ignored if the column mask is already defined as enabled for column access control.

DISABLE

Specifies that the column mask is to be disabled for column access control. If column access control is not currently activated for the table, the column mask will remain ineffective when column access control is activated for the table. If column access control is currently activated for the table, the column mask

becomes ineffective immediately and all packages and dynamic cached statements that reference the table are invalidated.

DISABLE is ignored if the column mask is already defined as disabled for column access control.

REGENERATE

Specifies that the column mask is to be regenerated. The column mask definition in the catalog is used, and existing dependencies and authorization, if any, are retained. The column mask definition is reevaluated as if the column mask was being created. The user-defined functions that are referenced in the column mask definition must be resolved to the same secure UDFs as that were resolved during the column mask creation.

Notes

Applying DB2 maintenance:

When DB2 maintenance is applied that affects how a column mask is generated, the column mask might need to be regenerated to ensure the column mask is still valid.

If the column mask is regenerated successfully, the status of the column mask is set to a blank in the catalog table. If the column mask is enabled and column access control is currently activated for the table, all packages and dynamic cached statements that reference the table are invalidated.

If the column mask cannot be regenerated successfully, an error is returned. The regeneration status of the column mask is an error. If the column mask is enabled and column access control is currently activated for the table, all packages and dynamic cached statements that reference the table are marked invalidated. To clear the status of the column mask, the column mask must be dropped and re-created with a modified definition. Or the column mask can be disabled if not disabled yet. A disabled column mask becomes ineffective to a column access control enforced table.

When the table is referenced in a data manipulation statement, the statement returns an error if any enabled column mask has a regeneration error.

Examples

Example 1:

Enable column mask M1.

```
ALTER MASK M1 ENABLE;
```

Example 2:

Regenerate column mask M1.

```
ALTER MASK M1 REGENERATE;
```

```
COMMIT;
```

ALTER PERMISSION

The ALTER PERMISSION statement alters a row permission that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER PERMISSION permission-name { ENABLE | DISABLE | REGENERATE }
```

The diagram shows the syntax for the ALTER PERMISSION statement. It starts with the keyword ALTER PERMISSION, followed by a placeholder for the permission name (*permission-name*). Then, there is a list of three options: ENABLE, DISABLE, and REGENERATE, each enclosed in a box and separated by vertical lines. The entire statement is enclosed in a larger box with arrows at both ends.

Description

permission-name

Identifies the permission to be altered. The name must identify a row permission that exists at the current server. The name must not identify a default row permission that is created implicitly by DB2.

ENABLE

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

A row permission with a regeneration error cannot be enabled. To clear the status of the row permission, the row permission must be dropped and re-created with a modified definition.

ENABLE is ignored if the row permission is already defined as enabled for row access control.

DISABLE

Specifies that the row permission is to be disabled for row access control. If row access control is not currently activated for the table, the row permission will remain ineffective when row access control is activated for the table. If row access control is currently activated for the table, the row permission

becomes ineffective immediately and all packages and dynamic cached statements that reference the table are invalidated.

DISABLE is ignored if the row permission is already defined as disabled for row access control.

REGENERATE

Specifies that the row permission is to be regenerated. The row permission definition in the catalog is used, and existing authorizations and dependencies, if any, are retained. The user-defined functions that are referenced in the row permission definition must be resolved to the same secure UDFs as that were resolved during the row permission creation.

Notes

Applying DB2 maintenance:

When DB2 maintenance is applied that affects how a row permission is generated, the row permission might need to be regenerated to ensure the row permission is still valid.

If the row permission is regenerated successfully, the status of the row permission is set to a blank in the catalog table. If the row permission is enabled and row access control is currently activated for the table, all packages and dynamic cached statements that reference the table are invalidated.

If the row permission cannot be regenerated successfully, an error is returned. The regeneration status of the row permission is set to an error. If the row permission is enabled and row access control is currently activated for the table, all packages and dynamic cached statements that reference the table are marked invalidated. To clear the status of the row permission, the row permission must be dropped and re-created with a modified definition. Or the row permission can be disabled if not disabled yet. A disabled row permission becomes ineffective to a row access control enforced table.

When the table is referenced in a data manipulation statement, the statement returns an error if any enabled row permission has an regeneration error.

Examples

Example 1:

Enable permission P1.

```
ALTER PERMISSION P1 ENABLE;
```

Example 2:

Regenerate permission P1.

```
ALTER PERMISSION P1 REGENERATE;
```

ALTER PROCEDURE (external)

The ALTER PROCEDURE statement changes the description of an external stored procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file, the Java archive file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

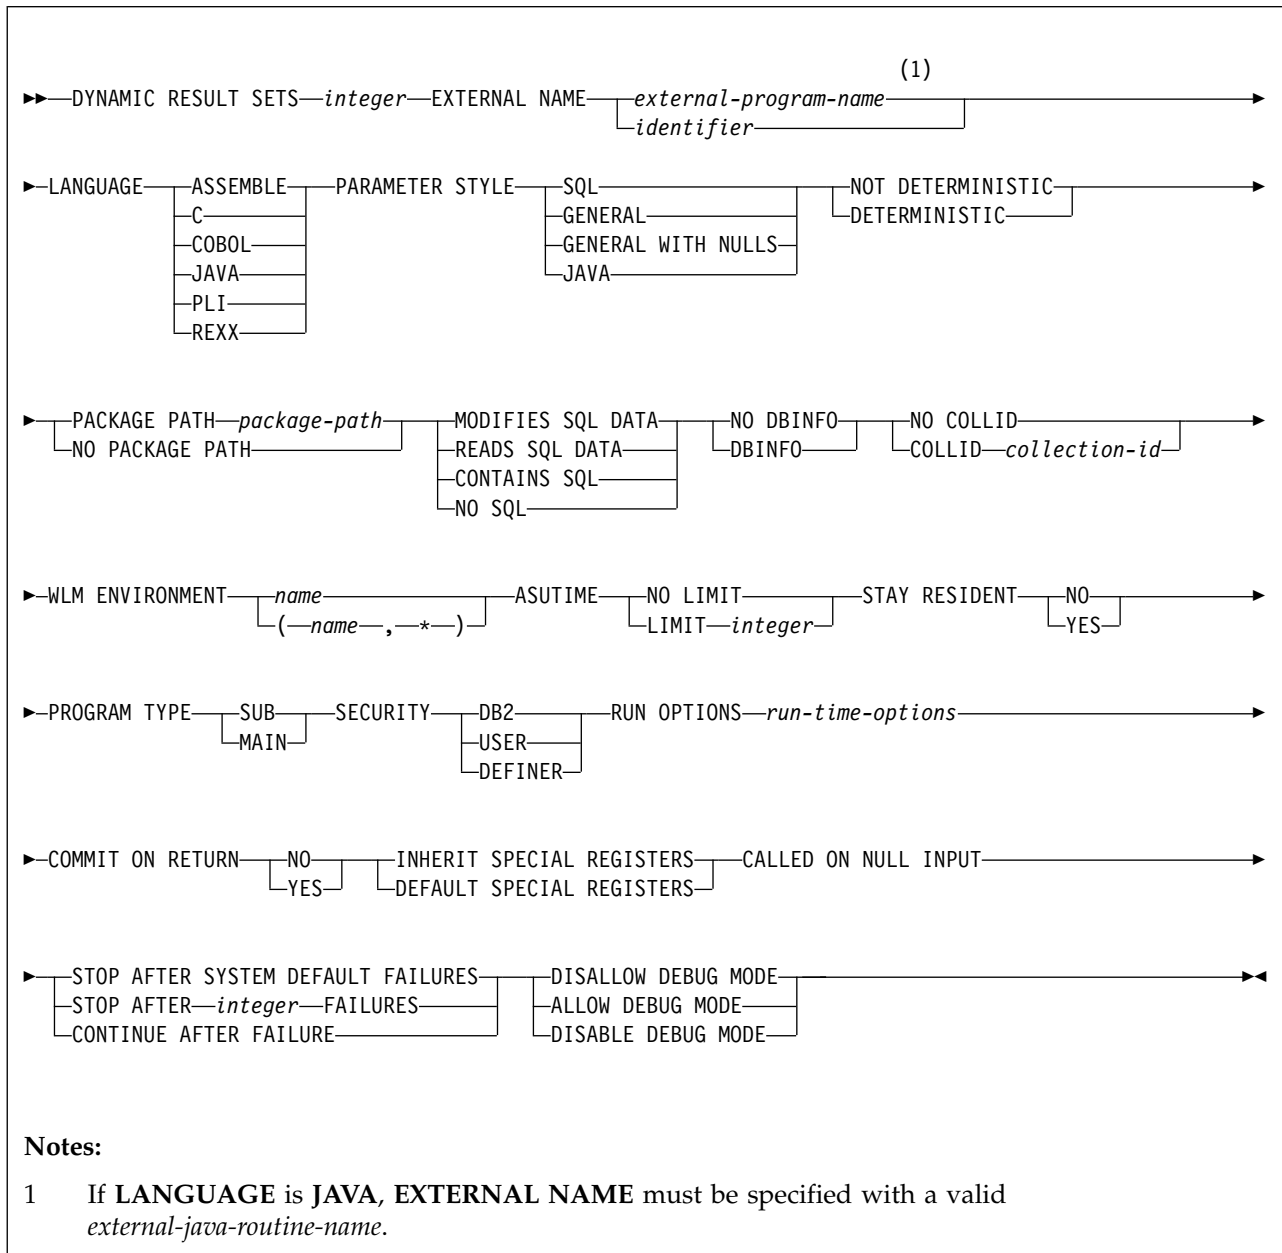

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

If the environment in which the stored procedure is to run is being changed, the authorization ID must have authority to use the WLM environment. This authorization is obtained from an external security product, such as RACF.

Syntax

```
▶▶ALTER PROCEDURE—procedure-name—| option-list |————▶▶
```

option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

external-java-routine-name:**jar-name:****method-name:****method-signature:****Notes:**

- 1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

Description*procedure-name*

Identifies the stored procedure to be altered.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the stored procedure can return. The value must be between 0 and 32767.

EXTERNAL NAME *external-program-name* **or** *identifier*

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement.

If **LANGUAGE** is **JAVA**, *external-program-name* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *external-program-name* values are specified, the total length of all of the values must not be greater than 1305 bytes and each value must be separated by a space or a line break. Do not specify a JAR file for a Java procedure for which **NO SQL** is in effect.

An *external-java-routine-name* contains the following parts:

jar-name

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the **QUALIFIER** bind option when the package or plan was created or last rebound. If the **QUALIFIER** was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the ALTER PROCEDURE statement is processed.

If *jar-name* is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

method-name

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

class-id

Identifies the class identifier of the Java object.

method-id

Identifies the method identifier with the Java class to be invoked.

method-signature

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER PROCEDURE statement.

For other values of **LANGUAGE**, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8

bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

LANGUAGE

Specifies the application programming language in which the stored procedure is written. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM's Language Environment.

ASSEMBLE

The stored procedure is written in Assembler.

C The stored procedure is written in C or C++.

COBOL

The stored procedure is written in COBOL, including the OO-COBOL language extensions.

JAVA

The stored procedure is written in Java and is executed in the Java Virtual Machine. When **LANGUAGE JAVA** is specified, the **EXTERNAL NAME** clause must also be specified with a valid *external-java-routine-name* and **PARAMETER STYLE** must be specified with **JAVA**. The procedure must be a public static method of the specified Java class.

Do not specify **LANGUAGE JAVA** when **DBINFO**, **PROGRAM TYPE MAIN**, or **RUN OPTIONS** is in effect.

PLI

The stored procedure is written in PL/I.

REXX

The stored procedure is written in REXX. Do not specify **LANGUAGE REXX** when **PARAMETER STYLE SQL** is specified.

PARAMETER STYLE

Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to the stored procedure that contain the parameters specified on the **CALL** statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see *DB2 Application Programming and SQL Guide*.

SQL

Specifies that, in addition to the parameters on the **CALL** statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first *n* parameters that are specified on the **CREATE PROCEDURE** statement.
- *n* parameters for indicator variables for the parameters.
- The **SQLSTATE** to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to DB2.
- If **DBINFO** is specified, the **DBINFO** structure.

Do not specify **PARAMETER STYLE SQL** when **LANGUAGE REXX** is specified.

GENERAL

Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

GENERAL WITH NULLS

Specifies that, in addition to the parameters on the CALL statement as specified in **GENERAL**, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short integers. The indicator array enables the stored procedure to accept or return null parameter values.

JAVA

Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. **PARAMETER STYLE JAVA** can be specified only if **LANGUAGE** is **JAVA**. If the ALTER PROCEDURE statement results in changing **LANGUAGE** to **JAVA**, **PARAMETER STYLE JAVA**, and an **EXTERNAL NAME** clause might need to be specified to provide appropriate values. **JAVA** must be specified for **PARAMETER STYLE** when **LANGUAGE** is **JAVA**.

INOUT and **OUT** parameters are passed as single-entry arrays. The **INOUT** and **OUT** parameters are declared in the Java method as single-element arrays of the Java type.

PARAMETER STYLE SQL cannot be used with **LANGUAGE REXX**.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same **IN** and **INOUT** arguments.

DETERMINISTIC

The stored procedure always returns the same results each time the stored procedure is called with the same **IN** and **INOUT** arguments, if the referenced data in the database has not changed.

NOT DETERMINISTIC

The stored procedure might not return the same result each time the procedure is called with the same **IN** and **INOUT** arguments, even when the referenced data in the database has not changed.

DB2 does not verify that the stored procedure code is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

NO PACKAGE PATH or PACKAGE PATH *package-path*

Identifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

NO PACKAGE PATH

Specifies that the list of package collections for the procedure is the same as the list of package collections for the calling program. If the calling program does not use a package, DB2 resolves the package by using the **CURRENT PACKAGE PATH** special register, the **CURRENT PACKAGESET** special register, or the **PKLIST** bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as used in the CURRENT PACKAGE PATH special register.

If the **COLLID** clause is specified with **PACKAGE PATH**, the **COLLID** clause is ignored when the routine is invoked.

The *package-path* value that is associated with the procedure definition is checked when the procedure is invoked. If *package-path* contains SESSION_USER, USER, PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies which SQL statements, if any, can be executed in the procedure or any routine that is called from this procedure. For the data access classification of each statement, see Table 217 on page 2318.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that procedure can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

NO SQL

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL. Do not specify **NO SQL** for a Java procedure that uses a JAR file.

NO DBINFO or DBINFO

Specifies whether additional status information is passed to the stored procedure when it is invoked.

NO DBINFO

Additional information is not passed.

DBINFO

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the procedure might be inserting into or updating, and identification of the database server that invoked the procedure. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

DBINFO can be specified only if **PARAMETER STYLE SQL** is specified.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.

NO COLLID

Specifies that the package collection for the stored procedure is the same as the package collection of the calling program. If the invoking program does

not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the **PKLIST** bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

COLLID *collection-id*

Identifies the package collection that is to be used when the stored procedure is executed. It is the name of the package collection into which the DBRM associated with the stored procedure is bound.

For REXX stored procedures, *collection-id* can be DSNREXRR, DSNREXRS, DSNREXCR, or DSNREXCS.

WLM ENVIRONMENT

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

name

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the stored procedure request to a different address space.

(name,)*

When the stored procedure is called directly by an SQL application program, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column in the resource limit specification table.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on CPU service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the service units.

LIMIT *integer*

The limit on the service units is a positive *integer* in the range of 1 to 2 147 483 647. If the stored procedure uses more service units than the specified value, DB2 cancels the stored procedure.

STAY RESIDENT

Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends.

NO The load module is deleted from memory after the stored procedure ends. Use **NO** for non-reentrant stored procedures.

YES

The load module remains resident in memory after the stored procedure ends.

PROGRAM TYPE

Specifies whether the stored procedure runs as a main routine or a subroutine. If PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for the change to take effect.

SUB

The stored procedure runs as a subroutine.

Do not specify **PROGRAM TYPE SUB** for stored procedures with a **LANGUAGE** value of **REXX**.

MAIN

The stored procedure runs as a main routine.

Do not specify **PROGRAM TYPE MAIN** when **LANGUAGE JAVA** is specified.

SECURITY

Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space.

USER

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

DEFINER

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

RUN OPTIONS *run-time-options*

Specifies the Language Environment run time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run time options to be passed to the REXX language interface to DB2. You must specify *run-time-options* as a character string that is no longer than 254 bytes. To replace any existing run time options with no options, specify an empty string with **RUN OPTIONS**. When you specify an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment run time options, see *z/OS Language Environment Programming Reference*.

Do not specify **RUN OPTIONS** when **LANGUAGE JAVA** is specified.

COMMIT ON RETURN

Indicates whether DB2 is to commit the transaction immediately on return from the stored procedure.

NO DB2 does not issue a commit when the stored procedure returns.

YES

DB2 issues a commit when the stored procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Indicates that values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Table 43 on page 199.

DEFAULT SPECIAL REGISTERS

Indicates that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Table 43 on page 199.

CALLED ON NULL INPUT

Specifies that the procedure is to be called even if any or all of the argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation field DSNTIPX.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether the procedure can be run in debugging mode.

Do not specify this option unless the procedure is defined with LANGUAGE JAVA.

ALLOW DEBUG MODE

Specifies that the procedure can be run in debugging mode.

DISALLOW DEBUG MODE

Specifies that the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE

Specifies that the procedure can never be run in debugging mode.

The procedure cannot be changed to specify **ALLOW DEBUG MODE** or **DISALLOW DEBUG MODE** when the procedure has been created or altered to use **DISABLE DEBUG MODE**. To change this option, you must drop and re-create the procedure using the option that you want.

Notes

Invalidation of packages: When an external procedure is altered, all the packages that refer to that procedure are marked invalid.

LANGUAGE C and the PARAMETER VARCHAR clause: The ALTER PROCEDURE statement does not allow you to alter the value of the **PARAMETER VARCHAR** or **PARAMETER CCSID** clauses that are associated with the procedure definition. However, you can alter the **LANGUAGE** clause for the procedure. If the **PARAMETER VARCHAR** clause is specified for the creation of a LANGUAGE C procedure, the catalog information for that option is not affected by subsequent ALTER PROCEDURE statements. The procedure might be changed to a language other than C, in which case the **PARAMETER VARCHAR** setting is ignored. If the procedure is later changed back to LANGUAGE C, the setting of the **PARAMETER VARCHAR** option that was specified for the CREATE PROCEDURE statement (which is still in the catalog) will be used.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- **DYNAMIC RESULT SET, RESULT SET, and RESULT SETS** as synonyms for **DYNAMIC RESULT SETS**
- **STANDARD CALL** as a synonym for **DB2SQL**
- **SIMPLE CALL** as a synonym for **GENERAL**
- **SIMPLE CALL WITH NULLS** as a synonym for **GENERAL WITH NULLS**
- **VARIANT** as a synonym for **NOT DETERMINISTIC**
- **NOT VARIANT** as a synonym for **DETERMINISTIC**
- **NULL CALL** as a synonym for **CALLED ON NULL INPUT**
- **PARAMETER STYLE DB2SQL** as a synonym for **PARAMETER STYLE SQL**

Example

Assume that stored procedure SYSPROC.MYPROC is currently defined to run in WLM environment PARTSA and that you have appropriate authority on that WLM environment and WLM environment PARTSEC. Change the definition of the stored procedure so that it runs in PARTSEC.

```
ALTER PROCEDURE SYSPROC.MYPROC WLM ENVIRONMENT PARTSEC;
```

ALTER PROCEDURE (SQL - external)

The ALTER PROCEDURE statement changes the description, at the current server, of an external SQL procedure.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

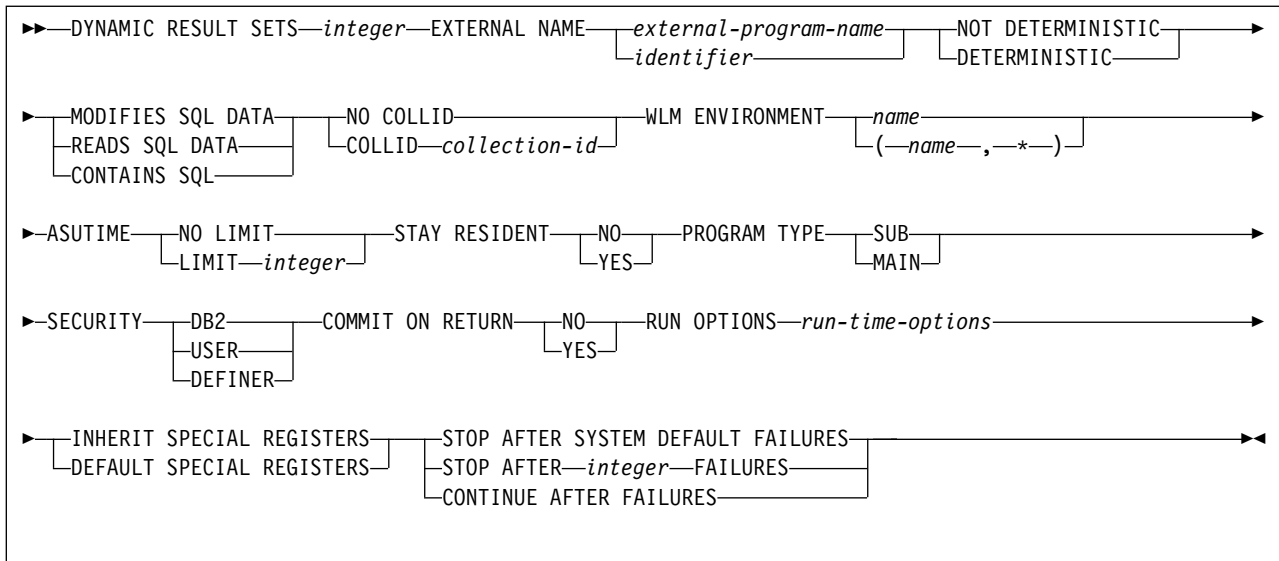

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

The SQL authorization ID that is used to alter the procedure definition must have appropriate authority for the WLM environment in which the procedure is currently defined to run. This authorization is obtained from an external security product, such as RACF.

Syntax

```
▶—ALTER PROCEDURE—procedure-name—| option-list |————▶
```

option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

Description

procedure-name

Identifies the stored procedure to be altered.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the procedure can return. The value must be between 0 and 32767.

EXTERNAL NAME *external-program-name* **or** *identifier*

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

NOT DETERMINISTIC **or** **DETERMINISTIC**

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

NOT DETERMINISTIC

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

DETERMINISTIC

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements that the procedure can execute. For the data access classification of each statement, see Table 217 on page 2318. Statements that are not supported in any procedure will return an error.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

NO COLLID

Indicates that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the **PKLIST** bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

COLLID *collection-id*

Specifies the package collection for the procedure.

WLM ENVIRONMENT *name* or (*name*,*)

Identifies the WLM (workload manager) environment in which the procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

name

Specifies the WLM environment in which the procedure must run. If another routine calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the procedure request to a different address space.

(*name*,*)

When an SQL application program directly calls a procedure, *name* specifies the WLM environment in which the stored procedure runs.

If another routine calls the procedure, the procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the number of CPU service units that the procedure can run.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the load module for the procedure is to remain resident in memory when the procedure ends.

NO The load module is deleted from memory after the procedure ends.

YES

The load module remains resident in memory after the procedure ends.

PROGRAM TYPE

Specifies whether the procedure runs as a main routine or a subroutine. If PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for the change to take effect.

SUB

The procedure runs as a subroutine.

MAIN

The procedure runs as a main routine.

SECURITY

Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.

USER

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

DEFINER

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

RUN OPTIONS *run-time-options*

Specifies the Language Environment run time options that are to be used for the procedure. You must specify *run-time-options* as a character string that is no longer than 254 bytes. If you do not specify **RUN OPTIONS** or pass an empty

string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see *z/OS Language Environment Programming Reference*.

COMMIT ON RETURN

Indicates whether DB2 commits the transaction immediately on return from the procedure.

NO DB2 does not issue a commit when the procedure returns.

YES

DB2 issues a commit when the procedure returns if the following statements are true:

- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a procedure in Table 43 on page 199.

DEFAULT SPECIAL REGISTERS

Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 43 on page 199.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies if the routine is stopped after failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURES

Specifies that this routine should not be placed in a stopped state after any failure.

Notes

Changing to a native SQL procedure: You cannot change an external SQL procedure to a native SQL procedure. You can drop the procedure that you want to change using the DROP statement and create a native SQL procedure with a similar definition using the CREATE PROCEDURE statement. Alternatively, you can create a native SQL procedure using a different schema.

Invalidation of packages: When an SQL procedure is altered, all packages that refer to that procedure are marked invalid.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 UDB family, DB2 supports the following keywords:

- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for **DYNAMIC RESULT SETS**.
- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**

Example

Modify the definition for an SQL procedure so that SQL changes are committed on return from the SQL procedure and the SQL procedure runs in the WLM environment named WLMSQLP.

```
ALTER PROCEDURE UPDATE_SALARY_1
  COMMIT ON RETURN YES
  WLM ENVIRONMENT WLMSQLP;
```

ALTER PROCEDURE (SQL - native)

The ALTER PROCEDURE statement changes the definition of an SQL procedure at the current server. The procedure options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER PROCEDURE statement.

For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 8, “SQL control statements for SQL routines,” on page 2251.

Invocation

This statement can only be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCtrl authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

Additional privileges might be required in the following situations:

- If *SQL-routine-body* is specified, the privilege set must include the privileges that are required to execute the statements in *SQL-routine-body*.
- If a user-defined type is referenced (as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following privileges or authorities:
 - Ownership of the distinct type
 - The USAGE privilege on the distinct type
 - SYSADM authority
- If the procedure uses a table as a parameter, the privilege set must also include at least one of the following privileges or authorities:
 - Ownership of the table
 - The SELECT privilege on the table
 - SYSADM authority
- If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, the privilege set must include the authority to define programs that run in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

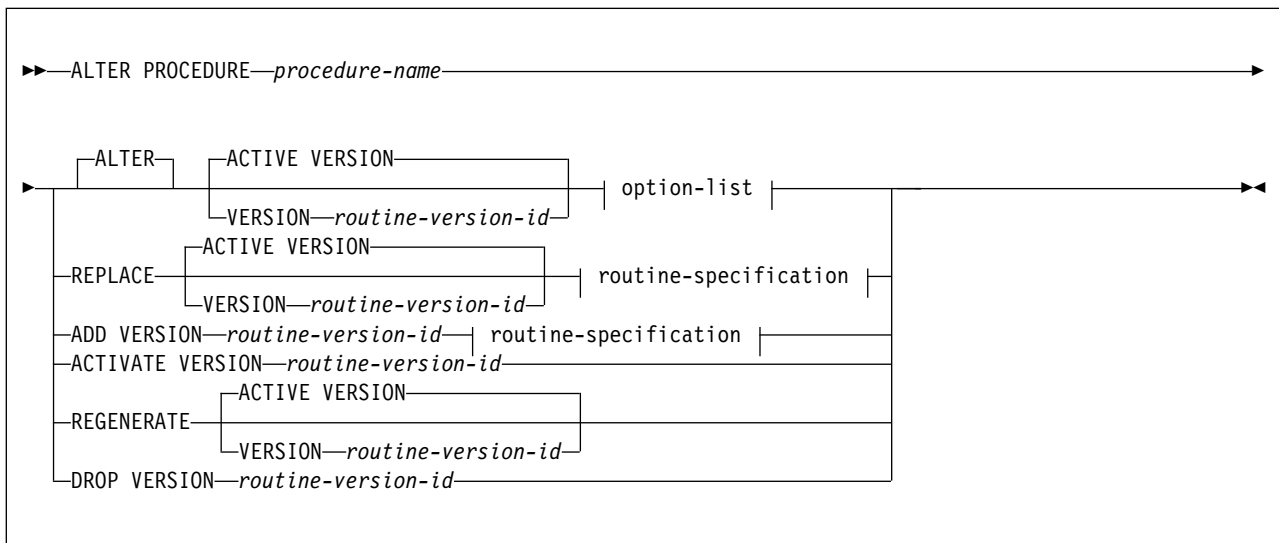

- When defining a new version of a procedure (using the ADD VERSION clause) or when replacing an existing version (using the REPLACE VERSION clause), the privilege set must include the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL authority.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

Syntax

routine-specification:

Notes:

- 1 All versions of the procedure must have the same number of parameters.

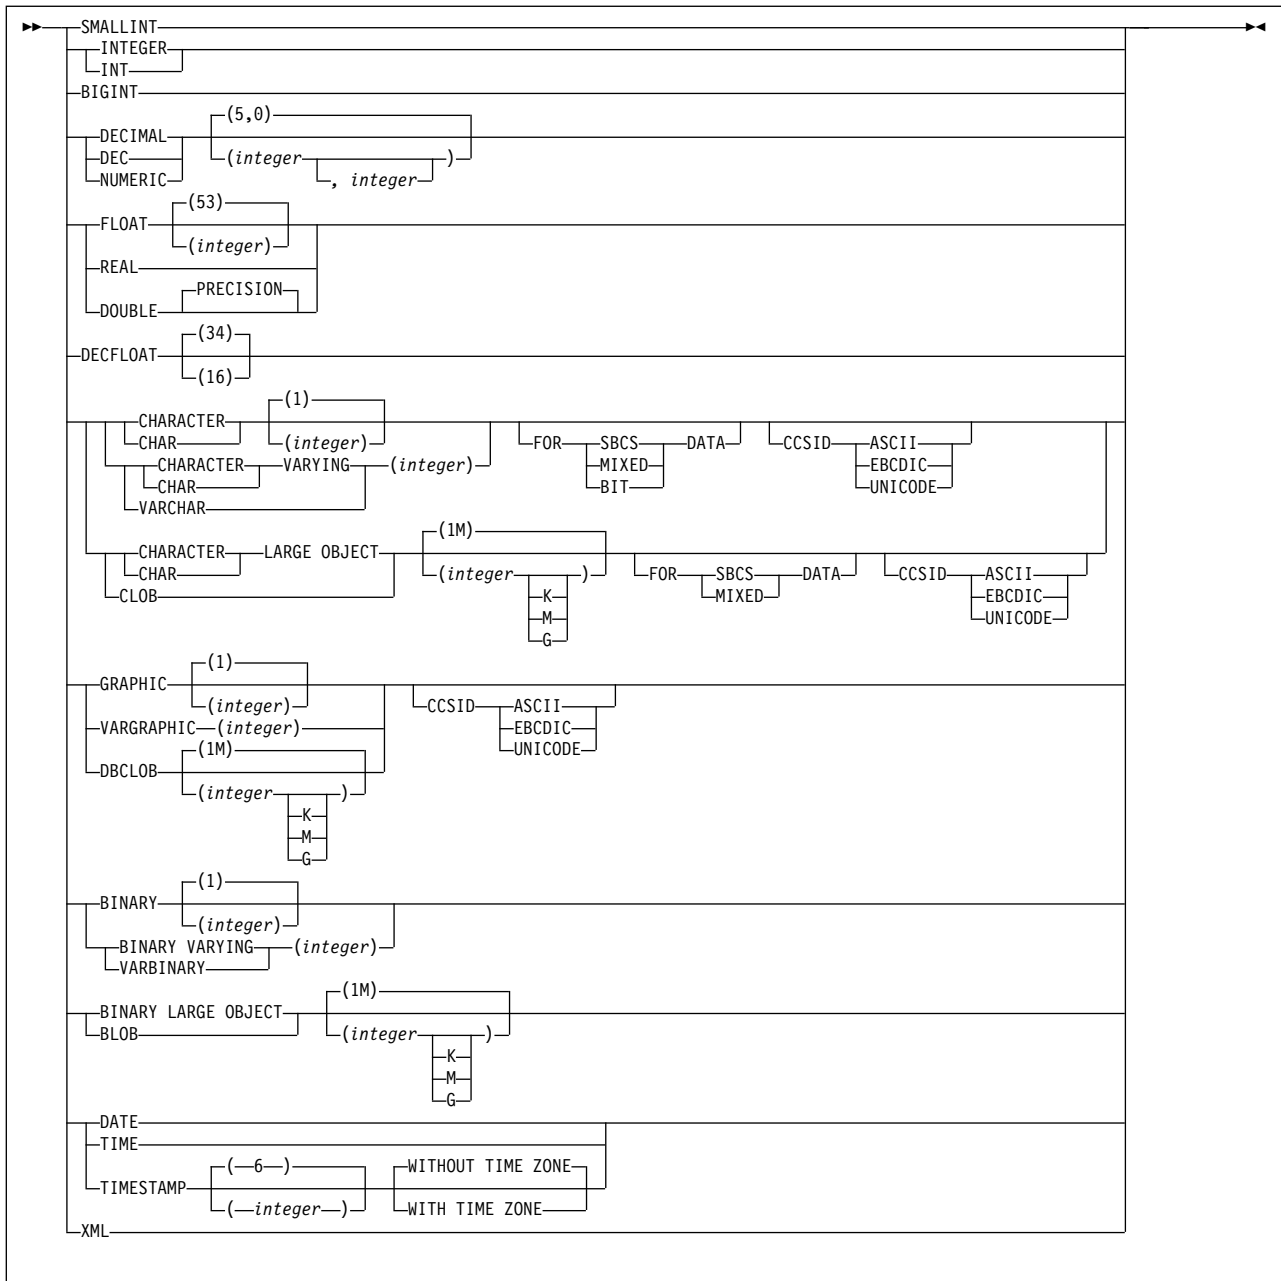

parameter-declaration:

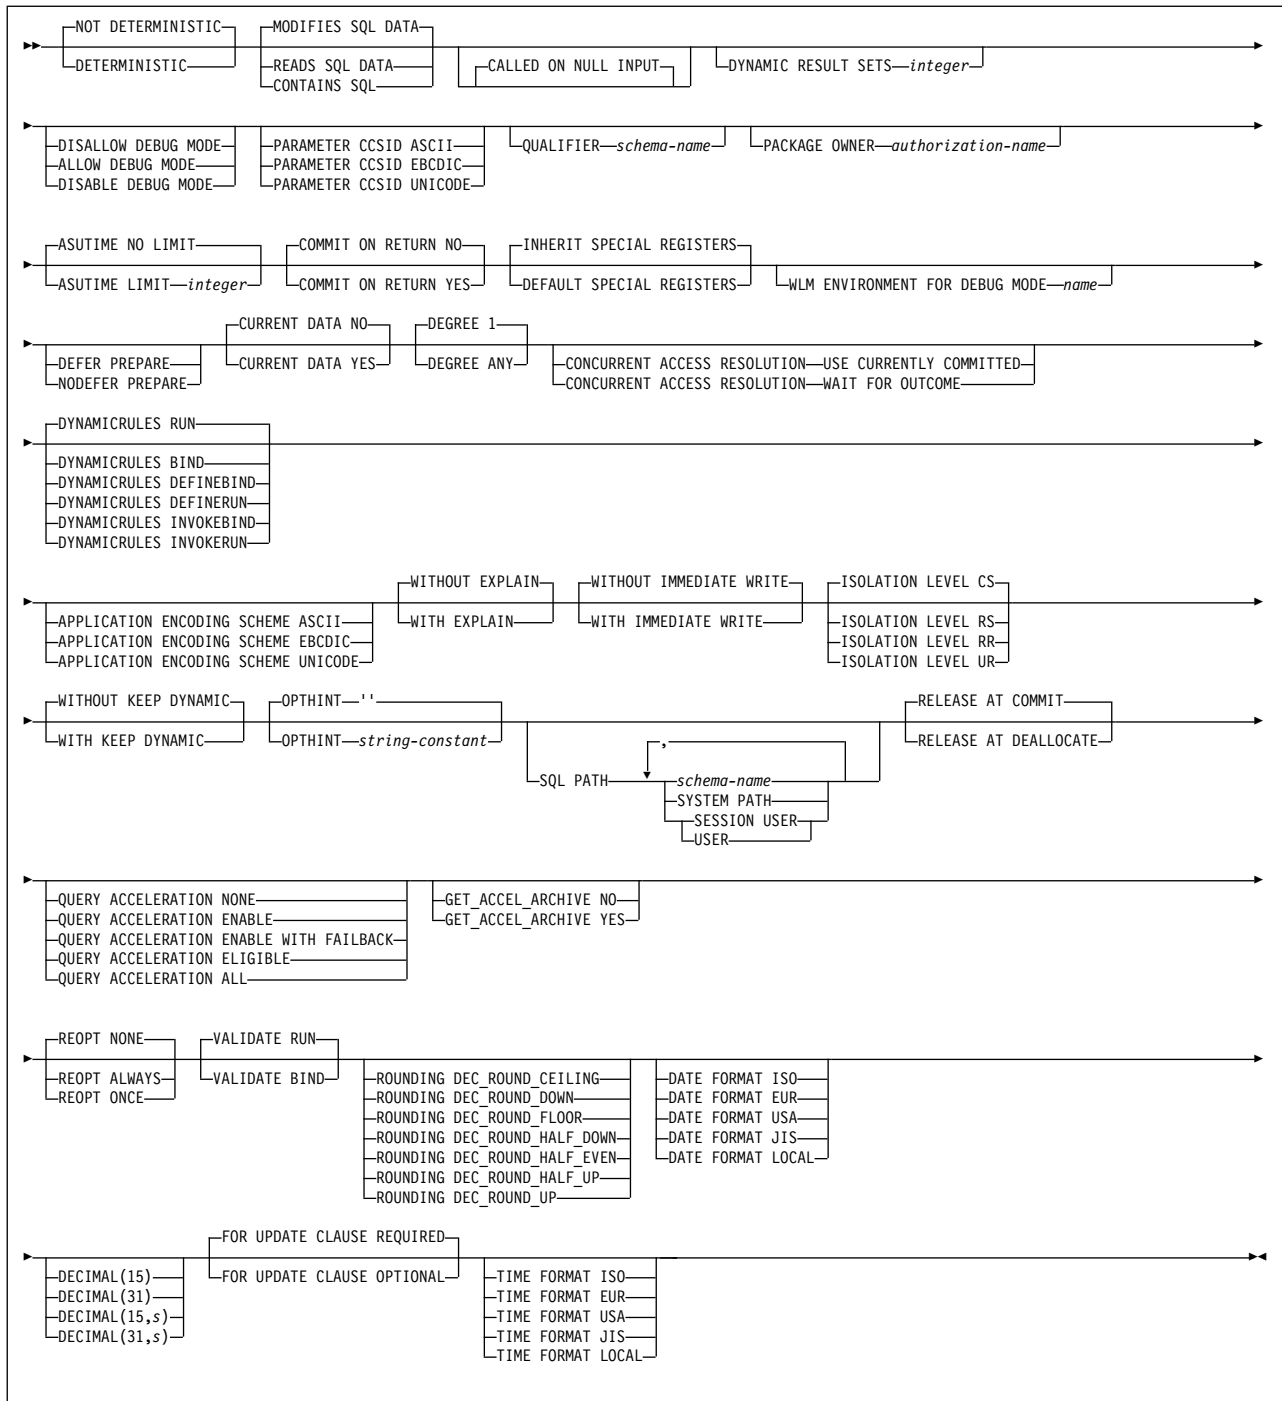

data-type:

built-in-type:

option-list: (The options can be specified in any order, but each option can be specified only one time.)

SQL-routine-body:

| | |
|---|--|
| SQL-control-statement | |
| ALTER DATABASE statement | |
| ALTER FUNCTION statement (external scalar, external table, sourced, SQL scalar, or SQL table) | |
| ALTER INDEX statement | |
| ALTER PROCEDURE statement (external, SQL - external, or SQL - native) | |
| ALTER SEQUENCE statement | |
| ALTER STOGROUP statement | |
| ALTER TABLE statement | |
| ALTER TABLESPACE statement | |
| ALTER TRUSTED CONTEXT statement | |
| ALTER VIEW statement | |
| COMMENT statement | |
| COMMIT statement | |
| CONNECT statement | |
| CREATE ALIAS statement | |
| CREATE DATABASE statement | |
| CREATE FUNCTION statement (external scalar, external table, or sourced) | |
| CREATE GLOBAL TEMPORARY TABLE statement | |
| CREATE INDEX statement | |
| CREATE PROCEDURE (external) statement | |
| CREATE ROLE statement | |
| CREATE SEQUENCE statement | |
| CREATE STOGROUP statement | |
| CREATE SYNONYM statement | |
| CREATE TABLE statement | |
| CREATE TABLESPACE statement | |
| CREATE TRUSTED CONTEXT statement | |
| CREATE TYPE statement | |
| CREATE VIEW statement | |
| DECLARE GLOBAL TEMPORARY TABLE statement | |
| DELETE statement | |
| DROP statement | |
| EXCHANGE statement | |
| EXECUTE IMMEDIATE statement | |
| GRANT statement | |
| INSERT statement | |
| LABEL statement | |
| LOCK TABLE statement | |
| MERGE statement | |
| REFRESH TABLE statement | |
| RELEASE statement | |
| RELEASE SAVEPOINT statement | |
| RENAME statement | |
| REVOKE statement | |
| ROLLBACK statement | |
| SAVEPOINT statement | |
| SELECT INTO statement | |
| SET CONNECTION statement | |
| SET special-register statement | |
| TRUNCATE statement | |
| UPDATE statement | |
| VALUES INTO statement | |

Notes:

- 1 An ALTER FUNCTION (SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION or REPLACE clause is not allowed in an *SQL-routine-body*.
- 2 The COMMIT statement and the ROLLBACK statement (without the TO SAVEPOINT clause) must not be issued in a routine body if the routine is in the calling chain of an SQL routine, an external routine, or a trigger.

Description

procedure-name

Identifies the procedure to alter. The procedure that is identified in *procedure-name* must exist at the current server.

ACTIVE VERSION or ALL VERSIONS or VERSION *routine-version-id*

Identifies the version of the procedure that is to be changed, replaced, or regenerated depending on whether the ALTER, REPLACE, or REGENERATE keyword is specified.

Important: Do not create additional versions of procedures that are supplied with DB2 by specifying the VERSION keyword. Only versions that are supplied with DB2 are supported. Additional versions of such routines cause the installation and configuration of the supplied routines to fail.

ACTIVE VERSION

Specifies that the currently active version of the procedure is to be changed, replaced, or regenerated.

VERSION *routine-version-id*

Identifies the version of the procedure that is to be changed, replaced, or regenerated. *routine-version-id* is the version identifier that is assigned when the version is defined. *routine-version-id* must identify a version of the specified procedure that exists at the current server.

ALTER

Specifies that a version of the procedure is to be changed.

When you change a procedure to add or replace a version of the procedure, any option that is not explicitly specified will use the existing value from the version of the procedure that is being changed.

REPLACE

Specifies that a version of the procedure is to be replaced.

Binding the replaced version of the procedure might result in a new access path even if the routine body is not changed.

When you replace a procedure, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the procedure that is being replaced. This is not the case for versions of the procedure that specified DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a version of a procedure, it cannot be changed by the REPLACE clause.

ADD VERSION *routine-version-id*

Specifies that a new version of the procedure is to be created. *routine-version-id* is the version identifier for the new version of the procedure. *routine-version-id* must not identify a version of the specified procedure that already exists at the current server.

When a new version of a procedure is created, the comment that is recorded in the catalog for the new version will be the same as the comment that is in the catalog for the currently active version.

When you add a new version of a procedure the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. The parameter names can differ from the other versions of the procedure. For options that are not explicitly specified, the system default values will be used.

ACTIVATE VERSION *routine-version-id*

Specifies the version of the procedure that is to be the currently active version of the procedure. *routine-version-id* is the version identifier that is assigned when the version of the procedure is defined. The version that is specified with *routine-version-id* is the version that will be invoked by the CALL statement, unless the value of the CURRENT ROUTINE VERSION special register overrides the currently active version of the procedure when the procedure is invoked. *routine-version-id* must identify a version of the procedure that already exists at the current server.

REGENERATE

Regenerates a version of the procedure. When DB2 maintenance is applied that changes how an SQL procedure is generated, the procedure might need to be regenerated to process the maintenance changes.

REGENERATE automatically rebinds, at the local server, the package for the SQL control statements for the procedure and rebinds the package for the SQL statements that are included in the procedure body. If a remote bind is also needed, the BIND PACKAGE COPY command must be explicitly done for all of the remote servers.

REGENERATE is different from a REBIND PACKAGE command where the SQL statements are rebound (i.e. to generate better access paths for those statements), but the SQL control statements in the procedure definition remain the same.

DROP VERSION *routine-version-id*

Drops the version of the procedure that is identified with *routine-version-id*. *routine-version-id* is the version identifier that is assigned when the version is defined. *routine-version-id* must identify a version of the procedure that already exists at the current server and must not identify the currently active version of the procedure. Only the identified version of the procedure is dropped.

When only a single version of the procedure exists at the current server, use the DROP PROCEDURE statement to drop the procedure. A version of the procedure for which the version identifier is the same as the contents of the CURRENT ROUTINE VERSION special register can be dropped if that version is not the currently active version of the procedure.

(parameter-declaration,...)

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the procedure that is being defined or changed. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

IN Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

parameter-name

Names the parameter for use as an SQL variable. The name cannot be the same as the name of any other *parameter-name* for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

built-in-type

Specifies the data type of the parameter. See “CREATE PROCEDURE (SQL - native)” on page 1668 for more information on data type specifications.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.

NOT DETERMINISTIC

The procedure might not return the same result each time it is called with the same IN and INOUT arguments, even when the data that is referenced in the database has not changed.

NOT DETERMINISTIC is the default.

DETERMINISTIC

The procedure always returns the same results each time it is called with the same IN and INOUT arguments if the data that is referenced in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements that the procedure can execute.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA

Specifies that procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

CALLED ON NULL INPUT

Specifies that the procedure will be called if any, or even if all parameter values are null.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether the version of the procedure can be run in debugging mode. The default for a new version of a procedure is determined using the value of the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE

Specifies that this version of the procedure can be run in debugging mode. When this version of the procedure is invoked and debugging is attempted, a WLM environment must be available.

DISALLOW DEBUG MODE

Specifies that the version of the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE

Specifies that the version of the procedure can never be run in debugging mode.

The version of the procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after the version of the procedure has been created, replaced, or altered to use DISABLE DEBUG MODE. To change DEBUG MODE for a version of a procedure that specifies DISABLE DEBUG MODE, you must drop and re-create the version of the procedure using the option that you want.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE option is ignored.

PARAMETER CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

QUALIFIER *schema-name*

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the procedure body. See “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67 for information about how the default for this option is determined.

PACKAGE OWNER *authorization-name*

Specifies the owner of the package that is associated with the version of the procedure. The SQL authorization ID of the process is the default value.

This authorization ID must have the privileges required to execute the SQL statements that are contained in the body of the routine and must contain the necessary bind privileges. The value of the PACKAGE OWNER option is subject to translation when sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID that contains the necessary bind privileges.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

Specifies that there is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

COMMIT ON RETURN NO or COMMIT ON RETURN YES

Indicates whether DB2 commits the transaction immediately on return from the procedure.

COMMIT ON RETURN NO

DB2 does not issue a commit when the procedure returns. NO is the default.

COMMIT ON RETURN YES,

DB2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 43 on page 199.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 43 on page 199.

WLM ENVIRONMENT FOR DEBUG MODE *name*

Specifies the WLM (workload manager) application environment used by DB2 when debugging the procedure. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space that is specified at installation time.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

To change the environment that DB2 uses for debugging this procedure, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

DEFER PREPARE or NODEFER PREPARE

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value that is specified for the REOPT option. If REOPT NONE is specified, the default is NODEFER PREPARE. Otherwise, the default is DEFER PREPARE.

DEFER PREPARE

Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

Refer to the DEFER(PREPARE) option in *DB2 Command Reference* for considerations with distributed processing.

NODEFER PREPARE

Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

CURRENT DATA

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors. For more information about updating the current row of a cursor, block fetch, and data currency, see *DB2 Application Programming and SQL Guide*.

YES

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquires page or row locks to ensure data currency. Block fetch is not allowed for distributed, ambiguous cursors.

NO Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA(NO) is not recommended if the procedure attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your procedure attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

No is the default.

DEGREE

Specifies whether to attempt to run a query using parallel processing to maximize performance.

1 Specifies that parallel processing should not be used.

1 is the default.

ANY

Specifies that parallel processing can be used.

CONCURRENT ACCESS RESOLUTION

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

WAIT FOR OUTCOME

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

DYNAMICRULES

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects

- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a native SQL procedure controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

RUN

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND

Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

DEFINERUN

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

INVOKEBIND

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

INVOKERUN

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See “Authorization IDs and dynamic SQL” on page 75 for information on the effects of these options.

APPLICATION ENCODING SCHEME

Specifies the default encoding scheme for SQL variables in static SQL statements in the procedure body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

ASCII

Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN

Specifies whether information will be provided about how SQL statements in the procedure will execute.

WITHOUT EXPLAIN

Specifies that information will not be provided about how SQL statements in the procedure will execute.

You can get EXPLAIN output for a statement that is embedded in a native SQL procedure that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the procedure body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the procedure body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN

Specifies that information will be provided about how SQL statements in the procedure will execute. Information is inserted into the table *owner.PLAN_TABLE*. *owner* is the authorization ID of the owner of the procedure package. Alternatively, the authorization ID of the owner of the procedure can have an alias as *owner.PLAN_TABLE* that points to the base table, *PLAN_TABLE*. *owner* must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. *PLAN_TABLE* must have a base table and can have multiple aliases with the same table name, *PLAN_TABLE*, but have different schema qualifiers; it cannot be a view or a synonym. It should exist before the version is added or replaced. In all inserts to *owner.PLAN_TABLE*, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables, if they exist: *DSN_STATEMNT_TABLE* and *DSN_FUNCTION_TABLE*. *DSN_STATEMNT_TABLE* contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. *DSN_FUNCTION_TABLE* contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1948.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDIATEWRITE subsystem parameter has no effect of this option. *DB2 Command Reference* shows the implied hierarchy of the IMMEDIATEWRITE bind option (which is similar to this procedure option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR

Specifies how far to isolate the procedure from the effects of other running applications. For information about isolation levels, see *DB2 Performance Monitoring and Tuning Guide*.

RR Specifies repeatable read.

RS Specifies read stability.

CS Specifies cursor stability. CS is the default.

UR Specifies uncommitted read.

WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC

Specifies whether DB2 keeps dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC

Specifies that DB2 does not keep dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC is the default.

WITH KEEP DYNAMIC

Specifies that DB2 keeps dynamic SQL statements after commit points. If you specify WITH KEEP DYNAMIC, the application does not need to prepare an SQL statement after every commit point. DB2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify WITH KEEP DYNAMIC, and the prepared statement cache is active, the DB2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread time outs, as described in *DB2 Installation Guide* for installation panel DSNTIPR.

If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The DB2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

OPHTINT *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the procedure.

string-constant is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *DB2 Installation Guide* for information about enabling optimization hints.

SQL PATH

Specifies the SQL path that the DB2 subsystem uses to resolve unqualified user-defined types, functions, and procedure names (in CALL statements) in the body of the procedure. The default value is "SYSIBM", "SYSFUN", "SYSPROC", and the value of the QUALIFIER option.

The maximum length of the SQL path is 2048 bytes. DB2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed 2048 bytes.

schema-name

Specifies a schema. DB2 does not validate that the specified schema actually exists when the ALTER statement is processed.

schema-name-list

Specifies a comma separated list of schema names. The same schema name should not appear more than one time in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.

SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC".

SESSION_USER or USER

Specifies the value of the SESSION_USER (or USER) special register. At the time the ALTER statement is processed, the actual length is included in the total length of the list of schema names that is specified for the PATH option. If you specify SESSION_USER (or USER) in a list of schema names, do not use delimiters around the SESSION_USER (or USER) keyword.

RELEASE AT

Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

COMMIT

Specifies that resources will be released at each commit point.

COMMIT is the default.

DEALLOCATE

Specifies that resources will be released only when the procedure terminates. DEALLOCATE has no effect on packages that run on a DB2 server through a DRDA connection with a client system. DEALLOCATE also has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and SQL data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).

- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package size because additional items become resident in the package. For more information about how the RELEASE clause affects locking and concurrency, see *DB2 Performance Monitoring and Tuning Guide*.

QUERY ACCELERATION

Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE

Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE

Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in DB2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and DB2 cannot route the static query to the accelerator for execution.

ENABLE WITH FAILBACK

Results in the same behavior as ENABLE, except if one of the error conditions occurs on the first OPEN of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, DB2 performs a temporary *statement-level* incremental bind of the query and runs the query in DB2. The application does not see the acceleration failure. Failback to DB2 is not possible after the application does a successful OPEN for the query on the accelerator.

ELIGIBLE

Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

ALL

Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If DB2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the BIND or

REBIND PACKAGE operation fails with an error message for that query. (A failure exception is made for declared global temporary tables (DGTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a *fullselect* or *WITH common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

NO Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in DB2.

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

YES

Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The QUERYACCELERATION bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a *fullselect* or *WITH common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

REOPT

Specifies if DB2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE

Specifies that DB2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

ALWAYS

Specifies that DB2 always determine the access path at run time each time an SQL statement is run.

ONCE

Specifies that DB2 determine the access path for any dynamic SQL statements only one time, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and needs to be prepared again.

VALIDATE RUN or VALIDATE BIND

Specifies whether to recheck, at run time, errors of the type "OBJECT not FOUND" and NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN

Specifies that if needed objects or privileges do not exist when the ALTER PROCEDURE statement is processed, warning messages are returned, but the ALTER PROCEDURE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the ALTER PROCEDURE statement. The authorization checks the use of the authorization ID of the owner of the procedure package.

VALIDATE RUN is the default.

VALIDATE BIND

Specifies that if needed objects or privileges do not exist at the time the ALTER PROCEDURE statement is processed, an error is issued and the ALTER PROCEDURE statement fails.

ROUNDING

Specifies the rounding mode for manipulation of DECFLOAT data.

DEC_ROUND_CEILING

Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN

Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR

Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN

Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

DEC_ROUND_HALF_UP

Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP

Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the date format for result values that are string representations of date or time values. See "String representations of datetime values" on page 101 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the procedure is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)

Specifies the maximum precision that is to be used for decimal arithmetic

operations. See “Arithmetic with two decimal operands” on page 231 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the procedure is defined. If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The procedure body can include positioned UPDATE statements that update columns that the user is authorized to update.

If the resulting DBRM for the procedure is very large, you might need extra storage when you specify FOR UPDATE CLAUSE OPTIONAL.

The FOR UPDATE clause of the select-statement with no column list applies to static or dynamic SQL statements. You can specify the FOR UPDATE OF clause of the select-statement with a column list to restrict updates to only the columns that are named in the column list and to specify the acquisition of update locks.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 101 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the procedure is defined. You cannot use the LOCAL option unless you have a date exit routine.

SQL-routine-body

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 8, “SQL control statements for SQL routines,” on page 2251. If an *SQL-procedure-statement* is the only statement in the procedure body, the statement must not end with a semicolon.

Notes

Considerations for altering a version of a procedure:

To alter a version of a procedure, the environment settings that are in effect when the ALTER PROCEDURE statement is issued must be the same as the environment settings that are in effect when the version of the procedure is first created using the CREATE PROCEDURE or ALTER PROCEDURE statements if one of the following options is specified:

- **QUALIFIER**
- **PACKAGE OWNER**
- **WLM ENVIRONMENT FOR DEBUG MODE**
- **OPTHINT**

- **SQL PATH**
- **DECIMAL** (if the value includes a comma)

Changing to a native SQL procedure:

You cannot change an external SQL procedure to a native SQL procedure. You can drop the external SQL procedure that you want to change by using the DROP statement and create a native SQL procedure with a similar definition using the CREATE PROCEDURE statement. Alternatively, you can create a native SQL procedure using a different schema.

Identifier resolution

See Chapter 8, “SQL control statements for SQL routines,” on page 2251 for information on how names are resolved to columns, SQL variables, or SQL routines for native SQL procedures. Name resolution is unchanged for external SQL procedures.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the procedure name for parameters, and the label name for SQL variables.

Characteristics of the package that is generated for a version of a procedure:

The package that is associated with a version of a procedure is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the procedure
- *package-id* is the same as the specific name of the procedure
- *version-id* is the same as the version identifier for the initial version of the procedure

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See Table 151 on page 1289 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:

- DBPROTOCOL(DRDA)
- FLAG(1)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

Considerations for a procedure that is defined using a TABLE LIKE name AS LOCATOR clause:

If a procedure is defined with a table parameter (the **TABLE LIKE name AS LOCATOR** clause was specified in the CREATE PROCEDURE statement to indicate that one of the input parameters is a transition table), the procedure cannot be changed with an ALTER PROCEDURE statement if the change requires that the parameter list be specified. For example, to add or replace a version of a native SQL procedure, the procedure must be dropped and re-created.

Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement

terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see *DB2 Application Programming and SQL Guide*.

Correspondence of procedure options to BIND options

The following table lists options for CREATE PROCEDURE and ALTER PROCEDURE and the corresponding options for the bind commands. See *DB2 Command Reference* for more information about the effects of the options of the bind commands.

Table 151. Correspondence of procedure options to bind options

| CREATE PROCEDURE or ALTER PROCEDURE option | bind commands option |
|---|---|
| APPLICATION ENCODING SCHEME | ENCODING(ASCII) ENCODING(EBCDIC) ENCODING(UNICODE) |
| CURRENT DATA NO | CURRENTDATA(NO) |
| CURRENT DATA YES | CURRENTDATA(YES) |
| DEFER PREPARE | DEFER(PREPARE) |
| NODEFER PREPARE | NODEFER(PREPARE) |
| DEGREE | DEGREE(ANY) DEGREE(1) |
| DYNAMICRULES | DYNAMICRULES(RUN) DYNAMICRULES(BIND) DYNAMICRULES(DEFINEBIND) DYNAMICRULES(DEFINERUN) DYNAMICRULES(INVOKEBIND) DYNAMICRULES(INVOKERUN) |
| GET_ACCEL_ARCHIVE NO | GETACCELARCHIVE(NO) |
| GET_ACCEL_ARCHIVE YES | GETACCELARCHIVE(YES) |
| ISOLATION LEVEL | ISOLATION(RR) ISOLATION(RS) ISOLATION(CS) ISOLATION(UR) |
| OPTHINT | OPTHINT |
| PACKAGE OWNER | OWNER |
| QUALIFIER | QUALIFIER |
| QUERY ACCELERATION NONE | QUERYACCELERATION(NONE) |
| QUERY ACCELERATION ENABLE | QUERYACCELERATION(ENABLE) |
| QUERY ACCELERATION ENABLE WITH FAILBACK | QUERYACCELERATION(ENABLE WITH FAILBACK) |
| QUERY ACCELERATION ELIGIBLE | QUERYACCELERATION(ELIGIBLE) |
| QUERY ACCELERATION ALL | QUERYACCELERATION(ALL) |
| RELEASE AT COMMIT | RELEASE(COMMIT) |
| RELEASE AT DEALLOCATE | RELEASE(DEALLOCATE) |
| REOPT ALWAYS | REOPT(ALWAYS) |
| REOPT NONE | REOPT(NONE) |
| REOPT ONCE | REOPT(ONCE) |

Table 151. Correspondence of procedure options to bind options (continued)

| CREATE PROCEDURE or ALTER PROCEDURE option | bind commands option |
|--|----------------------|
| ROUNDING DEC_ROUND_CEILING | ROUNDING(CEILING) |
| ROUNDING DEC_ROUND_DOWN | ROUNDING(DOWN) |
| ROUNDING DEC_ROUNDING_FLOOR | ROUNDING(FLOOR) |
| ROUNDING DEC_ROUNDING_HALF_DOWN | ROUNDING(HALFDOWN) |
| ROUNDING DEC_ROUNDING_HALF_EVEN | ROUNDING(HALFEVEN) |
| ROUNDING DEC_ROUNDING_HALF_UP | ROUNDING(HALFUP) |
| ROUNDING DEC_ROUNDING_UP | ROUNDING(UP) |
| SQL PATH | PATH |
| VALIDATE BIND | VALIDATE(BIND) |
| VALIDATE RUN | VALIDATE(RUN) |
| WITH EXPLAIN | EXPLAIN(YES) |
| WITHOUT EXPLAIN | EXPLAIN(NO) |
| WITH IMMEDIATE WRITE | IMMEDWRITE(YES) |
| WITHOUT IMMEDIATE WRITE | IMMEDWRITE(NO) |
| WITH KEEPYNAMIC | KEEPYNAMIC(YES) |
| WITHOUT KEEPYNAMIC | KEEPYNAMIC(NO) |

Invalidation of packages:

When a version of an SQL procedure is altered to change any option that is specified for the active version, all the packages that refer to that procedure are marked invalid. Additionally, when certain attributes of a native SQL procedure are changed, the body of the procedure might be rebound or regenerated. The following table summarizes when implicit rebind and regeneration occurs when specific options are changed. A value of Y in a row indicates that a rebind or regeneration occurs if the option is changed for a version of the procedure. A value of N in a row indicates that a rebind or regeneration does not occur.

Table 152. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed.

| CREATE PROCEDURE or ALTER PROCEDURE option | Change requires rebind of invoking applications? | Change results in implicit rebind of the non-control statements of the body of the procedure? | Change results in implicit regeneration of the entire body of the procedure? |
|--|--|---|--|
| ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE | Y ^{1,2} | Y ¹ | Y |
| APPLICATION ENCODING SCHEME | Y | Y | Y |
| ASUTIME | Y | N | N |
| COMMIT ON RETURN | Y | N | N |

Table 152. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed. (continued)

| CREATE PROCEDURE or ALTER PROCEDURE option | Change requires rebind of invoking applications? | Change results in implicit rebind of the non-control statements of the body of the procedure? | Change results in implicit regeneration of the entire body of the procedure? |
|---|--|---|--|
| CURRENT DATA | N | Y | N |
| DATE FORMAT | Y | Y | Y |
| DECIMAL | Y | Y | Y |
| DEFER PREPARE or NODEFER PREPARE | N | Y | N |
| DEGREE | N | Y | N |
| DYNAMIC RESULT SETS | Y | N | N |
| DYNAMICRULES | N | Y | N |
| FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED | Y | Y | Y |
| INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS | Y | N | N |
| ISOLATION LEVEL | N | Y | N |
| MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL | Y | Y | Y |
| NOT DETERMINISTIC or DETERMINISTIC | N | N | N |
| OPTHINT | N | Y | N |
| PACKAGE OWNER | N | Y | N |
| QUALIFIER | N | Y | N |
| RELEASE AT COMMIT or RELEASE AT DEALLOCATE | N | Y | N |
| REOPT | N | Y | N |
| SQL PATH | N | Y | N |
| STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER <i>nn</i> FAILURES, or CONTINUE AFTER FAILURES | Y | N | N |
| TIME FORMAT | Y | Y | Y |
| VALIDATE RUN or VALIDATE BIND | N | Y | N |
| WITH EXPLAIN or WITHOUT EXPLAIN | N | Y | N |
| WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE | N | Y | N |

Table 152. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed. (continued)

| CREATE PROCEDURE or ALTER PROCEDURE option | Change requires rebind of invoking applications? | Change results in implicit rebind of the non-control statements of the body of the procedure? | Change results in implicit regeneration of the entire body of the procedure? |
|--|--|---|--|
| WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC | N | Y | N |
| WLM ENVIRONMENT FOR DEBUG MODE | Y | N | N |

Note:

1. The procedure package is rebound or regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE.
2. Invoking applications are invalidated if a value of DISALLOW DEBUG MODE is changed to DISABLE DEBUG MODE.

Considerations for SYSENVIRONMENTS catalog table:

An ALTER statement that specifies a new environment settings will result in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the ALTER statement. Thus, a new SYSENVIRONMENTS row might be added even for an ALTER statement that fails.

Compatibilities:

For compatibility with previous versions of DB2, when any of the following options are implicitly or explicitly specified as part of *option-list*, a warning is issued, but the statement is executed. However, if REPLACE or ADD VERSION is specified with one of the following options, an error is issued, and the statement does not execute. For example, if ADD VERSION and STAY RESIDENT are specified, an error is issued.

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER *nn* FAILURES
- CONTINUE AFTER FAILURES

If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

For compatibility with the CREATE PROCEDURE statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for **DYNAMIC RESULT SETS**.
- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**

Considerations for catalog comments for a routine definition:

When a function definition is replaced any existing comment in the catalog for the definition is removed, and when a function definition is regenerated any existing comment in the catalog for the definition is retained.

Example

Example 1: The following statement changes the existing procedure options for the active version of the UPDATE_SALARY_1 native SQL procedure. If you need to change a different version of the procedure, you would specify *VERSION routine-version-id* in place of ACTIVE VERSION. Note that the ALTER clause that precedes the version specification can be omitted.

```
ALTER PROCEDURE UPDATE_SALARY_1
  ALTER ACTIVE VERSION
  NOT DETERMINISTIC
  CALLED ON NULL INPUT
  ALLOW DEBUG MODE
  ASUTIME LIMIT 10
```

Example 2: To change the procedure body of any existing version of a procedure, you need to use the REPLACE clause. The following statement changes both the procedure body and the existing SQL data access option for version V2 of the UPDATE_SALARY_1 SQL procedure. Note that the list of parameters is specified even though no changes are made to the list. To replace an existing version of a procedure, you must specify the list of parameters, any options that are to have non-default values (even if those options are specified in the version of the procedure that you are replacing), and the body of the procedure.

```
ALTER PROCEDURE UPDATE_SALARY_1
  REPLACE VERSION V2 (P1 INTEGER, P2 CHAR(5))
  MODIFIES SQL DATA
  UPDATE EMP SET SALARY = SALARY * RATE
  WHERE EMPNO = EMPLOYEE_NUMBER;
```

Example 3: To add a new version of an existing procedure, use the ADD VERSION clause. The following statement adds a new version of the UPDATE_SALARY_1 procedure to apply a larger salary increase. Note that the list of parameters is specified even though the new version of the procedure uses the same parameters as the existing version of the procedure. To add a new version of a procedure, you must specify the list of parameters, any options that will have non-default values, and the body of the procedure.

```
ALTER PROCEDURE UPDATE_SALARY_1
  ADD VERSION V3 (P1 INTEGER, P2 CHAR(5))
  UPDATE EMP SET SALARY = SALARY * (RATE*10)
  WHERE EMPNO = EMPLOYEE_NUMBER;
```

Example 4: When the new version of the procedure has been defined, as in Example 3, you must use the ALTER PROCEDURE statement with the ACTIVATE VERSION clause if the new version of the procedure is to be the currently active version, as in the following example.

```
ALTER PROCEDURE UPDATE_SALARY_1
  ACTIVATE VERSION V3;
```

Example 5: To regenerate the currently active version of a procedure, use the following statement.

```
ALTER PROCEDURE UPDATE_SALARY_1  
    REGENERATE ACTIVE VERSION;
```

ALTER SEQUENCE

The ALTER SEQUENCE statement changes the attributes of a sequence at the current server. Only future values of the sequence are affected by the ALTER SEQUENCE statement.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

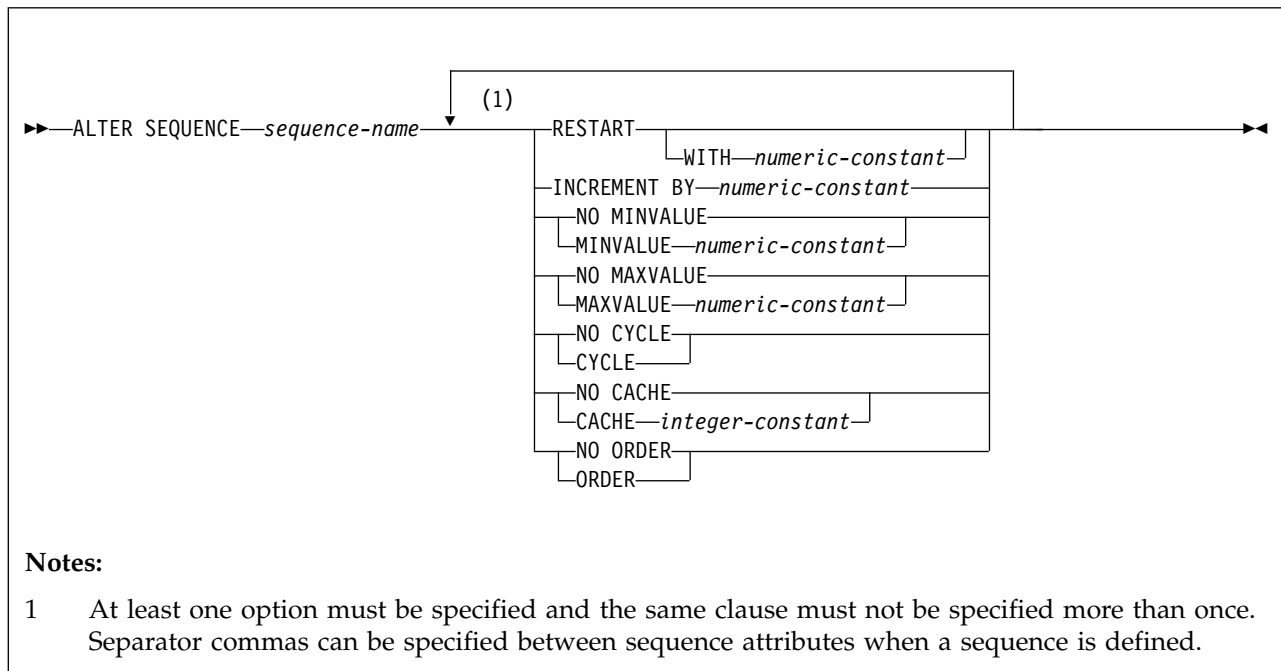

- Ownership of the sequence
- The ALTER privilege for the sequence
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

Installation SYSADM privilege is required to alter the SYSIBM.DSNSEQ_IMPLICITDB sequence (which specifies the maximum number of implicitly created databases).

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

Description

sequence-name

Identifies the sequence. The combination of sequence name and the implicit or explicit qualifier must identify an existing sequence at the current server. *sequence-name* must not identify a sequence that is generated by DB2 for an identity column or a `DB2_GENERATED_DOCID_FOR_XML` column.

RESTART

Restarts the sequence. If *numeric-constant* is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value on the `CREATE SEQUENCE` statement that originally created the sequence.

WITH *numeric-constant*

Specifies the value at which to restart the sequence. The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If `RESTART` is not specified, the sequence is not restarted. Instead, it resumes with the current values in effect for all the options after the `ALTER` statement is issued.

After a sequence is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated by the sequence previously.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point.

If INCREMENT BY *numeric-constant* is positive, the sequence ascends. If INCREMENT BY *numeric-constant* is negative, the sequence descends. If INCREMENT BY *numeric-constant* is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

NO MINVALUE or MINVALUE

Specifies whether or not there is a minimum end point of the range of values for the sequence.

NO MINVALUE

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the value for MINVALUE becomes one of the following:

- For an ascending sequence, the value is the original starting value.
- For a descending sequence, the value is the minimum of the data type that is associated with the sequence.

MINVALUE *numeric-constant*

Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

NO MAXVALUE or MAXVALUE

Specifies whether or not there is a maximum end point of the range of values for the sequence.

NO MAXVALUE

Specifies either explicitly or implicitly that the minimum end point of the range of values for the sequence has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence
- For a descending sequence, the value is the original starting value.

If NO MAXVALUE is explicitly specified in the ALTER SEQUENCE statement, the value of the MAXVALUE column in the catalog table is reset to the maximum value of the data type associated with the sequence if the sequence is ascending or the value stored in the START column of the catalog table if the sequence is descending. Whether the sequence is ascending or descending depends on whether or not the INCREMENT BY option is reset. If it is, the new INCREMENT BY VALUE determines if the sequence is ascending or descending. If it is not explicitly reset, the value stored in the INCREMENT column of the catalog table determines if the sequence is ascending or descending.

MAXVALUE *numeric-constant*

Specifies the maximum value at which an ascending sequence either cycles or stops generating values or a descending sequence cycles to after

reaching the minimum value. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

NO CYCLE or CYCLE

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it.

NO CYCLE

Specifies that the sequence cannot generate more values once the maximum or minimum value for the sequence has been reached.

CYCLE

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application conversion tools for converting applications from other vendor platforms to DB2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

NO CACHE or CACHE

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

NO CACHE

Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure. When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O to the log.

CACHE *integer-constant*

Specifies the maximum number of sequence values that DB2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that DB2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

NO ORDER or ORDER

Specifies whether the sequence numbers must be generated in order of request.

NO ORDER

Specifies that the sequence numbers do not need to be generated in order of request.

ORDER

Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested for next value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple DB2 members using the same sequence concurrently, specify the ORDER option.

Notes

Altering a sequence: The changes to the attributes of a sequence take effect after the ALTER SEQUENCE statement is committed. Only future sequence numbers are affected by the ALTER SEQUENCE statement. If the ALTER SEQUENCE request results in an error or is rolled back, nothing is changed; however, unused cache values might be lost.

- The data type of a sequence cannot be changed. Instead, drop and re-create the sequence specifying the desired data type for the new sequence.
- All cached values are lost when a sequence is altered.
- After restarting a sequence or changing it to cycle, it is possible that a generated value will duplicate a value previously generated for that sequence.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- NOCACHE (single key word) as a synonym for NO CACHE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOORDER (single key word) as a synonym for NO ORDER

Examples

Example 1: Reset a sequence to the START WITH value to generate the numbers from 1 up to the number of rows in the table:

```
ALTER SEQUENCE org_seq  
  RESTART;
```

ALTER STOGROUP

The ALTER STOGROUP statement changes the description of a storage group at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

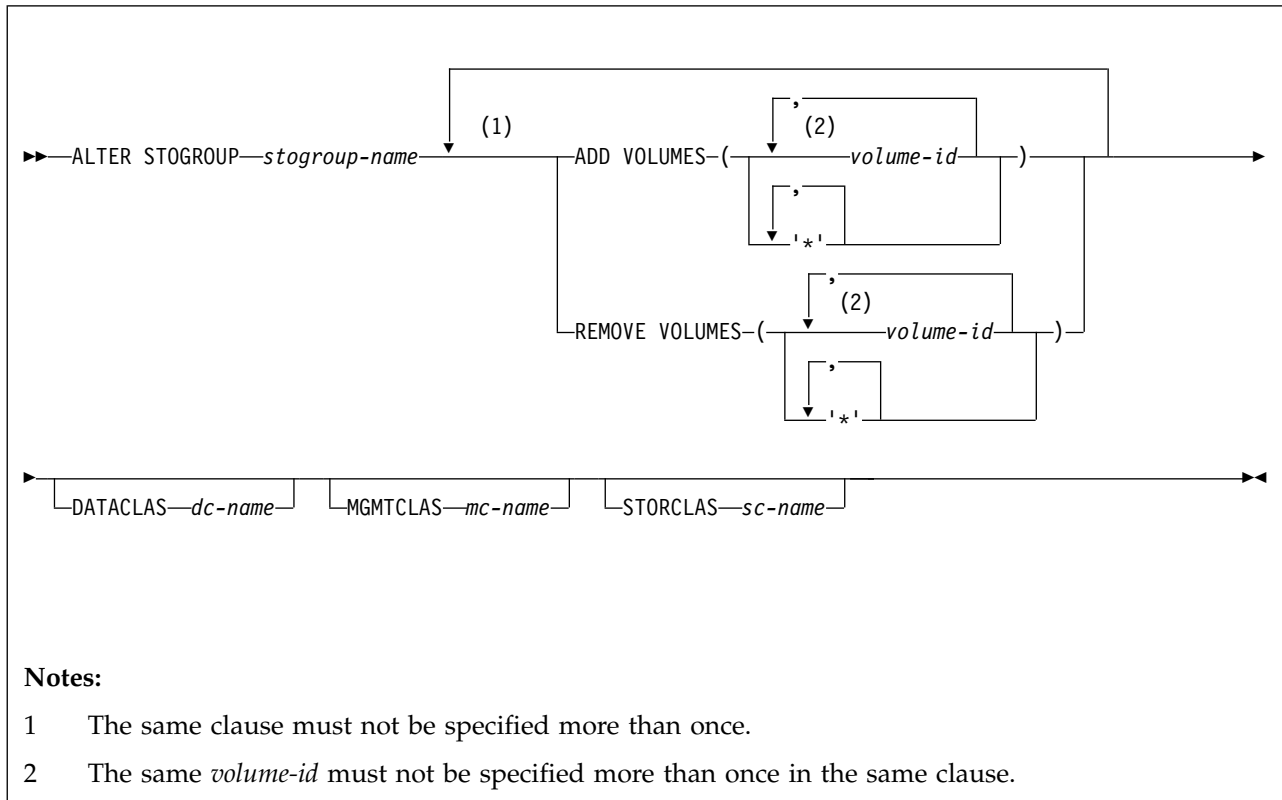

Authorization

The privilege set that is defined below must include one of the following:

- Ownership of the storage group
- SYSADM or SYSCTRL authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

Description

stogroup-name

Identifies the storage group to be altered. The name must identify a storage group that exists at the current server.

ADD VOLUMES(*volume-id*,...) or **ADD VOLUMES**('*',...)

Adds volumes to the storage group. Each *volume-id* is the volume serial number of a storage volume to be added. It can have a maximum of six characters and is specified as an identifier or a string constant.

A *volume-id* must not be specified if any volume of the storage group is designated by an asterisk (*). An asterisk must not be specified if any volume of the storage group is designated by a *volume-id*.

You cannot add a volume that is already in the storage group unless you first remove it with REMOVE VOLUMES.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified. SMS usage is recommended, rather than using DB2 to allocate data to specific volumes. Having DB2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

REMOVE VOLUMES(*volume-id*,...) or **REMOVE VOLUMES**('*',...)

Removes volumes from the storage group. Each *volume-id* is the volume serial number of a storage volume to be removed. Each *volume-id* must identify a volume that is in the storage group.

The REMOVE VOLUMES clause is applied to the current list of volumes before the ADD VOLUMES clause is applied. Removing a volume from a storage group does not affect existing data, but a volume that has been removed is not used again when the storage group is used to allocate storage for table spaces or index spaces.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified.

DATACLAS *dc-name*

Identifies the name of the SMS data class to associate with the DB2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

MGMTCLAS *mc-name*

Identifies the name of the SMS management class to associate with the DB2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

STORCLAS *sc-name*

Identifies the name of the SMS storage class to associate with the DB2 storage group. The SMS storage class name must be from 1-8 characters in length. The

SMS storage administrator defines the storage class that can be used. STORCLAS must not be specified more than one time.

Notes

Work file databases: If the storage group altered contains data sets in a work file database, the database must be stopped and restarted for the effects of the ALTER to be recognized. To stop and restart a database, issue the following commands:

```
-STOP DATABASE(database-name)
-START DATABASE(database-name)
```

Device types: When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

Number of volumes: There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

If the VOLUMES clause is specified, the maximum number of volumes is 59.

Verifying the existence of volumes and classes: When processing the VOLUMES, DATACLAS, MGMTCLAS, or STORCLAS clauses, DB2 does not check the existence of the volumes or classes or determine the types of devices that are identified or if SMS is active. Later, when the storage group allocates data sets, the list of volumes is passed in the specified order to Data Facilities (DFSMSdfp). See *DB2 Administration Guide* for more information about creating DB2 storage groups.

SMS data set management: You can have Storage Management Subsystem (SMS) manage the storage needed for the objects that the storage group supports. To do so, specify ADD VOLUMES(*) and REMOVE VOLUMES(current-vols) in the ALTER statement, where *current-vols* is the list of the volumes currently assigned to the storage group. SMS manages every data set created later for the storage group. SMS does not manage data sets created before the execution of the statement.

You can also specify ADD VOLUMES(volume-id) and REMOVE VOLUMES(*) to make the opposite change.

See *DB2 Administration Guide* for considerations for using SMS to manage data sets.

Examples

Example 1: Alter storage group DSN8G100. Add volumes DSNV04 and DSNV05.

```
ALTER STOGROUP DSN8G100
  ADD VOLUMES (DSNV04,DSNV05);
```

Example 2: Alter storage group DSN8G100. Remove volumes DSNV04 and DSNV05.

```
ALTER STOGROUP DSN8G100
  REMOVE VOLUMES (DSNV04,DSNV05);
```

ALTER TABLE

The ALTER TABLE statement changes the description of a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The ALTER privilege on the table
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

To alter a system-period temporal table when one or more of the changes also result in changes to the associated history table, the privileges that are held by the authorization ID of the statement must also include at least one of the following:

- The ALTER privilege on the history table
- Ownership of the history table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

The privilege set must include SECADM authority if one of the following clauses is specified:

- ACTIVATE
- DEACTIVATE

Additional privileges might be required in the following situations:

- FOREIGN KEY, ADD PRIMARY KEY, ADD UNIQUE, DROP PRIMARY KEY, DROP FOREIGN KEY, or DROP CONSTRAINT is specified.
- The data type of a column that is added to the table is a distinct type.
- A fullselect is specified.
- A column is defined as a security label column.
- A column is defined as ROWID GENERATED BY DEFAULT.

See the description of the appropriate clauses for the details about these privileges.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

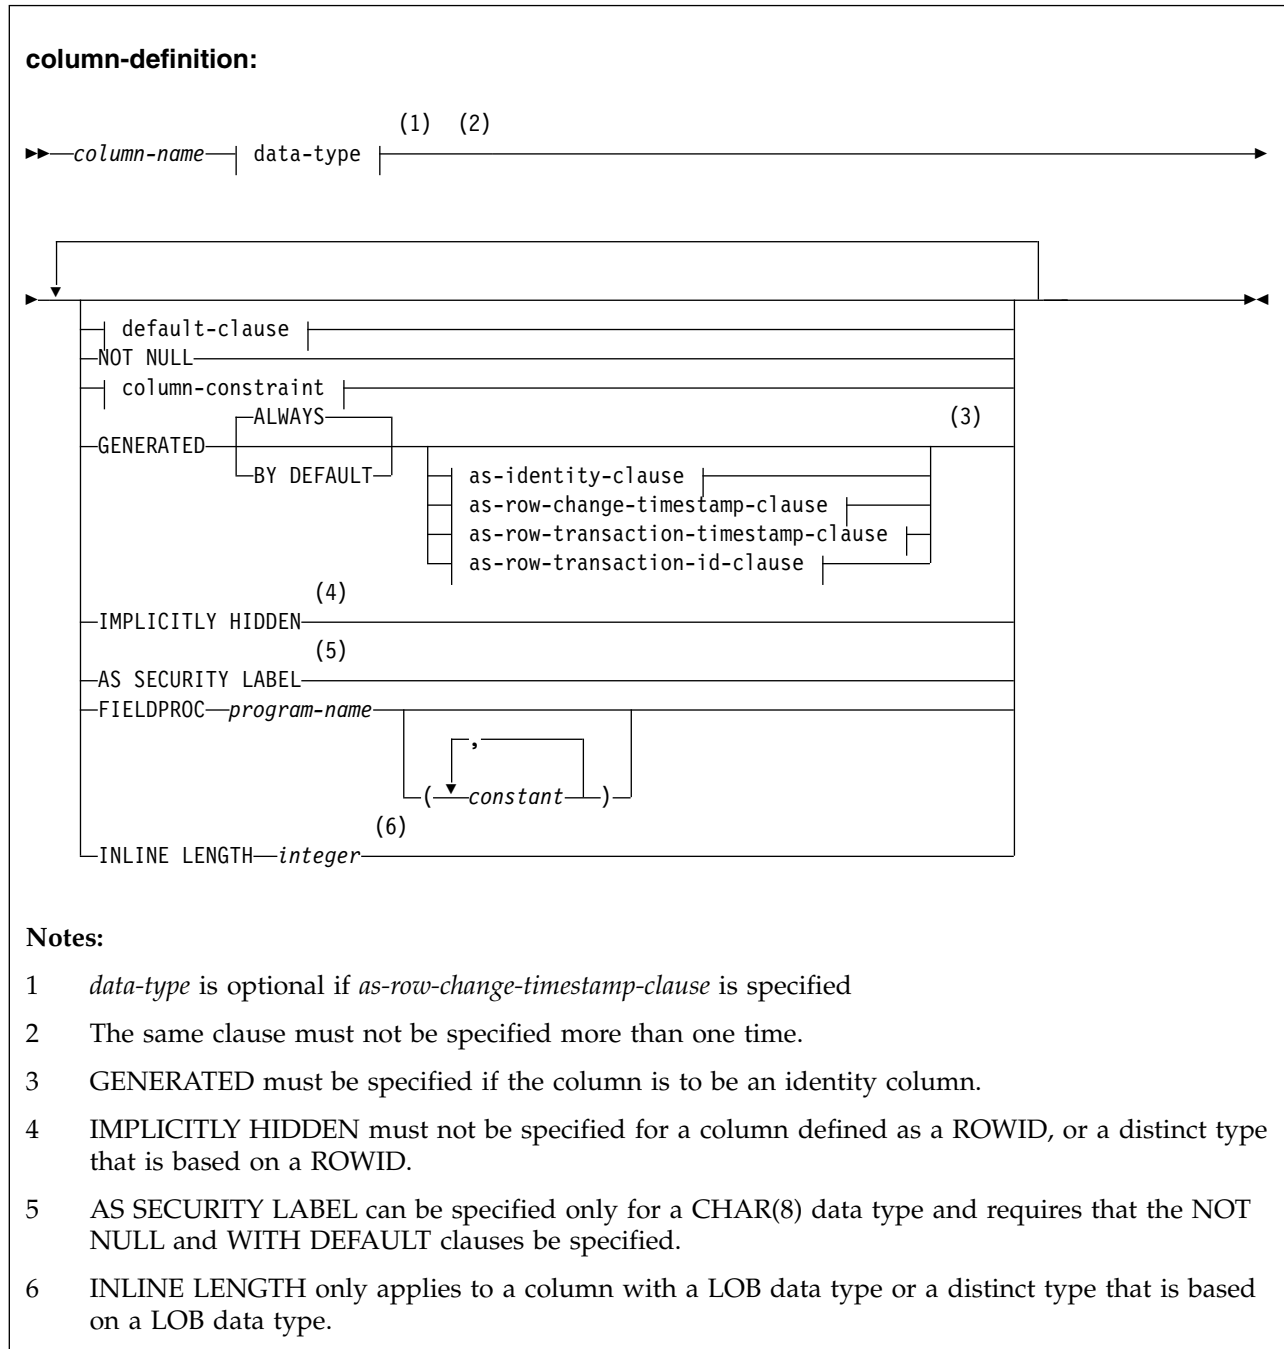

Notes:

- 1 The same clause must not be specified more than one time, except for the ADD COLUMN or ALTER COLUMN clauses. If multiple ADD COLUMN clauses are specified in the same statement, at most one ADD COLUMN clause can contain a *references-clause*. If ALTER COLUMN SET DATA TYPE is specified, it must be specified first.
- 2 The ALTER COLUMN, ADD PARTITION, ALTER PARTITION, and ROTATE PARTITION clauses are mutually exclusive with each other.
- 3 If ADD CLONE, DROP CLONE, RENAME COLUMN, ADD ORGANIZE BY HASH, ALTER

ORGANIZATION, DROP ORGANIZATION, ADD VERSIONING, DROP VERSIONING, ACTIVATE, or DEACTIVATE is specified, no other clause is allowed on the ALTER TABLE statement.

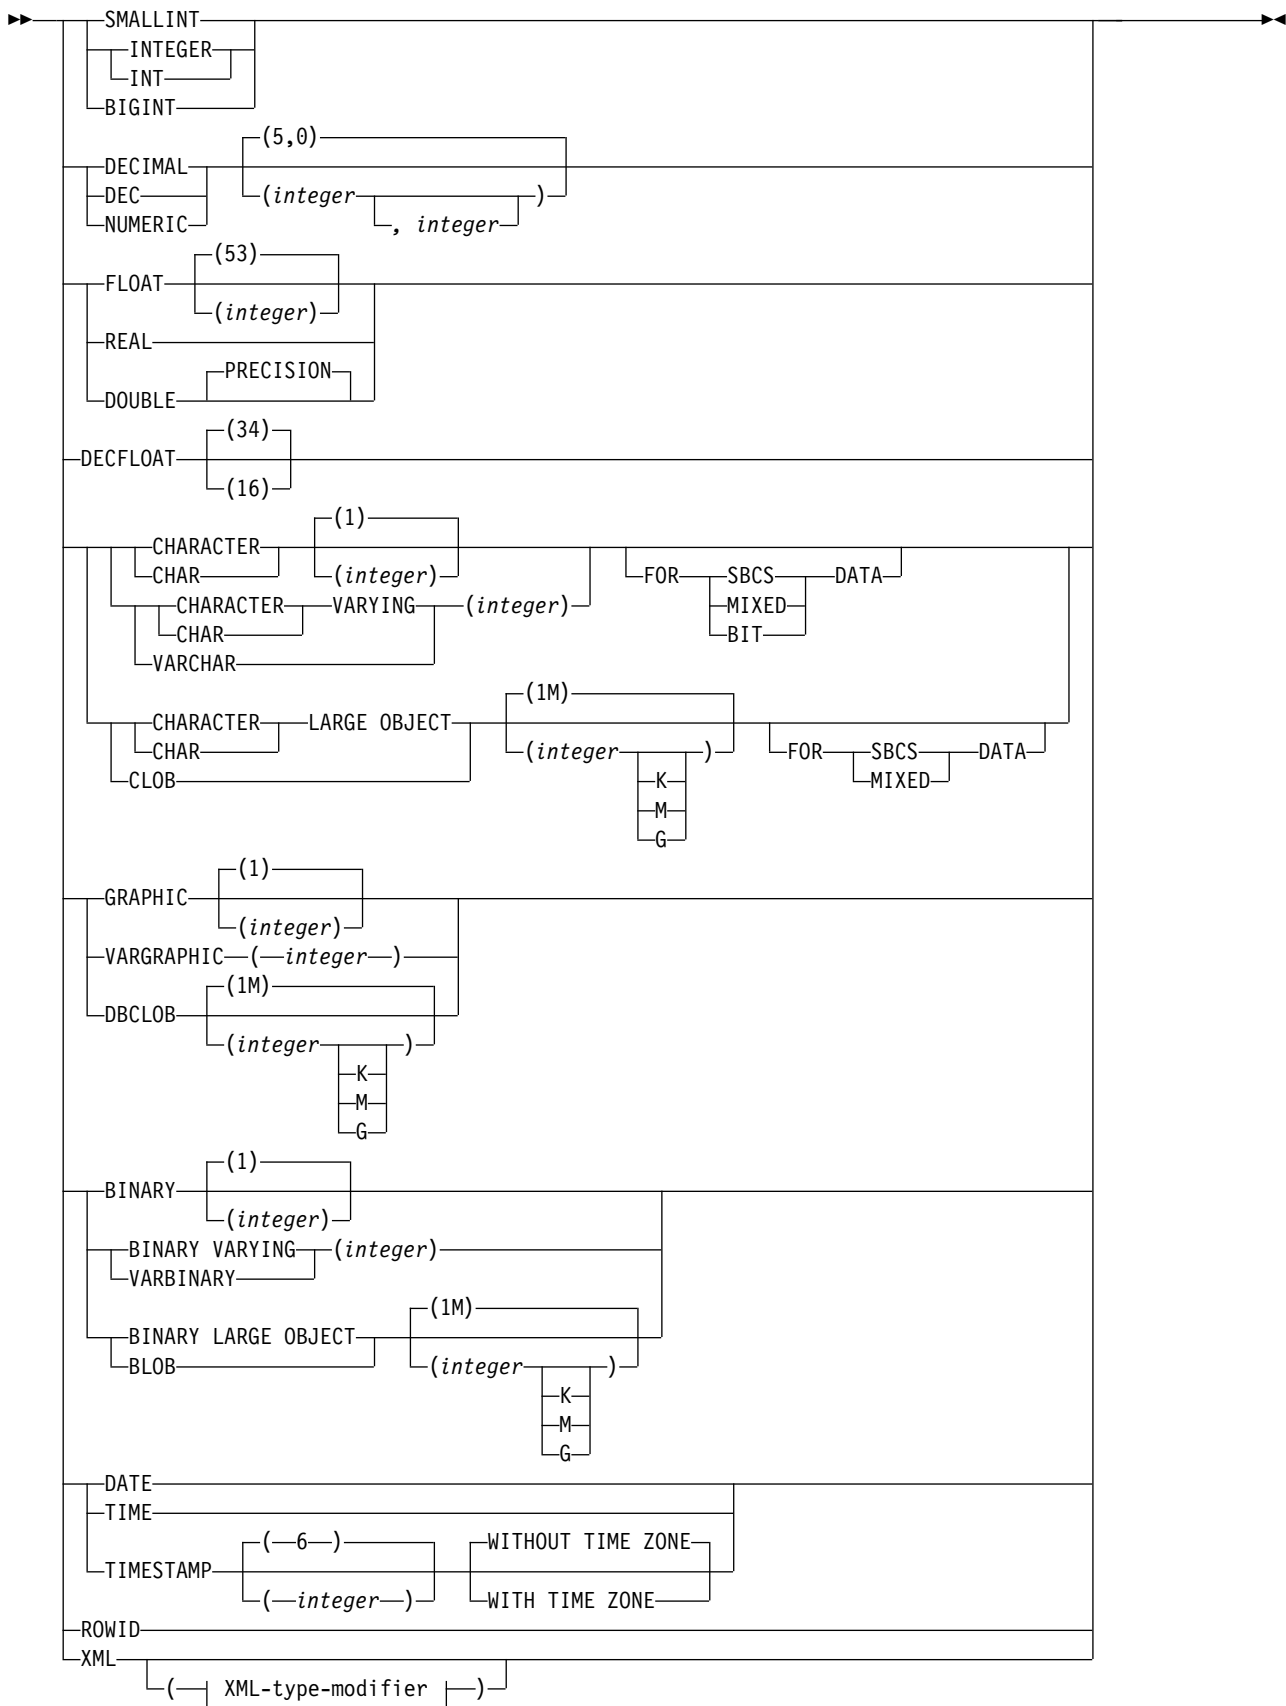

- 4 The ADD keyword is optional for *referential-constraint* or *unique-constraint* if it is the first clause specified in the statement. Otherwise, ADD is required.

data-type:

built-in-type:

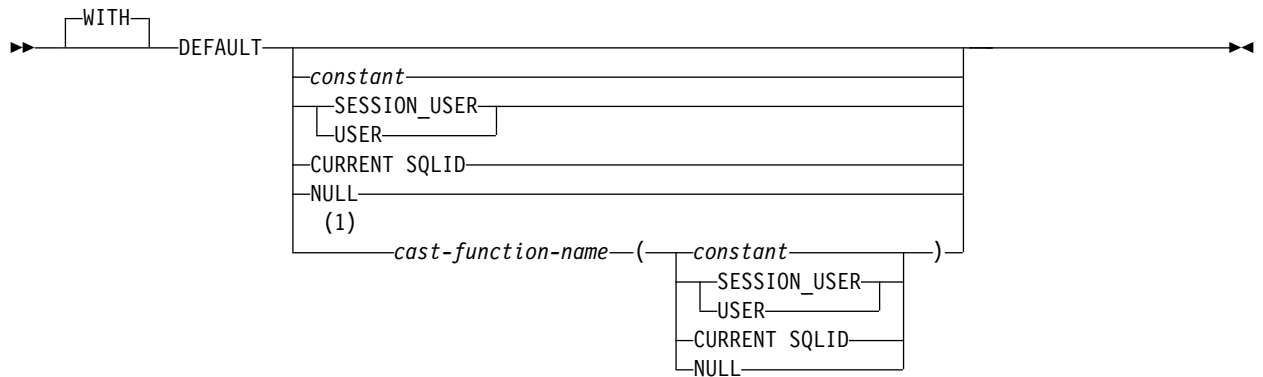

XML-type-modifier:

XML-schema-specification:

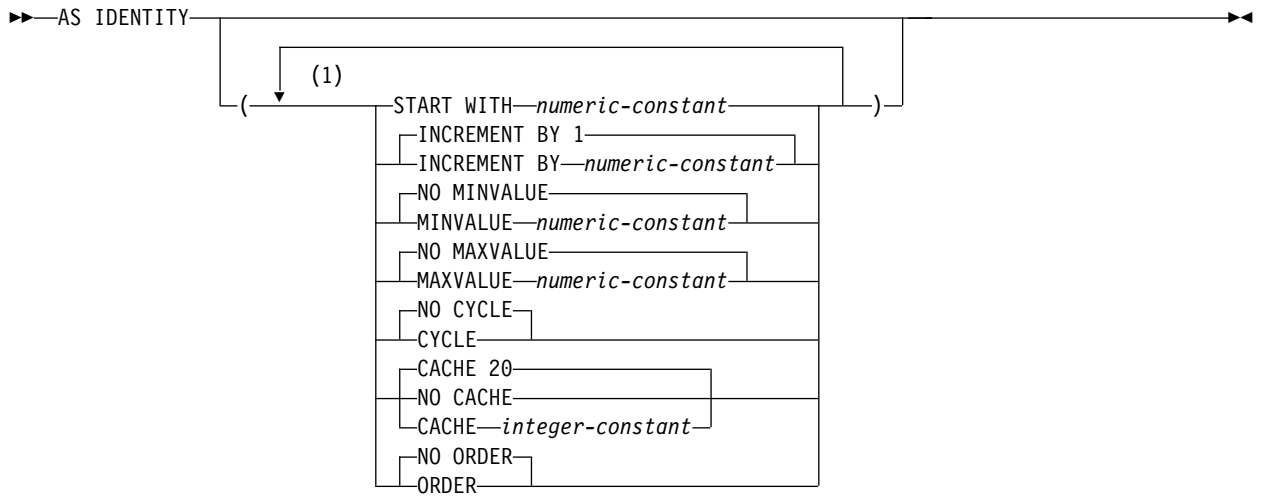

default-clause:

Notes:

- 1 The *cast-function-name* form of the `DEFAULT` value can only be used with a column that is defined as a distinct type.

as-identity-clause:

Notes:

- 1 Separator commas can be specified between attributes when an identity column is defined.

as-row-change-timestamp-clause:

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

as-row-transaction-timestamp-clause:

AS ROW BEGIN END

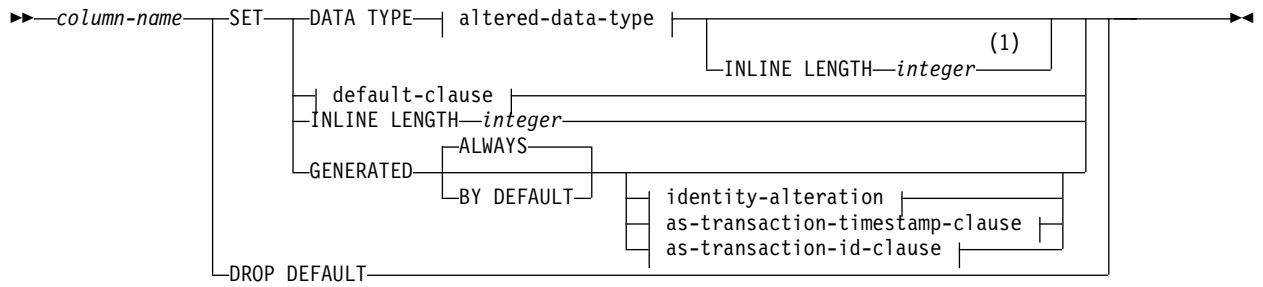

as-row-transaction-id-clause:

AS TRANSACTION START ID

column-constraint

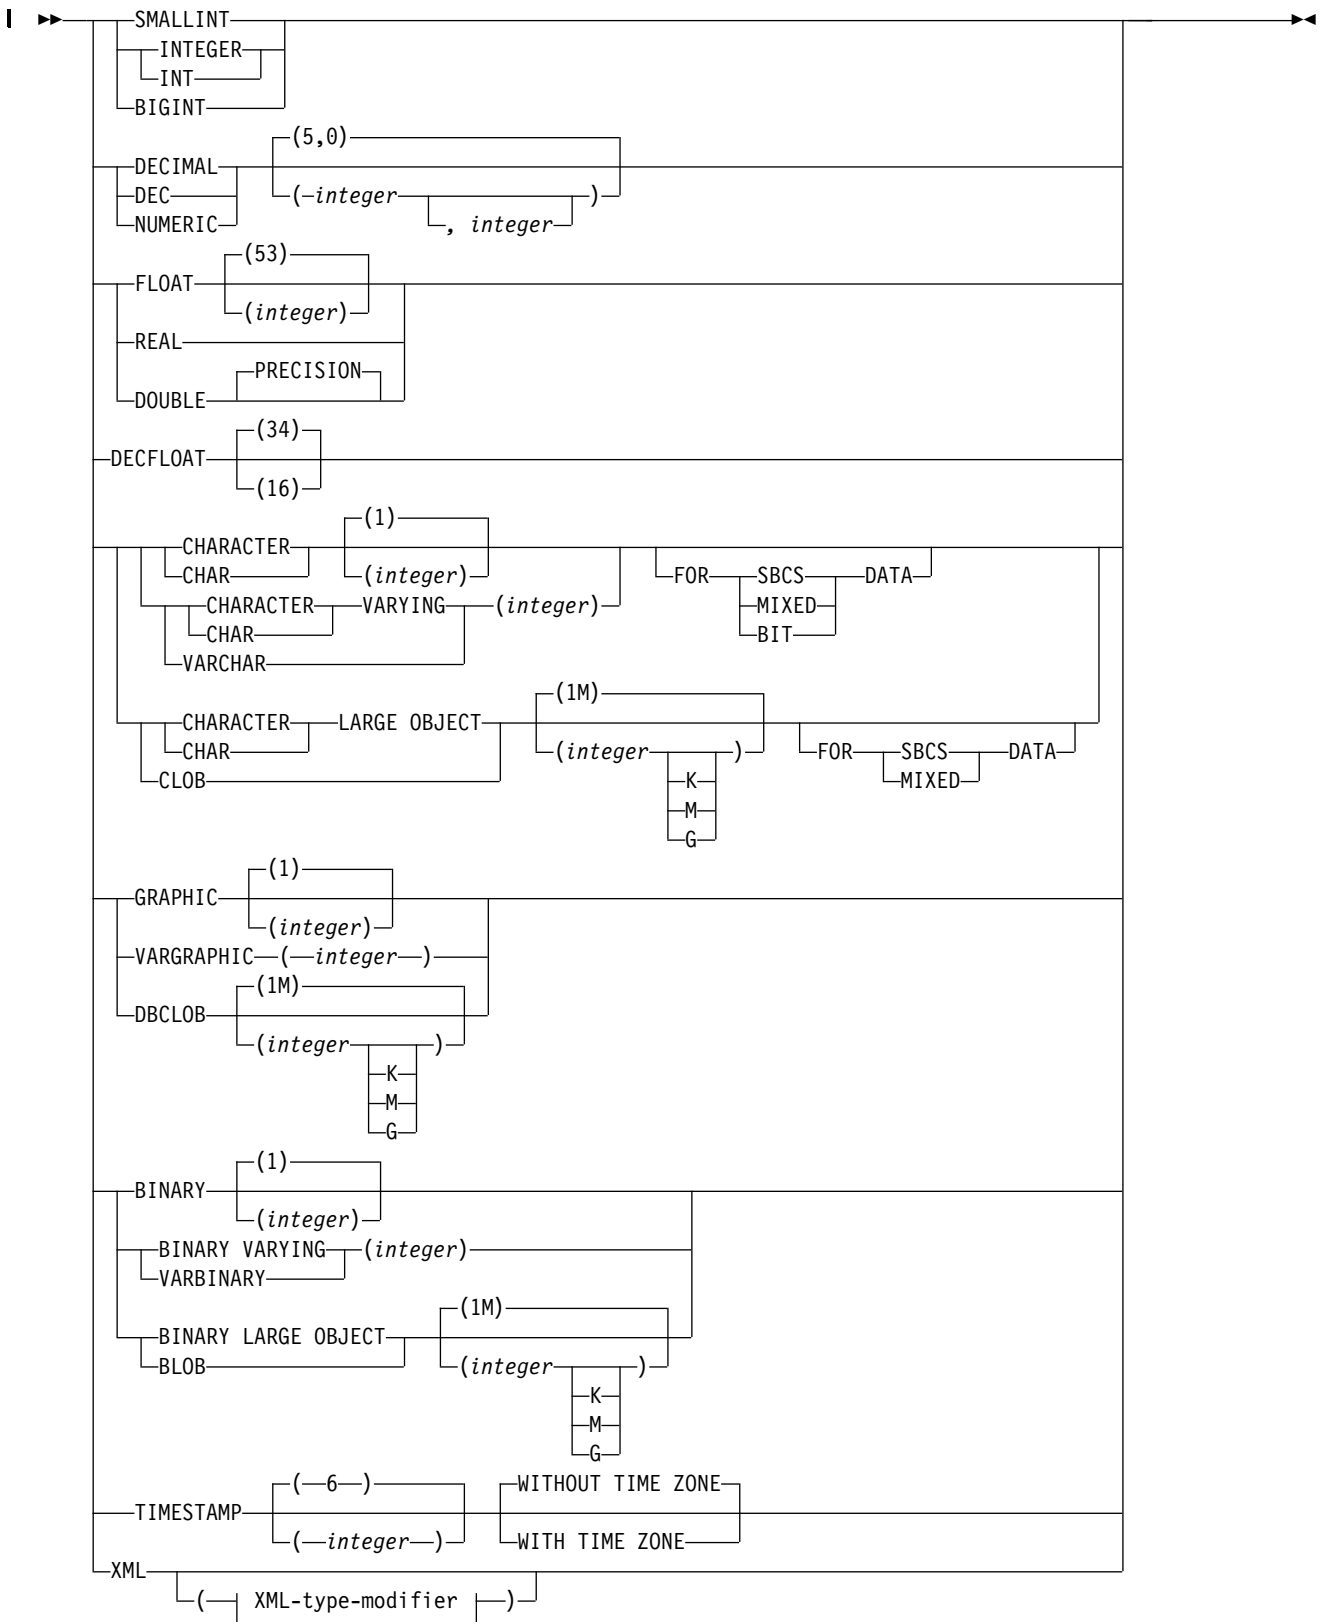

column-alteration:

Notes:

- 1 INLINE LENGTH can only be specified for LOB columns in tables that are in universal table spaces. INLINE LENGTH cannot be specified if FOR SBCS DATA or FOR MIXED DATA is also specified.

altered-data-type:

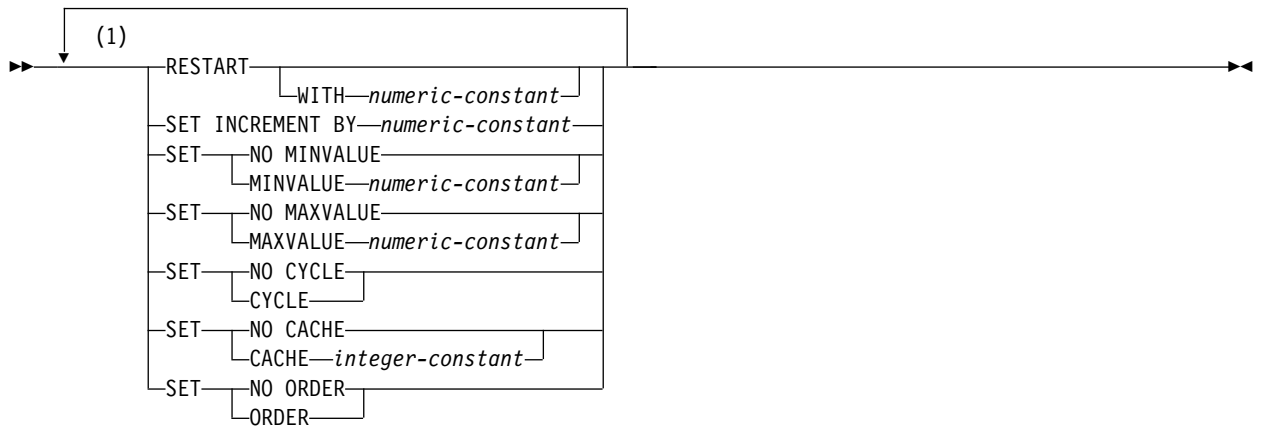

XML-type-modifier:

XML-schema-specification:

identity-alteration:

Notes:

- 1 At least one option must be specified and the same clause must not be specified more than one time.

unique-constraint:

referential-constraint:

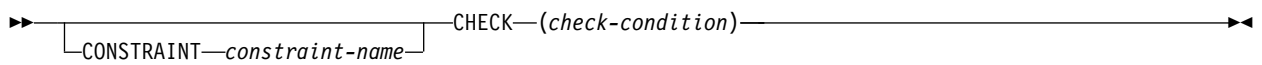

Notes:

- 1 For compatibility with prior releases, when the CONSTRAINT clause (shown above) is not specified, a *constraint-name* can be specified following FOREIGN KEY.

references-clause:

check-constraint:

partitioning-clause:

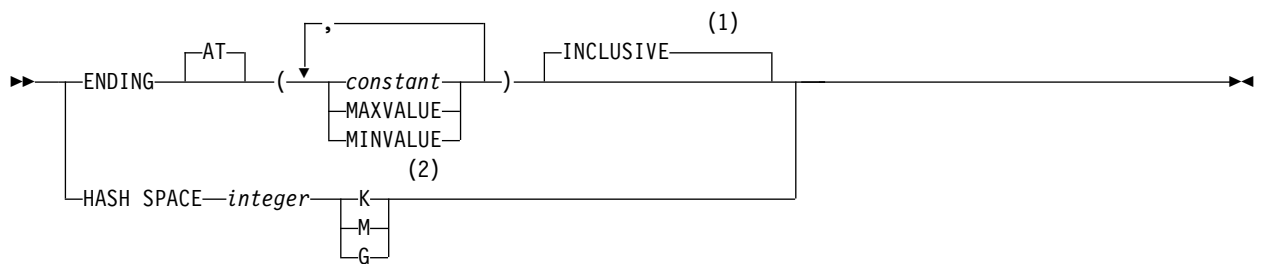

partition-expression:

partition-element:

partition-clause:

Notes:

- 1 The ENDING clause must not be specified for a partition-by-growth table space, but must be specified for a range partitioned table space.
- 2 The HASH SPACE clause can only be specified for the ALTER PARTITION clause.

Notes:

1 The same clause must not be specified more than one time.

period-definition:

►► SYSTEM_TIME—BUSINESS_TIME— (-begin-column-name-, -end-column-name-) |

organization-clause:

Description

table-name

Identifies the table to be altered. The name must identify a table that exists at the current server. The name must not identify a declared temporary table, view, or a table that was implicitly created for an XML column. If the name identifies a catalog table, DATA CAPTURE CHANGES is the only clause that can be specified. If the name identifies an accelerator-only table, ADD RESTRICT ON DROP or DROP RESTRICT ON DROP are the only clauses that can be specified.

If *table-name* identifies an auxiliary table, alterations are limited to the following clauses:

- APPEND

If *table-name* identifies a materialized query table, alterations are limited to the following clauses:

- AUDIT
- DATA CAPTURE
- ALTER MATERIALIZED QUERY
- DROP MATERIALIZED QUERY
- ADD RESTRICT ON DROP
- DROP RESTRICT ON DROP

ADD COLUMN

ADD COLUMN *column-definition*

Adds a column to the table. Except for the following columns, all values of the column in existing rows are set to its default value:

- ROWID column
- Identity column
- Row change timestamp column
- Row-begin column
- Row-end column
- Transaction-start-ID column

If the table has n columns, the ordinality of the new column is $n+1$. The value of n cannot be greater than 749. For a dependent table, n cannot be greater than 748.

The column cannot be added if the increase in the total byte count of the columns exceeds the maximum row size. The maximum row size for the table is eight less than the maximum record size as described in Maximum record size.

If you add a LOB column and the table does not already have a ROWID column, DB2 creates an implicitly hidden ROWID column. For details about adding a LOB column, such as the other objects that might be implicitly created or need to be explicitly created, see *Creating a table with LOB columns*. For more information about adding a ROWID column, see *Adding a ROWID column*.

For implicitly created LOB objects, the privilege set requires CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created) and the USE privilege on the buffer pool and the storage group that is used by the auxiliary table and the LOB table space. The implicitly created objects are owned by the owner of the base table.

If you add an XML column, the privilege set requires the CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created), INDEX on the base table for the first DOCID column that is added, and USE privilege on the buffer pool and the storage group that is used by the XML objects. These privileges are required for implicitly created XML objects. The implicitly created objects are owned by the owner of the base table.

When you add a column to a table, the table space is placed into advisory REORG-pending status.

The table must not be a history table.

If the table is a system-period temporal table, the column is also added to the associated history table. The following attributes of the column in the history table are the same as the attributes of the corresponding column of the system-period temporal table:

- Name
- Data type
- Length (including inline LOB lengths), precision, scale
- FOR BIT, SBCS, or MIXED DATA attribute for a character string column
- Null attribute
- Hidden attribute
- Field procedure

You cannot add the following columns:

- A column to a table that has an edit procedure that is defined as WITH ROW ATTRIBUTES.
- A ROWID column to a table that already has an explicitly defined ROWID column
- An identity column to a table that has an identity column
- A security label column to a table that already has a security label column
- A security label column to a system-period temporal table
- A row change timestamp column to a table that already has a row change timestamp column
- A LOB, ROWID, identity column, or row change timestamp column to a created temporary table
- A GRAPHIC, VARGRAPHIC, DBCLOB, or CHAR FOR MIXED DATA column, when the setting for installation option MIXED DATA is NO

If the column that is being added is a security label column, row permissions, including the default row permission, cannot exist for the table

column-name

Names of the column you want to add to the table. The name must not be the same as the name of an existing column of the table or the name of a period in the table. A column named SYSTEM_TIME or BUSINESS_TIME

cannot be added to a table that is defined as a system-period temporal table or a history table. Do not qualify *column-name*.

data-type

Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

built-in-type

Specifies that the data type of the column is one of the built-in data types. See built-in-type for information about the built-in data types that can be used when adding a column to a table.

distinct-type-name

Specifies the distinct type (user-defined data type) of the column. The length and scale of the column are respectively the length and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

NOT NULL

Prevents the column from containing null values. If NOT NULL is specified, the DEFAULT clause must be used to specify a nonnull default value for the column unless the column has a row ID data type or is an identity column. For a ROWID column, NOT NULL must be specified, and DEFAULT must not be specified. For an identity column, although NOT NULL can be specified, DEFAULT must not be specified.

DEFAULT

Specifies the default value that is assigned to the column in the absence of a value specified in a data change statement, or LOAD. Do not specify DEFAULT for the following types of columns:

- A ROWID column (DB2 generates default values)
- An identity column (DB2 generates default values)
- An XML column
- A row change timestamp column

Do not specify a value after the DEFAULT keyword for a security label column. DB2 provides the default for a security label column.

If a value is not specified after the DEFAULT keyword, the default value depends on the data type of the column as indicated in the following table:

| Data Type | Default Value |
|---|----------------------|
| Numeric | 0 |
| Fixed-length character or graphic string | Blanks |
| Fixed-length binary string | Hexadecimal zeros |
| Varying-length string | A string of length 0 |

| **Inline BLOB**

| Hexadecimal zeros

| **Inline CLOB**

| Blanks

| **Inline DBCLOB**

| Blanks

| **Date** For existing rows, a date corresponding to 1 January 0001. For added rows, CURRENT DATE.

| **Time** For existing rows, a time corresponding to 0 hours, 0 minutes, and 0 seconds. For added rows, CURRENT TIME.

| **Timestamp without time zone**

| For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and zeros for fractional seconds up to the timestamp precision. For added rows, CURRENT_TIMESTAMP(*p*) WITHOUT TIME ZONE where *p* is the corresponding timestamp precision.

| **Timestamp with time zone**

| For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and zeros for fractional seconds up to the timestamp precision, 0 time zone hours, 0 time zone minutes. For added rows, CURRENT_TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

| If the column is defined as timestamp with time zone, the default value must include a time zone.

| In a given column definition:

- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.
- Omission of NOT NULL and DEFAULT for a column other than an identity column is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and DB2 generates default values.

| A default value other than the one that is listed above can be specified in one of the following forms:

- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

| *constant*

| Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

| A character or string constant must be short enough so that its UTF-8 representation requires no more than 1536 bytes. A hexadecimal graphic string (GX) constant cannot be specified.

| In addition, the length of the constant value cannot be greater than the INLINE LENGTH attribute for LOB columns.

| **SESSION_USER or USER**

| Specifies the value of the SESSION_USER (USER) special register at the time of an SQL data change statement or LOAD, as the default for the column. If SESSION_USER is specified, the data type of the column

must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. If the data type of the column is an inline CLOB, the `INLINE LENGTH` attribute must be greater than or equal to 8 characters when the value is expressed as CCSID 37. For existing rows, the value is that of the `SESSION_USER` special register at the time the `ALTER TABLE` statement is processed.

CURRENT SQLID

Specifies the value of the SQL authorization ID of the process at the time of an SQL data change statement or `LOAD`, as the default for the column. If `CURRENT SQLID` is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the `CURRENT SQLID` special register. If the data type of the column is an inline CLOB, the `INLINE LENGTH` attribute must be greater than or equal to the length attribute of the `CURRENT SQLID` special register. For existing rows, the value is the SQL authorization ID of the process at the time the `ALTER TABLE` statement is processed.

NULL

Specifies null as the default value for the column.

cast-function-name

The name of the cast function that matches the name of the distinct type for the column. A cast function can be specified only if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.

constant

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type. The length of the constant cannot be greater than the `INLINE LENGTH` attribute for LOB columns.

SESSION_USER or USER

Specifies the value of the `SESSION_USER` (`USER`) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a `CHAR`, `VARCHAR`, or inline CLOB with a length attribute (inline length attribute for CLOB) that is greater than or equal to the length attribute of the `SESSION_USER` special register.

CURRENT SQLID

Specifies the value of the `CURRENT SQLID` special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a `CHAR`, `VARCHAR`, or inline CLOB with a length attribute (or inline length attribute for CLOB) that is greater than or equal to the length attribute of the `CURRENT SQLID` special register.

NULL

Specifies the `NULL` value as the argument.

GENERATED

Specifies that DB2 generates values for the column.

`GENERATED` is applicable only to the following columns:

- ROWID columns
- Identity columns
- Row change timestamp columns
- Row-begin columns
- Row-end columns
- Transaction-start-ID columns

If the table is a system-period temporal table or an archive-enabled table, GENERATED must not be specified for the column that is to be added, unless the column is a ROWID column. The default is GENERATED ALWAYS.

ALWAYS

Specifies that DB2 will generate a value for the column when a row is inserted into the table. ALWAYS is the recommended value unless you are using data propagation.

BY DEFAULT

Specifies that DB2 will generate a value for the column when a row is inserted unless a value was specified for the column on the data change statement.

If a user-supplied value is specified for a ROWID column, DB2 uses the value only if both of the following conditions are true:

- The value is a valid row ID value that was previously generated by DB2.
- The column has a unique, single-column index.

Until this index is created on the ROWID column, the insert, and update operations and the LOAD utility cannot be used to add rows to the table. If the table space name is not specified on the CREATE TABLE statement, DB2 implicitly creates the necessary object to make the table complete, including the index. The name of this index is 'I' followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, DB2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, DB2 inserts a specified value but does not verify that it is a unique value for the column unless the identity column has a unique, single-column index.

If a user-supplied value is specified for an identity column, DB2 inserts the specified value but does not perform any special validation on that value beyond the normal validation that is performed for any column. DB2 does not check how the specified value affects the sequential properties that are defined for the identity column. To ensure the uniqueness of an identity column that is defined as GENERATED BY DEFAULT, define a unique index on the identity column.

BY DEFAULT is the recommended value only when you are using data propagation.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale

of zero, or a distinct type that is based on one of these types). Separator commas between identity column attribute specifications are optional when the identity column is defined.

An identity column is implicitly NOT NULL. When adding an identity column to a table, you must also specify GENERATED ALWAYS or GENERATED BY DEFAULT.

Defining a column AS IDENTITY does not necessarily guarantee uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

START WITH *numeric-constant*

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that can be assigned to the column without non-zero digits to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after the maximum or minimum value for the identity column is reached. The START WITH clause can be used to start the generation of values outside the range that is used for cycles. The range that is used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant and can be assigned to the column without any non-zero digits to the right of the decimal point. The default is 1.

If the value is positive or zero, the sequence of values for the identity column ascends. If the value is negative, the sequence of values descends.

MINVALUE or NO MINVALUE

Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

NO MINVALUE

Specifies that the minimum end point of the range of values for the identity column is not set. In this case, the default value for MINVALUE becomes one of the following values:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH was not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

MINVALUE *numeric-constant*

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that can be assigned to this column without non-zero digits to the right of the decimal point. The value must be less than or equal to the maximum value.

MAXVALUE or NO MAXVALUE

Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

NO MAXVALUE

Specifies that the minimum end point of the range of values for the identity column is not set. In such a case, the default value for MAXVALUE becomes one of the following values:

- For an ascending identity column, the value is the maximum value of the data type of the column.
- For a descending identity column, the value is the START WITH value or -1 if START WITH is not specified.

MAXVALUE *numeric-constant*

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that can be assigned to this column without non-zero digits to the right of the decimal point. The value must be greater than or equal to the minimum value.

CYCLE or NO CYCLE

Specifies whether this identity column is to continue to generate values after reaching either its maximum or minimum value.

NO CYCLE

Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached. NO CYCLE is the default.

CYCLE

Specifies that values continue to be generated for this column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by DB2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

CACHE or NO CACHE

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is CACHE 20.

NO CACHE

Specifies that values for the identity column are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column results in synchronous I/O.

CACHE *integer-constant*

Specifies the maximum number of values of the identity column sequence that DB2 can preallocate and keep in memory.

During a system failure, all cached identity column values that are yet to be assigned might be lost and will not be used. Therefore, the value that is specified for CACHE also represents the maximum number of values for the identity column that could be lost during a system failure.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

ORDER or NO ORDER

Specifies whether the identity column values must be generated in order of request. The default is NO ORDER.

NO ORDER

Specifies that the values do not need to be generated in order of request.

ORDER

Specifies that the values are generated in order of request. Specifying ORDER might disable the caching of values. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different DB2 members might not result in the assignment of values in strict numeric order. For example, suppose that members DB2A and DB2B are using the identity column, DB2A gets the cache values 1 to 20, and DB2B gets the cache values 21 to 40. If DB2A requested a value first, then DB2B requested, and then DB2A again requested, the actual order of values that are assigned would be 1,21,2 . Therefore, to guarantee that identity values are generated in strict numeric order among multiple DB2 members using the same identity column, specify the ORDER option.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp and the values will be generated by DB2. DB2 generates a value for the column for each row as a row is inserted, and for any row for which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the time of the insert or update of the row. If multiple rows are inserted or updated with a single statement, the value of the row change timestamp column might be different for each row.

Adding a row change timestamp column to an existing table means that existing rows might be affected, and that an AREO* state might be set for the table space until a REORG is completed. For each existing row, a timestamp value is assigned for the new row change timestamp column.

|
|
|
|
|
|

If *data-type* is specified, it must be `TIMESTAMP WITHOUT TIME ZONE` with a precision of 6. You must specify `NOT NULL` with a row change timestamp column.

AS ROW BEGIN

Specifies that a value for the data type of the column is assigned when a row is inserted or any column in the row is updated. The value that is assigned for a `TIMESTAMP WITHOUT TIME ZONE` column is `TIMESTAMP` value '9999-12-30-00.00.00.000000000000'. The value that is assigned for a `TIMESTAMP WITH TIME ZONE COLUMN` is `TIMESTAMP` value '9999-12-30.00.00.00.000000000000 +00:00'.

A *row-begin* column is intended to be used for a system-period temporal table.

A table can have only one *row-begin* column. If *data-type* is not specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. If *data-type* is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP WITH TIME ZONE`, the values are stored in UTC, with a time zone of +00:00. The column cannot have a `DEFAULT` clause, and must be defined as `NOT NULL`.

A *row-begin* column is not updatable.

A value for a row-begin column is composed of a `TIMESTAMP(9)` value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

AS ROW END

Specifies that a value for the data type of the column is assigned when a row is inserted or any column in the row is updated. The value that is assigned for a timestamp without time zone column is `TIMESTAMP` '9999-12-30-00.00.00.000000000000'. The value that is assigned for a timestamp with time zone column is `TIMESTAMP` '9999-12-30.00.00.00.000000000000 +00:00'.

A *row-end* column is intended to be used for a system-period temporal table.

For a table with system-period data versioning, when a row is deleted as the result of an update or delete operation, the value of the *row-end* column in the historical row reflects when the row was deleted. The value that is generated for the column in the historical row is a timestamp that corresponds to the most recent transaction start time that is associated with the transaction. If a row that is to be updated would result in a value for the *row-end* column that is less than or equal to the value for the corresponding *row-begin* column, the timestamp value for the *row-end* column is adjusted. If multiple rows are deleted with a single SQL statement, the values for the column in the historical rows are the same.

A table can have only one *row-end* column. If *data-type* is not specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. If *data-type* is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP WITH TIME ZONE`, the values are stored in UTC, with a time zone of +00:00. The column cannot have a `DEFAULT` clause.

A *row-end* column is not updatable.

AS TRANSACTION START ID

Specifies that a timestamp value is assigned when the row is inserted or any column in the row is updated. If the value of the *row-begin* column is unique from *row-begin* column values that are generated for other transactions, the *row-begin* column value is assigned to the *transaction-start-ID* column. Otherwise, the value of the *transaction-start-ID* column is derived from the *row-begin* column value and adjusted to make it unique from *transaction-start-ID* column values that are generated for other transactions.

A *transaction-start-ID* column is intended to be used for a system-period temporal table.

A table can have only one *transaction-start-id* column. If *data-type* is not specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. If *data-type* is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP WITH TIME ZONE`, the values are stored in UTC, with a time zone of `+00:00`. The column cannot have a `DEFAULT` clause.

A *transaction-start-id* column is not updatable.

IMPLICITLY HIDDEN

Specifies that the column is not visible in the results of SQL statements unless you refer explicitly to the column by name. For example, assume that table T1 includes a column that is defined with the `IMPLICITLY HIDDEN` clause. The result of `SELECT * FROM T1` would not include the implicitly hidden column. However, the result of a `SELECT` statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

`IMPLICITLY HIDDEN` must not be specified for a column that is defined as a `ROWID`, or a distinct type that is based on a `ROWID`.

column-constraint

Provides a shorthand method of defining a constraint composed of a single column. If a *column-constraint* is specified in the definition of column C, the effect is the same as if that constraint were specified as a *unique-constraint*, *referential-constraint*, or *check-constraint* in which column C is the only identified column.

references-clause

The *references-clause* of a *column-definition* provides a shorthand method of defining a foreign key composed of a single column. Thus, if *references-clause* is specified in the definition of column C, the effect is the same as if that *references-clause* were specified as part of a `FOREIGN KEY` clause in which C is the only identified column.

Do not specify *references-clause* in the definition of the following types of columns because these types of columns cannot be a foreign key:

- LOB columns
- ROWID columns
- XML columns
- DECFLOAT columns
- Row change timestamp columns
- Security label columns

check-constraint

The *check-constraint* of a *column-definition* has the same effect as specifying a check constraint in a separate *ADD check-constraint* clause. For conformance with the SQL standard, a check constraint specified in the definition of column C should not reference any columns other than C.

Do not specify a check constraint in the definition of the following types of columns:

- LOB columns
- ROWID columns
- XML columns
- DECFLOAT columns
- Security label columns

AS SECURITY LABEL

Specifies that the table is defined with multilevel security with row level granularity and specifies that the column will contain the security label values. A table can have only one security label column. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column does not have any field procedures, check constraints, or referential constraints.
- The column must be defined as NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not be specified with a default value (DB2 provides the default value).
- The table does not have an edit procedure that is defined as WITH ROW ATTRIBUTES.
- The table is not the source table for a materialized query table.

For existing rows in the table, the value of the security label column defaults to the security label of the user at the time the ALTER statement is executed.

FIELDPROC *program-name*

Designates *program-name* as the field procedure exit routine for the column. A field procedure can be specified only for a column with a length attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data types. The column must not be one of the following:

- a LOB column
- a security label column
- a row change timestamp column
- a column with the TIMESTAMP WITH TIME ZONE data type

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the ALTER TABLE statement. When so invoked, the procedure provides DB2 with the

column's *field description*. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the ALTER TABLE statement defines the data characteristics of the decoded values.

If you omit FIELDPROC, the column has no field procedure.

Related information:

Field procedures (DB2 Administration Guide)

constant

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The *n*th parameter specified in the FIELDPROC clause on ALTER TABLE corresponds to the *n*th parameter of the specified field procedure. The maximum length of the parameter list is 255 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

INLINE LENGTH *integer*

Specifies the maximum length for the column, if the column is a LOB column and the table is in a universal table space. INLINE LENGTH cannot be specified if the column is not a LOB column (or a distinct type that is based on a LOB), if the table is not in a universal table space, or if the table is an accelerator-only table.

For BLOB and CLOB columns, *integer* specifies the maximum number of bytes that are stored in the base table space for the column. *integer* must be between 0 and 32680 (inclusive) for a BLOB or CLOB column.

For a DBCLOB column, *integer* specifies the maximum number of double-byte characters that are stored in the table space for the column. *integer* must be between 0 and 16340 (inclusive) for a DBCLOB column.

If INLINE LENGTH is specified, the value of *integer* cannot be greater than the maximum length of the LOB column.

If the INLINE LENGTH clause is not specified, the maximum length of the LOB column depends on the following conditions:

- If a distinct type is not used or the distinct type that is used has been created without the INLINE LENGTH attribute, the LOB column will use the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD as the default inline length when the value of LOB INLINE LENGTH does not exceed the maximum length of the LOB column. If the value of LOB INLINE LENGTH exceeds the maximum length of the LOB column, the maximum length is the inline length of this LOB column.
- If a distinct type that has been created with the INLINE LENGTH attribute is used, the LOB column inherits the inline length from the distinct type.

Regardless of how the length is determined, the inline length of the LOB cannot be greater than its maximum length.

ALTER COLUMN

ALTER COLUMN *column-alteration*

Alters the definition of an existing column, including the attributes of an existing identity column. Only the attributes specified are altered. Other attributes remain unchanged. Only future values of the column are affected by the changes made with an ALTER TABLE ALTER COLUMN statement.

The table being altered must not be in an incomplete state because of a missing unique index on a unique constraint (primary or unique key). An ALTER TABLE ALTER COLUMN statement might not be processed in the same unit of work as a data change statement. A column cannot be altered if any of the following conditions are true:

- The table has an edit procedure that is defined as WITH ROW ATTRIBUTES or a validation exit procedure
- The table is used in a materialized query table definition
- The table is a materialized query table
- The table is a system-period temporal table that is enabled for system-period data versioning
- The table is a history table
- The table is a created temporary table.
- There is an extended index that depends on that column
- The column is referenced in a field procedure
- The column is referenced in a referential constraint
- The column is referenced in a check constraint
- The column is referenced in the definition of a SYSTEM_TIME or BUSINESS_TIME period
- The column is defined as a *transaction-start-ID* column
- The column is defined as a security label column
- The column is defined as a row change timestamp column

You can modify all the attributes of an existing identity column, except for the data type of the column. To change the data type of an identity column, drop the table containing the column and recreate it. When the attributes of an identity column are altered, the column of the specified *column-name* must exist in the specified table and must have been defined with the IDENTITY attribute.

column-name

Identifies the column to be altered. The name must not be qualified and must identify an existing column in the table being altered when the ALTER statement is processed. The name must not identify a column that is being added in the same ALTER TABLE statement.

A column can only be referenced in one ALTER COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

SET DATA TYPE (*altered-data-type*)

Specifies the new data type of the column to be altered. For a character column, you can also use the clause to change the definition of the subtype that is stored in the DB2 catalog and OBD.

The following restrictions apply to use of the SET DATA TYPE clause:

- The data type of a column cannot be altered if the column is an identity column or is part of a hash key.
- The existing data type of the column cannot be a ROWID, date, time, or distinct type.
- The new data type must be compatible with the existing data type of the column.

- When the source data type is a LOB, the target data type must be the same LOB data type. If the source data type is a LOB and the maximum length is altered, the new maximum length must be at least as large as the existing length attribute.
- If the column is a partitioning column, and the existing data type is CHAR or VARCHAR FOR BIT DATA, the new data type cannot be VARBINARY or BINARY.
- If the column is CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, or BINARY, the new data type cannot be VARBINARY if the column is part of an index and is defined with the DESC attribute.
- If *altered-data-type* is XML, the old data type of the altered column must also be XML.
- A row in a table with PAGENUM RELATIVE or in a table space with PAGENUM RELATIVE must have a minimum data size of 3 bytes. If an ALTER TABLE ALTER COLUMN results in row size that is less than the minimum size, it will not be valid.

For more information on the compatibility of data types, see “Assignment and comparison” on page 119.

A TIMESTAMP column can only be altered to TIMESTAMP with a larger precision. A TIMESTAMP WITH TIME ZONE column can only be altered to TIMESTAMP WITH TIME ZONE with a larger precision. If the precision of a timestamp column is increased, the fractional seconds of existing data values are extended with zeros so that the number of fractional second digits matches the specified timestamp precision.

If any numeric data type is being converted to DECFLOAT, the ALTER statement will fail if there is a partitioning key, index, or a unique constraint on the column.

If the data type is a character or graphic string, the new length attribute must be at least as large as the existing length attribute of the column. If the data type is a numeric data type, the specified precision and scale must be at least as large as the existing precision and scale. If a decimal fraction is being converted to floating point, the ALTER statement will fail if there is a unique index or a unique constraint on the column.

If the specified column has a default value, the existing default value must represent a value that could be assigned to a column with the new data type in accordance with the rules for assignment. The default value is updated to reflect the new data type.

If the column is specified in an index, the new column length must not exceed the limit on an index size. For PADDED indexes, the sum of the length attributes of the columns must not be greater than $2000-n$, where n is the number of columns that can contain null values. For NOT PADDED indexes, the sum of the length attributes of the columns must not be greater than $2000-n-2m$, where n is the number of nullable columns and m is the number of varying length columns.

The total byte count of columns after the alteration must not exceed the maximum row size. If the column is in the partitioning key, the new partitioning key cannot exceed $255-n$.

Table 153 on page 1332 shows the numeric data type alterations that are supported for SET DATA TYPE:

Table 153. Supported numeric data type alterations for SET DATA TYPE

| From/To | SMALLINT | INTEGER | BIGINT | DECIMAL (q,t) | REAL | DOUBLE | DECFLOAT (16) | DECFLOAT (34) |
|------------------|------------|-------------|--------------|----------------------|------|--------|------------------|------------------|
| SMALLINT | Y | Y | Y | (q-t)>4 | Y | Y | Y | Y |
| INTEGER | N | Y | Y | (q-t)>9 | N | Y | Y | Y |
| BIGINT | N | N | Y | (q-t)>18 | N | N | N | Y |
| | | | | | p<7 | p<16 | p<17 | Y |
| DECIMAL (p,s) | s=0 p<5 | s=0 p<10 | s=0 p<=19 | q>=p (q-t)>=(p-s) | | | | |
| | N | N | N | N | N | N | Y | Y |
| DECFLOAT (16) | | | | | | | | |
| | N | N | N | N | N | N | N | Y |
| DECFLOAT (34) | | | | | | | | |
| | N | N | N | N | Y | Y | Y | Y |
| FLOAT (1-21) | | | | | | | | |
| | N | N | N | N | N | Y | Y | Y |
| FLOAT (22-53) | | | | | | | | |

Table 154 shows the character data type alterations that are supported for SET DATA TYPE:

Table 154. Supported character data type alterations for SET DATA TYPE (x > =0).

| From/To | CHARACTER (n+x) | VARCHAR (n+x) | LONG VARCHAR | GRAPHIC (n+x) | VARGRAPHIC (n+x) | LONG VARGRAPHIC |
|--------------------|--------------------|------------------|-----------------|------------------|---------------------|--------------------|
| CHARACTER(n) | Y | Y | N | N | N | N |
| VARCHAR(n) | Y | Y | N | N | N | N |
| LONG VARCHAR | N | Y | N | N | N | N |
| GRAPHIC(n) | N | N | N | Y | Y | N |
| VARGRAPHIC(n) | N | N | N | Y | Y | N |
| LONG VARGRAPHIC | N | N | N | N | Y | N |

When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, and there is an index defined on that column, the index will be put in RBDP.

Table 155. Supported binary data type alterations for SET DATA TYPE (x >= 0)

| From/To | BINARY(n+x) | VARBINARY(n+x) |
|-------------------------|----------------|----------------|
| CHAR(n) FOR BIT DATA | Y | Y |
| VARCHAR(n) FOR BIT DATA | Y | Y |
| BINARY(n) | Y | Y |
| VARBINARY(n) | Y ¹ | Y |

Note: ALTER from VARBINARY to BINARY is not allowed when the column is part of a unique index.

If the alteration results in the generation of a new table version, the table space that contains the table that is being changed is left in an advisory REORG-pending (AREO) status.

FOR *subtype* DATA

Alters the *subtype* of a character column. This clause does not change the data. The clause only updates the definition of the subtype as it is stored in the DB2 catalog and the OBD. The length and data type that are specified must match the existing length and data type of the column.

Only character strings are valid when subtype is BIT.

For more information on the subtype values (SBCS, MIXED, and BIT), see the subtype information under built-in-type.

INLINE LENGTH *integer*

Specifies the new inline length for the column. **INLINE LENGTH** can only be specified for an inline LOB column in a table that is in a universal table space. **INLINE LENGTH** cannot be specified if **FOR SBCS DATA** or **FOR MIXED DATA** is also specified in the same **ALTER TABLE** statement. Inline LOB columns cannot be added to a table that is in a table space that has basic row format. The new length can be smaller or larger than the original length. *integer* is a value between 0 and 32680 bytes (inclusive) for a BLOB or CLOB column or between 0 and 16340 characters (inclusive) for a DBCLOB column. The inline length cannot be changed in the following cases:

- The LOB column is referenced in an expression-based index or a spatial index.
- If the column has a default value, the new inline length is less than the length of the default value for the column.
- The new inline length is greater than the maximum length of the LOB column.

When the base table space is not empty, increasing the length puts the table space in an advisory REORG-pending state, and decreasing the length puts the table space in a REORG-pending state.

No expression-based indexes can be created after the inline length is changed until the REORG utility is run on the base table space.

SET INLINE LENGTH *integer*

Specifies the new inline length for the column. **SET INLINE LENGTH** can only be specified for an inline LOB column in a table that is in a universal table space. **INLINE LENGTH** cannot be specified if **FOR SBCS DATA** or **FOR MIXED DATA** is also specified in the same **ALTER TABLE** statement. Inline LOB columns cannot be added to a table that is in a table space that has basic row format. The new length can be smaller or larger than the original length. *integer* is a value between 0 and 32680 bytes (inclusive) for a BLOB or CLOB column or between 0 and 16340 characters (inclusive) for a DBCLOB column. The inline length cannot be changed in the following cases:

- The LOB column is referenced in an expression-based index or a spatial index.
- If the column has a default value, the new inline length is less than the length of the default value for the column.

- The new inline length is greater than the maximum length of the LOB column.

When the base table space is not empty, increasing the length puts the table space in an advisory REORG-pending state, and decreasing the length puts the table space in a REORG-pending state.

No expression-based indexes can be created after the inline length is changed until the REORG utility is run on the base table space.

SET *default-clause*

Specifies the new default value of the column to be altered. The new default value must conform to the current rules for assigning that value to the column. Existing rows will retain their current value. The new default value will only be reflected in the rows that are inserted after the alter. Sections that are dependent on the table that is being altered will be invalidated.

The table must not be referenced by a view. The table must not be defined with the DATA CAPTURE CHANGES attribute when the subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES.

If the column is specified in a unique constraint (unique key or primary key) or unique index, the default value might be altered to the same value as an existing row of that column. However, subsequent data change operations will fail in the absence of a value specified for that column on the insert operation.

For LOB columns, default values can be changed only for inline LOB. The length of the new default value cannot be greater than the inline length.

DROP DEFAULT

Drops the current default value of the column. For columns that are not nullable, the specified column must be defined with a default value. For columns that are nullable, the specified column cannot have a null default value. For columns that are nullable, the new default value is the null value.

The table that contains the specified column must not be referenced in a view. The table must not be defined with the DATA CAPTURE CHANGES attribute when the subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES.

Follow these steps to remove the default value for a column that was defined using ALTER TABLE with the ADD COLUMN clause:

1. Run the REORG utility or the UPDATE statement to reset the AREO* state:
 - Run the REORG utility on the table space that contains the table
 - If the table is in a universal table space and the table does not have row access control activated, run an UPDATE statement without the SKIP LOCKED DATA or WHERE clauses specified. The update operation must be done with a searched UPDATE statement and the expression in the SET clause cannot be a *scalar-fullselect* or a *row-fullselect*. An update operation within a SELECT statement will not reset the AREO* status.
2. Issue the ALTER TABLE statement that specifies the DROP DEFAULT clause

If the REORG is not done before the ALTER TABLE, or the UPDATE statement does not reset the AREO* statue, an error is returned for the ALTER TABLE statement.

SET GENERATED

Specifies that DB2 generates values for the column. SET GENERATED must not be specified for a column of a history table or for a column that already has the GENERATED attribute.

ALWAYS

Specifies that DB2 always generates a value for the column when a row is inserted or updated and a default value must be generated.

BY DEFAULT

Specifies that DB2 generates a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified. For a row change timestamp column, DB2 inserts or updates a specified value but does not verify that it is a unique value for the column unless the row change timestamp column has a unique constraint or a unique index that solely specifies the row change timestamp column.

RESTART

Specifies the next value for the identity column, If *numeric-constant* is not specified, the sequence is restarted at the value that is specified implicitly or explicitly as the starting value when the identity column was originally created.

WITH *numeric-constant*

Specifies that, when it is time to generate the next value for this identity column, *numeric-constant* will be used as the next value for the column. This value can be any positive or negative value (including 0) that could be assigned to this column without nonzero digits existing to the right of the decimal point.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values that are in effect for all the options after the ALTER statement is issued.

After an identity column is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated previously.

SET INCREMENT BY *numeric-constant*

For a definition, see the description of INCREMENT BY *numeric-constant* for defining an identity column.

SET MINVALUE or NO MINVALUE

For a definition, see the description of MINVALUE or NO MINVALUE for defining an identity column.

SET MAXVALUE or NO MAXVALUE

For a definition, see the description of MAXVALUE or NO MAXVALUE for defining an identity column.

SET CYCLE or NO CYCLE

For a definition, see the description of CYCLE or NO CYCLE for defining an identity column.

SET CACHE or NO CACHE

For a definition, see the description of CACHE or NO CACHE for defining an identity column.

SET ORDER or NO ORDER

For a definition, see the description of ORDER or NO ORDER for defining an identity column.

RENAME COLUMN:

RENAME COLUMN *source-column-name* **TO** *target-column-name*

Renames the specified column. The names must not be qualified.

source-column-name

Identifies the column that is to be renamed. The name must identify an existing column of the table.

target-column-name

Specifies the new name for the column. The name must not identify a column that already exists in the table, or the name of a period that exists in the table.

You cannot rename a column if any of the following conditions apply:

- The column is referenced in a view
- The column is referenced in the expression of an index definition
- The column is referenced in the definition of a row permission or a column mask
- The column is referenced in an SQL table user-defined function
- The column has a check constraint defined
- The column has a field procedure defined
- The table has a trigger
- The table is a materialized query table or is referenced by a materialized query table
- The table has a valid procedure, or an edit procedure that is defined as WITH ROW ATTRIBUTES
- The table is a DB2 catalog table
- The table is a system-period temporal table or a history table

ADD PERIOD:

ADD PERIOD *period-definition*

Adds a period to the table.

begin-column-name must not be the same as *end-column-name*. The data type, precision, and scale for *begin-column-name* must be the same as for *end-column-name*.

SYSTEM_TIME(*begin-column-name*, *end-column-name*)

Names the period **SYSTEM_TIME**. The name must not identify an existing column in the table. A table can have only one **SYSTEM_TIME** period.

The *begin-column-name* must specify a *row-begin* column and the *end-column-name* must specify a *row-end* column. Both columns must be defined as GENERATED ALWAYS. A column mask or row permission must not be defined for the table.

BUSINESS_TIME(*begin-column-name*, *end-column-name*)

Names the period **BUSINESS_TIME**. The name must not identify an existing column in the table. A table can have only one **BUSINESS_TIME** period.

An implicit check constraint is generated to ensure that the value of *end-column-name* is greater than the value of *begin-column-name*. The name of the implicitly created check constraint is DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME, and that name must not be defined as the name of an existing check constraint.

The columns that are specified for *begin-column-name* and *end-column-name* must be defined as DATE or TIMESTAMP(6) WITHOUT TIME ZONE, and must be defined as NOT NULL. The columns that are specified for *begin-column-name* and *end-column-name* must not identify a column that is defined with a GENERATED clause.

begin-column-name

Identifies the column that records the start value for the period. The name must identify an existing column in the table. *begin-column-name* must not be the same as a column that is used in the definition of another period for the table.

end-column-name

Identifies the column that records the end value for the period. The name must identify an existing column in the table. *end-column-name* must not be the same as a column that is used in the definition of another period for the table.

ADD unique-constraint:

CONSTRAINT *constraint-name*

Names the primary key or unique key constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table. If the table space is implicitly created, the enforcing primary key and unique key indexes are also implicitly created.

PRIMARY KEY(*column-name*,...)

Defines a primary key composed of the identified columns. Each column name must be an unqualified name that identifies a column of the table. The same column must not be identified more than one time. The following types of columns cannot be specified in a PRIMARY KEY clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- a row change timestamp column

The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than 2000 - 2*m*, where *m* is the number of varying-length columns in the key. The table must not have a primary key and the identified columns must be defined as NOT NULL.

The set of columns in the primary key cannot be the same as the set of columns of another unique key.

The table must have a unique index with a unique key that is identical to the primary key. The keys are identical only if they have the same number of columns and the *n*th column name of one is the same as the *n*th column name

of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, DB2 will automatically create a primary index. The privilege set must include the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created primary key index is owned by the owner of the base table.

The identified columns are defined as the primary key of the table. The description of the index is changed to indicate that it is a primary index. If the table has more than one unique index with a key that is identical to the primary key, the selection of the primary index is arbitrary.

BUSINESS_TIME WITHOUT OVERLAPS

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name* or *key-expression*. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

UNIQUE(*column-name*,...)

Defines a unique key composed of the identified columns with the specified *constraint-name*. If a *constraint-name* is not specified, a name is generated. Each column name must be an unqualified name that identifies a column of the table. The same column must not be identified more than one time. The following types of columns cannot be specified in a UNIQUE clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type

Each identified column must be defined as NOT NULL. The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than $2000 - n$ for padded indexes and $2000 - n - 2m$ for nonpadded indexes, where n is the number of columns that can contain null values and m is the number of varying-length columns in the key.

The set of columns in the unique key cannot be the same as the set of columns of the primary key or another unique key. A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table must have a unique index with a key that is identical to the unique key. The keys are identical only if they have the same number of columns and the n th column name of one is the same as the n th column name of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, DB2 will automatically create a unique index to enforce the unique key constraint. The privilege set must include the

INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created unique key index is owned by the owner of the base table.

The identified columns are defined as a unique key of the table. The description of the index is changed to indicate that it is enforcing a unique key constraint. If the table has more than one unique index with a key that is identical to the unique key, the selection of the enforcing index is arbitrary.

BUSINESS_TIME WITHOUT OVERLAPS

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name* or *key-expression*. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

ADD referential-constraint:

CONSTRAINT *constraint-name*

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

FOREIGN KEY (*column-name, ...*) *references-clause*

Specifies a referential constraint with the specified *constraint-name*.

FOREIGN KEY cannot be specified if the table is a history table.

Let T1 denote the object table of the ALTER TABLE statement. T1 is the child table for the referential constraint.

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T1. The same column must not be identified more than one time. The following types of columns cannot be specified in the FOREIGN KEY clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- a security label column
- a row change timestamp column

The number of identified columns must not exceed 64, and the sum of their length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and the parent table are the same as the FOREIGN KEY and parent table of an existing referential constraint on T1. The specification of a duplicate referential constraint is ignored with a warning.

The foreign key of the referential constraint cannot reference a parent key that contains BUSINESS_TIME WITHOUT OVERLAPS.

REFERENCES *table-name* (*column-name*,...)

The table name specified after REFERENCES is the parent table for the referential constraint. The *table-name* value must identify a table that exists at the current server. This table is referred to as the parent table in the constraint relationship.

table-name must not identify a catalog table, a declared global temporary table, or a history table.

Let T2 denote the identified parent table and let T1 denote the table that is being changed (T1 and T2 can be the same table).

T2 must have a unique index. The privilege set on T2 must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key, including the columns of the BUSINESS_TIME period if the PERIOD BUSINESS_TIME clause is specified.

The parent key of the referential constraint is composed of the identified columns, or columns of the BUSINESS_TIME period if PERIOD BUSINESS_TIME is specified. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than one time. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The following types of columns cannot be specified in a REFERENCES clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- a security label column
- a row change timestamp column

The list of column names in the parent key must match the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the same order as in the primary key or unique key. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme.

If a list of column names is not specified, then T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2 and, except for their names, default values, null attributes and check constraints, the description of the *n*th column of the foreign key must be identical to the description of the *n*th column of the nominated parent key. If the foreign key includes a column defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A *field description* is a description of the encoded value as it is stored in the database for a column that has been defined to have an associated field procedure.

The table space that contains T1 must be available to DB2. If T1 is populated, its table space is placed in a check pending status. A table in a segmented table space is populated if the table is not empty. A table in a table space that is not segmented is considered populated if the table space has ever contained any records.

The referential constraint specified by the FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

ON DELETE

The delete rule of the relationship is determined by the ON DELETE clause. For more on the concepts used here, see “Referential constraints” on page 25.

If T1 and T2 are the same table, CASCADE or NO ACTION must be specified. SET NULL must not be specified unless some column of the foreign key allows null values. Also, SET NULL must not be specified if any nullable column of the foreign key is a column of the key of a partitioning index. The default value for the rule depends on the value of the CURRENT RULES special register when the ALTER TABLE statement is processed. If the value of the register is 'DB2', the delete rule defaults to RESTRICT; if the value is 'SQL', the delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let p denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of p in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of p in T1 is set to null.

A cycle involving two or more tables must not cause a table to be delete-connected to itself. Thus, if the relationship would form a cycle:

- The referential constraint cannot be defined if each of the existing relationships that would be part of the cycle have a delete rule of CASCADE.
- CASCADE must not be specified if T2 is delete-connected to T1.

If T1 is delete-connected to T2 through multiple paths, those relationships in which T1 is a dependent and which form all or part of those paths must have the same delete rule and it must not be SET NULL. For example, assume that T1 is a dependent of T3 in a relationship with a delete rule of r and that one of the following is true:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendents of the same table and the deletion of rows from that table cascades to both T2 and T3.

In this case, the referential constraint cannot be defined when r is SET NULL. When r is other than SET NULL, the referential constraint can be defined, but the delete rule that is implicitly or explicitly specified in the FOREIGN KEY clause must be the same as r .

ENFORCED or NOT ENFORCED

Indicates whether or not the referential constraint is enforced by DB2 during normal operations, such as insert, update, or delete.

ENFORCED

Specifies that the referential constraint is enforced by DB2 during normal operations (such as data change operations) and that it is guaranteed to be correct. ENFORCED is the default.

NOT ENFORCED

Specifies that the referential constraint is not enforced by DB2 during normal operations (such as data change operations). NOT ENFORCED should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on DB2.

ENABLE QUERY OPTIMIZATION

Specifies that the constraint can be used for query optimization. DB2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

ADD check-constraint:**CONSTRAINT** *constraint-name*

Names the check constraint. If *constraint-name* is not specified, a unique constraint name is derived from the name of the first column in the *check-condition* specified in the definition of the check constraint. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

CHECK (*check-condition*)

Defines a check constraint. At any time, *check-condition* must be true or unknown for every row of the table. A *check-condition* can evaluate to unknown if a column that is an operand of the predicate is null. A *check-condition* that evaluates to unknown does not violate the check constraint. A *check-condition* is a search condition, with the following restrictions:

- It can refer only to the columns of table *table-name*.
- The columns cannot be any of the following types of columns:
 - LOB columns
 - ROWID columns
 - DECFLOAT columns
 - XML columns
 - distinct type columns that are based on LOB, ROWID, and DECFLOAT data types
 - security label columns
- It can be up to 7400 bytes long, not including redundant blanks.
- It must not contain any of the following:
 - Subselects
 - Built-in or user-defined functions
 - CAST specifications
 - Cast functions other than those created when the distinct type was created
 - Host variables
 - Parameter markers
 - Special registers
 - Columns that include a field procedure
 - CASE expressions
 - ROW CHANGE expressions
 - Row expressions
 - DISTINCT predicates

- GX constants (hexadecimal graphic string constants)
- Sequence references
- OLAP specifications
- If a *check-condition* refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the *check-condition* must be either a constant or a column name of a column in the table.
 - If the second operand of a predicate is a constant, and if the constant is:
 - A floating-point number, then the column data type must be floating point.
 - A decimal number, then the column data type must be either floating point or decimal.
 - A big integer number, then the column data type must not be an integer or a small integer
 - An integer number, then the column data type must not be a small integer.
 - A small integer number, then the column data type must be small integer.
 - A decimal constant, then its precision must not be larger than the precision of the column.
 - If the second operand of a predicate is a column, then both columns of the predicate must have:
 - The same data type
 - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes

Effects of defining a check constraint on a populated table: When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'DB2', the check constraint is not immediately enforced on the table. The check constraint is added to the description of the table, and the table space that contains the table is placed in a check pending status. For a description of the check pending status and the implications for utility operations, see *DB2 Utility Guide and Reference*.

When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'STD', the check constraint is checked against all rows of the table. If no violations occur, the check constraint is added to the table. If any rows violate the new check constraint, an error occurs and the description of the table is unchanged.

DROP constraint:

DROP PRIMARY KEY

Drops the definition of the primary key and all referential constraints in which the primary key is a parent key. The table must have a primary key and the privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table.

The description of the primary index is changed to indicate that it is not a primary index. If the table space was implicitly created, the corresponding enforcing index is dropped if the primary key is dropped.

DROP UNIQUE *constraint-name*

Drops the definition of the unique key constraint and all referential constraints in which the unique key is a parent key. The table must have a unique key. The privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table. The description of the enforcing index is changed to indicate that it is not enforcing a unique key constraint. If the table space is implicitly created, the corresponding enforcing index is dropped if the unique key is dropped.

DROP FOREIGN KEY *constraint-name*

Drops the referential constraint *constraint-name*. The *constraint-name* must identify a referential constraint in which the table is the dependent table, and the privilege set must include the ALTER or REFERENCES privilege on the parent table of that relationship, or the REFERENCES privilege on the columns of the parent table of that relationship.

DROP CHECK *constraint-name*

Drops the check constraint *constraint-name*. The *constraint-name* must identify an existing check constraint defined on the table.

DROP CONSTRAINT *constraint-name*

Drops the constraint *constraint-name*. The *constraint-name* must identify an existing primary key, unique key, check, or referential constraint defined on the table.

DROP CONSTRAINT must not be used on the same ALTER TABLE statement as DROP PRIMARY KEY, DROP UNIQUE KEY, DROP FOREIGN KEY or DROP CHECK.

ADD partitioning:**ADD PARTITION BY RANGE**

Specifies the range partitioning scheme for the table (the columns used to partition the data). When this clause is specified, the table uses table-controlled partitioning. The number of partitions specified in the ADD PARTITION BY RANGE clause has to be the same as the number of partitions defined in the table space.

This clause applies only to tables in a partitioned table space. If the table is already complete by having established either table-controlled partitioning or index-controlled partitioning, the ADD PARTITION BY RANGE clause is not allowed. If this clause is used, then the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

partition-expression

Specifies the key data over which the range is defined to determine the target data partition of the data.

column-name

Specifies the columns of the key. Each *column-name* must identify a column of the table. Do not specify more than 64 columns, the same column more than one time, a qualified column name, or any of the following types of columns:

- a BINARY or VARBINARY column
- a LOB column
- DECFLOAT column
- an XML column
- a column with a distinct type that is based on any of the preceding data types

- a row change timestamp column

The sum of length attributes of the columns must not be greater than $255 - n$, where n is the number of columns that can contain null values.

A timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) can only be specified as the last column in a partitioning key.

NULLS LAST

Specifies that null values are treated as positive infinity for purposes of comparison.

ASC

Puts the entries in ascending order by the column. ASC is the default.

DESC

Puts the entries in descending order by the column.

partition-element

Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

PARTITION integer

Specifies a number of a physical partition in the table space. A PARTITION clause must be specified for every partition of the table space. In the context, highest means highest in the sorting sequence of the columns. In a column that is defined as ascending (ASC), highest and lowest have the usual meanings. In a column that is defined as descending (DESC), the lowest actual value is the highest in the sorting sequence.

ENDING AT (constant, MAXVALUE, or MINVALUE...)

Specifies the limit key for a partition boundary. Specify at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key for ascending and the lowest for descending.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the partition that is associated with the partition element. If HASH SPACE is omitted from the partition element, the HASH SPACE value that is specified in the ORGANIZE BY CLAUSE is used.

The HASH SPACE keyword in the *partition-element* must only be specified if the table is defined to use hash organization.

K Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

M Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

G Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

ADD PARTITION:

ADD PARTITION

Specifies that a partition is added to the table and each partitioned index on the table. The new partition is the next physical partition not being used until the maximum for the table space has been reached. ADD PARTITION must not be specified for nonpartitioned tables. Adding a partition is not allowed if the table is a materialized query table or a materialized query table is defined on the table. However, adding a partition is allowed if an accelerated query table is defined on the table. A partition cannot be added if the table space definition is incomplete because a partitioning key or partitioning index is missing. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

If the table is in a partition-by-growth table space, a new partition can be added until the number of partitions reaches the MAXPARTITIONS limit. The

total number of table space partitions cannot exceed the value that is specified for MAXPARTITIONS for the table space.

The maximum number of partitions allowed depends on how the table space was originally created. If DSSIZE was specified when the table space was created, it is non-zero in the catalog. The maximum number of partitions allowed is shown in the following table.

Table 156. Maximum number of partitions allowed

| DSSIZE | Page size 4 | Page size 8 KB | Page size 16 | Page size 32 KB |
|---------|-------------|----------------|--------------|-----------------|
| | KB | | KB | |
| 1GB-4GB | 4096 | 4096 | 4096 | 4096 |
| 8GB | 2048 | 4096 | 4096 | 4096 |
| 16GB | 1024 | 2048 | 4096 | 4096 |
| 32GB | 512 | 1024 | 2048 | 4096 |
| 64GB | 256 | 512 | 1024 | 2048 |
| 128GB | 128 | 256 | 512 | 1024 |
| 256GB | 64 | 128 | 256 | 512 |

If LARGE was specified when the table space was created, the maximum number of partitions is shown in the fourth row of Table 157. For more than 254 partitions when LARGE or DSSIZE is not specified, the maximum number of partitions is determined by the page size of the table space.

Table 157. Maximum number of partitions when DSSIZE = 0

| Type of table space | Number of existing partitions | Maximum partitions |
|---------------------|-------------------------------|--------------------|
| non-large | 1 to 16 | 16 |
| non-large | 17 to 32 | 32 |
| non-large | 33 to 64 | 64 |
| large | N/A | 4096 |

The attributes of the new partition are inherited or calculated. Most of the attributes are inherited from the last logical partition, but some are inherited from the table space. If it is necessary to change specific attributes for the new partition, you must issue separate ALTER TABLESPACE and ALTER INDEX statements after adding the partition.

HASH SPACE cannot be specified with ADD PARTITION. For partition-by-growth table spaces, the hash space value is not applicable at the partition level.

ENDING AT (constant, MAXVALUE, or MINVALUE, ...)

Specifies the high key limit for the new partition.

The high key limit value of the new partition must be beyond the limit key value of the last logical partition. That is, it must be higher for ascending partitioning and lower for descending partitioning. Specify at least one value after ENDING AT in the PARTITION clause. You can specify as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index. ENDING AT cannot be specified for a table in a partition-by growth table space, but must be specified if the table is in a range-partitioned table space.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. If the limit was not previously enforced, any existing key values that are greater than the value that is specified for the added partition are placed into the discard data set when REORG is run.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions * (106 + limit key size in bytes) < 65394
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

ALTER PARTITION:

ALTER PARTITION

Specifies that the partitioning limit key for the identified partition is to be changed.

This clause applies only to tables in a partitioned table space. ALTER PARTITION must not be specified for a table in a partition-by-growth table space or for tables that have XML columns.

ALTER PARTITION must also not be specified if the table is a materialized query table or if a materialized query table is defined on the specified table. However, adding a partition is allowed if an accelerated query table is defined on the table.

integer

If *integer* is specified, it must be in the range 1 to *n*, where *n* is the number of partitions in the table. *integer* is the physical partition number. Changing a partition boundary is not allowed if the table is a materialized query table or if a materialized query table is defined from this table. When this option is specified for any partition except for the last, both the identified partition and the partition following are placed in REORG-pending (REORP) status.

ENDING AT (*constant*, MAXVALUE, or MINVALUE...)

Specifies the highest value of the partitioning key for the identified partition.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT in each ALTER PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

The value that is specified must not be equal to or beyond the range of the partition boundaries of the adjacent partitions.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the partition that is associated with the partition element. If HASH SPACE is omitted from the partition element, the HASH SPACE value that is specified in the ORGANIZE BY CLAUSE is used.

The HASH SPACE keyword in the *partition-element* must only be specified if the table is defined to use hash organization.

K Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

M Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

G Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

ROTATE PARTITION:

ROTATE PARTITION FIRST or *integer*TO LAST

Specifies that the first logical partition or the physical partition that corresponds to *integer* is to be rotated to become the last partition. Processing resets the specified partition to empty, and the limit key that is associated with the partition is set to the constant that is specified with the boundary specification clause. For ascending limit keys, the new limit key must be higher than the limit key for the preexisting last logical partition prior to this statement being processed. For descending limit keys, the new limit must be lower than the limit for the preexisting last logical partition prior to this statement being processed.

The table definition must be complete and must contain more than one partition. This clause must be followed by the ENDING AT clause, which specifies the new high key limit for this partition, which is now logically last.

Rotating a partition occurs immediately. If there is a referential constraint with DELETE RESTRICT on the table, the ROTATE might fail. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

After an ALTER TABLE statement with the ROTATE PARTITION clause is run, the RUNSTATS utility or the REORG utility with the STATISTICS option should be run on the table space to ensure effective access paths are available for selection.

If the table has a security label column, the user must have a valid security label to rotate partitions. In addition, if write-down is in effect, the user must have the write-down privilege.

ROTATE PARTITION must not be specified in the following situations:

- The table is a materialized query table or a materialized query table is defined on the table.
- The table is in a partition-by-growth table space.
- The table has XML columns.
- The table is a system-period temporal table or a history table.

Adding a partition is allowed if an accelerated query table is defined on the table.

integer

Specifies a positive integer that represents a physical partition number as identified by the PARTITION column of the SYSIBM.SYSTABLEPART catalog table. The partition must be a data partition that exists in the table. The partition cannot be the last partition of the table.

ENDING AT (*constant*, MAXVALUE, or MINVALUE...)

The ENDING AT clause specifies the new high key limit for the existing partition holding the oldest data.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key

of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

RESET

Specifies that the existing data in the first logical partition is deleted. In addition the key entries from the associated physical and logical index partitions are deleted. In a partitioned table with limit values that are in ascending sequence, ALTER TABLE ROTATE PARTITION FIRST TO LAST logically operates as if the partition with the lowest high key limit were dropped and then a new partition was added with the specified high key limit. The new key limit for the partition must be higher than any other partition in the table. For descending limit keys, the rotation operates as the partition with the highest limit values becomes the partition with the lowest limit values.

If the partition contains any of the following attributes, each data row in the partition must be deleted individually:

- Referential integrity parent relationships
- DATA CAPTURE logging enabled
- Delete row triggers

If the table resides in a range-partitioned universal table space and does not have any of the previous attribute, the data rows can be removed using mass delete processing (individual data rows are neither touched nor logged).

ADD organization:

ADD ORGANIZE BY HASH

Specifies that a hash is to be used for the data organization of the table.

ADD ORGANIZE BY HASH must not be specified if the table is already defined with the APPEND YES clause, or if the table space is defined with the MEMBER CLUSTER clause

ALTER TABLE ADD ORGANIZE BY HASH is allowed only if the table is in either a partition-by-growth table space or a range-partitioned universal table space.

ALTER TABLE ADD ORGANIZE BY HASH is not allowed for table spaces with relative numbering.

ADD ORGANIZE BY HASH must not be specified on tables that are using basic row format.

ADD ORGANIZE BY HASH must not be specified if a user specified clustering index exists.

ADD ORGANIZE BY HASH must not be specified for global temporary tables.

After ALTER TABLE with ADD ORGANIZE BY HASH runs:

- Any packages that are dependent on the table are invalidated.
- All columns that are part of the hash key are no longer updatable. SQL statements that update a column of the hash key return an error.

- The entire table space that contains the table must be reorganized.

UNIQUE

Specifies that DB2 enforces uniqueness of the hash key columns, preventing the table from containing two or more rows with the same value of the hash key.

(column-name,...)

The list of column names defines the hash key that is used to determine where a row will be placed.

Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be specified more than one time and the specified columns must be defined as NOT NULL. The number of specified columns must not exceed 64, and the sum of their length attributes must not exceed 255. A specified column cannot be any of the following types of columns:

- a LOB column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on one of the preceding data types

If the table is defined as partition by range, the list of column names must specify all of the column names that are specified in the *partition-expression* for the table, and must specify the column names in the same order as *partition-expression*. If the ORGANIZE BY clause contains more columns than the *partition-expression* for the table, *partition-expression* determines the partition number.

HASH SPACE *integer*|M|G

Specifies the amount of fixed hash space to preallocate for the table. If the table is range-partitioned, this is the space for each partition.

The default is 64M for a table in a partition-by-growth universal table space or 64M for each partition of a partition by range universal table space.

- | | |
|----------|--|
| K | Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456. |
| M | Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144. |
| G | Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table. |

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

ALTER ORGANIZATION:

ALTER ORGANIZATION SET HASH SPACE *integer*

Changes the fixed hash space that is used for the data organization for the table. The table must be defined to use hash organization.

If the table is defined as range-partitioned, the value specified by *integer* is per partition and applies to each partition of the table. For tables that are not range-partitioned, *integer* applies to the whole table.

The new hash space value will be applied when the table space is reorganized using the REORG utility.

HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the table. If the table is range-partitioned, this is the space for each partition.

K Indicates that the integer value is to be multiplied by 1,024 to specify the hash space size in bytes. The integer must be between 256 and 67,108,864.

M Indicates that the integer value is to be multiplied by 1,048,576 to specify the hash space size in bytes. The integer must be between 1 and 65,536.

G Indicates that the integer value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The integer must be between 1 and 64 for a range-partitioned table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

DROP ORGANIZATION:

DROP ORGANIZATION

Specifies that the data organization definition for the table is dropped. The entire table becomes inaccessible and is placed in REORG-pending status. REORG must be run to make the table accessible. If the table is in a partition by range universal table space, the entire table space must be reorganized at one time.

If any type of clustering is required, you must create the clustering index or add the MEMBER CLUSTER clause to the table.

After the next time the REORG utility is run, the hash space value will be cleared and the implicitly created hash overflow index will be dropped.

DROP ORGANIZATION must only be specified if the table is defined to use hash organization.

To change the columns that are specified for the hash key for a table that uses hash organization, the definition of the hash key must be dropped by using ALTER DROP ORGANIZATION, then the new columns for the hash key can be specified with ALTER ADD *organization-clause*.

ADD VERSIONING:

ADD VERSIONING

Specifies that the table is a system-period temporal table.

The table must not already be defined as a system-period temporal table or a history table.

A SYSTEM_TIME period and a *transaction-start-ID* column must be defined for the table. The data type, length, precision, and scale for a *transaction-start-ID* column must be defined the same as the *row-begin* column and *row-end* column

of the `SYSTEM_TIME` period in the table. The table must be the only table in the table space. The table must not be a materialized query table, an incomplete table, an auxiliary table, a table that is involved in a clone relationship, a table that was implicitly created for an XML column, or a table that contains a security label column. `ADD VERSIONING` must not be specified with other clauses on the `ALTER TABLE` statement.

The privilege set must include the privileges to issue an `ALTER TABLE` statement for the associated history table.

Historical versions of the rows in the table are retained by DB2. A system-period temporal table contains extra information that indicates when a row is inserted into the table, and when it is updated or deleted. An associated history table is used to store the historical rows of the table. When data in the system-period temporal table is updated, the previous version of the row is kept in the associated history table. When data in a system-period temporal table is deleted, the last version of the row is inserted into the history table.

References to the table can include a period clause to indicate which versions of the data are returned.

USE HISTORY TABLE *history-table-name*

Specifies a history table in which to keep the historical rows of the system-period temporal table.

If the history table contains data, ensure that the data accurately represents historical rows. If the data does not accurately represent historical rows, the results of temporal queries might be unexpected.

history-table-name must identify a table that exists at the current server and must not identify one of the following tables:

- A catalog table.
- A system-period temporal table. The table was defined as a system-period temporal table by a previous statement, or the current statement defines the table as a system-period temporal table.
- An existing history table.
- A declared global temporary table.
- A created global temporary table.
- A materialized query table.
- A view.
- An auxiliary table.
- A table that was implicitly created for an XML column.
- A table that is involved in a clone relationship.

The history table must be the only table in the table space.

Restrictions:

- The history table must not contain any of the following columns:
 - Identity column
 - Row change timestamp column
 - Row-begin column
 - Row-end column
 - Transaction-start-ID column
 - Column mask
 - Security label column.

- The history table must not include a period.
- The history table must not have an incomplete table definition.
- A row permission must not be defined for the history table.

The encoding scheme and CCSID for the system-period temporal table and identified history table must be the same.

The system-period temporal table and the identified history table must have the same number and order of columns. The following attributes of the corresponding columns of the two tables must be the same:

- name
- data type
- length (excluding inline LOB length), precision, and scale
- subtype and CCSID
- null attribute
- hidden attribute
- field procedure

If a column of the system-period temporal table is defined as ROWID GENERATED ALWAYS, the corresponding history column should be defined as ROWID GENERATED ALWAYS.

If a column of the system-period temporal table is defined as GENERATED ALWAYS FOR EACH ROW ON UPDATE OF ROW CHANGE TIMESTAMP or GENERATED AS IDENTITY, the corresponding column in the history table cannot be defined with a GENERATED attribute.

Related information:

Temporal tables (DB2 Administration Guide)

DROP VERSIONING:

DROP VERSIONING

Specifies that the table is no longer a system-period temporal table. *table-name* must identify a system-period temporal table. Historical data will no longer be recorded and maintained for the table. The definition of the columns and data of the table *table-name* are not changed, but the table is no longer treated as a system-period temporal table. The SYSTEM_TIME period is retained. The relationship between the system-period temporal table and history table is removed. The history table is not dropped, only the relationship between the two tables is removed. Subsequent queries that reference the table must not specify a SYSTEM_TIME period specification for the table.

Packages and statements in the dynamic statement cache that use the SYSTEM_TIME period are invalidated.

Versioning cannot be dropped if there are any views, materialized query table definitions, or SQL table functions that depend on the SYSTEM_TIME period.

DROP VERSIONING must not be specified with any other clauses on the ALTER TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated history table.

ADD MATERIALIZED QUERY:

ADD MATERIALIZED QUERY *materialized-query-definition*

Changes a base table to a materialized query table. Supplies a definition for a regular table to make it a materialized query table. The table specified by *table-name* and the result columns of the fullselect must not have the following characteristics:

- Be already defined as a materialized query table
- Have any primary keys, unique constraints (unique indexes), referential constraints (foreign keys), check constraints, or triggers defined
- Be referenced in the definition of another materialized query table
- Be directly or indirectly referenced in the *fullselect*
- Be in an incomplete state
- Be a system-period temporal table or a history table
- Be a base table that has been activated for the row access controls or column access controls
- Be a base table for which a row permission or a column mask has been defined

If *table-name* does not meet these criteria, an error occurs.

The fullselect must not contain a period specification.

The object that is specified in the FROM clause of the fullselect cannot be a view with columns of length 0.

fullselect

Defines the query on which the table is based. The columns of the existing table must meet the following characteristics:

- Have the same number of columns
- Have exactly the same column definitions
- Have the same column names in the same ordinal positions

The *fullselect* must not directly or indirectly reference a base table that has been activated for the row access controls or column access controls or reference a base table for which a row permission or a column mask has been defined.

If fullselect is specified, the owner of the table being altered must have the SELECT privilege on the tables or views referenced in the fullselect. Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the table of the fullselect reside

Additional privileges might be necessary for accessing other objects that are referenced in the fullselect.

If the owner of the table does not have the SELECT privilege, the following authorization IDs must have SYSADM authority or DBADM authority for the database in which the tables of the fullselect reside:

- For embedded statements, the authorization ID of the owner of the plan or package
- For dynamically prepared statements, the SQL authorization ID of the process

For details about specifying *fullselect* for a materialized query table, see the definition of *fullselect* in the “CREATE TABLE” on page 1706 statement.

Altering a table to change it from a base table to a materialized query table with REFRESH DEFERRED causes any packages that are dependent on the table to be invalidated.

refreshable-table-options

Specifies the materialized query table options for altering a regular table to a materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

DATA INITIALLY DEFERRED

Specifies that the data in the table is not validated as part of the ALTER TABLE statement. A REFRESH TABLE statement can be used to make sure the data in the materialized query table is the same as the result of the query in which the table is based.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or as updated by the user for a user-maintained materialized query table.

MAINTAINED BY SYSTEM or MAINTAINED BY USER

Specifies how the data in the materialized query table is maintained.

MAINTAINED BY SYSTEM

Specifies that the data in the materialized query table *table-name* is to be maintained by the system. Only the REFRESH TABLE statement is allowed on the table.

MAINTAINED BY USER

Specifies that the data in materialized query table *table-name* is to be maintained by the user, who can use LOAD utility or SQL data change statements and REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for optimization.

ENABLE QUERY OPTIMIZATION

Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the restrictions for query optimization, an error occurs. For detailed rules to satisfy query optimization, see *materialized-query-definition* in the “CREATE TABLE” on page 1706 statement.

DISABLE QUERY OPTIMIZATION

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

ALTER MATERIALIZED QUERY:

ALTER MATERIALIZED QUERY *materialized-query-table-alteration*

Changes attributes of a materialized query table. The *table-name* must identify a materialized query table.

SET *refreshable-table-alteration*

Changes how the table is maintained or whether the table can be used in query optimization.

MAINTAINED BY SYSTEM

Specifies that the data in a materialized query table *table-name* is to be maintained by the system.

MAINTAINED BY USER

Specifies that the data in the materialized query table *table-name* is to be maintained by the user.

ENABLE QUERY OPTIMIZATION

Specifies that materialized query table *table-name* can be used in query optimization. If the fullselect specified for the materialized query table does not satisfy the restrictions for automatic query optimization, an error occurs. For detailed rules to satisfy query optimization, see "CREATE TABLE" on page 1706.

DISABLE QUERY OPTIMIZATION

Specifies that materialized query table *table-name* cannot be used for query optimization. The table can still be queried directly.

DROP MATERIALIZED QUERY:

DROP MATERIALIZED QUERY

Changes a materialized query table so that it is no longer considered a materialized query table. The table specified by *table-name* must be defined as a materialized query table. The definition of columns and data of the name are not changed, but the table can no longer be used for query optimization and is no longer valid for use with the REFRESH TABLE statement.

Altering a table to change from a materialized query table to a base table with the DROP MATERIALIZED QUERY clause causes any packages dependent on the table to be invalidated.

DATA CAPTURE:

DATA CAPTURE

Specifies whether the logging of the following actions on the table is augmented by additional information:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause)
- Changing columns (using the ALTER COLUMN clause)

For guidance on intended uses of the expanded log records, see:

- The description of data propagation to IMS in *IMS DataPropagator: An Introduction*
- The instructions for using Remote Recovery Data Facility (RRDF) in *Remote Recovery Data Facility Program Description and Operations*
- The instructions for reading log records in *DB2 Administration Guide*

NONE

Do not record additional information to the log.

CHANGES

Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available. Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

The DATA CAPTURE CHANGES clause can be specified for a table for which row access controls or column access control are active. However, the access controls do not protect data that is written to the log.

For details about the recording of additional data for logged updates to catalog tables, see "Notes" on page 1299.

VOLATILE:

VOLATILE or NOT VOLATILE

Specifies how DB2 is to choose access to the table.

VOLATILE

Specifies that DB2 is to use index access to the table whenever possible for SQL operations. However, be aware that list prefetch and certain other optimization techniques might be disabled when VOLATILE is used.

One instance in which you might want to use VOLATILE is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows.

Another instance in which you might want to use VOLATILE is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation. For this usage, the primary index must be the only index that is defined on the table, and list prefetch is disabled to ensure the sequence in which the rows are locked.

NOT VOLATILE

Specifies that DB2 is to base SQL access to the table on the current statistics.

CARDINALITY

An optional keyword that currently has no effect, but that is provided for DB2 family compatibility.

ADD CLONE:

ADD CLONE *clone-table-name*

Specifies that a clone table, identified by *clone-table-name*, is created for the table that is being altered. The name, including the implicit or explicit qualifiers, must not identify a table, view, alias, or synonym that exists at the current server. The name must not identify a table that exists in the SYSPENDINGOBJECTS catalog table. The clone table is created in the same table space as the base table and has the same structure as the base table. This includes, but is not limited to, column names, data types, null attributes, check constraints, indexes. When ADD CLONE is used to create a clone of the specified base table, the base table must conform to the following rules:

- Reside in a DB2-managed universal table space

- If the table space or any of its dependent objects (LOBs, XMLs, or indexes) is created with the `DEFINE NO` clause, all data sets must already be created
- Be the only table in the table space
- Not be defined with a clone table
- Not be defined to use hash organization.
- Not be involved in any referential constraint
- Not be defined with any after triggers
- Not be a materialized query table
- Not have any pending changes
- Not have any active versioning
- Not have an incomplete definition
- Not be a created global temporary table or a declared global temporary table
- Not be a system-period temporal table or a history table
- Not be altered to a clone table, if the base table uses relative numbering

The base table and the clone table are considered unrelated with regard to access controls. Row access control or column access control can be activated independently for the base table, the clone table, or both.

DROP CLONE:

DROP CLONE

Specifies that the clone table that is associated with the specified base table is dropped. *table-name* must identify a base table that exists at the current server and the table must have a clone table defined.

When a clone table is dropped, any row permissions or column masks that are defined for the clone table are also dropped. If the clone table is referenced in the definition of a row permission or a column mask, the `ALTER` statement returns an error

RESTRICT ON DROP:

ADD RESTRICT ON DROP

Restricts dropping the table and the database and table space that contain the table.

DROP RESTRICT ON DROP

Removes the restriction on dropping the table and the database and table space that contain the table.

ROW ACCESS CONTROL:

ACTIVATE ROW ACCESS CONTROL

Specifies that row access control should be activated for the table. If the table is an alias or a synonym, row access control is activated for the base table.

The table must not be one of the following tables:

- A created temporary table
- A table that is directly or indirectly referenced in the definition of a materialized query table
- A table that has a security label column
- A system-period temporal table
- A history table

If a trigger exists for the table, the trigger must be defined with the SECURED clause.

The table must not be referenced in the definition of a view if the following conditions are true:

- The view is defined with the WITH CHECK OPTION clause
- An INSTEAD OF trigger exists for the view and the trigger is not defined with the SECURED clause.

A default row permission is implicitly created for the table and allows no access to any of the rows of the table, unless there is another row permission that is enabled and that provides access for the authorization IDs or roles that are specified in the definition of the row permission. A query that references the table before such a row permission exists and is enabled will return a warning that there is no data in the table.

ACTIVATE ROW ACCESS CONTROL must not be specified if a period is defined for the table, because a default row permission cannot be defined for a table with a period specification.

When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, all row permissions that are enabled for the table, including the default row permission, are applied to control the set of rows that are accessible for the table. If any row permission that is enable is invalid because a previous attempt to regenerate the row permission was unsuccessful, row access control cannot be activated.

ACTIVATE ROW ACCESS CONTROL is ignored if row access control is already activated for the table.

DEACTIVATE ROW ACCESS CONTROL

Specifies that row access control for the table is deactivated. When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, any existing row permissions for the table that are enable are not applied to control the set of rows that are accessible for the table.

DEACTIVATE ROW ACCESS CONTROL is ignored if row access control is already defined as not activated for the table.

COLUMN ACCESS CONTROL:

ACTIVATE COLUMN ACCESS CONTROL

Specifies that column access control should be activated for the table. If the table is an alias or a synonym, column access control is activated for the base table.

The table must not be one of the following tables:

- A created temporary table
- A table that is directly or indirectly referenced in the definition of a materialized query table
- A system-period temporal table
- A history table

If a trigger exists for the table, the trigger must be defined with the SECURED clause.

The table must not be referenced in the definition of a view if the following conditions are true:

- The view is defined with the WITH CHECK OPTION clause

- An INSTEAD OF trigger exists for the view and the trigger is not defined with the SECURED clause.

When column access control is activated, access to the table is not restricted. However, when the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, all column masks that are enabled for the table are applied to mask the values that are returned for the columns that are referenced in the final result table or to determine the new values that are used in the SQL data change statements. If any enabled column mask is invalid because a previous attempt to regenerate it was unsuccessful, column access control cannot be activated.

ACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already activated for the table.

DEACTIVATE COLUMN ACCESS CONTROL

Specifies that column access control for the table is deactivated. When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, any existing column masks that are enabled for the table are not applied to control the values that are returned for the columns that are referenced in the final result table or to determine if the new values can be used in the SQL data change statements.

DEACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already defined as not activated for the table.

APPEND:

APPEND NO or APPEND YES

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a range-partitioned table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition-by-growth table space, the APPEND attributes of LOB table will be inherited by each partition.

NO Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key columns.

YES

Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.

AUDIT:

AUDIT

Alters the auditing attribute of the table. For information about audit trace classes, see *DB2 Administration Guide*.

NONE

Specifies that no auditing is to be done when the table is accessed.

CHANGES

Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

ALL

Specifies that auditing is to be done when the table is accessed during the

first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

The ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- **AUDIT** attribute is changed to **NONE**, **CHANGES**, or **ALL** on an audited or non-audited table.
- **AUDIT CHANGES** or **AUDIT ALL** is in effect.

VALIDPROC:

VALIDPROC

Names a validation procedure for the table or inhibits the execution of any existing validation procedure.

program-name

Designates *program-name* as the new validation exit routine for the table.

The validation procedure can inhibit a data change operation on any row of the table. Before the operation takes place, the row is passed to the procedure. The values that are represented by any LOB or XML columns in the table are not passed to the validation procedure. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns.

A table can have only one validation procedure at a time. When you name a new procedure, any existing procedure is no longer used. The new procedure is not used to validate existing table rows. It is used only to validate rows that are loaded, inserted, updated, or deleted after execution of the ALTER TABLE statement.

Related information:

Validation routines (DB2 Administration Guide)

NULL

Discontinues the use of any validation routine for the table.

Notes

Order of processing of clauses:

When there is more than one clause, they are processed in the following order:

1. VALIDPROC
2. AUDIT
3. DATA CAPTURE
4. ROTATE
5. VOLATILE clauses
6. APPEND clauses
7. DROP clauses
8. ALTER clauses

9. RENAME clause

10. ADD clauses

Within each of these stages, the order in which the user specifies the clauses is the order in which they are performed.

Altering the data type, length, precision, or scale of a column:

When you change the data type, length, precision, or scale of a column, consider the following information:

- *Altering character data.*

When columns are converted from CHAR to VARCHAR, normal assignment rules apply, which means that trailing blanks are kept instead of being stripped out. If you want varying length character strings without trailing blanks, use the STRIP function for data in the column after changing the data type to VARCHAR.

When a CHAR FOR BIT DATA column is converted to a BINARY data type, the following applies:

- The existing space characters in the table will not be changed to hexadecimal zeros (X'00')
- If the new length attribute is greater than current length attribute of the column, the values in the table are padded with hexadecimal zeros (X'00')

When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, the existing default value will be cast as a binary string. The resulting binary string will be at least twice the original size. The alter will fail if the resulting binary string length exceeds 1536 UTF-8 bytes.

- *Altering fixed-length to varying-length or increasing varying-length column.*
When you change a column from a fixed to varying length or change the length of a varying-length column, process the ALTER TABLE statements in the same unit of work or do a reorganization between the ALTER TABLE statements to avoid anomalies with the lengths and padding of individual values.
- *Altering DECIMAL(19,0) to BIGINT.*

In releases of DB2 prior to DB2 9, use of the DECIMAL(19,0) data type for applications that work with BIGINT data was encouraged. For performance reasons, columns it is best to alter the DECIMAL(19,0) columns to BIGINT. Note that altering from DECIMAL(19,0) to BIGINT is provided only for DECIMAL(19,0) columns that are used for applications that work with BIGINT (thus, the data in those columns is within the range of the BIGINT).

When altering from DECIMAL(19,0) to BIGINT you should ensure that all values in the DECIMAL(19,0) column are within the range of BIGINT before the alter. The following query or a similar query can be run to determine which rows (if any) contain values that are outside of the range of BIGINT:

```
SELECT * FROM table_name
       WHERE dec19_0_column > 9223372036854775807
       OR dec19_0_column < -9223372036854775808;
```

- *Altering a column in a partitioning key.*

When a partitioning key column with a numeric data type is altered to a larger numeric data type, and the limit key value for the original numeric data type of the column is X'FF', the limit key value for the new numeric data type of the column is left-padded with X'FF'. For example,

if a column is converted from SMALLINT to INTEGER, and a limit key value for the SMALLINT column is 32767 (which is 2 bytes of X'FF'), the limit key for the INTEGER column is 2147483647 (which is 4 bytes of X'FF').

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is neither all X'FF' nor all X'00', the limit key value for the new character data type of the column is right-padded with blank(s) of the encoding scheme of the table. For example, if a column is converted from CHAR(1) to VARCHAR(2), and a limit key value for the CHAR(1) column is 'A' (which is X'C1'), the limit key for the VARCHAR(2) column is 'A ' (which is X'C140' when the encoding scheme of the table is EBCDIC, or is X'C120' when the encoding scheme of the table is UNICODE or ASCII).

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is all X'FF', the limit key value for the new character data type of the column is right-padded with X'FF' and the table space that contains the table being altered is left in REORG-pending (REORP) status.

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is all X'00', the limit key value for the new character data type of the column is right-padded with X'00' and the table space that contains the table being altered is left in REORG-pending (REORP) status.

- *Statistics.* New COLUMN statistics should be collected for all altered columns. Even though the COLCARDF value is valid, the HIGH2KEY and LOW2KEY values are invalid, and any SYSCOLSTATS catalog entries for the column are removed. Any frequencies or histogram statistics which include this column should also be collected again.

Considerations for altering an XML column

If *altered-data-type* is XML, the old data type of the altered column must also be XML:

- If the old data type has no XML type modifier and the new data type does, you should ensure that all values in the XML column are valid according to the XML schema that is specified in the type modifier. The XML table space for the column that is being changed is left in CHECK-pending status.
- If the old data type has the XML type modifier but the new data type has no type modifier, the existing values do not need to be re-validated. The state of the table space is not changed.

If the XML schemas that are specified in the old XML type modifier are a subset of the XML schemas that are specified in the new XML type modifier, the existing values do not need to be re-validated. The state of the XML table space is not changed.

- If the XML schemas that are specified in the old XML type modifier are NOT a subset of the XML schemas that are specified in the new XML type modifier, the XML table space for the column that is being changed is left in the CHECK-pending status.

Changing an XML column to use a different type modifier does not result in the invalidation of dependent packages or statements in the dynamic statement cache. Also, changing an XML column to use a different type modifier will not generate a new version of the table.

Referencing columns in ADD, ALTER, and RENAME clauses:

A column can only be referenced once in an ADD COLUMN, an ALTER COLUMN, or a RENAME COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB, ROWID, and DECFLOAT columns apply to distinct type columns that are based on LOBs, row IDs, and DECFLOATs. For example, if a table has an explicitly created ROWID column, you cannot add a column with a distinct type that is sourced on a row ID.

Adding a column to table T only changes the description of T. If the catalog description of T is used to create a table T' and a facility such as DSN1COPY is used to effectively copy T into T', queries that refer to the added column in T' will fail because the data does not match its description. To avoid this problem, run the REORG utility against the table space of T before making the copy.

Restrictions on a clone table:

Tables that are involved in a clone relationship (base tables and their associated clone tables) have the following restrictions:

- You cannot use the RUNSTATS utility on a clone table.
- Objects that are involved in a clone relationship do not use the FASTSWITCH naming convention when the REORG utility is run. This includes both the base table and the clone table objects (data and index), as well as LOB and XML objects.
- For a partitioned table, if a mixture of 'I' and 'J' data sets exists when a clone table is created, the mixture of 'I' and 'J' data sets can be changed only by first dropping the clone table.
- Catalog and directory tables cannot have clone tables.
- Indexes cannot be created on a clone table. When an index is created on a base table that is involved in a clone relationship, the index on the clone table will be created implicitly and will be put into rebuild-pending status.
- Implicitly created auxiliary table spaces (table spaces for LOB and XML columns) and auxiliary indexes for the base table are always created as DEFINE YES.
- Before triggers cannot be created on a clone table. Before triggers that are created on a base table apply to both the base table and the clone table.
- You cannot rename a base table that has a clone and you cannot rename a clone table.
- Real-time statistics tables cannot have clone tables.
- You cannot drop an auxiliary table or an auxiliary index of an object that is involved in a clone relationship.

If the table is involved in a clone relationship, no other table altering can take place. If a table change is required, the clone table objects must be

dropped so that the base table object attributes can be modified. After the table and index changes and such are completed, the clone table objects can be recreated.

Size restriction for the object descriptor of a table in the SYSIBM.SYSOBDS catalog table:

The following cases might result in an error being returned if the ALTER TABLE statement results in a versioned object descriptor that is larger than 30,000 bytes being added (or updated) in the SYSIBM.SYSOBDS catalog table:

- An ALTER TABLE statement that results in the first version of the object descriptor being generated for the table
- An ALTER TABLE statement that results in the first version of the object descriptor being generated for one or more of the indexes that are defined on the table
- An ALTER TABLE ALTER COLUMN SET DATA TYPE statement on an existing decimal column on a versioned table

You might need to drop and recreate the table if the object descriptor for the table exceeds 30,000 bytes. Alternatively, you can reduce the size of the object descriptor for the table by reducing the size of the default value for varying-length columns in the table by issuing an ALTER TABLE ALTER COLUMN SET DEFAULT statement. You can also drop unnecessary column defaults to reduce the size of the object descriptor for the table.

Altering the attributes of an existing identity column:

Existing values for the identity column are unaffected by the ALTER TABLE statement. The changed identity column attributes affect values generated after the ALTER statement has executed. DB2 does not validate any of the existing identity column values against the new identity column attributes. For example, duplicate values might be generated even if NO CYCLE is in effect, such as when an ascending identity column altered to become a descending identity column.

Any existing values in the cache that have not yet been used might be lost. Loss of cached values can also occur if the ALTER statement returns an error or is rolled back.

Restrictions when objects have pending definition changes:

ALTER TABLE is not allowed if the table space that contains the table, or any objects within that table space, have pending definition changes.

Adding a LOB column:

If the table space that contains the table is implicitly created and you add a LOB column to the table, the following objects are implicitly created:

- A LOB table space
- An auxiliary table
- An auxiliary index

If the base table is involved in a clone relationship, implicitly created LOB table spaces and implicitly created indexes are always created with the DEFINE YES attribute.

Adding a ROWID column:

When you add a ROWID column to an existing table, DB2 ensures that the same, unique row ID value is returned for a row whenever it is accessed. If the table already has an implicitly hidden ROWID column, DB2 also ensures that the values in the two ROWID columns are identical.

If the table space that contains the table is implicitly created and you add a ROWID column that is defined as GENERATED BY DEFAULT to the table, an enforcing index for the ROWID column is implicitly created. If the table already has an implicitly hidden ROWID column and the ROWID column that you add is defined as GENERATED BY DEFAULT, DB2 changes the implicitly hidden ROWID column to have the GENERATED BY DEFAULT attribute and does not implicitly create an enforcing index for the ROWID column.

When you add a ROWID column that is defined as GENERATED BY DEFAULT and the ROWID index is implicitly created, the privilege set requires the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created ROWID index is owned by the owner of the table.

Reorganizing a table space has no effect on the values in a ROWID column.

Adding an identity column:

When you add an identity column to a table that is not empty, DB2 places the table space that contains the table in the REORG pending state. When the REORG utility is subsequently run, DB2 generates the values for the identity column in all existing rows and then removes the REORG pending status. These values are guaranteed to be unique, and their order is system-determined.

Adding a row change timestamp column:

When you add a row change timestamp column to an existing table, the initial value for existing rows is not stored at the time of the ALTER statement. DB2 places the table space into an advisory-REORG pending state. When the REORG utility is subsequently run, DB2 generates the values for the row change timestamp column in all existing rows and then removes the REORG pending status. These values will not change unless the row is updated.

XML version support when adding an XML column:

When an XML column is added to a table that is in a universal table space, the XML column and the associated XML table will support XML versions if it is the first XML column in the table or if all the other XML columns in the table support XML versions. Similarly, when a clone table is associated with the base table, any XML columns and associated XML tables will support XML versions if the existing XML columns in the base table support XML versions.

Effect of adding a column on views:

Adding a column to a table has no effect on existing views.

Considerations for implicitly hidden columns:

A column that is defined as implicitly hidden can be explicitly referenced on the ALTER statement. For example, an implicitly hidden column can be altered, can be specified as part of a referential constraint or a check constraint, or a materialized query table definition.

Cascaded effects of adding or altering a column:

Adding a column to a table has no cascaded effects to views that reference the table. For example, adding a column to a table does not cause the column to be added to any dependent views, even if those views were created with a SELECT clause. But altering a column can cause other cascaded effects. The following table lists the cascaded effect of altering the data type, precision, scale, or length of a column.

Table 158. Cascaded effect of altering a column's data type, precision, scale, or length

| Operation | Effect |
|--|---|
| Alter of a column referenced by a view | If the data type, length, precision, or scale for a column is altered, all the views that are dependent on the altered table are reevaluated at alter time with the new column attributes. If errors are encountered during the view regeneration process, the ALTER TABLE statement fails. The new internal structure of each dependent view is not saved at alter time, and subsequent references to a dependent view will cause the view to be regenerated again. Use the ALTER VIEW statement to regenerate a dependent view and have the new internal structure saved. |
| Alter of a column referenced in the key of an index or a unique constraint (unique key or primary key) | The alter is allowed unless DECIMAL with a fraction is being converted to a floating value. In this case, the loss of precision can result in a loss of uniqueness. For numeric data type conversions, the index is placed in REBUILD-pending status. For character data type conversions, the index key columns are converted on first-write access. The index is not placed in REBUILD-pending status. |
| Alter of a column referenced in a package | The alter is allowed. All packages dependent on the table in which the column is being altered are invalidated. |
| Alter of a column referenced in the body of a user-defined function or procedure | Alter is allowed. If there is a package associated with the function or procedure, it is invalidated. |
| Alter of a column referenced in the parameter list of a user-defined function or procedure | Alter is allowed. The attributes of the existing function or procedure are unchanged. To access the new definition of the column, the function or procedure must be dropped and recreated. If the function is an SQL table function, the function is reevaluated at alter time with the new column attributes. If errors are encountered during the reevaluation process, the ALTER TABLE statement fails. |
| Alter of a column referenced by a trigger | Alter is allowed. All trigger packages that are dependent on the table of the column are invalidated. |

Table 158. Cascaded effect of altering a column's data type, precision, scale, or length (continued)

| Operation | Effect |
|---|---|
| Alter of a column referenced in a row permission or column mask | <p>Alter is allowed.</p> <p>Changing the data type, precision, scale, or length of a column can affect a row permission or a column mask that is defined on the table. If the data type, length, precision, or scale for the column is changed and a column mask is defined for this column, or a row permission or a column mask references this column, these row permissions and column masks are reevaluated using the new column attributes of the column. If an error is encountered during the reevaluation process, the ALTER statement returns the error.</p> <p>During the reevaluation of the column mask or row permission, user-defined functions that are referenced in the definition of the column mask or the row permission must be resolved to the same functions that were resolved during the creation of the column mask or the row permission.</p> |

If the column that is being changed is part of an index, an exception state might be set for the index. Possible settings are shown in Table 159:

Table 159. Informational settings for ALTER COLUMN when the column is in an index

| Alteration type | Exception state for index |
|--|---|
| VARCHAR to CHAR | <ul style="list-style-type: none"> For a NOT PADDED index: PSRBD and AREO*, or RBDP and AREO*¹ For a PADDED index: AREO* |
| VARGRAPHIC to GRAPHIC | <ul style="list-style-type: none"> For a NOT PADDED index: PSRBD and AREO*, or RBDP and AREO*¹ For a PADDED index: AREO* |
| CHAR to VARCHAR | AREO* |
| GRAPHIC to VARGRAPHIC | AREO* |
| VARCHAR to VARCHAR | AREO* (for a PADDED index only) |
| VARGRAPHIC to VARGRAPHIC | AREO* (for a PADDED index only) |
| CHAR to CHAR | AREO* |
| CHAR FOR BIT DATA or VARCHAR FOR BIT DATA to BINARY or VARBINARY | RBDP or PSRBD ¹ |
| GRAPHIC to GRAPHIC | AREO* |
| Any changed numeric column | RBDP or PSRBD ¹ |
| TIMESTAMP WITHOUT TIME ZONE to TIMESTAMP WITHOUT TIME ZONE | AREO* |
| TIMESTAMP WITH TIME ZONE to TIMESTAMP WITH TIME ZONE | AREO* |

Table 159. Informational settings for ALTER COLUMN when the column is in an index (continued)

| Alteration type | Exception state for index |
|---|---------------------------|
| Notes: | |
| 1. An index on a nonpartitioned table, or a partitioned index on a partitioned table is set to RBDP status. A nonpartitioned index on a partitioned table is set to PSRBD status. | |

For information about resetting informational or restrictive exception states after schema changes, see Reorganizing table spaces (DB2 Administration Guide).

Adding a partition:

When you add a partition to a table, if the boundary for the last partition was not previously enforced, it is enforced after the partition is added, and the last two logical partitions are left in REORG-pending (REORP) status. If the last partition before the new one is added was in REORG-pending status, the added partition is also placed in REORG-pending status.

Adding a partition for a table that is in a partition-by-growth table space and has LOB columns:

If a table resides in the partition-by-growth table space that has LOB columns, its associated LOB table spaces can be created either explicitly or implicitly when the base table is created, depending on value that is in effect for SQLRULES:

- When SQLRULES = STD, the LOB table space is created implicitly for the first partition or for the number of partitions in the Numparts clause, if it is specified in the CREATE TABLESPACE statement.
- When SQLRULES = DB2, the table definition will remain incomplete until the LOB table space is explicitly created for the first partition or for the number of partitions in the Numparts clause, if it is specified in the CREATE TABLESPACE statement. In this case, if the LOB table space is not created before the first SQL data change statement operates against the table, the table that resides in the partition-by-growth table space remains with its definition in incomplete state. The table cannot be updated through SQL or LOAD.

Attributes that are inherited from the previous LOB table space partition when a LOB table space is created implicitly:

The following attributes apply to implicitly created LOB table space:

- BUFFERPOOL
- DATASET
- ERASERULE
- GBPCACHE
- LOCKMAX
- LOG
- CLOSE
- DSSIZE
- LOCKSIZE

Row format for newly added partitions:

When the value of the RRF subsystem parameter is ENABLE, newly added partitions that are created using the ADD PARTITION clause (or partitions that are added because the table space is partition-by-growth) will be created in re-ordered row format. When the value of the RRF subsystem

parameter is `DISABLE`, newly added partitions will be created in basic row format, except for the following table spaces:

- For table spaces that are already using basic row format and that contain tables with edit procedures, newly created partition will always be in basic row format regardless of value of the `RRF` parameter.
- For table spaces that are already using re-ordered row format and that contain tables with edit procedures, newly created partition will always be in re-ordered row format regardless of value of the `RRF` parameter.
- Newly created partitions of an XML table space will always be in re-ordered format.

Rotating a partition from first to last:

Running `ALTER TABLE` to rotate the first logical partition to become the last logical partition can be very time consuming. During the reset operation, all rows from the partition are deleted. In addition, the keys for the deleted rows are also deleted from all nonpartitioned indexes, which requires that each nonpartitioned index must be scanned.

When you rotate partitions, if the boundary for the last partition was not previously enforced, it is enforced after `ROTATE FIRST TO LAST` is issued, and the last two logical partitions are left in REORG-pending (`REORP`) status. If the last partition before `ROTATE FIRST TO LAST` was issued was in REORG-pending status, the last two logical partitions are left in REORG-pending status.

Effect of changes on applications:

Applications might need to be changed to correspond to changes to the columns in a table. For example, if you increase the length of a column, you need to increase the length of variables into which that column is fetched. If you change the data type of a column, you also might need to change the data type of the corresponding variable to avoid performance degradation.

If you rename a column, you need to change any references to that column to avoid unexpected results.

Invalidation of packages:

All of the packages that refer to the table are invalidated when any of the following conditions are true:

- The table is a created temporary table or a materialized query table.
- The table is changed to add or drop a materialized query definition.
- The `AUDIT` attribute of the table is changed.
- A `DATE`, `TIME`, `TIMESTAMP WITHOUT TIME ZONE`, or `TIMESTAMP WITH TIME ZONE` column is added and its default value for added rows is `CURRENT DATE`, `CURRENT TIME`, `CURRENT TIMESTAMP (with corresponding timestamp precision) WITHOUT TIME ZONE`, or `CURRENT TIMESTAMP (with corresponding timestamp precision) WITH TIME ZONE` respectively.
- A security label is added.
- A column is renamed.
- The table is partitioned and a partition is added or one of the existing partitions is changed or rotated
- A column is altered.

When a referential constraint is defined with a delete rule of `CASCADE` or `SET NULL`, all packages that refer to the parent table of the constraint are

invalidated. Furthermore, all packages that refer to tables from which deletes cascade to this parent table are also invalidated.

Altering a base table or a user-maintained materialized query table to change it to a system-maintained materialized query table causes any packages that are dependent on the table to be invalidated because data change statements are not allowed on system-maintained materialized query tables. Altering a materialized query table to change it to a base table causes any packages that are dependent on the table to be invalidated because the REFRESH TABLE statement is invalid on a base table.

Invalidation of packages by RENAME COLUMN:

ALTER TABLE RENAME COLUMN will invalidate any package that is dependent on the table in which the column is renamed. Any attempt to execute the invalidated package will trigger an automatic rebind of the package.

The automatic rebind will fail if the column is referenced in the package because the referenced column no longer exists in the table. In this case, applications that reference the package need to be modified, recompiled, and rebound to return the expected result.

The automatic rebind will succeed in either of the following cases:

- The package does not reference the column. In this case, the renaming of the column does not affect the query results that are returned by the package. The application does not need to be modified as a result of renaming the column.
- The package does reference the column, but after the column is renamed, another column with the name of the original column is added to the table. In this case, any query that references the name of the original column might return a different result set. In order to restore the expected results, the application would need to be modified to specify the new column name.

Example: The following scenario shows how renaming a column can cause a package to return unexpected results:

```
CREATE TABLE MYTABLE (MYCOL1 INT);
INSERT INTO TABLE MYTABLE
VALUES (1);
SELECT MYCOL1 FROM MYTABLE -- this is the statement in
                           -- the package MYPACKAGE,
                           -- the query returns
                           -- a value of 1

ALTER TABLE MYTABLE
  RENAME COLUMN
    MYCOL1 TO MYCOL2;      -- MYPACKAGE is invalidated
                           -- and automatic rebind
                           -- of MYPACKAGE will fail
                           -- at this point

ALTER TABLE MYTABLE
  ADD COLUMN MYCOL1 VARCHAR(10); -- automatic rebind
                                 -- of MYPACKAGE
                                 -- will be successful

INSERT INTO TABLE MYTABLE (MYCOL1)
VALUES ('ABCD');
```

At this point an application executes MYPACKAGE, which results in a successful automatic rebind. However, the statement in the package will return 'ABCD' instead of the expected '1'.

Dropping constraints and check pending status:

If a table space or partition is in check pending status because it contains a table with rows that violate constraints, dropping the constraints removes the check pending status.

Altering materialized query tables:

The ALTER TABLE statement can be used to register an existing table at the current server as a materialized query table, change the attributes of an existing materialized query table, or change an existing materialized query table into a base table.

The isolation level at the time when a base table is first altered to become a materialized query table by the ALTER TABLE statement is the isolation level for the materialized query table.

Altering a table to change it to a materialized query table with query optimization enabled makes the table eligible for use in query rewrite immediately. Therefore, pay attention to the accuracy of the data in the table. If necessary, the table should be altered to a materialized query table with query optimization disabled, and then the table should be refreshed and enabled with query optimization.

When a base table is altered into a materialized query table or a user-maintained query table is altered into a system-maintained one, the REFRESH_TIME column of the row for the table in SYSIBM.SYSVIEWS contains the current timestamp. When a system-maintained materialized query table is altered into a user-maintained materialized query table, the REFRESH_TIME column of the row for the table in SYSIBM.SYSVIEWS does not change.

The LOAD utility is not allowed on a system-maintained query table, but it is allowed on a user-maintained materialized query table.

Considerations for running utilities while altering tables:

You cannot execute the ALTER TABLE statement while a utility has control of the table space that contains the table.

Restrictions on field procedures, edit procedures, and validation exit procedures:

Field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table will be invalidated.

Consider using triggers to replace the functionality on field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

Restrictions on SQL data change statements in the same commit scope as ALTER TABLE:

SQL data change statements that affect an index cannot be performed in the same commit scope as ALTER TABLE statements that affect that index.

Restrictions on DATA CAPTURE CHANGES:

If the table is in advisory REORG-pending state, you cannot alter the table to use the DATA CAPTURE CHANGES clause.

Capturing changes to the DB2 catalog:

To have logged changes to a DB2 catalog table augmented with

information for data capture, specify ALTER TABLE *xxx* DATA CAPTURE CHANGES where *xxx* is the name of a catalog table (SYSIBM.*xxx*). Data capture of catalog table changes provides the possibility of creating and managing a shadow of the catalog.

When changes to the hash organization of a table take place:

An alter of the table that uses hash organization will take effect immediately in terms of enforcing the unique hash key. However, the physical organization of the table space is converted to hash organization after REORG.

In a range-partitioned universal table space, if individual partitions are altered to specify HASH SPACE, the new hash space values take effect after the REORG utility is run on the individual partitions.

Buffer pool, DSSIZE, and MAXPARTITIONS considerations for tables using hash organization:

DB2 will calculate an optimum buffer pool size for hash organization based on the definition of the table and validate the calculated buffer pool size with the buffer pool of the explicitly created table space. If the buffer pool sizes are different, DB2 will return an error.

If the table is a range-partitioned universal table space, the DSSIZE value for the table space must be large enough to fit the HASH SPACE specification for each partition.

If the table is in a partition-by-growth table space, the total space calculated from the DSSIZE and MAXPARTITIONS values for the table space must be large enough for the implicitly or explicitly specified HASH SPACE.

Changing the hash space value:

To change the HASH SPACE value for all partitions of a range-partitioned universal table space or to change the total HASH SPACE for a partition-by-growth table space, use the ALTER ORGANIZATION SET HASH SPACE (*integer*) clause. To change HASH SPACE value for more than one, but not all partitions of a range-partitioned universal table space you must specify separate ALTER TABLE statements for each partition and specify the ALTER PARTITION (*integer*) and HASH SPACE (*integer*) clauses.

Hash space and DB2 page size:

If the specified hash space is less than or equal to 64 MB (the DB2 default), DB2 will add extra space for DB2 system pages. If the specified hash space is greater than 64 MB, DB2 will use part of the hash space for DB2 system pages. The amount of space needed for DB2 system pages depends on SEGSIZE and PAGESIZE. The larger the SEGSIZE and/or PAGESIZE becomes, the larger the requirement for DB2 system pages. DB2 can reserve up to 5 MB for system pages for the highest SEGSIZE value (64) and PAGESIZE value (32K).

Hash space and DSSIZE:

Depending on certain table space characteristics, DB2 needs to reserve space for the hash overflow area. Therefore, the amount of hash space cannot be equal to the DSSIZE value. The maximum amount of hash space that can be specified is approximately 20% less than the DSSIZE value. DB2 returns an error if the amount of hash space is too large. If the amount of hash space is too large, specify a larger value of DSSIZE, or decrease the amount of hash space.

| **Specifying APPEND for tables that use hash organization:**

| Append processing is not applicable to tables with hash organization since
| there is no key clustering in hash organization. For insert operations into
| tables with hash organization, DB2 will use the internal hash algorithm to
| determine the location of the row.

| **Restrictions for tables with hash organization:**

| Tables that use hash organization are subject to the following restrictions:

- | • If the table already uses hash organization, DB2 will returns an error.
- | • A table that is defined to use hash organization cannot be created in a
| LOB table space or XML table space.
- | • The data type of columns that are specified in a hash key cannot be
| changed.
- | • Partition level REORG is not allowed after the table is changed using the
| ALTER ADD HASH ORGANIZATION clause or the ALTER DROP
| ORGANIZATION clause.
- | • The MAXROWS clause is applicable only to the hash overflow area of
| the table space for tables with hash organization. The fixed hash area of
| each page will contain as many rows as it can hold, up to a maximum of
| 255.
- | • DB2 implicitly creates a hash overflow index when hash organization is
| added to a table. The hash overflow index is in rebuild-pending state
| until the REORG utility is run.

| **Row access control that is activated explicitly:**

| The ACTIVATE ROW ACCESS CONTROL clause is used to activate row
| access control for a table. When this happens, a default row permission is
| implicitly created and allows no access to any rows of the table, unless
| later another enabled row permission exists that provides access for the
| authorization IDs or roles that are specified in the definition of the
| permission. The default row permission is always enabled.

| When the table is referenced in a data manipulation statement, all enabled
| row permissions that have been created for the table, including the default
| row permission, are implicitly applied by DB2 to control which rows in the
| table are accessible. A row access control search condition is derived by
| application of the logical OR operator to the search condition in each
| enabled row permission. This derived search condition acts as a filter to
| the table before any user specified operations such as predicates, grouping,
| ordering, etc. are processed. This derived search condition permits the
| authorization IDs or roles that are specified in the permission definitions to
| access certain rows in the table. See the description of subselect for
| information on how the application of enabled row permissions affects the
| fetch operation. See the data change statements for information on how the
| application of enabled row permissions affects the data change operation.

| When the ACTIVATE ROW ACCESS CONTROL clause is used, all the
| packages and dynamic cached statements that reference the table are
| invalidated.

| Row access control remains enforced until the DEACTIVATE ROW
| ACCESS CONTROL clause is used to stop enforcing it.

| **Implicit object that is created when row access control is activated for a table:**

| When the ACTIVATE ROW ACCESS CONTROL clause is used to activate
| row access control for a table, DB2 implicitly creates a default row
| permission for the table. The default row permission prevents all access to

the table. The implicitly created row permission is in the same schema of the base table and has a name in the form of SYS_DEFAULT_ROW_PERMISSION_*table-name* ... up to 128 UTF-8 bytes. Notice two underscores after "PERMISSION". If this name is not unique, the last 4 bytes are reserved for a unique number '*nnnn*', where '*nnnn*' is a four alphanumeric characters starting at '0000' and is incremented by 1 value each time until a unique name is found. The owner of the default row permission is SYSIBM.

The default row permission is always enabled.

The default row permission is dropped when row access control is deactivated or when the table is dropped.

Activating column access control:

The ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for a table. The access to the table is not restricted but when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are applied to mask the column values referenced in the final result table of the queries or to determine the new values used in the data change statements.

When column masks are used to mask the column values, they determine the values in the final result table. If a column has a column mask and the column (a simple reference to a column name or embedded in an expression) appears in the outermost select list, the column mask is applied to the column to produce the values for the final result table. If the column does not appear in the outermost select list but it participates in the final result table, for example, it appears in a materialized table expression or view, the column mask is applied to the column in such a way that the masked value is included in the result table of the materialized table expression or view so that it can be used in the final result table.

The application of column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY. The rows returned in the final result table remain the same, except that the values in the resultant rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY sort-key, the order is based on the original column values and the masked values in the final result table might not reflect that order; similarly, the masked values might not reflect the uniqueness enforced by SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression can become different because the column mask is applied on the column before the expression evaluation can take place. If the expression in a query is the same as the expression used to mask the column value in the column mask definition, the result of the expression in the query might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression appears in the column mask definition. In this particular example, the user can replace the expression in the query with column SSN to avoid the same expression gets evaluated twice.

The following are the contexts where the column masks are used by DB2 to mask the column values for the result of a query. Certain restrictions might apply to some contexts. Those restrictions are described in a separate list.

- The outermost SELECT clause of a SELECT or SELECT INTO statement, or if the column does not appear in the outermost select list but it participates in the final result table, the outermost SELECT clause of the corresponding materialized table expression or view where the column appears.
- The outermost SELECT clause of a SELECT FROM INSERT, UPDATE, DELETE, or MERGE statement
- The outermost SELECT clause that are used to derive the new values for an INSERT, UPDATE, or MERGE statement, or a SET *transition-variable* assignment statement
- The same applies to a scalar-fullselect expression that does not use set operators and appears in the outermost SELECT clause of the above statements, the right side of a SET variable assignment statement, the VALUES INTO statement, or the VALUES statement.
- The same applies to the SQL statements or the equivalences such as the assignment statement that appears in a native SQL procedure or a compiled user-defined SQL scalar function.

If a CASE expression appears in the above contexts, the column masks are not applied in the search conditions of the WHEN clauses.

A column mask is created as a stand alone object without knowing all of the contexts in which it might be used. To mask a column value in the final result table, the column mask definition is merged into the statement by DB2. When the column mask definition is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of a column mask can return an error. The following describes when the error might be returned:

1. The column masks cannot be applied to the columns in the select lists that derive the final result table of set operations because one of the set operators that are used to derive the final result table is UNION ALL, UNION DISTINCT, EXCEPT ALL, EXCEPT DISTINCT, INTERSECT ALL, or INTERSECT DISTINCT.
The rows in the final result table are derived from multiple result tables (R1 and R2) combined by the set operators. DB2 does not guarantee which rows are derived from which result table (R1 or R2). Therefore, the rows in the final result table can vary each time if the column masks are applied but one result table (R1) has column masks and the other result table (R2) does not have column masks or has different column masks. DB2 returns a bind time error without checking whether the columns in the final result table rows have the same column masks.
2. The column mask cannot be applied to the column in the select lists of a scalar-fullselect expression if the result of scalar-fullselect expression is derived from any set operations. That is, the application of column masks supports the scalar-subselect expression only.
3. If the subselect contains a GROUP BY clause, the column mask cannot be applied to a column in the corresponding select list if none of the following conditions is satisfied:
 - The column must identify a *column-name* in the GROUP BY clause and the column must not be referenced in an expression in the GROUP BY clause. Furthermore, its column mask definition must satisfy the following condition:

- any columns that are referenced in the column mask definition that come from the same table of the column to which the column mask is applied must identify a column-name in the GROUP BY clause
 - the column mask must not be referenced in an expression in the GROUP BY clause
 - The column must be specified under an aggregate function and its column mask definition must satisfy the following conditions:
 - The column mask definition must not reference a scalar-fullselect
 - The column mask definition must not reference an aggregate function
4. If the subselect contains a GROUP BY clause, and a column in the corresponding select list maps directly or indirectly to a column name or an expression in a materialized table expression or view, the column in the subselect where the GROUP BY is specified must be specified under an aggregate function.
 5. If the subselect does not contain a GROUP BY clause, and a column in the corresponding select list is specified under an aggregate function, the column mask cannot be applied if the column mask definition references:
 - a scalar-fullselect
 - an aggregate function
 6. If the FROM clause in a subselect references a recursive common table expression, and if the result of the recursive common table expression is used to derive the final result table, the column mask cannot be applied to a column that is referenced in the fullselect of the recursive common table expression.
 7. If the FROM clause in a subselect contains a *data-change-table-reference*, and if an INCLUDE clause is specified as part of the SQL data change statement, the column mask cannot be applied to the columns that are used to derive the values for these additional columns in the outermost select list.
 8. If the FROM clause in a subselect references an external table user-defined function or an SQL table user-defined function, and if the result of the function is used to derive the final result table, the column mask cannot be applied to the column that is an argument of the function.
 9. If an OLAP specification is referenced in a select list that derives the final result table, the column mask cannot be applied to the column that is referenced in the partitioning expression or the sort key expression of the OLAP specification.
 10. If a user-defined function is defined with the NOT SECURED option, the argument of the function must not reference a column for which a column mask is enabled and the column access control is activated for its table. This rule applies to user-defined functions that are referenced anywhere in the statement.

To avoid the above error situations at bind time, one of the following actions must be taken:

- modify or remove the above contexts from the statement
- disable the column mask

- drop the column mask, modify the definition, and recreate the column mask
- deactivate the column access control for the table

In other situations, if the statement contains a `SELECT DISTINCT`, and a column mask is applied to a column that directly or indirectly derives the result of `SELECT DISTINCT`, the statement might return a result that is not deterministic. The following examples illustrate when such results might be returned:

1. If the column mask definition references other columns from the same table of the column to which the column mask is applied, the result of `SELECT DISTINCT` can not be deterministic.
2. If the column is referenced in the argument of built-in scalar functions (such as `COALESCE`, `IFNULL`, `NULLIF`, `MAX`, `MIN`, `LOCATE`, `TOTALORDER`), the result of `SELECT DISTINCT` might not be deterministic.
3. If the column is referenced in the argument of an aggregation function, the result of `SELECT DISTINCT` might not be deterministic. If `DISTINCT` is specified, the argument of the function must not reference a column with a column mask.
4. If the column is embedded in an expression and the expression contains a function that is not deterministic or has an external action, the result of `SELECT DISTINCT` might not be deterministic.

If the column is not nullable, most likely its column mask definition will not consider a null value for the column. After the column access control is activated for the target table, if the target table is the null-padded table in an outer join operation, the column value in the final result table might be a null.

When the columns are used to derive the new values for an `INSERT`, `UPDATE`, `MERGE`, or a `SET` transition-variable assignment statement, the original column values, not the masked values, are used. If the columns have column masks, those column masks are applied to ensure the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time. The rules that are used to apply column masks in order to derive the new values follow the same rules described above for the final result table of a query. See the data change statements for how the column masks are used to affect the insertability and updatability

A column mask can be applied only to a base table column. If a materialized table expression, materialized view, or common table expression column is involved in the final result table, the above error situations can occur inside the materialized table expression, materialized view, or common table expression definition.

Column access control does not affect the `XMLTABLE` built-in function. If the input to the `XMLTABLE` function is a column with a column mask, the column mask is not applied.

When the `ACTIVATE COLUMN ACCESS CONTROL` clause is used, all the packages and dynamic cached statements that reference the table are invalidated. However, if no enabled column mask exists for the table, the invalidation does not occur.

Column access control remains activated until the DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing it.

Row and column access control are not enforced when EXPLAIN tables are populated by DB2:

Row and column access control can be enforced for EXPLAIN tables. However, the enabled row permissions and column masks are not applied when DB2 inserts rows into those tables.

Stop enforcing row or column access control:

The DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing row access control for a table. The default row permission is dropped. Thereafter, when the table is referenced in a data manipulation statement, explicitly created row permissions are not applied. The table is accessible based on the granted privileges.

The DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing column access control for a table. Thereafter, when the table is referenced in a data manipulation statement, the column masks are not applied. The unmasked column values are used for the final result table.

The explicitly created row permissions or column masks, if any, remain but have no effect.

All the packages and dynamic cached statements that reference the table are invalidated when row or column access control is deactivated.

Secure triggers for row and column access control:

Triggers are used for database integrity, and as such a balance between row and column access control (security) and database integrity is needed. Enabled row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for any transition variables or transition tables referenced in the trigger body. To ensure there is no security concern for SQL statements in the trigger action to access sensitive data in transition variables and transition tables, the trigger must be created or altered with the SECURED option. If a trigger is not secure, row and column access control cannot be enforced for the triggering table.

Secure user-defined functions for row and column access control:

If a row permission or column mask definition references a user-defined function, the function must be altered with the SECURED option because the sensitive data might be passed as arguments to the function.

DB2 considers the SECURED option an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. It is assumed that such a control audit procedure is in place for all versions of the user-defined function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

Database operations where row and column access control is not applicable:

Row and column access control must not compromise database integrity. Columns involved in primary keys, unique keys, indexes, check constraints, and referential integrity (RI) must not be subject to row and column access control. Column masks can be defined for those columns but they are not applied during the process of key building or constraint or RI enforcement.

Read-only cursors and read-only views:

The rules that are used to determine a read-only cursor or a read-only

view remain unaffected by row and column access control because those rules are determined at bind time. The effect of application of enabled column masks is not known until run time. Therefore, the data change operation on a writable cursor or a writable view could still fail at run time.

Considerations for adding a column to a system-period temporal table:

- If the data type of the column is a distinct type:
 - The owner of the history table must implicitly or explicitly have the USAGE privilege on the distinct type.
 -
 - If the distinct type is unqualified, the implicit schema for the distinct type for the column in the history table is the same as the implicit schema that is determined for the distinct type in the system-period temporal table.
- The syntax LONG VARCHAR or LONG VARGRAPHIC must not be specified when you add a column to a system-period temporal table. Use VARCHAR or VARGRAPHIC instead.
- If the data type of the column is a LOB and the INLINE LENGTH clause is not specified, DB2 determines the length. The implicit inline length that is used for the column in the system-period temporal table is also used for the corresponding column in the history table.
- If the data type of the column is a LOB, auxiliary objects are implicitly created for it in the system-period temporal table. Auxiliary objects are also created for the corresponding column of the history table.

Effect of renaming a column on statistics profiles:

When you execute ALTER TABLE with RENAME COLUMN, statistics profiles that refer to that column are no longer valid. An error occurs when RUNSTATS is run with a profile that contains a renamed column. After you execute ALTER TABLE with RENAME COLUMN, complete these tasks:

1. Delete any statistics profiles that refer to the renamed column.
2. Create the statistics profiles again.

Related information:

- Syntax and options of the RUNSTATS control statement (DB2 Utilities)
- The statistics profile syntax (DB2 Utilities)
- Deleting statistics profiles (DB2 Performance)
- Creating statistics profiles (DB2 Performance)

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
- NOMINVALUE (single clause) as a synonym for NO MINVALUE
- NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
- NOORDER (single clause) as a synonym for NO ORDER
- PART *integer* VALUES can be specified as an alternative to PARTITION *integer* ENDING AT.
- VALUES as a synonym for ENDING AT

- DEFINITION ONLY as a synonym for WITH NO DATA
- SET MATERIALIZED QUERY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
- SET SUMMARY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
- SET MATERIALIZED QUERY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
- SET SUMMARY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Column DEPTNAME in table DSN8A10.DEPT was created as a VARCHAR(36). Increase its length to 50 bytes. Also, add the column BLDG to the table DSN8A10.DEPT. Describe the new column as a character string column that holds SBCS data.

```
ALTER TABLE DSN8A10.DEPT
  ALTER COLUMN DEPTNAME SET DATA TYPE VARCHAR(50)
  ADD BLDG CHAR(3) FOR SBCS DATA;
```

Example 2: Assign a validation procedure named DSN8EAEM to the table DSN8A10.EMP.

```
ALTER TABLE DSN8A10.EMP
  VALIDPROC DSN8EAEM;
```

Example 3: Disassociate the current validation procedure from the table DSN8A10.EMP. After the statement is executed, the table no longer has a validation procedure.

```
ALTER TABLE DSN8A10.EMP
  VALIDPROC NULL;
```

Example 4: Define ADMRDEPT as the foreign key of a self-referencing constraint on DSN8A10.DEPT.

```
ALTER TABLE DSN8A10.DEPT
  FOREIGN KEY(ADMRDEPT) REFERENCES DSN8A10.DEPT ON DELETE CASCADE;
```

Example 5: Add a check constraint to the table DSN8A10.EMP which checks that the minimum salary an employee can have is \$10,000.

```
ALTER TABLE DSN8A10.EMP
  ADD CHECK (SALARY >= 10000);
```

Example 6: Alter the PRODINFO table to define a foreign key that references a non-primary unique key in the product version table (PRODVER_1). The columns of the unique key are VERNAME, RELNO.

```
ALTER TABLE PRODINFO
  FOREIGN KEY (PRODNAME,PRODVNO)
  REFERENCES PRODVER_1 (VERNAME,RELNO) ON DELETE RESTRICT;
```

Example 7: Assume that table DEPT has a unique index defined on column DEPTNAME. Add a unique key constraint named KEY_DEPTNAME consisting of column DEPTNAME to the DEPT table:

```
ALTER TABLE DSN8A10.DEPT
  ADD CONSTRAINT KEY_DEPTNAME UNIQUE( DEPTNAME );
```

Example 8: Register the base table TRANSCOUNT as a materialized query table. The result of the fullselect must provide a set of columns that match the columns in the existing table (same number of columns, same column definitions, and same names). So that you can maintain the table with insert, update, and delete operations as well as the REFRESH TABLE statement, define the materialized query table as user-maintained.

```
ALTER TABLE TRANSCOUNT ADD MATERIALIZED QUERY
(SELECT ACCTID, LOCID, YEAR, COUNT(*) as cnt
FROM TRANS
GROUP BY ACCTID, LOCID, YEAR )
DATA INITIALLY DEFERRED
REFRESH DEFERRED
MAINTAINED BY USER;
```

Example 9: Assume that table TB1 has a column, COL1 that is defined as CHAR(4) FOR BIT DATA WITH DEFAULT 'AB'. The value that is stored in the table will be X'C1C24040'. After the following ALTER TABLE statement is run, the resulting value that is stored in the table will be BX'C1C240400000':

```
ALTER TABLE TB1
ALTER COLUMN COL1
SET DATA TYPE BINARY(6);
```

Examples for column access controls

Example 1:

Based on the data in the CUSTOMER table, the SELECT DISTINCT statement returns one row with the SALARY value 100,000. A column mask, SALARY_MASK, is created to mask the salary value. After column access control is activated for the CUSTOMER table, the column mask is applied to SALARY column. A user with the 'MGR' ID (or role) issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of the SALARY column, but the value that is returned in that row is based on the masked SALARY value, which can be either 125,000 or 110,000.

The table CUSTOMER contains:

| SALARY | COMMISSION | EMPID |
|---------|------------|--------|
| 100,000 | 25,000 | 123456 |
| 100,000 | 10,000 | 654321 |

```
CREATE MASK SALARY_MASK ON CUSTOMER
FOR COLUMN SALARY RETURN
CASE WHEN(SESSION_USER = 'MGR')
THEN SALARY + COMMISSION
ELSE SALARY
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT SALARY FROM CUSTOMER;
```

Example 2:

Based on the data in T1 and T2 tables, the SELECT DISTINCT statement using the COALESCE function returns one row with the T1.C1 value of 1. A column mask, C1_MASK, is created to mask the value of T1.C1. After column access control is activated for table T1, the column mask is applied to column C1 of table T1. A user with the 'EMP' ID (or role) issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of T1.C1 from the COALESCE function, but the value that is returned in that row is based on the masked value of T1.C1 from the COALESCE function. The returned value can be either 2 or 3.

```
INSERT INTO T1(C1) VALUES(1);
INSERT INTO T1(C1) VALUES(1);
INSERT INTO T2(C1) VALUES(2);
INSERT INTO T2(C1) VALUES(3);

CREATE MASK C1_MASK ON T1
FOR COLUMN C1 RETURN
CASE WHEN(SESSION_USER = 'EMP')
THEN NULL
ELSE C1
END
ENABLE;

COMMIT;

ALTER TABLE T1
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT COALESCE(T1.C1, T2.C1) FROM T1, T2;
```

Example 3:

Based on the data in the CUSTOMER table, the maximum income is the same in the states CA and IL, 50,000, thus, the SELECT DISTINCT statement returns one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column before the MAX aggregate function is evaluated. However, the INCOME_MASK column mask, masks the income value of 0 as 100,000 in state IL. As a result, the maximum income becomes 100,000 for state IL, but the maximum income is still 50,000 for state CA. X.B is used in a predicate in the SELECT DISTINCT statement, therefore, the original INCOME values and the original results of the MAX(INCOME) function must be preserved. So the SELECT DISTINCT statement still returns one row, but the value in that row might not be deterministic, that is, the value might be 50,000 from the 'CA' row or might be 100,000 from the 'IL' row.

The CUSTOMER table contains:

| STATE | INCOME |
|-------|--------|
| CA | 40,000 |
| CA | 50,000 |
| IL | 0 |
| IL | 10,000 |
| IL | 50,000 |

```

CREATE MASK INCOME_MASK ON CUSTOMER
FOR COLUMN INCOME RETURN
CASE WHEN(INCOME = 0)
THEN 100000
ELSE INCOME
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT B FROM
(SELECT STATE, MAX(INCOME) FROM CUSTOMER
GROUP BY STATE)
X(A, B)
WHERE B > 10000;

```

Example 4:

The expression `INCOME + RAND()` is not deterministic because the `RAND` function is not deterministic. Based on the data in the `CUSTOMER` table, the `SELECT DISTINCT` statement will, most likely, return two distinct rows. However, it could return only one row. A column mask, `INCOME_MASK`, is created to mask the income value. After column access control is activated for the `CUSTOMER` table, the column mask is applied to the `INCOME` column, which causes the masked value for both rows to be the same. Because the `RAND` function is not deterministic, the `SELECT DISTINCT` statement will, most likely, still return two distinct rows, but it could return only one row. The uncertainty caused by the `RAND` function causes the result of the `SELECT DISTINCT` statement to not be deterministic.

The `CUSTOMER` table contains:

| STATE | INCOME |
|-------|--------|
| CA | 40,000 |
| CA | 50,000 |

```

CREATE MASK INCOME_MASK ON CUSTOMER
FOR COLUMN INCOME RETURN
CASE WHEN(INCOME = 40,000)
THEN 50000
ELSE INCOME
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT A FROM
(SELECT INCOME + RAND() FROM CUSTOMER)
X(A)
WHERE A > 10000;

```

Example 5:

A column mask, `STATE_MASK`, is created for the `STATE` column of the

CUSTOMER table to return a value that shows the city name with the state if the city is SJ, SFO, or OKLD. Otherwise the city is not returned, just the state. After column access control is activated for the CUSTOMER table, a SELECT statement which groups results using the STATE column is issued. However, because the CITY column that is referenced in the STATE_MASK column mask is not a grouping column, a bind time error is returned to signify that the STATE_MASK column mask is not appropriate for this statement.

The CUSTOMER table contains:

| STATE | CITY | INCOME |
|-------|------|--------|
| CA | SJ | 40,000 |
| CA | SC | 30,000 |
| CA | SB | 60,000 |
| CA | SFO | 80,000 |
| CA | OKLD | 50,000 |
| CA | SJ | 70,000 |
| NY | NY | 50,000 |

```

CREATE MASK STATE_MASK ON CUSTOMER
FOR COLUMN STATE RETURN
CASE WHEN(CITY = 'SJ')
    THEN CITY||', '||STATE
WHEN(CITY = 'SFO')
    THEN CITY||', '||STATE
WHEN(CITY = 'OKLD')
    THEN CITY||', '||STATE
ELSE ' , '||STATE
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT STATE, AVG(INCOME) FROM CUSTOMER
GROUP BY STATE
HAVING STATE = 'CA';

```

ALTER TABLESPACE

The ALTER TABLESPACE statement changes the description of a table space at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

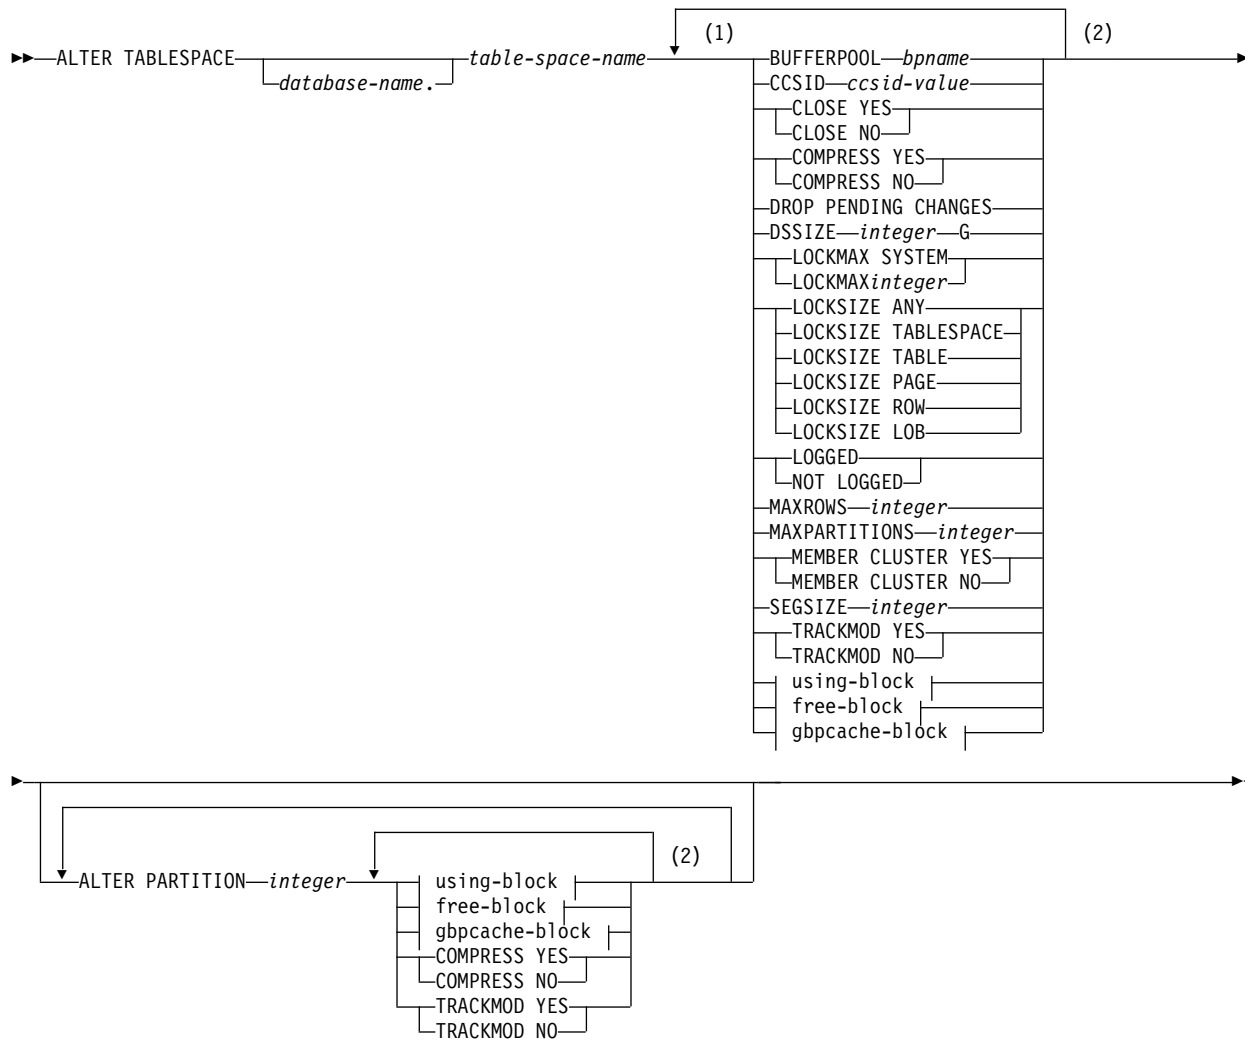

- Ownership of the table space
- DBADM authority for its database
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If BUFFERPOOL or USING STOGROUP is specified, additional privileges might be required, as explained in the description of those clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

Notes:

- 1 If you specify `DROP PENDING CHANGES`, `DSSIZE`, or `SEGSIZE`, no other clauses can be specified in the same `ALTER TABLESPACE` statement.
- 2 The same clause must not be specified more than one time in a single `ALTER TABLESPACE` statement. For example, if `TRACKMOD YES` is specified at the table space level, it must not also be specified after `ALTER PARTITION`.

using-block:

free-block:

gbpcache-block:

Description

database-name.table-space-name

Identifies the table space that is to be altered. The name must identify a table space that exists at the current server. Omission of *database-name* is an implicit specification of DSNDB04.

If you identify a partitioned table space, you can use the PARTITION clause.

A table space cannot be altered if it is associated with an accelerator-only table.

BUFFERPOOL *bpname*

Identifies the buffer pool that is to be used for the table space. *bpname* must identify an activated buffer pool.

The privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

If *bpname* specifies a buffer pool with a smaller page size than the current page size, the maximum record size of all tables in the table space must fit in the smaller page size.

If *bpname* specifies a buffer pool with a different page size, the table space can only be a universal table space (excluding XML table spaces) or a LOB table space. If the table space is a partition-by-growth universal table space, the page size must be valid depending on the values that are in effect for the MAXPARTITIONS and DSSIZE options of the table space. If the table space is a range-partitioned universal table space, the page size must be valid

depending on the values that are in effect for the current number of partitions and the DSSIZE option of the table space.

The buffer pool change is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or any associated indexes.
- The specified buffer pool has a different page size than the buffer pool that is currently being used for the table space.

Otherwise, the change is considered an immediate change.

For an immediate change where the page size of both buffer pools is the same, the table space and all data sets are immediately available. The data sets do not need to be closed and reopened for the table space to be available.

If the change is considered an immediate change, the change to the description of the table space takes effect the next time the data sets of the table space are opened. The data sets can be closed and reopened by using a STOP DATABASE command to stop the table space followed by a START DATABASE command to start the table space.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

When the pending page size change is applied, if the table space is a universal table space that uses partition-by-growth organization, the number of partitions is determined based on the amount of existing data and the new page size value. Changing the page size to be larger can cause automatic creation of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-created partitions independent of whether SQLRULES (DB2) or SQLRULES (STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

CCSID *ccsid-value*

Identifies the CCSID value to be used for the table space. *ccsid-value* must identify a CCSID value that is compatible with the current value of the CCSID for the table space. See “Notes” on page 1162 for a list that shows the CCSID to which a given CCSID can be changed and details about changing it.

Do not specify CCSID for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

The CCSID of a table space cannot be changed if any of the following conditions are true:

- The table space contains any table that has an index that contains expressions.
- The table space contains a system-period temporal table or a history table.

CLOSE

When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

YES

Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

NO Eligible for closing after all eligible CLOSE YES data sets are closed.

For a table space in a work file database, DB2 uses CLOSE NO regardless of the value specified

COMPRESS

Specifies whether data compression applies to the rows of the table space or partition.

Do not specify COMPRESS for a LOB table space or a table space in a work file database.

YES

Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition, or until an insert operation is performed through the INSERT statement or the MERGE statement.

NO Specifies no data compression. Inserted rows will not be compressed. Updated rows will be decompressed. The dictionary used for compression will be erased when the LOAD REPLACE, LOAD RESUME NO, or REORG utility is run. See *DB2 Performance Monitoring and Tuning Guide* for more information about the dictionary and data compression.

DROP PENDING CHANGES

Drops pending changes to the definition of the table space and any objects within the table space. Pending changes to the definition of the table space or any object within the table space must exist.

When the DROP PENDING CHANGES clause is specified, no other options are allowed in the same ALTER TABLESPACE statement.

DSSIZE integer G

A value, in gigabytes, that indicates the maximum size for each partition, or for a LOB table space, the maximum size of each data set. DSSIZE can only be specified for a universal table space or a LOB table space. When DSSIZE is specified, no other options are allowed in the same ALTER TABLESPACE statement.

The following are valid values for *integer*:

integer value

Meaning

| | |
|-------------|---------------|
| 1 | 1 gigabyte |
| 2 | 2 gigabytes |
| 4 | 4 gigabytes |
| 8 | 8 gigabytes |
| 16 | 16 gigabytes |
| 32 | 32 gigabytes |
| 64 | 64 gigabytes |
| 128G | 128 gigabytes |
| 256G | 256 gigabytes |

If *integer* is greater than 4, the data sets for the table space must be associated with a DFSMS data class that has been specified with an extended format and extended addressability.

If the table space is a partition-by-growth universal table space, the DSSIZE value must be valid depending on the values that are in effect for the MAXPARTITIONS option and the page size of the table space.

If the table space is a partition by range universal table space, the DSSIZE value must be valid depending on the values that are in effect for the current number of partitions and the page size of the table space.

The DSSIZE value must be valid depending on the maximum PIECESIZE of any associated non-partitioned secondary indexes.

The change to the DSSIZE is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or any associated indexes.
- The specified DSSIZE is different than the value that is currently being used for the table space.

Otherwise, the change takes effect immediately.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If the table space is a partition-by-growth universal table space with the pending DSSIZE change is applied, the number of partitions is determined based on the amount of existing data in the table space and the new DSSIZE value. Changing the DSSIZE value to be smaller might cause automatic growth of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions independently of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

LOCKMAX

Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented table is promoted to S or X mode. If you specify LOCKMAX a for table space in a work file database, DB2 ignores the value because these types of locks are not used.

For an application that uses Sysplex query parallelism, a lock count is maintained on each member.

integer

Specifies the number of locks allowed before escalating, in the range 0 to 2 147 483 647.

Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

SYSTEM

Indicates that the value of field LOCKS PER TABLE(SPACE) on installation panel DSNTIPJ specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

If you change LOCKSIZE and omit LOCKMAX, the following results occur:

| LOCKSIZE | Resultant LOCKMAX |
|---------------------|-------------------|
| TABLESPACE or TABLE | 0 |
| PAGE, ROW, or LOB | Unchanged |
| ANY | SYSTEM |

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

LOCKSIZE

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not specify LOCKSIZE for a table space in a work file database.

ANY

Specifies that DB2 can use any lock size.

In most cases, DB2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (an installation parameter), the page or LOB locks are released and locking is set at the next higher level. If the table space is segmented, the next higher level is the table. If the table space is not segmented, the next higher level is the table space.

TABLESPACE

Specifies table space locks.

TABLE

Specifies table locks. Use TABLE only for a segmented table space. Do not use TABLE for a universal table space.

PAGE

Specifies page locks. Do not use PAGE for a LOB table space.

ROW

Specifies row locks. Do not use ROW for a LOB table space.

LOB

Specifies LOB locks. Use LOB only for a LOB table space.

| The LOCKSIZE change affects a dynamic SQL statement if the statement is
| prepared and executed after the change. The LOCKSIZE change affects a static
| SQL statement if the statement is executed after the change.

LOGGED or NOT LOGGED

Specifies whether changes that are made to the data in the specified table space are recorded in the log.

LOGGED

Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are

created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This can affect the logging attribute of associated LOB table spaces. See “ Notes ” on page 1404 for more information.

If the base table space is in informational copy-pending status (meaning updates have been made to the table space) when you change from NOT LOGGED to LOGGED, the base table space is placed in copy-pending status. All indexes of tables in the table space are unchanged from their current state; that is, if an index is currently in informational copy-pending status, it will remain in information copy-pending status.

Specifying LOGGED for a LOB table space requires that the base table space also specifies the LOGGED parameter.

LOGGED cannot be specified for XML table spaces. The logging attribute of an XML table space is inherited from its base table space.

LOGGED cannot be specified for table spaces in DSNDB06 (the DB2 catalog) or in a work file database.

NOT LOGGED

Specifies that changes that are made to data in the specified table space are not recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This parameter can affect the logging attribute of associated LOB table spaces. See “ Notes ” on page 1404 for more information.

NOT LOGGED prevents undo and redo information from being recorded in the log for the base table space; however, control information for the specified base table space will continue to be recorded in the log. For a LOB table space, changes to system pages and to auxiliary indexes are logged.

NOT LOGGED is mutually exclusive with the DATA CAPTURE CHANGES parameter of CREATE TABLE and ALTER TABLE. NOT LOGGED will not be applied to the table space if any table in the table space specifies DATA CAPTURE CHANGES.

NOT LOGGED cannot be specified for XML table spaces.

NOT LOGGED cannot be specified for table spaces in the following databases:

- DSNDB06 (the DB2 catalog)
- a work file database

MAXROWS *integer*

Specifies the maximum number of rows that DB2 will consider placing on each data page. The integer can range from 1 through 255.

The change takes effect immediately for new rows added. However, the space class settings for some pages might be incorrect and could cause unproductive page visits. It is highly recommended to reorganize the table space after altering MAXROWS.

After ALTER TABLESPACE with MAXROWS is run, the table space is placed into an advisory REORG-pending status. Run the REORG TABLESPACE utility to remove the status.

Do not specify MAXROWS for a LOB table space, a table space that is implicitly created for an XML column, a table space in a work file database, or the DB2 catalog table spaces that are listed under “SQL statements allowed on the catalog” on page 2697.

MAXPARTITIONS *integer*

Specifies that the table space is partition-by-growth. *integer* specifies the maximum number of partitions to which the table space can grow or shrink. *integer* must be in the range of 1 to 4096, depending on the value that is in effect for DSSIZE and the page size of the table space, and must not be less than the number of physical partitions that are already allocated for the table space. See “CREATE TABLESPACE” on page 1775 for more information about how DSSIZE and the page size are related.

MAXPARTITIONS can only be specified for a simple table space that contains only one table, a segmented table space that contains only one table, or a partitioned-by-growth universal table space. The table space must have DB2-managed data sets.

Although physical data sets are not defined when the MAXPARTITIONS value is issued, there can be storage and cpu overhead. If an increase in the number of partitions is expected by using the MAXPARTITIONS clause, be aware that specifying an value larger than necessary, such as 4096 (the maximum value), as a default for all of your partition-by-growth table spaces can cause larger than expected storage requests.

The change to the value of MAXPARTITIONS is a pending change to the definition of the table space if the data sets of the table space are already created and one of the following conditions is true:

- Pending changes to the definition of the table space or associated indexes already exist.
- The table space is converted from a simple table space to a partition-by-growth universal table space.
- The table space is converted from a segmented table space to a partition-by-growth universal table space.

Otherwise, the change is an immediate change.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If MAXPARTITIONS is specified on a simple or segmented table space, the table space is converted to a partition-by-growth universal table space that can grow to a maximum number of *integer* partitions. The SEGSIZE is set to the default of 32 if the SEGSIZE prior to conversion is less than 32. Otherwise, the value of SEGSIZE is inherited from the original table space. The DSSIZE is set to the default 4 gigabytes.

If the data sets of the table space are not defined, the number of partitions is set to 1 during the conversion to a partition-by-growth universal table space from a simple or segmented table space.

If the data sets of the table space are created, the number of partitions is determined based on amount of existing data at the time the pending change to the definition of the table space is applied. Partition growth can happen. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions, regardless of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and thereby authorization from the existing LOB objects.

If the table space is defined with LOCKSIZE TABLE, the lock size will be reset to LOCKSIZE TABLESPACE during conversion to a partition-by-growth universal table space.

MEMBER CLUSTER YES or MEMBER CLUSTER NO

Specifies whether the table space uses the MEMBER CLUSTER page set structure. The MEMBER CLUSTER clause can only be specified for a partition-by-growth or range-partitioned universal table space. Changing the MEMBER CLUSTER structure for a table space results in a pending definition change for the table space. The table space is placed in advisory REORG-pending state (AREOR). Running a utility like REORG with SHRLEVEL(CHANGE) or SHRLEVEL(REFERENCE) on the entire table space resets this state.

MEMBER CLUSTER YES

Specifies that the MEMBER CLUSTER page set structure is to be used for the specified table space when the table space is already defined as a partition-by-growth or range-partitioned universal table space.

MEMBER CLUSTER YES cannot be specified for LOB, workfile, or XML table spaces, or for table spaces that are organized for hash access.

MEMBER CLUSTER NO

Specifies that the table space does not use the MEMBER CLUSTER page set structure when the table space is already defined as a partition-by-growth or range-partitioned universal table space. If the universal table space is already defined to use the MEMBER CLUSTER page set structure, specifying **MEMBER CLUSTER NO** on the ALTER TABLESPACE statement removes the MEMBER CLUSTER page set structure from the table space.

MEMBER CLUSTER NO is the default.

SEGSIZE *integer*

Specifies that the table space is a universal table space, where *integer* specifies the number of pages that are to be assigned to each segment of the table space. *integer* must be a multiple of 4 between 4 and 64 (inclusive). When SEGSIZE is specified, no other options are allowed in the same ALTER TABLESPACE statement.

SEGSIZE can only be specified for a universal table space or a partitioned table space that uses table-controlled partitioning.

The change to the value of SEGSIZE is a pending change to the definition of the table space if the data sets of the table space are already created and one of the following conditions is true:

- Pending changes to the definition of the table space or its associated indexes already exist.
- The specified SEGSIZE value for a universal table space is different than the existing value.

- The table space is converted from a partitioned table space to a range-partitioned universal table space.

Otherwise, the change is an immediate change.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If the existing FREEPAGE value (the number of pages to be left free) is greater than or equal to the new SEGSIZE value, the number of pages is adjusted to be one less than the new SEGSIZE value.

If the table space is a partitioned table space, the partitioned table space is converted to a range-partitioned universal table space with a segment size specified by *integer*. The MEMBER CLUSTER attribute is inherited from the original table space. The number of partitions is inherited from the original table space. If the original DSSIZE attribute has a value of 0, the DSSIZE is set to the original maximum partition size. Otherwise, the DSSIZE attribute is inherited from the original table space.

If the table space is a partition-by-growth universal table space when the pending SEGSIZE change is applied, the number of partitions is determined based on the amount of existing data in the table space and the new SEGSIZE value. Changing the SEGSIZE value to be smaller might cause automatic growth of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions independently of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

TRACKMOD

Specifies whether DB2 tracks modified pages in the space map pages of the table space or partition. Do not specify TRACKMOD for a LOB table space or a table space in a work file database.

For the changed TRACKMOD option to take effect, the table space or partition needs to be stopped and restarted. The table space or partition can be stopped and restarted by running the STOP DATABASE command followed by the START DATABASE command, or by running the REORG utility on the table space or partition. See -STOP DATABASE (DB2) (DB2 Commands) and -START DATABASE (DB2) (DB2 Commands) or REORG TABLESPACE (DB2 Utilities) for information.

YES

DB2 tracks changed pages in the space map pages to improve the performance of incremental image copy. For data sharing, changing TRACKMOD to YES causes additional SCA (shared communication area) storage to be used until after the next full or incremental image copy is taken or until TRACKMOD is set back to NO.

NO DB2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

FREEPAGE *integer*

Specifies how often to leave a page of free space when the table space is loaded or reorganized. One free page is left after every *integer* pages; *integer*

can range from 0 to 255. FREEPAGE 0 leaves no free pages. Do not specify FREEPAGE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

Related information:

Reserving free space for table spaces (DB2 Performance)

Reserving free spaces for indexes (DB2 Performance)

PCTFREE *smallint*

Specifies what percentage of each page to leave as free space when the table space is loaded or reorganized. The default value is PCTFREE 5, which specifies that 5% of the space on each data page is reserved as free space. The first record on each page is loaded without restriction. When additional records are loaded, at least *integer* percent of free space is left on each page. *integer* can range from 0 to 99. Do not specify PCTFREE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

Related information:

Reserving free space for table spaces (DB2 Performance)

Reserving free spaces for indexes (DB2 Performance)

USING

Specifies whether a data set for the table space or partition is managed by the user or is managed by the DB2 system. If the table space is partitioned, USING applies to the data set for the partition that is identified in the PARTITION clause. If the table space is a partition-by-growth table space, USING can only be specified at the table space level. If the table space is not partitioned, USING applies to every data set that is eligible for the table space. (A nonpartitioned table space can have more than one data set if PRIQTY+118 × SECQTY is at least 2 gigabytes.)

If the USING clause is specified, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. See Altering storage attributes to determine how and when changes take effect. Do not specify the USING clause if the table space is in a work file database.

VCAT *catalog-name*

Specifies a user-managed data set with a name that starts with *catalog-name*. The VCAT clause must not be specified if the table space is a partition-by-growth table space. You must specify the catalog name in the form of an SQL identifier. You must specify an alias²⁶ if the name of the integrated catalog facility catalog is longer than eight characters. When the

26. The alias of an integrated catalog facility catalog

new description of the table space is applied, the integrated catalog facility catalog must contain an entry for the data set that conforms to the DB2 naming conventions set forth in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

STOGROUP *stogroup-name*

Specifies a DB2-managed data set that resides on a volume of the identified storage group. *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. When the new description of the table space is applied, the description of the storage group must include at least one volume serial number, each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

If you specify USING STOGROUP and the current data set for the table space or partition is managed by DB2:

- Omission of the PRIQTY clause is an implicit specification of the current PRIQTY value.
- Omission of the SECQTY clause is an implicit specification of the current SECQTY value.
- Omission of the ERASE clause is an implicit specification of the current ERASE rule.

If you specify USING STOGROUP to convert from user-managed data sets to DB2-managed data sets:

- Omission of the PRIQTY clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the SECQTY clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the ERASE clause is an implicit specification of ERASE NO.

PRIQTY *integer*

Specifies the minimum primary space allocation for a DB2-managed data set of the table space or partition. *integer* must be a positive integer, or -1. This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is the value of *integer*. However, the following exceptions exist:

For non-LOB table spaces, the exceptions are:

- For 4KB page sizes, if *integer* is greater than 0 and less than 12, *n* is 12.
- For 8KB page sizes, if *integer* is greater than 0 and less than 24, *n* is 24.
- For 16KB page sizes, if *integer* is greater than 0 and less than 48, *n* is 48.

- For 32KB page sizes, if *integer* is greater than 0 and less than 96, *n* is 96.
- For any page size, if *integer* is greater than 67108864, *n* is 67108864.

For LOB table spaces, the exceptions are:

- For 4KB page sizes, if *integer* is greater than 0 and less than 200, *n* is 200.
- For 8KB page sizes, if *integer* is greater than 0 and less than 400, *n* is 400.
- For 16KB page sizes, if *integer* is greater than 0 and less than 800, *n* is 800.
- For 32KB page sizes, if *integer* is greater than 0 and less than 1600, *n* is 1600.
- For any page size, if *integer* is greater than 67108864, *n* is 67108864.

The maximum value allowed for PRIQTY is 64GB (67108864 kilobytes).

If you specify PRIQTY with a value of -1, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value for primary space allocation, see Rules for primary and secondary space allocation.

If PRIQTY is omitted and USING STOGROUP is specified, the value of PRIQTY is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of USING STOGROUP.)

If you specify PRIQTY, and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of *p* KB not less than *n*, where *p* is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

At least one of the volumes of the identified storage group must have enough available space for the primary quantity. Otherwise, the primary space allocation will fail.

See Altering storage attributes to determine how and when changes to PRIQTY take effect.

SECQTY *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set of the table space or partition. *integer* must be a positive integer, 0, or -1. This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If you specify SECQTY with a value of -1, DB2 uses a default value for the secondary space allocation.

If USING STOGROUP is specified and SECQTY is omitted, the value of SECQTY is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of USING STOGROUP.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or DB2 uses a default value, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of *p* KB not less than *integer*, where *p* is the page size of the table

space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs) for z/OS DFSMS Access Method Services for catalogs.

See Altering storage attributes to determine how and when changes to SECQTY take effect.

ERASE

Indicates whether the DB2-managed data sets for the table space or partition are to be erased before they are deleted during the execution of a utility or an SQL statement that drops the table space.

NO Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2.

YES

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If you specify ERASE, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. If you specify ERASE for a partitioned table space, you must also specify the ALTER PARTITION clause. See Altering storage attributes to determine how and when changes take effect.

GBPCACHE

In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or not). In addition, you cannot alter the GBPCACHE value of some DB2 catalog table spaces; for a list of these table spaces, see "SQL statements allowed on the catalog" on page 2697.

CHANGED

When there is inter-DB2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

ALL

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating DB2 when no other DB2 subsystems have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

SYSTEM

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

Use SYSTEM only for a LOB table space.

NONE

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the table space or partition must not be in recover pending status when the ALTER TABLESPACE statement is executed.

If you specify GBPCACHE in a data sharing environment, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed.

ALTER PARTITION *integer*

Specifies that the identified partition of the table space is to be changed. For a table space that has *n* partitions, you must specify an integer in the range 1 to *n*. You must not use this clause for a nonpartitioned table space, for a LOB table space, or a partition-by-growth table space. At least one of the following clauses must be specified:

- COMPRESS
- ERASE
- FREEPAGE
- GBPCACHE
- PCTFREE
- PRIQTY
- SECQTY
- TRACKMOD
- USING

The changes specified by these clauses affect only the identified partition.

Do not specify the following clauses for ALTER PARTITION for partitions of a table space that is implicitly created for an XML column.

- CCSID
- FREEPAGE
- MAXROWS
- PCTFREE

Notes

ALTER TABLESPACE and INSERT statements in the same commit scope:

You might encounter problems when an ALTER TABLESPACE statement is followed by an INSERT statement in the same commit scope. If that happens, add a COMMIT statement between the ALTER TABLESPACE and INSERT statements.

Running utilities:

You cannot execute the ALTER TABLESPACE statement while a DB2 utility has control of the table space.

Altering more than one partition:

To change FREEPAGE, PCTFREE, USING, PRIQTY, SECQTY, COMPRESS, ERASE, or GBPCACHE for more than one partition, you must use separate ALTER TABLESPACE statements.

Altering storage attributes:

The USING, PRIQTY, SECQTY, and ERASE clauses define the storage attributes of the table space or partition. If you specify USING or ERASE when altering storage attributes, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. You can use a STOP DATABASE...SPACENAM... command to stop the table space or partition.

If the catalog name changes, the changes take effect after you move the data and start the table space or partition using the START DATABASE...SPACENAM... command. The catalog name can be implicitly or explicitly changed by the ALTER TABLESPACE statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in *DB2 Administration Guide*.

Changes to the secondary space allocation (SECQTY) take effect the next time DB2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the REORG, RECOVER, or LOAD REPLACE utility on the table space or partition. The changes to the other storage attributes take effect the next time the page set is reset. For a non-LOB table space, the page set is reset when you use the REORG, RECOVER, or LOAD REPLACE utilities on the table space or partition. For a LOB table space, the page set is reset when RECOVER is run on the LOB table space or LOAD REPLACE is run on its associated base table space. If there is not enough storage to satisfy the primary space allocation, a REORG might fail. If you change the primary space allocation parameters or erase rule, you can have the changes take effect earlier if you move the data before you start the table space or partition.

Recommended GBPCACHE setting for LOB table spaces:

For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

Altering table spaces for tables that use hash organization:

Certain attributes of the table space, such as buffer pool and page size, might affect performance of tables that use hash organization. Changes related to the hash organization of a table will be validated and might generate error messages as described in "CREATE TABLE" on page 1706 and "ALTER TABLE" on page 1304.

Altering the logging attribute of a table space:

If the logging attribute (specified with the LOGGED or NOT LOGGED parameter) of a table space is altered frequently, the size of SYSIBM.SYSCOPY might need to be increased.

The logging attribute of the table space cannot be altered if the table space has been updated in the same unit of recovery.

A full image copy of the table space should be taken:

- Before altering a table space to NOT LOGGED
- After altering a table space to LOGGED

If a table space has data changes after an image copy is taken (the table space is in informational COPY-pending state), and the table space is altered from NOT LOGGED to LOGGED, the table space is marked COPY-pending and a full image copy of the table space must be taken.

An XML table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the XML table space is said to be *linked* to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated XML table spaces are altered back to LOGGED, and all of these links are dissolved.

A LOB table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the LOB table space is said to be *linked* to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated LOB table spaces are altered back to LOGGED, and all of these links are dissolved.

You can dissolve the link between these logging attributes by altering the logging attribute of the LOB table space to NOT LOGGED, even though it has already been implicitly given this logging attribute. After such an alter, the logging attribute of the LOB table space is unaffected when the logging attribute of the base table is altered back to LOGGED. A LOB table space with the NOT LOGGED logging attribute does not have this attribute changed in any way if the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When altered in this way, the logging attributes of the LOB table space and the base table space are not linked. If the base table space is altered back to LOGGED, the logging attribute of any LOB table spaces that are not linked to the logging attribute of the base table space remain unchanged.

Altering table spaces for DB2 catalog tables:

For details on altering options on catalog tables, see “SQL statements allowed on the catalog” on page 2697.

Invalidation of packages:

All of the packages that refer to that table space are invalidated when any of the following conditions are true:

- The SBCS CCSID attribute of a table space is changed.
- When increasing the MAXPARTITIONS attribute of a table space.
- The SEGSIZE attribute of a partitioned table space is changed to convert the table space to a range-partitioned universal table space.
- The DSSIZE attribute of a partitioned table space is changed

Pending changes to the definition of a table space:

Issuing the ALTER TABLESPACE statement with certain options can cause a pending change to the definition of a table space. When an ALTER TABLESPACE statement that causes pending changes to the definition is executed, semantic validation and authorization checking are performed. However, changes to the table space definition and data are not applied

and the table space is placed in advisory REORG-pending state (AREOR). The pending changes are recorded in the SYSIBM.SYSPENDINGDDL catalog table. The REORG utility that specifies SHRLEVEL CHANGE or REFERENCE should be run on the table space to apply the pending changes to the definition and data of the table space. When the pending changes are applied, dependent packages are invalidated, the corresponding entries in the SYSIBM.SYSPENDINGDDL catalog table are removed, and the advisory REORG-pending state is removed.

The following ALTER TABLESPACE options can cause pending changes to the definition of the table space under certain conditions:

- BUFFERPOOL
- DSSIZE
- MAXPARTITIONS
- SEGSIZE

The changes that are caused by all other options occur when the ALTER TABLESPACE statement is executed.

Restrictions on ALTER TABLESPACE statements that cause pending changes:

ALTER TABLESPACE statements that cause pending changes have the following restrictions:

- Options that cause pending changes cannot be specified with options that take effect immediately
- Options that cause pending changes cannot be specified for the following objects:
 - The catalog
 - System objects
 - Objects in a workfile database
- The DROP PENDING CHANGES clause cannot be specified for a catalog table space
- If the DROP PENDING CHANGES clause is specified, no other clauses can be specified on the ALTER TABLESPACE statement
- If there are pending changes to the table space, you cannot use ALTER TABLESPACE to change from a DB2-managed data set to a user-managed data set
- If there are pending changes to the table space, you cannot specify the following clauses:
 - FREEPAGE
 - ALTER PARTITION FREEPAGE
 - CCSID
- If the table space, or any table it contains is in an incomplete state, you cannot specify options that cause pending changes

Alternative syntax and synonyms:

For compatibility with previous releases of DB2, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. DB2 treats all partitioned table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, DB2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, DB2 locks every partition of the table space.

- When altering the partitions of a partitioned table space, the ALTER keyword that precedes PARTITION keyword is optional and if ALTER keyword is omitted, then you can specify PART as a synonym for PARTITION.
- You can specify LOG YES as a synonym for LOGGED and LOG NO as a synonym for NOT LOGGED.

Examples

Example 1: Alter table space DSN8S10D in database DSN8D10A. BP2 is the buffer pool associated with the table space. PAGE is the level at which locking is to take place.

```
ALTER TABLESPACE DSN8D10A.DSN8S10D
  BUFFERPOOL BP2
  LOCKSIZE PAGE;
```

Example 2: Alter table space DSN8S10E in database DSN8D10A. The table space is partitioned. Indicate that the data sets of the table space are not to be closed when there are no current users of the table space. Also, change all of the partitions so that DB2 will use a formula to determine any secondary space allocations, and change partition 1 to use a PCTFREE value of 20.

```
ALTER TABLESPACE DSN8D10A.DSN8S10E
  CLOSE NO
  SECQTY -1
  ALTER PARTITION 1 PCTFREE 20;
```

Example 3: The following statement changes the maximum number of partitions in a partition-by-growth table space:

```
ALTER TABLESPACE TS01DB.TS01TS
  MAXPARTITIONS 30;
```

ALTER TRIGGER

The ALTER TRIGGER statement changes the description of a trigger at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the trigger
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). However, if the schema name is not the same as one of the authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM authority, SYSCTRL authority, or system DBADM authority.
- The authorization ID of the process has the ALTERIN privilege on the schema.

At least one of the following privileges is required if the SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Note: If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

Syntax

```
ALTER TRIGGER trigger-name [SECURED | NOT SECURED]
```

Description

trigger-name

Identifies the trigger that is to be changed. The trigger must exist at the current server.

SECURED or NOT SECURED

Specifies that the trigger is to be changed to be secure or not secure. Changing a trigger between SECURED and NOT SECURED causes an implicit rebind of the trigger package. If an error is encountered during the implicit rebind of the trigger package, the ALTER TRIGGER statement returns the error.

SECURED

Specifies the trigger is considered secure.

SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies the trigger is considered not secure.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Notes

Altering a trigger from NOT SECURED to SECURED:

Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the owner of the trigger. After the trigger is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the ALTER TRIGGER statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, DB2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Altering a trigger from SECURED to NOT SECURED:

The ALTER TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

| **Row access control and column access control that is not enforced for transition variables and transition tables:**

| If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be changed to use the SECURED option. If a trigger is not secure, row access control and column access control cannot be enforced for the triggering table.

| **Examples**

| *Example 1:* Change the definition of trigger TRIGGER1 to secured:

| ALTER TRIGGER TRIGGER1
| SECURED;

ALTER TRUSTED CONTEXT

The ALTER TRUSTED CONTEXT statement modifies the definition of a trusted context at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

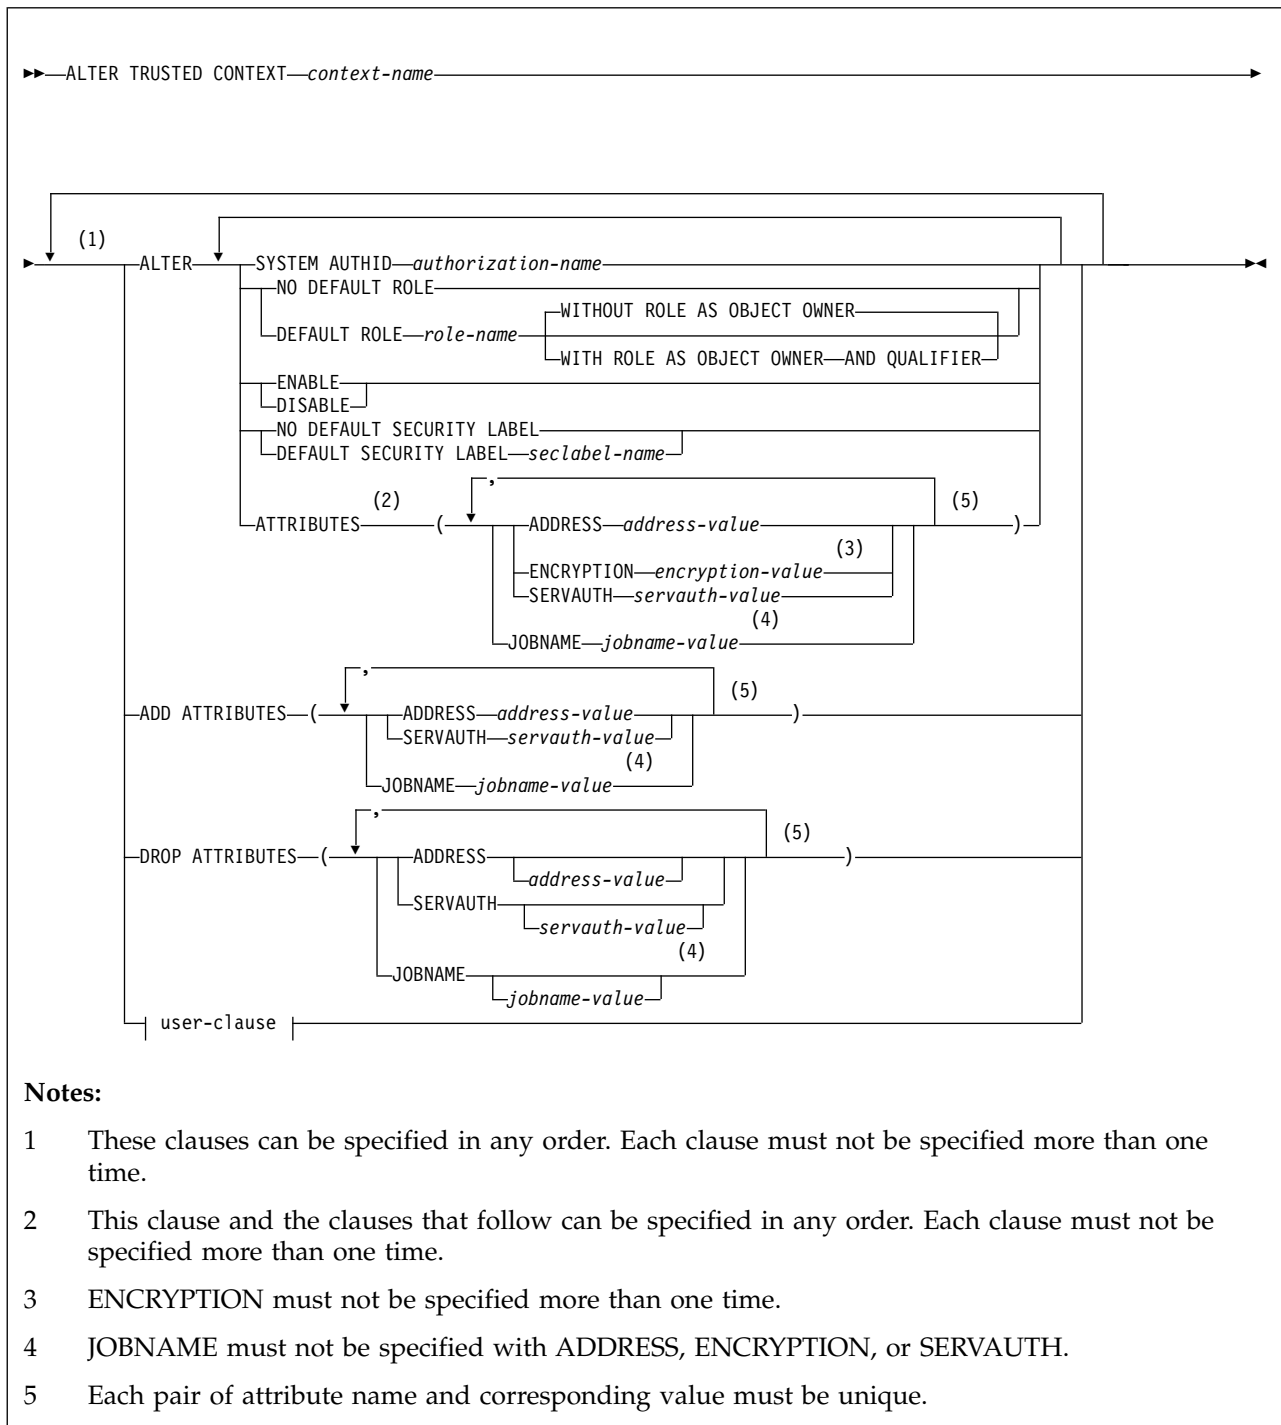

The privilege set that is defined below must include at least one of the following:

- SYSADM authority
- SECADM authority

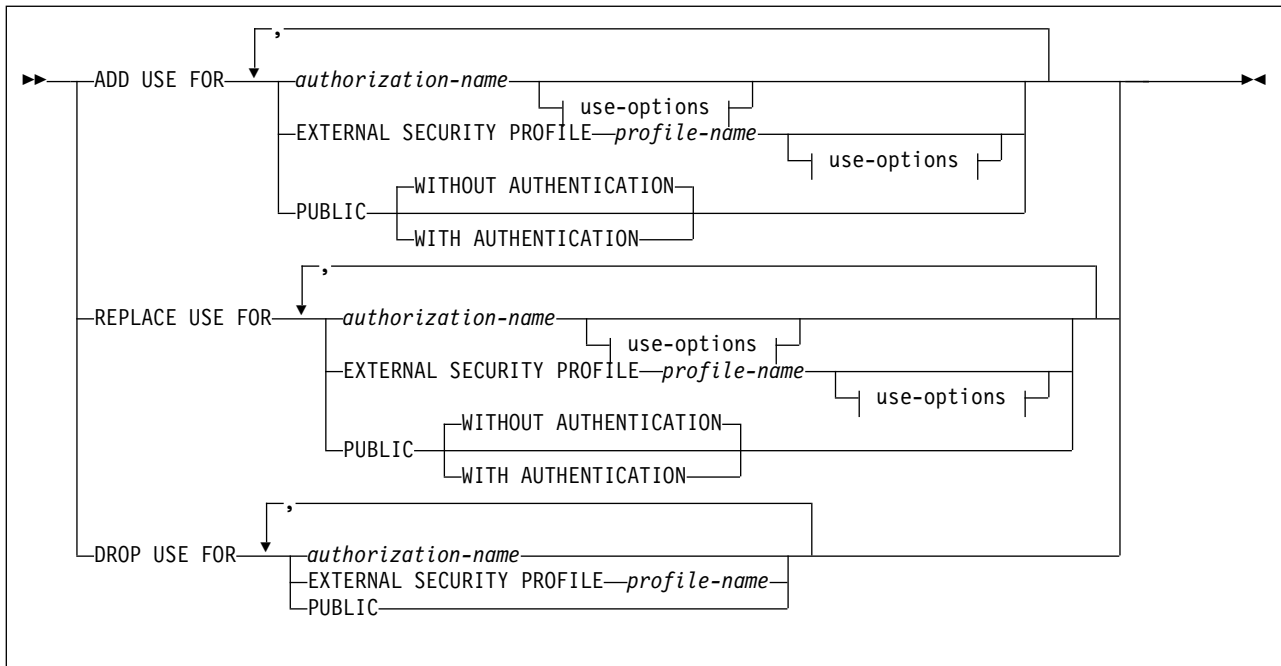

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the union of the set of privileges that are held by each authorization ID of the process. If the statement is run in a trusted context with a role, the privilege set is the union of the set of privileges that are held by the role that is associated with the primary authorization ID and the set of privileges that are held by each authorization ID of the process.

Syntax

user-clause:

use-options:

Description

context-name

Identifies the trusted context to alter. *context-name* must refer to a trusted context that exists at the current server.

ALTER

Specifies that changes are to be made to the definition of an existing trusted context.

SYSTEM AUTHID *authorization-name*

Specifies that *authorization-name* is the system authorization ID for the trusted context. The system authorization ID is the primary authorization ID of the DB2 system that establishes the connection. For a remote connection, the authorization ID is derived from the system used ID that is provided by the external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 160.

Table 160. System authorization ID for a local connection

| Source of local connection | System authorization ID |
|----------------------------|---|
| Started task (RRSAF) | USER parameter on JOB statement or RACF USER. |
| TSO | TSO logon ID |
| BATCH | USER parameter on JOB statement |

authorization-name must not be associated with an existing trusted context.

NO DEFAULT ROLE or DEFAULT ROLE *role-name*

Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

NO DEFAULT ROLE

Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

DEFAULT ROLE *role-name*

Specifies that *role-name* is the role for the trusted context. *role-name* must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER

Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

WITHOUT ROLE AS OBJECT OWNER

Specifies that a role is not used as the owner of the objects that are created using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

WITH ROLE AS OBJECT OWNER AND QUALIFIER

Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context. That role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

AND QUALIFIER

Specifies that the *role-name* will be used as the default for the CURRENT SCHEMA special register. The *role-name* will also be included in the SQL PATH (in place of CURRENT SQLID).

When **WITH ROLE AS OBJECT OWNER AND QUALIFIER** is not specified, there is no change to the default of the CURRENT SCHEMA special register and SQL PATH.

DISABLE or ENABLE

Specifies whether the trusted context is in the enabled or disabled state.

DISABLE

Specifies that the trusted context is disabled. A trusted context that is disabled is not considered when a trusted connection is established.

ENABLE

Specifies that the trusted context is enabled.

NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL *seclabel-name*

Specifies whether a default security label is associated with a trusted connection that is based on this trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

NO DEFAULT SECURITY LABEL

Specifies that the trusted context does not have a default security label.

DEFAULT SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the default security label for the trusted context. *seclabel-name* is the security label that is used for multilevel security verification. *seclabel-name* must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used in a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, *seclabel-name* must also identify one of the RACF SECLABEL values that is defined for the user.

ALTER ATTRIBUTES or ADD ATTRIBUTES

Specifies a list of one or more connection trust attributes to change or add to the definition of a trusted context. The connection trust attributes are used to define the trusted context. If ALTER ATTRIBUTES is specified and the attribute is not currently part of the definition of the specified trusted context, an error is returned. Existing specifications for the specified attributes are changed to the new value if ALTER is specified. Attributes that are not specified retain the previously specified values.

ADDRESS *address-value*

Specifies the actual communication address that is used by the connection to communicate with the database manager. The protocol supported is only for TCP/IP. Previously specified ADDRESS values are removed when ALTER ATTRIBUTES is specified. The ADDRESS attribute can be specified multiple times, but each *address-value* must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the values that are defined for the ADDRESS attribute of the trusted context.

address-value specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of *address-value* is done at the time the ALTER TRUSTED CONTEXT statement is processed. *address-value* must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111.

- An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. This address can also be express in a compressed form as 2001:DB8::8:800:200C:417A.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

ENCRYPTION *encryption-value*

Specifies the minimum level of encryption of the data stream (network encryption) for the connection.

encryption-value specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

ENCRYPTION cannot be specified if ADD ATTRIBUTES is specified. See "CREATE TRUSTED CONTEXT" on page 1820 for more information about the ENCRYPTION attribute.

JOBNAME *jobname-value*

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. Previously specified values for JOBNAME are removed when ALTER ATTRIBUTES is specified. The JOBNAME attribute can be specified multiple times, but each *jobname-value* must be unique.

jobname-value specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. *jobname-value* is an EBCDIC 8 byte job name or started task name. *jobname-value* must be left justified within the string constant. The last character in the name can be a wildcard character (*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that match the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space).

Table 161. Job name for local connection

| Source of the address space | Job name |
|-----------------------------|-------------------------------|
| RRSAF | Job name or started task name |
| TSO | TSO logon ID |
| BATCH | Job name on JOB statement |

SERVAUTH *servauth-value*

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with DB2.

Previously specified values for SERVAUTH are removed when ALTER

ATTRIBUTES is specified. The SERVAUTH attribute can be specified multiple times but each *servauth-value* must be unique.

servauth-value specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. *servauth-value* is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. *servauth-value* must be left justified in the string constant. No validation of *servauth-value* is done at the time the ALTER TRUSTED CONTEXT statement is processed.

DROP ATTRIBUTES

Specifies that one or more attributes are dropped from the definition of a trusted context. If the attribute is not currently specified as part of the definition of a trusted context, an error is returned. The specification of DROP ATTRIBUTES must not attempt to drop all of the existing attributes for a trusted context.

ADDRESS *address-value*

Specifies that the identified communication address is removed from the definition of the trusted context. *address-value* specifies a string constant that contains the value of an existing ADDRESS trust attribute.

JOBNAME *jobname-value*

Specifies that the identified job name is removed from the definition of the trusted context. *jobname-value* specifies a string constant that contains the value of an existing JOBNAME trust attribute.

SERVAUTH *servauth-value*

Specifies that the identified servauth that is removed from the definition of the trusted context. *servauth-value* specifies a string constant that contains the value of an existing SERVAUTH trust attribute.

ADD USE FOR

Specifies additional users who can use a trusted connection that is based on the specified trusted context.

authorization-name

Specifies that the trusted connection can be used by the specified *authorization-name*. This is the DB2 primary authorization ID. The *authorization-name* must not identify an authorization ID that is already defined to use the trusted context, and must not be specified more than one time in the ADD USE FOR clause.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by the specified *authorization-name*. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

EXTERNAL SECURITY PROFILE *profile-name*

Specifies that the trusted connection can be used by the DB2 primary authorization IDs that are permitted to use the specified *profile-name* in

RACF. *profile-name* must not already be defined to use the trusted context, and must not be specified more than one time in the **ADD USE FOR** clause.

After you specify an external security profile, any user who is permitted access to the RACF profile can use the trusted context in addition to any users that are specified using the **ADD USE FOR** *authorization-name* clause.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

PUBLIC

Specifies that a trusted connection that is based on the specified trusted context can be used by any user. **PUBLIC** must not already be defined to use the trusted context and must not be specified more than one time in the **ADD USE FOR** clause.

All users that are using a trusted connection that is defined with **PUBLIC** use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- **EXTERNAL SECURITY PROFILE** *profile-name*
- **PUBLIC**

For example, assume that a trusted context is defined with use for **JOE WITH AUTHENTICATION**, **EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION** (with **JOE** and **SAM** permitted to use the RACF **PROFILE SPROFILE**), and **PUBLIC WITH AUTHENTICATION**. If the trusted connection is used by **JOE**, authentication is required. If the trusted connection is used by **SAM**, authentication is not required. However, if the trusted connection is used by **SALLY**, authentication is required.

REPLACE USE FOR

Specifies a change to the specified user or PUBLIC for who can use the trusted context.

authorization-name

Specifies the *authorization-name* that is changed for use of the trusted context. The trusted context must already be defined to allow use by *authorization-name*, and *authorization-name* must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with *authorization-name* is changed as indicated.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is using the specified trusted context. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

EXTERNAL SECURITY PROFILE *profile-name*

Specifies the *profile-name* to change attributes for use of the trusted connection. The trusted context must already be defined to allow the use of *profile-name*. *profile-name* must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with the profile name is changed as indicated.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The role name must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

PUBLIC

Specifies that the attributes for use of the trusted connection by PUBLIC are to be changed. PUBLIC must already be defined to use the trusted context, and PUBLIC must not be specified more than one time in the REPLACE USE FOR clause.

All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted

context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user.

DROP USE FOR

Specifies who can no longer use the trusted context. The users that are removed from the definition of the trusted context are the specified users (or PUBLIC) that are currently allowed to use the trusted context. If multiple users are specified to be dropped, and one or more of those users cannot be dropped, those users that can be dropped are dropped and a warning is returned. If none of the specified users can be removed from the definition of the trusted context, an error is returned.

authorization-name

Specifies the *authorization-name* that will no longer be able to use this trusted context.

EXTERNAL SECURITY PROFILE *profile-name*

Removes the ability for the specified *profile-name* to use the trusted context.

PUBLIC

Specifies that PUBLIC users will no longer be able to use this trusted context. The system authorization ID and individual authorization IDs that have been explicitly enabled can still use the trusted context.

Notes

Precedence for *authorization-name* and authentication requirements: If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same authorization name that is specified in the ADD or REPLACE USE FOR *authorization-name* clauses, the role or the security label that is specified for the *authorization-name* takes precedence over the default value and the value that is specified for the EXTERNAL SECURITY PROFILE *profile-name* (if one is specified). If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the specified profile names and is not specified in ADD or REPLACE USE for *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

Authentication is required for SYSTEM AUTHID if the AUTHENTICATION clause is specified in the ADD or REPLACE USE FOR clauses, or if the subsystem parameter TCP/IP Already Verified is set to NO. For example, if *authorization-name* is the same as the authorization name that is specified in the SYSTEM AUTHID clause and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP

Already Verified subsystem parameter is set to NO, authentication is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, authentication is still required for SYSTEM AUTHID.

Order of precedence for users of a trusted connection: The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- **EXTERNAL SECURITY PROFILE** *profile-name*
- **PUBLIC**

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

User-clause SYSTEM AUTHID considerations: If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same as the *authorization-name* that is specified in the user-clause *authorization-name*, the role or the security label that is specified for *authorization-name* takes precedence over the default value. The value that is specified for the *profile-name*, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the *user-clause* or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if *authorization-name* is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

Order of operations: The order in which the clauses of the ALTER TRUSTED CONTEXT statement are applied are as follows:

- DROP ATTRIBUTES
- DROP USE FOR
- ALTER
- ADD ATTRIBUTES
- ADD USE FOR
- REPLACE USE FOR

Effect of changes on existing trusted connections: If trusted connections exist for the trusted context that is changed, the connections continue to use the unchanged definition of the trusted context until the connection is terminated or an attempt at

reuse is made. If the trusted context is disabled while there are active trusted connections that are based on this trusted context, the connections continue to be used until terminated or an attempt at reuse is made. If the trust attributes are changed, trusted connections that exist at the time that the trusted context is changed will continue to be used.

When changes to a trusted context take place: The changes to the definition of a trusted context take effect after the ALTER TRUSTED CONTEXT statement is committed. If the ALTER TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not changed.

Role privileges: If no role is associated with the user or the trusted context, only the privileges that are associated with the user are applicable. This is the same as not using a trusted context.

Examples

Example 1: The following statement updates the default role of the trusted context CTX1:

```
ALTER TRUSTED CONTEXT CTX1
ALTER DEFAULT ROLE CTXROLE2;
```

Example 2: The following statement changes the CTX3 trusted context to allow use for BILL, and it also puts the trusted context into the disabled state:

```
ALTER TRUSTED CONTEXT CTX3
DISABLE
ADD USE FOR BILL;
```

Example 3: The following statement changes the CTX4 trusted context to allow the previously defined user JOE to use the trusted context without authentication. The statement also adds use for PUBLIC with authentication and TOM with a role of SPLROLE:

```
ALTER TRUSTED CONTEXT CTX4
REPLACE USE FOR JOE WITHOUT AUTHENTICATION
ADD USE FOR PUBLIC WITH AUTHENTICATION,
TOM ROLE SPLROLE;
```

Example 4: The following statement changes the REMOTECTX to use a different IPv4 address than it was originally defined to use. It also changes the encryption settings from NONE to LOW. After the ALTER statement is processed, the connection will be considered trusted only when it is established from 9.12.155.200 with low encryption. The connection will no longer be considered trusted if it is established from the previously defined addresses:

```
ALTER TRUSTED CONTEXT REMOTECTX
ALTER ATTRIBUTES (ADDRESS '9.12.155.200',
ENCRYPTION 'LOW');
```

ALTER VIEW

The ALTER VIEW statement regenerates a view using an existing view definition at the current server. ALTER VIEW is primarily used during DB2 migration or when DB2 maintenance is applied. To change a view definition (for example, to add additional columns), you must drop the view and create a new view using the CREATE VIEW statement.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the view
- SYSADM authority
- SYSCTRL authority
- System DBADM

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
▶▶ALTER VIEW—view-name—REGENERATE—▶▶
```

Description

view-name

Identifies the view to be regenerated. The name must identify a view that exists at the current server.

REGENERATE

Specifies that the view is to be regenerated. The view definition in the catalog is used, and existing authorizations and dependent views are retained. The catalog is updated with the regenerated view definition. If the view cannot be successfully regenerated, an error is returned.

Examples

Check the catalog to find any views that were marked with view regeneration errors during catalog migration:

```
SELECT CREATOR,NAME FROM SYSIBM.SYSTABLES  
WHERE TYPE = 'V' AND STATUS = 'R' AND TABLESTATUS = 'V';
```

Assume that the query returned MYVIEW as the name of a view with a regeneration error. Issue an ALTER VIEW statement to regenerate the view:

```
ALTER VIEW MYVIEW REGENERATE;
```

ASSOCIATE LOCATORS

The ASSOCIATE LOCATORS statement gets the result set locator value for each result set returned by a stored procedure.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

Authorization

None required.

Syntax

Description

rs-locator-variable

Identifies a result set locator variable that has been declared according to the rules for declaring result set locator variables.

WITH PROCEDURE *procedure-name* **or** *host-variable*

Identifies the stored procedure that returned one or more result sets. When the ASSOCIATE LOCATORS statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one-part, two-part, or three-part name. The procedure name in the ASSOCIATE LOCATORS statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the ASSOCIATE LOCATORS statement.

If a host variable is used to specify the name:

- It must be a character string variable with a length attribute that is not greater than 255.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the server. Regardless of the server, the specification must:
 - Be left justified within the host variable
 - Not contain embedded blanks
 - Be padded on the right with blanks if its length is less than that of the host variable

Notes

Assignment of locator values: If the ASSOCIATE LOCATORS statement specifies multiple locator variables, locator values are assigned to the locator variables in the order that the associated cursors are opened regardless of whether they are still open or not at run time. Locator values are assigned to the locator variables in the same order that they would be placed in the SQLVAR entries in the SQLDA as a result of a DESCRIBE PROCEDURE statement.

Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later opened again before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values assigned for the following ASSOCIATE LOCATORS statement will be in the order A, C, B:

```
ASSOCIATE RESULT SET LOCATORS (:loc1, :loc2, :loc3) WITH PROCEDURE P1;
  -- assigns locators for result set cursors A, C, and B
```

More than one locator can be associated with a result set. You can issue multiple ASSOCIATE LOCATORS statements for the same stored procedure with different result set locator variables to associate multiple locators with each result set.

- If the number of result set locator variables specified in the ASSOCIATE LOCATORS statement is less than the number of result sets returned by the stored procedure, all locator variables specified in the statement are assigned a value, and a warning is issued. For example, assume procedure P1 exists and returns four result sets. Each of the following ASSOCIATE LOCATORS statement returns information on the first result set along with a warning that not enough locators were provided to obtain information about all the result sets.

```
CALL P1;
ASSOCIATE RESULT SET LOCATORS (:loc1) WITH PROCEDURE P1;
  -- :loc1 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc2) WITH PROCEDURE P1;
  -- :loc2 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc3) WITH PROCEDURE P1;
  -- :loc3 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc4) WITH PROCEDURE P1;
  -- :loc4 is assigned a value for first result set, and a warning is returned
```

- If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is greater than the number of locators returned by the stored procedure, the extra locator variables are assigned a value of 0.

Accessing result sets from multiple CALL statements: An application can access to result sets created by multiple CALL statements. The result sets can be created by different procedure or by the same procedure invoked multiple times.

- *Invoking different procedures:* Invoking different procedures with the same name can be done either explicitly by specifying the different collections or implicitly with the use of the PACKAGE PATH. For example, to identify the different collections explicitly, specify qualified names on the CALL statement. Although both procedures are named P2, they are different procedures. After the second CALL statement, result sets from both procedures are accessible to the application.

```
CALL X.P2;  
CALL Y.P2;
```

The collections for the two different procedures can also be determined implicitly from the PACKAGE PATH when unqualified procedure names are specified as part of the CALL statement. For example, assume that procedure P4 exists in collections X and Z. An application contains two CALL statements to invoke procedure P4. The references to procedure P4 in the CALL statements are unqualified. So, the PACKAGE PATH special register is used to resolve the procedure name. Procedure X.P4 is invoked for the first CALL statement and procedure Z.P4 is invoked by the second CALL statement. Following the second CALL statement, result sets from both procedures are accessible to the application.

```
SET CURRENT PACKAGE PATH = X, Y, Z;  
CALL P4;  
SET CURRENT PACKAGE PATH = PATH Z, Y, X;  
CALL P4;
```

- *Invoking the same procedure multiple times:* If the server and requester are both the same version of DB2, you can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors. For more information on this situation, see Multiple calls to the same stored procedure.

When a procedure is invoked multiple times in an application and there is a need to process the result sets from the different instances at the same time, be sure to use the ASSOCIATE LOCATORS statement after each CALL statement to capture the locator values returned from each invocation of the procedure. For example, assume that procedure P exists in collection Z and that an application contains two CALL statements to invoke procedure P. The PACKAGE PATH is used to determine the collection for the procedure in the first CALL statement, and the collection is explicitly specified in the second CALL statement. Result sets from both procedures can be accessible to the application following both CALL statements if the locators for the result sets produced by the first CALL statement are captured with an ASSOCIATE LOCATOR statement before invoking the procedure the second time.

```
SET CURRENT PACKAGE PATH = X, Y, Z;  
CALL P3;  
ASSOCIATE LOCATORS ...  
CALL Z.P3;  
ASSOCIATE LOCATORS ...  
-- process the result sets using the locators
```

Using host variables: If the ASSOCIATE LOCATORS statement contains host variables, the following conditions apply:

- If the statement is executed statically, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.
- If the statement is executed dynamically, the contents of the host variables are assumed to be in the encoding scheme that is specified in the APPLICATION ENCODING bind option.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets returned by stored procedure P1. Assume that the stored procedure is called with a one-part name from current server SITE2.

```
EXEC SQL CONNECT TO SITE2;  
EXEC SQL CALL P1;  
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)  
      WITH PROCEDURE P1;
```

Example 2: Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSCHEMA is used.

```
EXEC SQL CONNECT TO SITE2;  
EXEC SQL CALL MYSCHEMA.P1;  
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)  
      WITH PROCEDURE MYSCHEMA.P1;
```

Example 3: Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets that are returned by the stored procedure named by host variable HV1. Assume that host variable HV1 contains the value SITE2.MYSCHEMA.P1 and the stored procedure is called with a three-part name.

```
EXEC SQL CALL SITE2.MYSCHEMA.P1;  
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)  
      WITH PROCEDURE :HV1;
```

The preceding example would be invalid if host variable HV1 had contained the value MYSCHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the ASSOCIATE LOCATORS statement.

```
EXEC SQL CONNECT TO SITE2;  
EXEC SQL CALL SITE2.MYSCHEMA.P1;  
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)  
      WITH PROCEDURE :HV1;
```

BEGIN DECLARE SECTION

The BEGIN DECLARE SECTION statement marks the beginning of an SQL declare section. An SQL declare section contains declarations of host variables that are eligible to be used as host variables in SQL statements in a program.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

▶▶—BEGIN DECLARE SECTION—▶▶

Description

The BEGIN DECLARE SECTION statement can be coded in the application program wherever variable declarations can appear in accordance with the rules of the host language. It is used to indicate the beginning of a host variable declaration section. A host variable section ends with an END DECLARE SECTION statement, described in “END DECLARE SECTION” on page 1938.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) SQL processing option is specified:

- A variable referred to in an SQL statement must be declared within a host variable declaration section of the source program in all host languages, other than Java and REXX. Furthermore, the declaration of each variable must appear before the first reference to the variable. Host variables are declared without the use of these statements in Java, and they are not declared at all in REXX.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- Host variable declaration sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

Notes

Host variable declaration sections are only required if the STDSQL(YES) option is specified or the host language is C. However, declare sections can be specified for any host language so that the source program can conform to IBM SQL. If declare sections are used, but not required, variables declared outside a declare section must not have the same name as variables declared within a declare section.

Example

```
EXEC SQL BEGIN DECLARE SECTION;  
  
    -- host variable declarations  
  
EXEC SQL END DECLARE SECTION;
```

CALL

The CALL statement invokes a stored procedure.

Invocation

This statement can be embedded in an application program. This statement can be executed interactively using the command line processor. Refer to Command line processor CALL statement (DB2 Application programming and SQL) for information about using the command line processor with the CALL statement. This statement can also be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements. IBM's ODBC and CLI drivers provide this capability.

Authorization

Invoking a stored procedure requires the EXECUTE privilege on the following:

- The stored procedure
You do not need the EXECUTE privilege on a stored procedure that was created prior to Version 6 of DB2 for z/OS.
- Additional authority is needed for the stored procedure package and most packages that run in the stored procedure.
The authorization that is required for which packages is explained in detail in Authorization to execute packages under the stored procedure.

Authorization to execute the stored procedure

The authorization ID or role that must have the EXECUTE privilege on the stored procedure depends on the form of the CALL statement:

- For static SQL programs that use the syntax *CALL procedure*, the owner of the plan or package that contains the CALL statement must have one of the following:
 - The EXECUTE privilege on the stored procedure
 - Ownership of the stored procedure
 - DATAACCESS authority
 - SYSADM authority
- For static SQL programs that use the syntax *CALL :host-variable*, the authorization ID or role of the plan or package that contains the CALL statement must have one of the following:
 - The EXECUTE privilege on the stored procedure
 - Ownership of the stored procedure
 - DATAACCESS authority
 - SYSADM authority

The DYNAMICRULES behavior for the plan or package that contains the CALL statement determines both the authorization ID or role and the privilege set that is held by that authorization ID or role:

Run behavior

The privilege set is the union of the set of privileges that are held by the SQL authorization ID and each authorization ID or role of the process.

Bind behavior

The privilege set is the privileges that are held by the primary authorization ID of the owner of the package or plan.

Define behavior

The privilege set is the privileges that are held by the authorization ID or role of the owner (definer) of the stored procedure or user-defined function that issued the CALL statement.

Invoke behavior

The privilege set is the privileges that are held by the authorization ID or role of the invoker of the stored procedure or user-defined function that issued the CALL statement. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, the privilege set is the union of the set of privileges that are held by each authorization ID or role.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see Table 6 on page 75.

Authorization to execute packages under the stored procedure (including nested stored procedures)

The authorization that is required to run the stored procedure package and any packages that are used under the stored procedure (including nested stored procedures) apply to any form of the CALL statement as follows:

- **Stored procedure package:** One of the authorization IDs or roles that are defined in Set of authorization IDs must have at least one of the following privileges or authorities on the stored procedure package:
 - The EXECUTE privilege
 - Ownership of the package
 - PACKADM authority for the package's collection
 - SYSADM authority

A PKLIST entry is not required for the stored procedure package.

- **User-defined function packages and trigger packages:** If a stored procedure or any application under the stored procedure invokes a user-defined function, DB2 requires only the owner (the definer), and not the invoker of the user-defined function, to have EXECUTE authority on the user-defined function package. However, the authorization ID or role of the SQL statement that invokes the user-defined function must have EXECUTE authority on the function.

Similarly, if a trigger is used under a stored procedure, DB2 does not require EXECUTE authority on the trigger package; however, the authorization ID or role of the SQL statement that activates the trigger must have EXECUTE authority on the trigger.

PKLIST entries are not required for any user-defined function packages or trigger packages that are used under the stored procedure.

- **Packages other than user-defined function, trigger, and stored procedure packages:** One of the authorization IDs or roles that is defined below under Set of authorization IDs must have at least one of the following privileges or authorities on any packages other than user-defined function and trigger packages that are used under the stored procedure:
 - The EXECUTE privilege
 - Ownership of the package

- PACKADM authority for the package's collection
- SYSADM authority

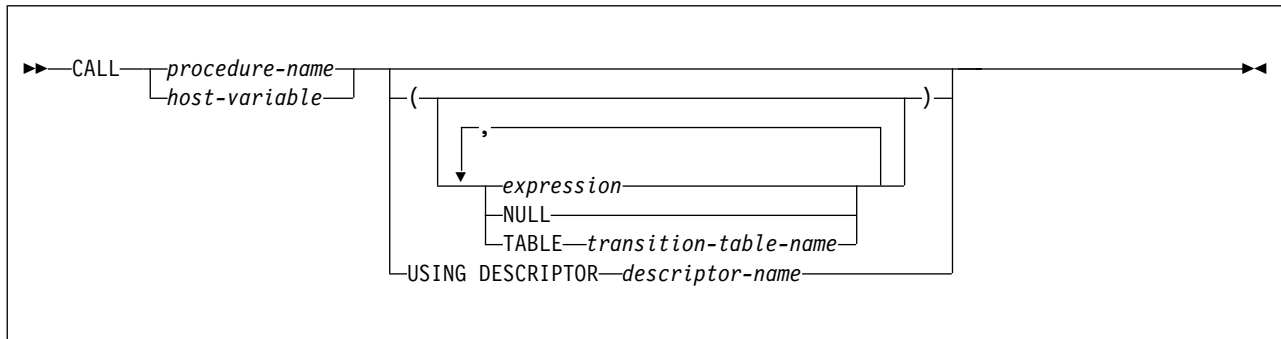

PKLIST entries are required for any of these packages that are used under the stored procedure.

For improved performance and simplicity, consider granting the EXECUTE ON PACKAGE privilege for the stored procedure package, and for any packages that run under the stored procedure, to the owner of the stored procedure.

Set of authorization IDs: DB2 checks the following authorization IDs, in the order in which they are listed, for the required authorization to execute the stored procedure package and any packages that run under the stored procedure other than user-defined function and trigger packages as described previously. Authorization checking ends after the first authorization ID that has EXECUTE ON PACKAGE privileges for the target package is found.

- The owner (the definer) of the stored procedure.
- The owner of the plan that contains the CALL statement that invokes the stored procedure if either of the following conditions is true:
 - The calling application (a package or a DBRM that is bound directly to the plan) is local.
 - The calling application is distributed, the DB2 subsystem is both the requester and the server, and the PRIVATE_PROTOCOL subsystem parameter is not set to NO.
- The owner of the package that contains the CALL statement that invokes the stored procedure if the calling application is distributed and either of the following conditions is true:
 - The DB2 subsystem is the server but not the requester.
 - The DB2 subsystem is both the server and the requester and the PRIVATE_PROTOCOL subsystem parameter is set to NO.
 - The calling application uses Recoverable Resources Management Services attachment facility (RRSAF) and has no plan.
- The authorization ID as determined by the value of the DYNAMICRULES bind option for the plan or package that contains the CALL statement if the CALL statement is in the form of CALL *:host-variable*.
 - If the calling application is bound with the DYNAMICRULES(RUN) option, DB2 checks either the authorization ID of the process at run time and its secondary authorization IDs or the single authorization ID that is determined by the other DYNAMICRULES bind option values.
 - If the calling application is bound with a value other than DYNAMICRULES(RUN), DB2 checks only a single authorization ID, even if that ID fails the EXECUTE ON PACKAGE authorization check.
 - If the calling application is a package and is bound with DYNAMICRULES(BIND), DB2 checks the authorization ID of the package owner. DB2 does not check the authorization ID of the plan owner.

Syntax

Description

procedure-name or *host-variable*

Identifies the procedure to call by the specified *procedure-name* or the procedure name contained in the *host-variable*. The identified procedure must exist at the current server.

If *procedure-name* specifies any of the three special characters that are alphabetic extenders for national languages, \$#@, specify the procedure name with a *host-variable*.

If a host variable is used:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the server.

Regardless of the server, the specification must:

- Be left justified within the host variable
- Not contain embedded blanks
- Be padded on the right with blanks if its length is less than that of the host variable

In addition, the specification can:

- Contain upper and lowercase characters. Lowercase characters are not folded to uppercase.
- Use a delimited identifier for any part of a three-part procedure name.

If the server is DB2 for z/OS, the specification must be a procedure name as defined above.

When the CALL statement is executed, the procedure name or specification must identify a stored procedure that exists at the server.

When the package that contains the CALL statement is bound, the stored procedure that is invoked must be created if VALIDATE(BIND) is specified. Although the stored procedure does not need to be created at bind time if VALIDATE(RUN) is specified, it must be created when the CALL statement is executed.

expression, **NULL**, or **TABLE** *transition-table-name*

Identifies a list of values to be passed as parameters to the stored procedure. If USING DESCRIPTOR is specified, each host variable described by the identified SQLDA is a parameter, or part of an expression that is a parameter, of the CALL statement. If host structures are not specified in the CALL

statement, the *n*th parameter of the CALL statement corresponds to the *n*th parameter in the stored procedure, and the number of parameters in each must be the same. Otherwise, each reference to a host structure is replaced by a reference to each of the variables contained in that host structure, and the resulting number of parameters must be the same as the number of parameters defined for the stored procedure.

However, a character FOR BIT DATA parameter cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

Each parameter of a stored procedure is described at the server. In addition to attributes such as data type and length, the description of each parameter indicates how the stored procedure uses it:

- IN means as an input value
- OUT means as an output value
- INOUT means both as an input and an output value

When the CALL statement is executed, the value of each of its parameters is assigned to the corresponding parameter of the stored procedure. In cases where the parameters of the CALL statement are not an exact match to the data types of the parameters of the stored procedure, each parameter specified in the CALL statement is converted to the data type of the corresponding parameter of the stored procedure at execution. The conversion occurs according to the same rules as assignment to columns. For details on the rules used to assign parameters, see “Assignment and comparison” on page 119.

Conversion can occur when precision, scale, length, encoding scheme, or CCSID differ between the parameter specified in the CALL statement and the data type of the corresponding parameter of the stored procedure. Conversion might occur for a character string parameter specified in the CALL statement when the corresponding parameter of the stored procedure has a different encoding scheme or CCSID. For example, an error occurs when the CALL statement passes mixed data that actually contains DBCS characters as input to a parameter of the stored procedure that is declared with an SBCS subtype. Likewise, an error occurs when the stored procedure returns mixed data that actually contains DBCS characters in the parameter of the CALL statement that has an SBCS subtype.

Control is passed to the stored procedure according to the calling conventions of the host language. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

expression

The parameter is the result of the specified expression, which is evaluated before the stored procedure is invoked.

If *expression* is a single host variable, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. In addition, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of the variables contained in the host structure.

If the result of the expression can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN *expression* can contain references to multiple host variables. In addition to the rules stated in “Expressions” on page 228 for *expression*, *expression* cannot include a column name, a scalar subselect, a file reference variable, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT *expression* can only be a single host variable. *expression* cannot include a file reference variable.

NULL

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

TABLE *transition-table-name*

The parameter is a transition table, and it is passed to the procedure as a table locator. You can use the CALL statement with the TABLE clause only within the definition of the triggered action of a trigger. The name of a transition table must be specified in the CALL statement if the corresponding parameter of the procedure was defined in the TABLE LIKE clause of the CREATE PROCEDURE statement. For information about creating a trigger, see “CREATE TRIGGER” on page 1802 and *DB2 Application Programming and SQL Guide*.

There is no effect on the transition table on the return from the procedure regardless of whether the parameter was defined as IN, INOUT, or OUT.

USING DESCRIPTOR *descriptor-name*

Identifies an SQLDA that contains a valid description of the host variables that are to be passed as parameters to the stored procedure. If the stored procedure has no parameters, an SQLDA is ignored.

Before the CALL statement is processed, the user must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA. This number must not be less than SQLD. This field is not part of the REXX SQLDA and therefore does not need to be set for REXX programs.
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA. This number must not be less than $SQLN * 44 + 16$. This field is not part of the REXX SQLDA and therefore does not need to be set for REXX programs.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement. This number must be the same as the number of parameters of the stored procedure.
- SQLVAR occurrences to indicate the attributes of the variables.

There are additional considerations for setting the fields of the SQLDA when a variable that is passed as a parameter to the stored procedure has a LOB data type or is a LOB locator. For more information, see “SQL descriptor area (SQLDA)” on page 2366.

The SQL CALL statement ignores distinct type information in the SQLDA. Only the base SQL type information is used to process the input and output parameters described by the SQLDA.

See “Identifying an SQLDA in C or C++” on page 2385 for how to represent *descriptor-name* in C.

Notes

Parameter assignments: When the CALL statement is executed, the value of each of its arguments is assigned with storage assignment rules to the corresponding IN or INOUT parameter of the stored procedure. In cases where the arguments of the CALL statement are not an exact match to the data types of the parameters of the stored procedure, each argument specified in the CALL statement is converted to the data type of the corresponding parameter of the stored procedure at execution. The conversion occurs according to the same rules as assignment to columns.

Control is passed to the stored procedure according to the calling conventions of the host language.

When execution of the stored procedure is complete, the value of each parameter of the stored procedure defined as OUT or INOUT is assigned to the corresponding argument of the CALL statement. If an error is returned by the procedure, OUT arguments are undefined, and INOUT arguments are unchanged.

A timestamp without time zone value must not be assigned to a timestamp with time zone target.

For details on the rules used to assign parameters, see “Assignment and comparison” on page 119.

Conversion can occur when precision, scale, length, encoding scheme, or CCSID differ between the argument specified in the CALL statement and the data type of the corresponding parameter of the stored procedure. Conversion might occur for a character string argument specified in the CALL statement when the corresponding parameter of the stored procedure has a different encoding scheme or CCSID. For example, an error occurs when the CALL statement passes an argument of mixed data that actually contains DBCS characters as input for a parameter of the stored procedure that is defined as FOR SBCS DATA. Likewise, an error occurs when the stored procedure returns mixed data that actually contains DBCS characters for an argument of the CALL statement that is defined as FOR SBCS DATA.

Procedure signatures: A procedure is identified by its schema, a procedure name, and its number of parameters. This is called a procedure signature, which must be unique within the database. DB2 for z/OS does not support overloaded procedure names (procedures with the same schema and procedure name, but with different numbers of parameters).

SQL path: A procedure can be invoked by referring to a qualified name (schema and procedure name), followed by an optional list of arguments that are enclosed in parentheses. A procedure can also be invoked without the schema name, which results in a choice of possible procedures in different schemas that have the same procedure name and same number of parameters. In this case, the SQL path is used to assist in procedure resolution. The SQL path is a list of schemas that is searched to identify a procedure with the same name and number of parameters as the procedure in the CALL statement. For CALL statements that explicitly specify a

procedure name, the SQL path is specified by using the platform-specific bind option. For `CALL host-variable` statements, the SQL path is the value of the `CURRENT PATH` special register when the procedure is invoked.

Procedure resolution: Given a procedure invocation, the database manager must decide which of the possible procedures that has the same name to call.

A procedure name is a qualified or unqualified name. Each part of the name must be composed of SBCS characters:

- A fully qualified procedure name is a three-part name. The first part is an SQL identifier that contains the location name that identifies the DBMS at which the procedure is stored. The second part is an SQL identifier that contains the schema name of the stored procedure. The last part is an SQL identifier that contains the name of the stored procedure. A period must separate each of the parts. Any or all of the parts can be a delimited identifier.
- A two-part procedure name has one implicit qualifier. The implicit qualifier is the location name of the current server. The two parts identify the schema name and the name of the stored procedure. A period must separate the two parts.
- An unqualified procedure name is a one-part name with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier depends on the server. If the server is DB2 for z/OS, the implicit qualifier is the schema name. DB2 uses the SQL path to determine the value of the schema name.
 - If the procedure name is specified as a string constant on the `CALL` statement (`CALL procedure-name`), the SQL path is the value of the `PATH` bind option that is associated with the calling package or plan.
 - If a host variable is specified for the procedure name on the `CALL` statement (`CALL host-variable`), the SQL path is the value of the `CURRENT PATH` special register.

DB2 searches the schema names in the SQL path from left to right until a stored procedure with the specified schema name is found in the DB2 catalog. When a matching *schema.procedure-name* is found, the search stops only if the following conditions are true:

- The user is authorized to call the stored procedure.
- The number of parameters in the definition of the stored procedure matches the number of parameters specified on the `CALL` statement.

If the list of schemas in the SQL path is exhausted before the procedure name is resolved, an error is returned.

When the procedure is resolved depends on how the procedure name is specified. For a `CALL` statement that specifies the procedure name using a host variable, procedure resolution occurs at run time. For a `CALL` statement that contains the name of the procedure as an identifier, procedure resolution occurs when the `CALL` statement is bound.

Procedure resolution is done by the database manager using the following steps:

1. Find all procedures from the catalog where all of the following conditions are true:
 - For invocations where the schema name is specified (qualified references), the schema name and the procedure name match the invocation name.

For invocations where the schema name is not specified (unqualified references), the procedure name matches the invocation name, and the procedure has a schema name that matches one of the schemas in the SQL path.

- The number of defined parameters matches the number of arguments that are specified in the invocation.
 - The invoker has the EXECUTE privilege on the procedure.
2. Of the candidate procedures that remain from step 1, choose the procedure whose schema is first in the SQL path. If no candidate procedures remain after step 1, an error is returned.
 3. For CALL statements that use a host variable to specify the procedure name, the CURRENT ROUTINE VERSION special register can affect which version of the native SQL procedure is invoked. If the CURRENT ROUTINE VERSION special register is set, check if there is a version of the procedure with that version name. If not, choose the currently active version of the procedure.

For CALL statements that do not use a host variable to specify the procedure name, choose the currently active version of the procedure.

Version resolution: Normally, the currently active version of a native SQL procedure will be used on a CALL statement. However, if the CALL statement is a recursive call inside the body of the same stored procedure, and the original CALL statement uses a version that is different from the currently active version, the active version will not be used. The version from the original CALL statement will be used for any recursive CALL statements until the entire stored procedure finishes executing. This preserves the semantics of the version that is used by the original CALL statement. This includes the case where the recursive call is indirect. For example, assume that procedure SP1 call procedure SP2, which in turn recursively calls SP1. The second invocation of procedure SP1 will use the version of the procedure that is active at the time of the original CALL statement that invoked procedure SP1.

Since the currently active version can be used at the next CALL statement, it is possible that two or more versions of the same procedure can run at the same time. There could be different versions of an SQL procedure loaded by a given thread. For example, a CALL SP1 statement in an application will cause the currently active version, SP1_V1, to load and execute. After this CALL statement has completed, an ALTER PROCEDURE ALTER ACTIVE VERSION could execute and change the active version of the procedure SP1 to version SP1_V2. Subsequent CALL SP1 statements from the same thread will load the currently active version of the procedure, SP1_V2, and execute it.

Parameter assignments: When the CALL statement is executed, the value of each of its parameters is assigned with storage assignment rules to the corresponding parameter of the procedure. Control is passed to the procedure according to the calling conventions of the host language. When execution of the procedure is complete, the value of each parameter of the procedure is assigned with storage assignment rules to the corresponding parameter of the CALL statement defined as OUT or INOUT. If an error is returned by the procedure, OUT arguments are undefined and INOUT arguments are unchanged. For details on the assignment rules, see “Assignment and comparison” on page 119.

Cursors and prepared statements in procedures: All cursors opened in the called procedure that are not result set cursors are closed and all statements prepared in the called procedure are destroyed when the procedure ends.

Result sets from procedures: Any cursors specified using the WITH RETURN clause that the procedure leaves open when it returns identifies a result set. In a procedure written in Java, all cursors are implicitly defined WITH RETURN.

Results sets are returned only when the procedure is called from CLI, JDBC, or SQLJ. If the procedure was invoked from CLI or Java, and more than one cursor is left open, the result sets can only be processed in the order in which the cursors were opened. Only unread rows are available to be fetched. For example, if the result set of a cursor has 500 rows, and 150 of those rows have been read by the procedure at the time the procedure is terminated, then rows 151 through 500 will be returned to the procedure.

Errors from procedures: A procedure can return errors or warnings using an SQLSTATE like other SQL statements. Applications should be aware of the possible SQLSTATES that can be expected when a procedure is invoked. The possible SQLSTATES depend on how the procedure is coded. Procedures might also return SQLSTATES such as those that begin with '38' or '39' if DB2 encounters problems executing the procedure. Applications should therefore be prepared to handle any error SQLSTATE that can result from issuing a CALL statement.

Improving performance: The capability of calling stored procedures is provided to improve the performance of DRDA distributed access. The capability is also useful for local operations. The server can be the local DB2. In which case, packages are still required.

All values of all parameters are passed from the requester to the server. To improve the performance of this operation, host variables that correspond to OUT parameters and have lengths of more than a few bytes should be set to null before the CALL statement is executed.

Using the CALL statement in a trigger: When a trigger issues a CALL statement to invoke a stored procedure, the parameters that are specified in the CALL statement cannot be host variables and the USING DESCRIPTOR clause cannot be specified.

Nesting CALL statements: A program that is executing as a stored procedure, a user-defined function, or a trigger can issue a CALL statement. When a stored procedure, user-defined function, or trigger calls a stored procedure, user-defined function, or trigger, the call is considered to be nested. Stored procedures, user-defined functions, and triggers can be nested up to 64 levels deep on a single system. Nesting can occur within a single DB2 subsystem or when a stored procedure or user-defined function is invoked at a remote server.

If a stored procedure returns any query result sets, the result sets are returned to the caller of the stored procedure. If the SQL CALL statement is nested, the result sets are visible only to the program that is at the previous nesting level. For example, Figure 34 on page 1442 illustrates a scenario in which a client program calls stored procedure PROCA, which in turn calls stored procedure PROCB. Only PROCA can access any result sets that PROCB returns; the client program has no access to the query result sets. The number of query result sets that PROCB returns does not count toward the maximum number of query results that PROCA can return.

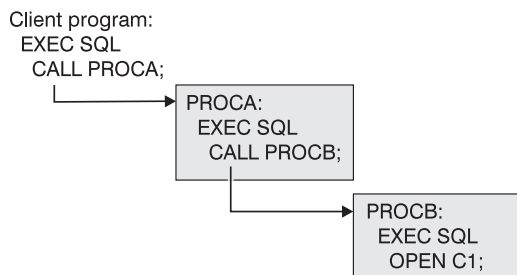

Figure 34. Nested CALL statements

Some stored procedures cannot be nested. A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN attribute.

Multiple calls to the same stored procedure: You can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors.

The application might receive a "resource unavailable message" if the CALL statement causes the values of the maximum number of active stored procedures or maximum number open cursors to be exceeded. The value of field MAX STORED PROCEDURES (on installation panel DSNTIPX) defines the maximum number of active stored procedures that are allowed per thread. The value of field MAX OPEN CURSORS (on installation panel DSNTIPX) defines the maximum number of open cursors (both result set cursors and regular cursors) that are allowed per thread.

If you make multiple calls to the same stored procedure within an application, be aware of the following considerations:

- A DESCRIBE PROCEDURE statement describes the last instance of the stored procedure.
- The ASSOCIATE LOCATORS statement works on the last instance of the stored procedure.
- The ALLOCATE CURSOR statement must specify a unique cursor name for a result set returned from an instance of the stored procedure. Otherwise, you will lose the data from the result sets that are returned from prior instances or calls to the stored procedure.

You should issue an ASSOCIATE LOCATORS statement (or DESCRIBE PROCEDURE statement) after each call to the stored procedure to get a unique locator value for each result set.

Using host variables: If the CALL statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples

Example 1: A PL/I application has been precompiled on DB2 ALPHA and a package was created at DB2 BETA with the BIND subcommand. A CREATE PROCEDURE statement was issued at BETA to define the procedure SUMARIZE,

which allows nulls and has two parameters. The first parameter is defined as IN and the second parameter is defined as OUT. Some of the statements that the application that runs at DB2 ALPHA might use to call stored procedure SUMARIZE include:

```
EXEC SQL CONNECT TO BETA;
V1 = 528671;
IV = -1;
EXEC SQL CALL SUMARIZE(:V1,:V2 INDICATOR :IV);
```

Example 2: Suppose that stored procedure MYPROC exists and produces several result sets. An application might include statements like the following to access the result sets produced by MYPROC:

```
-- Invoke stored procedure MYPROC that returns several result sets
EXEC SQL CALL MYPROC (...);
-- Copy the locator values for the result sets into result set locator variables
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:RS1, :RS2, :RS3) WITH PROCEDURE MYPROC;
-- Allocate cursors for the result set cursors
EXEC SQL ALLOCATE CSR1 CURSOR FOR RESULT SET :RS1;
EXEC SQL ALLOCATE CSR2 CURSOR FOR RESULT SET :RS2;
EXEC SQL ALLOCATE CSR3 CURSOR FOR RESULT SET :RS3;
-- Process data returned with the result set cursors
DO WHILE (SQLCODE = 0);
EXEC SQL FETCH CSR1 INTO .....
END;
EXEC SQL CLOSE CSR1;
-- do similar processing with other result sets
...
```

CLOSE

The CLOSE statement closes a cursor. If a temporary copy of a result table was created when the cursor was opened, that table is destroyed.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

See "DECLARE CURSOR" on page 1846 for the authorization required to use a cursor.

Syntax

```
▶▶—CLOSE—cursor-name—————▶▶
```

Description

cursor-name

Identifies the cursor to be closed. The cursor name must identify a declared cursor as explained in "DECLARE CURSOR" on page 1846. When the CLOSE statement is executed, the cursor must be in the open state.

Notes

Implicit cursor close: At the end of a unit of work, all open cursors declared without the WITH HOLD option that belong to an application process are implicitly closed.

Close cursors for performance: Explicitly closing cursors as soon as possible can improve performance.

Procedure considerations: Special rules apply to cursors within procedures that have not been closed before returning to the calling program. For more information, see "CALL" on page 1432.

Allocated cursors: The cursor could have been allocated. See "ALLOCATE CURSOR" on page 1159.

Example

A cursor is used to fetch one row at a time into the application program variables DNUM, DNAME, and MNUM. Finally, the cursor is closed. If the cursor is reopened, it is again located at the beginning of the rows to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8A10.DEPT
  WHERE ADMRDEPT = 'A00'
END-EXEC.
```

```
EXEC SQL OPEN C1 END-EXEC.  
  
EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.  
  
IF SQLCODE = 100  
    PERFORM DATA-NOT-FOUND  
ELSE  
    PERFORM GET-REST-OF-DEPT  
    UNTIL SQLCODE IS NOT EQUAL TO ZERO.  
  
EXEC SQL CLOSE C1 END-EXEC.  
  
GET-REST-OF-DEPT.  
    EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.
```

COMMENT

The COMMENT statement adds or replaces comments in the descriptions of various objects in the DB2 catalog at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

For a comment on the following objects, the privilege set must include at least one of the listed authorities or privileges:

Table, view, alias, index, or column:

- Ownership of the table, view, alias, or index
- DBADM authority for its database (tables and indexes only)
- SYSADM or SYSCTRL authority
- System DBADM
- SECADM authority (if the table has an activated row permission or column access control)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Distinct type, stored procedure, trigger, or user-defined function:

- Ownership of the distinct type, stored procedure, trigger, or user-defined function
- The ALTERIN privilege on the schema (for the addition of comments)
- SYSADM or SYSCTRL authority
- System DBADM

Secure trigger or secure user-defined function:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Package:

- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority
- System DBADM

Role or a trusted context:

- Ownership of the object
- SYSADM or SYSCTRL authority
- SECADM

If the installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM and SYSCTRL authority and can drop a role or trusted context.

Sequence:

- Ownership of the sequence

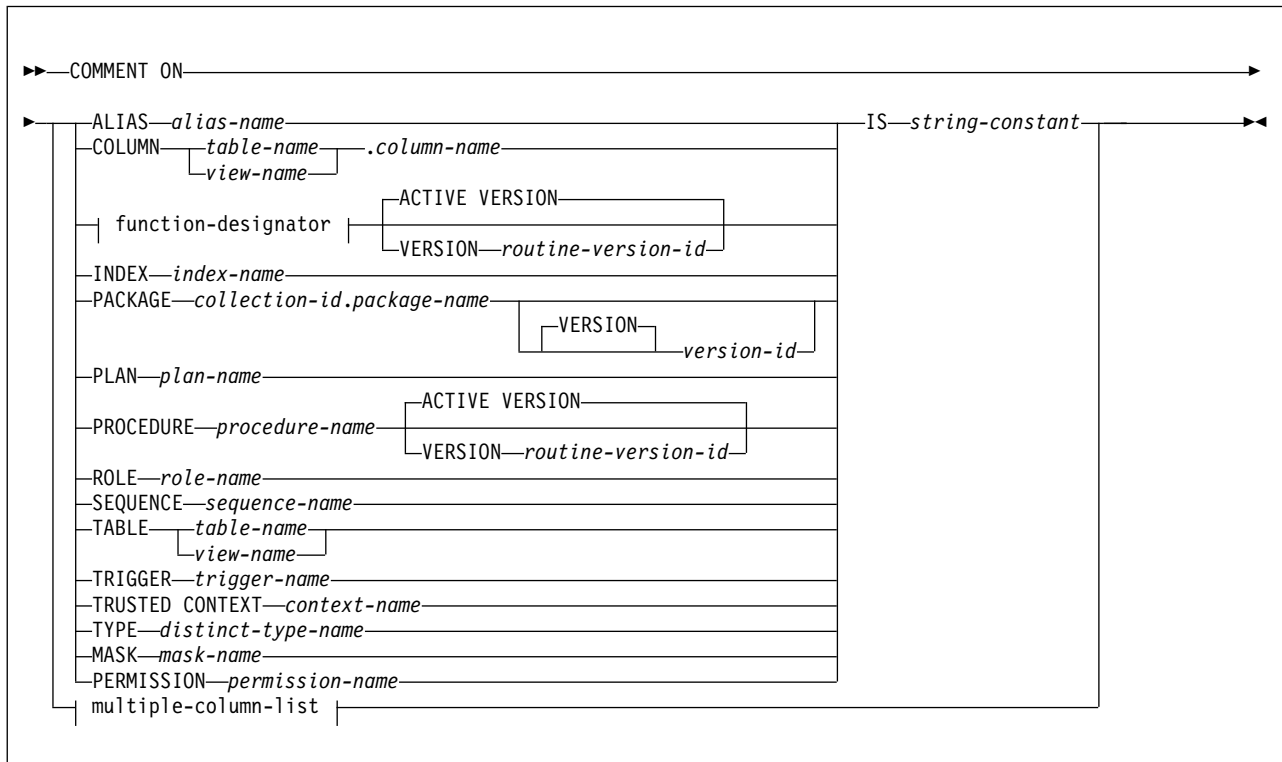

- The ALTER privilege for the sequence
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Row permission or column mask:
SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 147 on page 1153. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 75.)

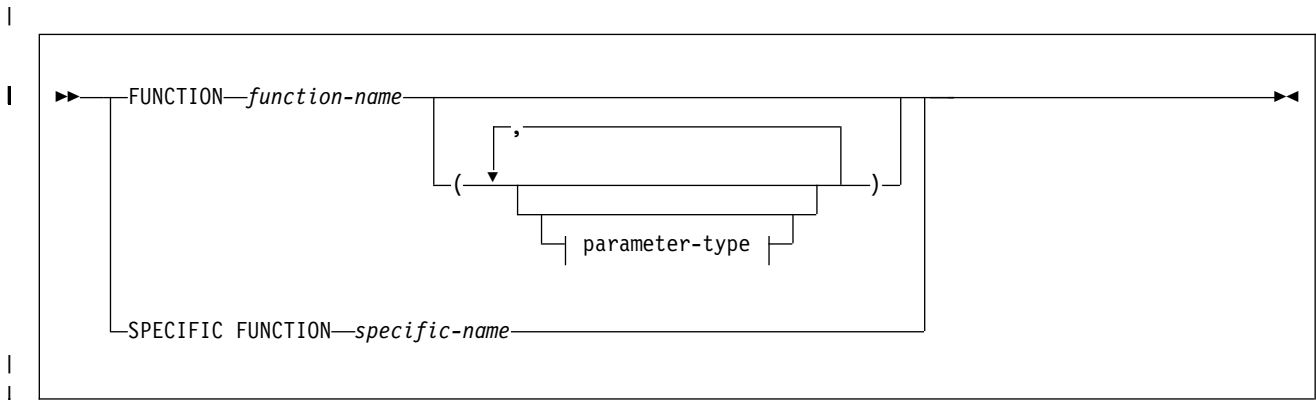

Syntax

multiple-column-list

| **function-designator**

| **parameter-type**

| **data-type**

| **built-in-type**

Description

ALIAS *alias-name*

Identifies the alias to which the comment applies. *alias-name* must identify an alias that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the alias.

COLUMN *table-name.column-name* **or** *view-name.column-name*

Identifies the column to which the comment applies. The name must identify a column of a table or view that exists at the current server. The name must not identify a column of a declared temporary table. The comment is placed into the REMARKS column of the SYSIBM.SYSCOLUMNS catalog table, for the row that describes the column.

Do not use TABLE or COLUMN to comment on more than one column in a table or view. Give the table or view name and then, in parentheses, a list in the form:

```
column-name IS string-constant,  
column-name IS string-constant,...
```

The column names must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

FUNCTION or SPECIFIC FUNCTION

Identifies the function to which the comment applies. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The comment is placed in the REMARKS column of the SYSIBM.SYSROUTINES catalog table for the row that describes the function.

The function can be identified by its name, function signature, or specific name. If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), you must identify the function with its function name, if it is unique, or with its specific name.

FUNCTION *function-name*

Identifies the function by its function name. There must be exactly one function with *function-name* in the schema. The function can have any number of input parameters. If the schema does not contain a function with *function-name*, or if the schema contains more than one function with this name, an error is returned.

FUNCTION *function-name (parameter-type,...)*

Identifies the SQL function by its function signature, which uniquely identifies the function. A function with the function signature must exist in the explicitly or implicitly specified schema.

If *function-name()* is specified, the function that is identified must have zero parameters.

function-name

Identifies the name of the function. If the function was defined with a table parameter (the **LIKE TABLE *name* AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or with its specific name.

(parameter-type,...)

Specifies the number of input parameters of the function and the name and data type of each parameter.

(data-type,...)

Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.

For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

The specific value for FLOAT(*n*) does not have to exactly match the defined value of the source function because $1 \leq n \leq 21$ indicates REAL and $22 \leq n \leq 53$ indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the **FOR subtype DATA** clause or the **CCSID** clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION *specific-name*

Identifies a particular user-defined function by its specific name. The name is implicitly or explicitly qualified with a schema name. A function with the specific name must exist in the schema. If the specific name is not qualified, it is implicitly qualified with a schema name as described in the description for **FUNCTION** *function-name*.

ACTIVE VERSION

Specifies that the comment applies to the currently active version of the routine that is specified by *function-name*.

ACTIVE VERSION is the default.

VERSION *routine-version-id*

Specifies that the comment applies only to the version of the routine that is identified by *routine-version-id*. *routine-version-id* must identify a version of the specified routine that already exists at the current server.

INDEX *index-name*

Identifies the index to which the comment applies. *index-name* must identify an

index that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSINDEXES catalog table for the row that describes the index.

MASK *mask-name*

Identifies the column mask to which the comment applies. *mask-name* must identify a column mask that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTROLS catalog table for the row that describes the column mask.

PACKAGE *collection-id.package-name*

Identifies the package to which the comment applies. You must qualify the package name with a collection ID. *collection-id.package-name* must identify a package that exists at the current server. The name plus the implicitly or explicitly specified *version-id* must identify a package that exists at the current server. Omission of the *version-id* is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. Specify this clause to comment on a package that was created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

VERSION *version-id*

version-id is the version identifier that was assigned to the package's DBRM when the DBRM was created. If *version-id* is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in *DB2 Application Programming and SQL Guide*.

PERMISSION *permission-name*

Identifies the row permission to which the comment applies. *permission-name* must identify a row permission that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTROLS catalog table for the row that describes the row permission.

PLAN *plan-name*

Identifies the plan to which the comment applies. *plan-name* must identify a plan that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure to which the comment applies. *procedure-name* must identify a procedure that exists at the current server.

ACTIVE VERSION

Specifies that the comment applies to the currently active version of the routine that is specified by *procedure-name*.

ACTIVE VERSION is the default.

VERSION *routine-version-id*

Specifies that the comment applies only to the version of the routine that is identified by *routine-version-id*. *routine-version-id* must identify a version of the specified routine that already exists at the current server.

ROLE *role-name*

Identifies the role to which the comment applies. *role-name* must identify a role that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSROLES catalog table for the row that describes the role.

SEQUENCE *sequence-name*

Identifies the sequence to which the comment applies.

sequence-name must identify a sequence that exists at the current server. *sequence-name* must not be the name of an internal sequence object that is used by DB2. The comment is placed in the REMARKS column of the SYSIBM.SYSSEQUENCES catalog table for the row that describes the sequence.

TABLE *table-name or view-name*

Identifies the table or view to which the comment applies. *table-name* or *view-name* must identify a table, auxiliary table, or view that exists at the current server. *table-name* must not identify a declared temporary table. The comment is placed in the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

TRIGGER *trigger-name*

Identifies the trigger to which the comment applies. *trigger-name* must identify a trigger that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSTRIGGERS catalog table for the row that describes the trigger.

TRUSTED CONTEXT *context-name*

Identifies the trusted context to which the comment applies. *context-name* must identify a trusted context that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTEXT catalog table for the row that describes the trusted context.

TYPE *distinct-type-name*

Identifies the distinct type to which the comment applies. *distinct-type-name* must identify a distinct type that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSDATATYPES catalog table for the row that describes the distinct type.

IS *string-constant*

Introduces the comment that you want to make. *string-constant* can be any SQL character string constant of up to 762 bytes.

multiple-column-list

To comment on more than one column in a table or view with a single COMMENT statement, specify the table or view name, followed by a list in parentheses of the form:

```
(column-name IS string-constant,
  column-name IS string-constant,
  ...)
```

Each column name must not be qualified, and must identify a column of the specified table or view that exists at the current server.

Notes**Alternative syntax and synonyms:**

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following syntax alternatives:

- DATA TYPE or DISTINCT TYPE as a synonym for TYPE

Examples

Example 1: Enter a comment on table DSN8A10.EMP.

```
COMMENT ON TABLE DSN8A10.EMP
  IS 'REFLECTS 1ST QTR 81 REORG';
```

Example 2: Enter a comment on view DSN8A10.VDEPT.

```
COMMENT ON TABLE DSN8A10.VDEPT
  IS 'VIEW OF TABLE DSN8A10.DEPT';
```

Example 3: Enter a comment on the DEPTNO column of table DSN8A10.DEPT.

```
COMMENT ON COLUMN DSN8A10.DEPT.DEPTNO
  IS 'DEPARTMENT ID - UNIQUE';
```

Example 4: Enter comments on the two columns in table DSN8A10.DEPT.

```
COMMENT ON DSN8A10.DEPT
  (MGRNO IS 'EMPLOYEE NUMBER OF DEPARTMENT MANAGER',
   ADMRDEPT IS 'DEPARTMENT NUMBER OF ADMINISTERING DEPARTMENT');
```

Example 5: Assume that you are SMITH and that you created the distinct type DOCUMENT in schema SMITH. Enter comments on DOCUMENT.

```
COMMENT ON TYPE DOCUMENT
  IS 'CONTAINS DATE, TABLE OF CONTENTS, BODY, INDEX, and GLOSSARY';
```

Example 6: Assume that you are SMITH and you know that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Enter comments on ATOMIC_WEIGHT.

```
COMMENT ON FUNCTION CHEM.ATOMIC_WEIGHT
  IS 'TAKES ATOMIC NUMBER AND GIVES ATOMIC WEIGHT';
```

Example 7: Assume that you are SMITH and that you created the function CENTER in schema SMITH. Enter comments on CENTER, using the signature to uniquely identify the function instance.

```
COMMENT ON FUNCTION CENTER (INTEGER, FLOAT)
  IS 'USES THE CHEBYCHEV METHOD';
```

Example 8: Assume that you are SMITH and that you created another function named CENTER in schema JOHNSON. You gave the function the specific name FOCUS97. Enter comments on CENTER, using the specific name to identify the function instance.

```
COMMENT ON SPECIFIC FUNCTION JOHNSON.FOCUS97
  IS 'USES THE SQUARING TECHNIQUE';
```

Example 9: Assume that you are SMITH and that procedure OSMOSIS is in schema BIOLOGY. Enter comments on OSMOSIS. Your comments will apply to the currently active version of the procedure OSMOSIS.

```
COMMENT ON PROCEDURE BIOLOGY.OSMOSIS
  IS 'CALCULATIONS THAT MODEL OSMOSIS';
```

Example 11: Assume that you are SMITH and that trigger BONUS is in your schema. Enter comments on BONUS.

```
COMMENT ON TRIGGER BONUS
  IS 'LIMITS BONUSES TO 10% OF SALARY';
```

Example 12: Provide a comment for package MYPKG, which is in collection COLLIDA.

```
COMMENT ON COLLIDA.MYPKG
  IS 'THIS IS MY PACKAGE';
```

Example 14: Provide a comment on role ROLE1:

```
COMMENT ON ROLE ROLE1
  IS 'Role defined for trusted context, ctx1';
```

Example 15: Provide a comment on trusted context CTX1:

```
COMMENT ON TRUSTED CONTEXT CTX1
  IS 'WEBSPHERE SERVER';
```

Example 15: Provide a comment on column mask M1:

```
COMMENT ON MASK M1
  IS 'Column mask for column EMP.SALARY';
```

|
|

COMMIT

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It cannot be used in the IMS or CICS environment.

Authorization

None required.

Syntax

Description

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work. For more information see Chapter 7, “Statements,” on page 1145.

Notes

Recommended coding practices: Code an explicit COMMIT or ROLLBACK statement at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK statement before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

Effect of COMMIT: All savepoints that are set within the unit of recovery are released, and all changes are committed for the following statements that are executed during the unit of recovery:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL

- MERGE
- RENAME
- REVOKE
- UPDATE
- SELECT INTO with an SQL data change statement
- subselect with an SQL data change statement

SQL connections are ended when any of the following conditions apply:

- The connection is in the release pending status
- The connection is not in the release pending status but it is a remote connection and:
 - The DISCONNECT(AUTOMATIC) bind option is in effect, or
 - The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection.

For existing connections, all LOB locators are disassociated, except for those locators for which a HOLD LOCATOR statement has been issued without a corresponding FREE LOCATOR statement. All open cursors that were declared without the WITH HOLD option are closed. All open cursors that were declared with the WITH HOLD option are preserved, along with any SELECT statements that were prepared for those cursors. All other prepared statements are destroyed unless dynamic caching is enabled for your system. In that case, all prepared SELECT and data change statements that are bound with KEEP DYNAMIC(YES) are kept past the commit.

Prepared statements cannot be kept past a commit if any of the following conditions is true:

- SQL RELEASE has been issued for that site.
- Bind option DISCONNECT(AUTOMATIC) was used.
- Bind option DISCONNECT(CONDITIONAL) was used and there are no open WITH HOLD cursors for that site.

All implicitly acquired locks are released, except for the following locks:

- Locks that are required for the cursors that were not closed
- Table and table space locks when the RELEASE parameter on the bind command was not RELEASE(COMMIT)
- LOB locks and LOB table space locks that are required for held LOB locators

For an explanation of the duration of explicitly acquired locks, see *DB2 Performance Monitoring and Tuning Guide*.

All rows of every created temporary table of the application process are deleted with the exception that the rows of a created temporary table are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table. In addition, if RELEASE(COMMIT) is in effect, the logical work files for the created temporary tables whose rows are deleted are also deleted.

All rows of every declared temporary table of the application process are deleted with these exceptions:

- The rows of a declared temporary table that is defined with the ON COMMIT PRESERVE ROWS attribute are not deleted.

- The rows of a declared temporary table that is defined with the ON COMMIT DELETE ROWS attribute are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table.

Implicit commit operations: In all DB2 environments, the normal termination of a process is an implicit commit operation.

Restrictions on the use of COMMIT: The COMMIT statement cannot be used in the IMS or CICS environment. To cause a commit operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these commit operations on DB2 data is the same as that of the SQL COMMIT statement.

The COMMIT statement cannot be used in a stored procedure if the procedure is in the calling chain of a user-defined function or a trigger or DB2 is not the commit coordinator.

Effect of commit on special registers: Issuing a COMMIT statement may cause special registers to be re-initialized. Whether one of these special registers is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see "CURRENT PATH" on page 181.

Example

Commit all DB2 database changes made since the unit of recovery was started.

```
COMMIT WORK;
```

CONNECT

The CONNECT statement connects an application process to a database server. This server becomes the *current server* for the process. The CONNECT statement of DB2 for z/OS is equivalent to CONNECT (Type 2) in IBM DB2 SQL Reference for Cross-Platform Development.

Refer to “Distributed data” on page 38 for complete information about connections, the current server, commit processing, and distributed and remote units of work.

Invocation

This statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The primary authorization ID of the process or the authorization ID that is specified in this statement must be authorized to connect to the specified server. The server performs the authorization check when the statement is executed, and determines the specific authorization that is required. See *DB2 Administration Guide* for further information.

Syntax

authorization:

Description

TO *location-name* or *host-variable*

Identifies the server by the specified location name or by the location name that is contained in the host variable. If a host variable is specified:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes long.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

- It must not contain lowercase characters.
- If used with an SQL procedure language application, host variable must be a qualified SQL-variable name or a qualified SQL-parameter name.

When the CONNECT statement is executed:

- The location name must identify a server known to the local DB2 subsystem. Hence, the location name must be the location name of the local DB2 subsystem or it must appear in the LOCATION column of the SYSIBM.LOCATIONS table.
- The application process must not have an existing connection to the specified server, if the SQLRULES(STD) bind option is in effect.
- The application process must be in a connectable state, if the transaction is participating in a remote unit of work.

RESET

CONNECT RESET is equivalent to CONNECT TO *x* where *x* is the location name of the local DB2 subsystem.

- If the SQLRULES(DB2) bind option is in effect, CONNECT RESET establishes the local DB2 subsystem as the current SQL connection.
- If the SQLRULES(STD) bind option is in effect, CONNECT RESET establishes the local DB2 subsystem as the current SQL connection only if the connection does not exist.

authorization

Specifies an authorization ID and a password that is used to verify that the authorization ID is authorized to connect to the server. Authorization cannot be specified when the connection type is IMS or CICS for a connection to the local DB2 subsystem. An attempt to do so causes an SQL error.

USER *host-variable*

Identifies the authorization name to use when connecting to the server. The value of *host-variable* must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified within the host variable and must conform to the rules for forming an authorization name.
- The value must not be followed by an indicator variable.
- The value must be padded on the right with blanks if the length of the authorization name is less than the length of the host variable.

For a connection to the local DB2 subsystem, a user ID that is longer than 8 characters causes an SQL error.

USING *host-variable*

Identifies the password of the authorization name to use when connecting to the server. The value of *host-variable* must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified.
- The value must not include an indicator variable.
- The value must be padded on the right with blanks if the length of the password is less than the length of the host variable.
- The value must not contain lowercase characters.

For a connection to a DB2 subsystem, a password that is longer than 8 characters causes an SQL error.

CONNECT USER/USING is equivalent to CONNECT TO *x* USER/USING where *x* is the location name of the local DB2 subsystem (which has the semantic of CONNECT RESET).

CONNECT with no operand

This form of the CONNECT statement returns information about the current server in the SQLERRP field of the SQLCA. SQLERRP returns blanks if the application process is in the unconnected state.

Executing a CONNECT with no operand has no effect on connection states.

In a remote unit of work, this form of CONNECT does not require the application process to be in a connectable state.

Notes

Successful connection: With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is successful:

- One of the following scenarios takes place in a **distributed unit of work**:
 - If the location name does not identify a server to which the application process is already connected, an SQL connection to the server is created and placed in the current and held state. The previously current SQL connection, if any, is placed in the dormant state.
 - If the location name identifies a server to which the application process is already connected, the associated SQL connection is dormant, and the SQLRULES(DB2) option is in effect, the SQL connection is placed in the current state. The previously current SQL connection, if any, is placed in the dormant state.
 - If the location name identifies a server to which the application process is already connected, the associated SQL connection is current, and the SQLRULES(DB2) option is in effect, the states of all SQL connections of the application process are unchanged.
- The following actions occur in a **remote unit of work**:
 - The application process is connected to the specified server.
 - An existing SQL connection of the application process is ended. As a result, all cursors of that SQL connection are closed, all prepared statements of that connection are destroyed, and so on.
- The location name is placed in the CURRENT SERVER special register.
- When CONNECT is used to connect back to the local DB2 subsystem, the CURRENT SQLID special register is reinitialized if the USER/USING clause is specified.
- Information about the server is placed in the SQLERRP field of the SQLCA. If the server is a DB2 product, the information has the form *pppvrrm*.

The format of product identifier values is *pppvrrm*, where *ppp* is a 3-letter product code (such as DSN for DB2), *vv* is the version, *rr* is the release, and *m* is the modification level. For example, DSN10015 identifies DB2 10 in new-function mode, the value is 'DSN10015'. The product code (*ppp*) is one of the following values:

AQT for IBM DB2 Analytics Accelerator for z/OS

ARI for DB2 Server for VSE & VM

DSN for DB2 for z/OS

JCC for IBM Data Server Driver for JDBC and SQLJ

QSQ for DB2 for i

SQL for DB2 for Linux, UNIX, and Windows

Modification (*m*) values have the following meanings:

- Values '0' and '1' identify modification levels in conversion and enabling-new-function mode from Version 8 (CM8, CM8*, ENFM8, and ENFM8*)
 - Values '2' and '3' identify modification levels in conversion and enabling-new-function mode from Version 9 (CM9, CM9*, ENFM9, and ENFM9*)
 - Value 4 is reserved.
 - Values '5', '6', '7', '8', and '9' identify modification levels in new-function mode.
- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. The contents are product-specific.

Tip: Use the GET DIAGNOSTICS statement to get detailed diagnostic information about the last SQL statement that was executed.

Unsuccessful connection: With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is unsuccessful:

- In a **distributed unit of work**, the connection state of the application process and the states of its SQL connections are unchanged unless the failure was because an authorization check failed. If this is the case, the connection is placed in the connectable and unconnected state.
- In a **remote unit of work**, the SQLERRP field of the SQLCA is set to the name of the DB2 requester module that detected the error.

If execution of the CONNECT statement is unsuccessful because the application process is not in the connectable state, the connection state of the application process is unchanged. If execution of the CONNECT statement is unsuccessful for any other reason, CURRENT SERVER is set to blanks and the application process is placed in the connectable and unconnected state.

Authorization: If the server is a DB2 subsystem, a user is authenticated in the following way:

- DB2 invokes RACF via the RACROUTE macro with REQUEST=VERIFY to verify the password.
- If the password is verified, DB2 then invokes RACF again via the RACROUTE macro with REQUEST=AUTH, to check whether the authorization ID is allowed to use DB2 resources defined to RACF.
- DB2 then invokes the connection exit routine if one has been defined.
- The connection then has a primary authorization ID, possibly one or more secondary IDs, and an SQL ID.

If the server is a remote DB2 subsystem, the requester generates authentication tokens and sends them to the remote site in the following way:

- The SECURITY_OUT column in SYSIBM.LUNAMES for SNA or the SECURITY_OUT column in SYSIBM.IPNAMES for TCP/IP must have one of the following values:
 - 'A' (already verified)
 - 'D' (userid and security-sensitive data encryption; TCP/IP only)
 - 'E' (userid, password, and security-sensitive data encryption; TCP/IP only)
 - 'P' (password)

When the value is 'A', the user ID and password specified on the CONNECT is still sent.

When the value is 'D', 'E', or 'P', the requester encrypts the user ID and password specified on the CONNECT for TCP/IP. However, if the Integrated Cryptographic Service Facility (ICSF) is not configured at the requester or if the server does not support encryption, one of the following actions occurs:

- If the value of SECURITY_OUT in SYSIBM.IPNAMES is 'D' or 'E', SQLCODE -904 is returned if ICSF is not configured at the requester, and SQLCODE -30082 is returned if the server does not support encryption.
- If the value of SECURITY_OUT in SYSIBM.IPNAMES is 'P', the requester does not encrypt the user ID and password and flows the tokens in clear text.
- For SNA, the ENCRYPTPSWDS column in SYSIBM.SYSLUNAMES must be not contain 'Y'.
- The authorization ID and password are verified at the server.
- In all cases, outbound translation—as specified in SYSIBM.USERNAMES—is not done.

Distributed unit of work: In general, the following are true:

- A CONNECT statement with the TO clause and the USER/USING clause can be executed only if no current or dormant connection to the named server exists. However, if the named server is the local DB2 subsystem and the CONNECT statement is the first SQL statement that is executed after the DB2 thread is created, the CONNECT statement executes successfully.
- A CONNECT statement without the TO clause but with the USER/USING clause can be executed only if no current or dormant connection to the local DB2 subsystem exists. However, if the CONNECT statement is the first SQL statement that is executed after the DB2 thread is created, the CONNECT statement executes successfully.

Remote unit of work: If the authorization check fails, the connection is placed in the connectable and unconnected state.

Precompiler options: Regardless of whether a program is precompiled with the CONNECT(1) or CONNECT(2) option, DB2 for z/OS negotiates with the remote server during the connection process to determine how to perform commits. If the remote server does not support the two-phase commit protocol, DB2 downgrades to perform one-phase commits.

Programs containing CONNECT statements that are precompiled with different CONNECT precompiler options cannot execute as part of the same application process. An error occurs when an attempt is made to execute the invalid CONNECT statement.

Host variables: If a CONNECT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Error processing: A CONNECT statement can return and indicate a successful execution even when no physical connection yet exists. DB2 delays the physical connection process, when possible, to economize on the number of messages it sends to a server. Therefore, errors in CONNECT statement processing can be reported following the next executable SQL statement, not immediately following the CONNECT statement.

Examples

Example 1: Connect an application to a DBMS. The location name is in the character-string variable *LOCNAME*, the authorization identifier is in the character-string variable *AUTHID*, and the password is in the character-string variable *PASSWORD*.

```
EXEC SQL CONNECT TO :LOCNAME USER :AUTHID USING :PASSWORD;
```

Example 2: Obtain information about the current server.

```
EXEC SQL CONNECT;
```

Example 3: Execute SQL statements in a distributed unit of work. The first *CONNECT* statement creates a connection to the *EASTDB* server. The second *CONNECT* statement creates a connection to the *WESTDB* server, and places the SQL connection to *EASTDB* in the dormant state.

```
EXEC SQL CONNECT TO EASTDB;  
-- execute statements referencing objects at EASTDB  
EXEC SQL CONNECT TO WESTDB;  
-- execute statements referencing objects at WESTDB
```

Example 4: Connect the application to a DBMS whose location identifier is in the character-string variable *LOC* using the authorization identifier in the character-string variable *AUTHID* and the password in the character-string variable *PASSWORD*. Perform work for the user, and then release the connection and connect again using a different user ID and password.

```
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;  
-- execute SQL statements accessing data on the server  
RELEASE :LOC;  
EXEC SQL COMMIT;  
-- set AUTHID and PASSWORD to new values  
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;  
-- execute SQL statements accessing data on the server
```

Example 5: Change servers in a remote unit of work. Assume that the application connected to a remote DB2 server, opened a cursor, and fetched rows from the cursor's result table. Subsequently, to connect to the local DB2 subsystem, the application executes the following statements:

```
EXEC SQL COMMIT WORK;  
EXEC SQL CONNECT RESET;
```

The *COMMIT* is required because opening the cursor caused the application to enter the unconnectable and connected state.

If the cursor was declared with the *WITH HOLD* clause and was not closed with a *CLOSE* statement, it would still be open even after execution of the *COMMIT* statement. However, it would be closed with the execution of the *CONNECT* statement.

(Managing Security)

CREATE ALIAS

The CREATE ALIAS statement defines an alias for a table or view. The definition is recorded in the DB2 catalog at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

To create an alias, the privilege set must include at least one of the listed authorities or privileges:

- The CREATEALIAS privilege
- SYSADM or SYSCTRL authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner of the plan or package is a role, this role must hold the privileges for the privilege set. If the specified alias name includes a qualifier that is not the same as this authorization ID, the privilege set must include one of the following authorities:

- SYSADM or SYSCTRL authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. If the process is not running in a trusted context that is defined with the ROLE AS OBJECT OWNER clause and the specified alias name includes a qualifier that is not the same as this authorization ID:

- The privilege set must include SYSADM or SYSCTRL authority.

- The privilege set must include DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES.
- The qualifier must be the same as one of the authorization IDs of the process and the privileges that are held by that authorization ID must include the CREATEALIAS privilege. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

Syntax

Description

alias-name

Names the alias.

The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

When an application uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names.

FOR *table-name* or *view-name*

Identifies the table or view for which the alias is defined. If a table is identified, it must not be an auxiliary table, a declared temporary table, or a table that is implicitly created for an XML column. The table or view need not exist at the time the alias is defined. If it does exist, it can be at the current server or at another server. The name must not be the same as the alias name and must not identify an alias that exists at the current server.

An alias can be defined for a table, view, or alias that is not at the current server. When so defined, the existence of the referenced object is not verified at the time the alias is created. But the object must exist when a statement that contains the alias is executed. And if that object is also an alias, it must refer to a table or view at the server where that alias is defined.

A warning occurs if an alias is defined for a table or view that is local to the current server but does not exist.

Notes

Owner privileges:

There are no specific privileges on an alias. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 70.

Example

Example 1: Create an alias for a catalog table at a DB2 with location name DB2USCALABOA5281.

```
CREATE ALIAS LATABLES FOR DB2USCALABOA5281.SYSIBM.SYSTABLES;
```

CREATE AUXILIARY TABLE

The CREATE AUXILIARY TABLE statement creates an auxiliary table at the current server for storing LOB data.

Invocation

This statement can be embedded in an application program or issued interactively if the value of special register CURRENT RULES is 'DB2' and the table space is explicitly created when the statement is executed. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Do not use this statement if the value of special register CURRENT RULES is 'STD' or if the table space is implicitly created. When the values of the CURRENT RULES special register is 'STD' and a base table is created with LOB columns or altered such that LOB columns are added, DB2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column. DB2 also automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column if the table space is implicitly created. DB2 chooses the names and characteristics of these objects. For more information about the names and the characteristics, see Creating a table with LOB columns.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database implicitly or explicitly specified by the IN clause
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specifies, a role is the owner. Otherwise, an authorization ID is the owner. If the specified table name includes a qualifier that is not the same as this authorization ID, the privilege set must include SYSADM or SYSCTRL authority, DBADM authority for the database, or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case,

the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. If the process is in a trusted context, any authorization ID can be the qualifier. However, if the process is not in a trusted context and if the specified table name includes a qualifier that is not the same as the SQL authorization ID of the process, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
- If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all²⁷ privileges needed to create the table.

Syntax

Description

AUXILIARY or AUX

Specifies a table that is used to store the LOB data for a LOB column (or a column with a distinct type that is based on a LOB data type).

aux-table-name

Names the auxiliary table. The name, including the implicit or explicit qualifiers, must not identify a table, view, alias, or synonym that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

IN *database-name.table-space-name* or **IN** *table-space-name*

Identifies the table space in which the auxiliary table is created. The name must identify an empty LOB table space that currently exists at the current server. The LOB table space must be in the same database as the associated base table.

If you specify a database and a table space, the table space must belong to the specified database. If you specify only a table space, it must belong to the database that contains the specified table space. If you specify only a table space, this table space must belong to DSNDB04. This type of table space is only created when SET CURRENT RULES='DB2' is specified.

STORES *table-name* **COLUMN** *column-name*

Identifies the base table and the column of that table that is to be stored in the auxiliary table. If the base table is nonpartitioned, an auxiliary table must not

27. Exception: The CREATETAB privilege is checked on the SQL authorization ID of the process.

already exist for the specified column. If the base table is partitioned, an auxiliary table must not already exist for the specified column and specified partition.

The encoding scheme for the LOB data stored in the auxiliary table is the same as the encoding scheme for the base table. It is either ASCII, EBCDIC, or UNICODE depending on the value of the CCSID clause when the base table was created.

APPEND NO or APPEND YES

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a range-partitioned table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition-by-growth table space, the APPEND attributes of LOB table will be inherited by each partition.

APPEND NO

Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key columns.

APPEND NO is the default

APPEND YES

Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.

PART *integer*

Specifies the partition of the base table for which the auxiliary table is to store the specified column. You can specify PART only if the base table is defined in a partitioned table space, and no other auxiliary table exists for the same LOB column of the base table.

Notes

Owner privileges: There are no specific privileges on an auxiliary table. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 70.

Determining the number of auxiliary tables to create: If the base table is nonpartitioned, you might need to create one LOB table space and one auxiliary table for each LOB column in the base table. If the base table is partitioned, for each LOB column, you might need to create one LOB table space and one auxiliary table for each partition. For example if your base table has three partitions and two LOB columns, you might need to create three LOB table spaces and three auxiliary tables for each LOB column. In other words, you might need a total of six LOB table spaces and six auxiliary tables.

Auxiliary tables in LOB table spaces that are logged: When you create an auxiliary table in a LOB table space that is LOGGED, and the associated base table space is NOT LOGGED, the logging attribute of the LOB table space is implicitly changed to NOT LOGGED and the logging attributes of the base table space and the LOB table space are linked.

Append processing and unused free space in a table: An update or delete of LOB data creates some free space in the LOB table that can be used by the next insert. If

the table uses append processing, any free space that is not at the end of the table space will not be reused during the insert operation. Any unused free space in the table can be reclaimed by running the REORG utility with either the SHRELEVEL REFERENCE or SHRLEVEL CHANGE keywords. The REORG utility is not influenced by the APPEND option.

Example

Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to sample employee table DSN8A10.EMP for each employee's photo. Create auxiliary table EMP_PHOTO_ATAB to store the BLOB data for the BLOB column in LOB table space DSN8D10A.PHOTOLTS.

```
CREATE AUX TABLE EMP_PHOTO_ATAB
  IN DSN8D10A.PHOTOLTS
  STORES DSN8A10.EMP
  COLUMN EMP_PHOTO;
```

CREATE DATABASE

The CREATE DATABASE statement defines a DB2 database at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEDBA privilege
- The CREATEDBC privilege
- SYSADM or SYSCTRL authority
- System DBADM

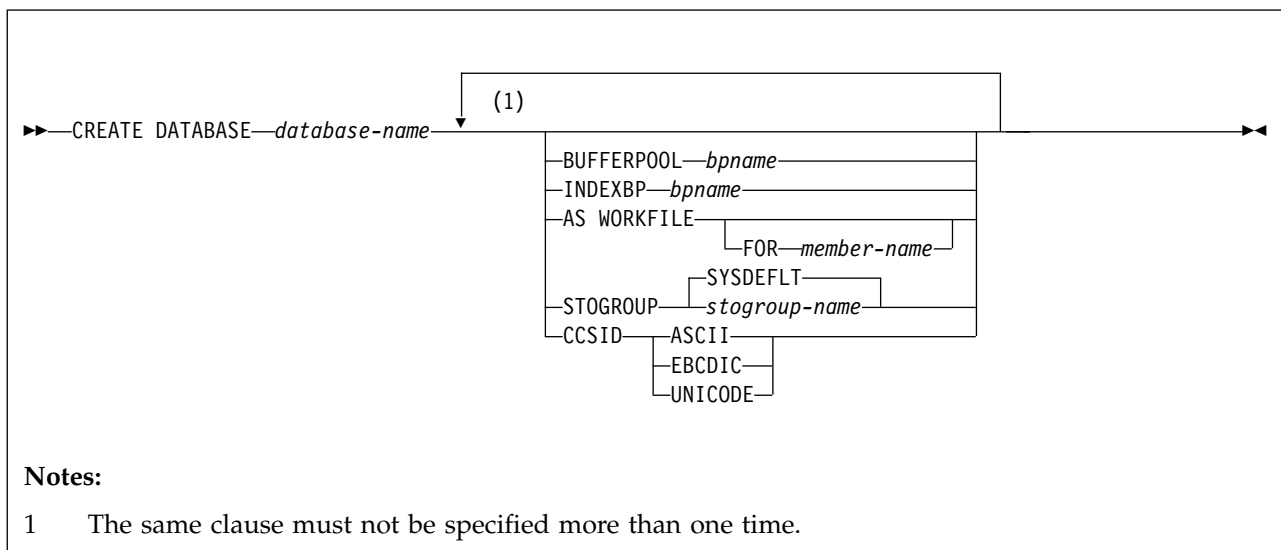

If the database is created as a workfile database, the privilege set that is defined below must include SYSADM authority.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process.

See "Notes" on page 1475 for the authorization effect of a successful CREATE DATABASE statement.

Syntax

Description

database-name

Names the database. The name must not start with DSNDB and must not identify a database that exists at the current server. *database-name* must not be in the form of eight characters that start with DSN followed by exactly five digits. If the database is to be a work file database in a data sharing environment, DSNDB07 is an acceptable work file database name. However, only one member of a data sharing group can use DSNDB07 as the name of its work file database.

BUFFERPOOL *bpname*

Specifies the default buffer pool name to be used for table spaces created within the database. If the database is a work file database, 8KB and 16KB buffer pools cannot be specified. See "Naming conventions" on page 59 for more details about *bpname*.

If you omit the BUFFERPOOL clause, the default 4-KB buffer pool for user data that is specified on installation panel DSNTIP1 is used.

INDEXBP *bpname*

Specifies the default buffer pool name to be used for the indexes created within the database. The name can identify a 4KB, 8KB, 16KB, or 32KB buffer pool. See "Naming conventions" on page 59 for more details about *bpname*.

If you omit the INDEXBP clause, the buffer pool specified for user indexes on installation panel DSNTIP1 is used. The default value for the user indexes field on that panel is BP0.

AS WORKFILE

Specifies the database is a work file database. AS WORKFILE can be specified only in a data sharing environment. Only one work file database can be created for each DB2 subsystem. The work file database is used for work files, created global temporary table, declared temporary tables, and sensitive static scrollable cursors.

PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority) to define a declared temporary table in the work file database. This implicit privilege is not recorded in the DB2 catalog and cannot be revoked.

The CCSID clause is not supported for a work file database. If you specify AS WORKFILE, do not use the CCSID clause.

FOR *member-name*

Specifies the member for which this database is to be created. Specify FOR *member-name* only in a data sharing environment.

If FOR *member-name* is not specified, the member is the DB2 subsystem on which the CREATE DATABASE statement is executed.

STOGROUP *stogroup-name*

Specifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. The default is SYSDEFLT.

CCSID *encoding-scheme*

Specifies the default encoding scheme for data stored in the database. The default applies to table spaces created in the database. All tables stored within a table space must use the same encoding scheme.

ASCII Specifies that the data must be encoded using the ASCII CCSIDs of the server.

EBCDIC

Specifies that the data must be encoded using the EBCDIC CCSIDs of the server.

UNICODE

Specifies that the data must be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

The option defaults to the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Do not use the CCSID clause if you specify the AS WORKFILE clause.

Notes

If the statement is embedded in an application program, the owner of the plan or package is the owner of the database. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the database.

If the owner of the database has the CREATEDBA, SYSADM, or SYSCTRL authority, the owner acquires DBADM authority for the database. DBADM authority for a database includes table privileges on all tables in that database. Thus, if a user with SYSCTRL authority creates a database, that user has table privileges on all tables in that database. This is an exception to the rule that SYSCTRL authority does not include table privileges.

If the owner of the database has the CREATEDBC privilege, but not the CREATEDBA privilege, the owner acquires DBCTRL authority for the database. In this case, no authorization ID has DBADM authority for the database until it is granted by an authorization ID with SYSADM authority.

Examples

Example 1: Create database DSN8D10P. Specify DSN8G100 as the default storage group to be used for the table spaces and indexes in the database. Specify 8KB buffer pool BP8K1 as the default buffer pool to be used for table spaces in the database, and BP2 as the default buffer pool to be used for indexes in the database.

```
CREATE DATABASE DSN8D10P
  STOGROUP DSN8G100
  BUFFERPOOL BP8K1
  INDEXBP BP2;
```

Example 2: Create database DSN8TEMP. Use the defaults for the default storage group and default buffer pool names. Specify ASCII as the default encoding scheme for data stored in the database.

```
CREATE DATABASE DSN8TEMP
  CCSID ASCII;
```

CREATE FUNCTION

The CREATE FUNCTION statement registers a user-defined function with a database server. Each type of function that you can register with this statement is described separately.

External scalar

The function is written in a programming language and returns a scalar value. The external executable routine is registered with a database server along with various attributes of the function. See “CREATE FUNCTION (external scalar)” on page 1501.

External table

The function is written in a programming language. It returns a table to the subselect from which it was started by returning one row at a time, each time that the function is started. The external executable routine is registered with a database server along with various attributes of the function. See “CREATE FUNCTION (external table)” on page 1526.

Sourced

The function is implemented by starting another function (either built-in, external, SQL, or sourced) that exists at the server. The function inherits the attributes of the underlying source function. See “CREATE FUNCTION (sourced)” on page 1555.

SQL scalar

The function is written exclusively in SQL statements and returns a scalar value. The body of an SQL scalar function is written in the SQL procedural language. The function is defined at the current server along with various attributes of the function.

See “CREATE FUNCTION (compiled SQL scalar)” on page 1477 and “CREATE FUNCTION (inlined SQL scalar)” on page 1544.

SQL table

The function is written exclusively as an SQL RETURN statement and returns a set of rows. The body of an SQL table function is written in the SQL procedural language. The function is defined at the current server along with various attributes of the function. See “CREATE FUNCTION (SQL table)” on page 1569.

Related concepts:

“User-defined functions” on page 219

“Sample user-defined functions” on page 2848

Related tasks:

 Defining a user-defined function (DB2 Application programming and SQL)

CREATE FUNCTION (compiled SQL scalar)

The CREATE FUNCTION (compiled SQL scalar) statement defines a compiled SQL scalar function at the current server and specifies the source statements for the function. The body of the function is written in the SQL procedural language. The function returns a single value each time it is invoked.

A package is created for a compiled SQL scalar function.

For compiled SQL scalar functions, you can define multiple versions of the function. Use CREATE FUNCTION (compiled SQL scalar) to define the initial version, and ALTER FUNCTION to define subsequent versions. For information about the SQL statements that are supported in SQL functions, refer to “SQL-procedure-statement” on page 2256.

Invocation

For a compiled SQL function, this statement can only be dynamically prepared but the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema and the required authorization to add a new package or a new version of an existing package, depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

If a distinct type is referenced (as the data type of a parameter or an SQL variable), the privilege set must also include at least one of the following:

- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:

- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified

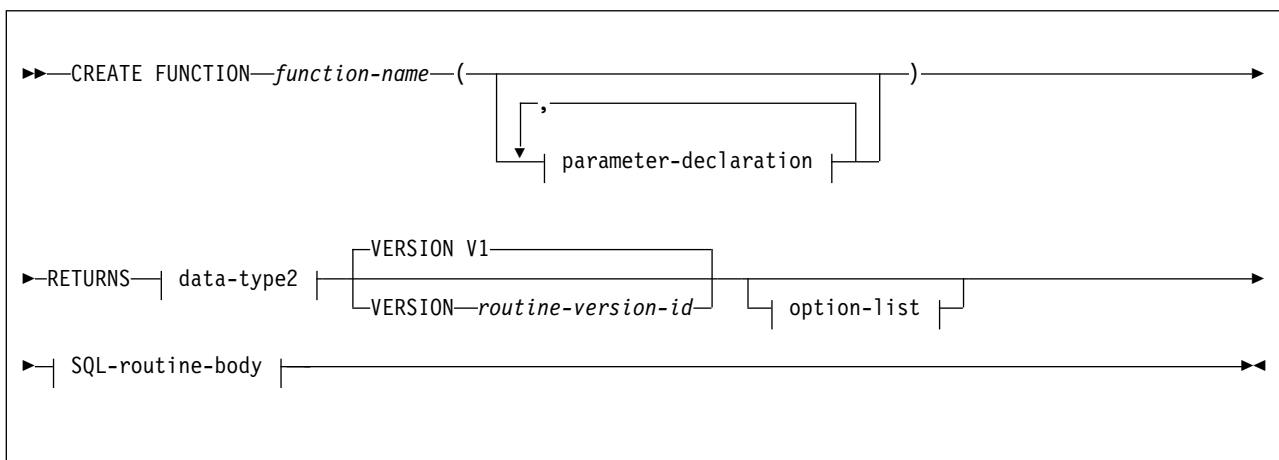

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

parameter-declaration:

parameter-type:

data-type:

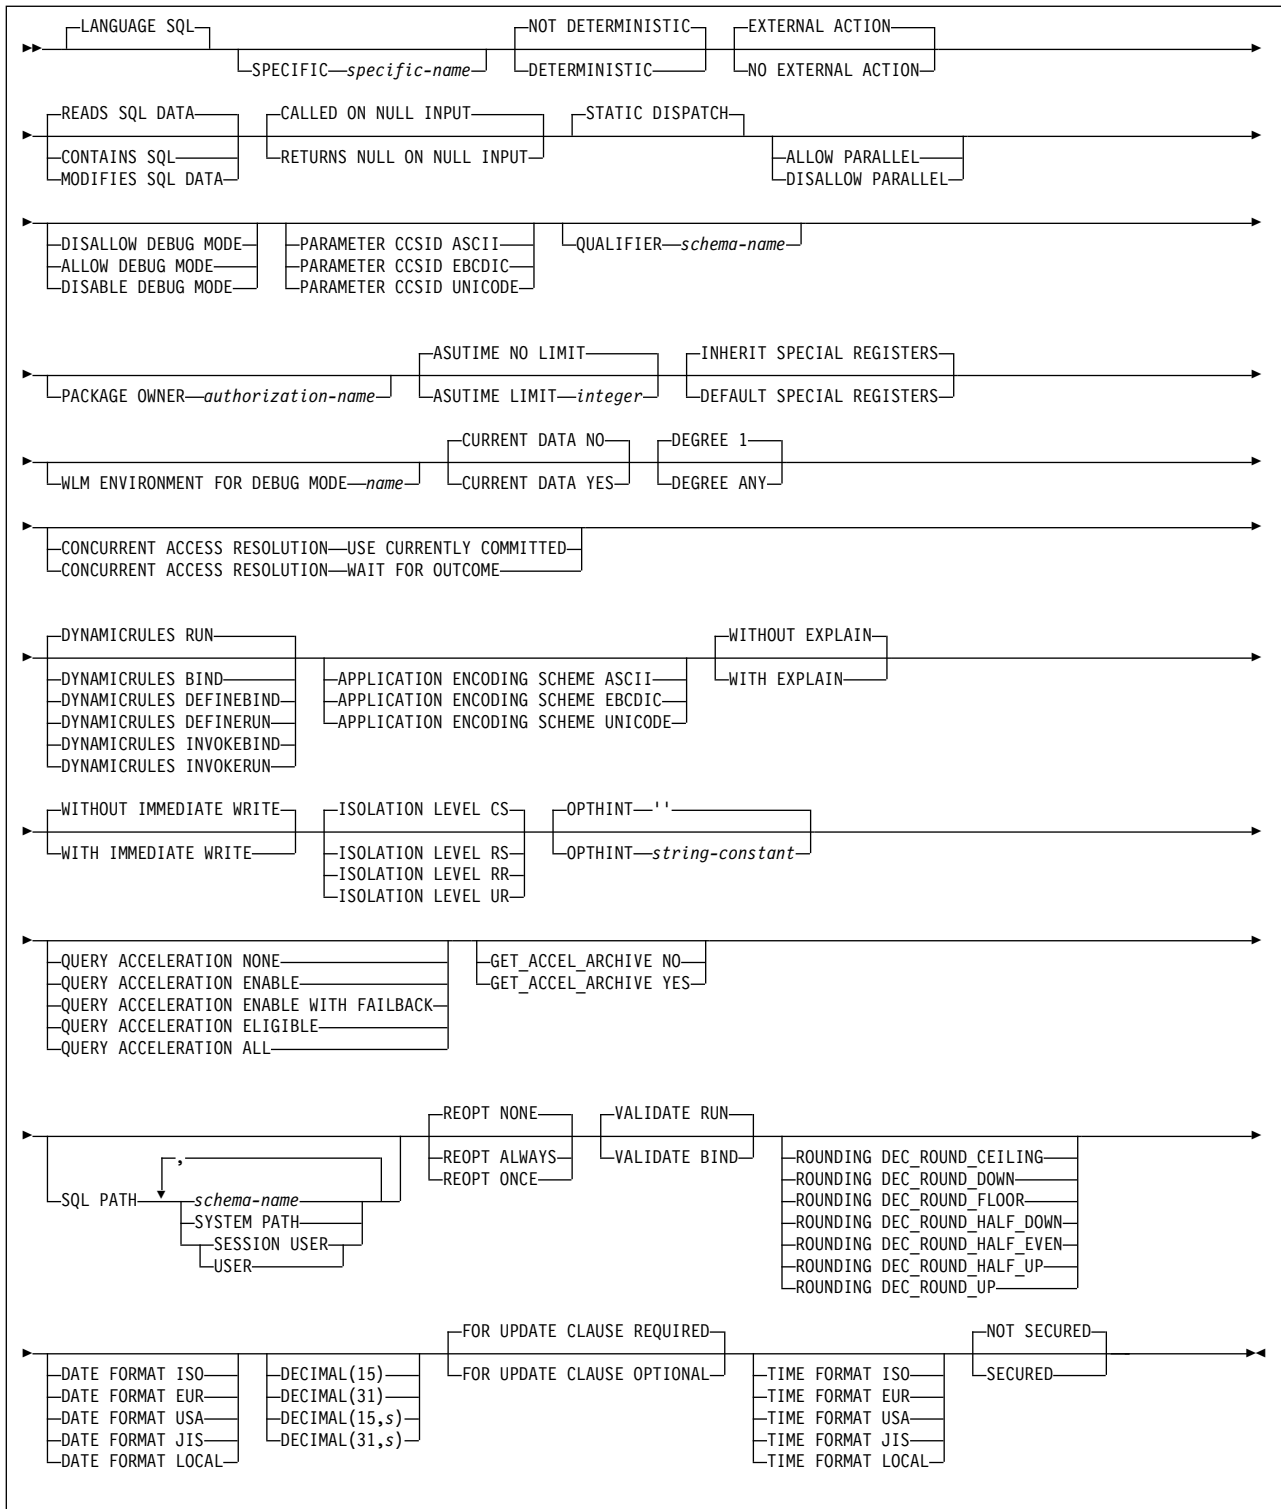

built-in-type:

SQL-routine-body:

▶—SQL-control-statement—▶

option-list: (The options in the *option-list* can be specified in any order, but each one can only be specified one time)

Description

function-name

Names the function. If *function-name* already exists with the specified signature,

| an error is returned even if VERSION is specified with a *routine-version-id* that
| is different from any existing version identifier for the function that is specified
| in *function-name*.²⁸

(*parameter-declaration*,...)

| Specifies the number of input parameters of the function and the name and
| data type of each parameter. Each *parameter-declaration* specifies an input
| parameter for the function. A function can have zero or more input parameters.
| There must be one entry in the list for each parameter that the function expects
| to receive. All of the parameters for a function are input parameters and are
| nullable. If the function has more than 30 parameters, only the first 30
| parameters are used to determine if the function is unique.

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier,
and each name in the parameter list must not be the same as any other
name.

data-type

Specifies the data type of the input parameter. The data type can be a
built-in data type or a distinct type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the
PARAMETER CCSID clause or CCSID clause indicates the encoding
scheme of the parameter. If you do not specify either of these clauses,
the encoding scheme is the value of field DEF ENCODING SCHEME
on installation panel DSNTIPF.

distinct-type-name

| The data type of the input parameter is a distinct type. Any length,
| precision, scale, subtype, or encoding scheme attributes for the
| parameter are those of the source type of the distinct type. The distinct
| type must not be based on a LOB data type.

| If you specify the name of the distinct type without a schema name,
| DB2 resolves the distinct type by searching the schemas in the SQL
| path.

TABLE LIKE *table-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the
function is invoked, the actual values in the transition table are not
passed to the function. A single value is passed instead. This value is a
locator for the table, which the function uses to access the columns of
the transition table. The table that is identified can contain XML
columns; however, the function cannot reference those XML columns.

A function with a table parameter can only be invoked from the
triggered action of a trigger.

The implicitly or explicitly specified encoding scheme of all of the
parameters with a character or graphic string data type must be the
same—either all ASCII, all EBCDIC, or all UNICODE.

28. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

RETURNS

Identifies the output of the function.

data-type2

Specifies the data type of the output. The output is nullable.

The same considerations that apply to the data type of input parameter, as described under *data-type*, apply to the data type of the output of the function.

VERSION *routine-version-id*

Specifies the version identifier for the first version of the function that is to be generated. You can use an ALTER FUNCTION statement with the ADD VERSION clause or the BIND DEPLOY command to create additional versions of the function.

routine-version-id

An SQL identifier of up to 64 EBCDIC bytes that designates a version of a routine. The UTF-8 representation of the identifier must not exceed 122 bytes.

V1 is the default version identifier.

LANGUAGE SQL

Specifies that the function is written exclusively in SQL.

SPECIFIC *specific-name*

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the **SPECIFIC** clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

```
SQLXXXXXXXXXXXX
```

where 'XXXXXXXXXXXX' is a string of 12 characters that make the name unique.

The specific name is stored in the **SPECIFIC** column of the **SYSROUTINES** catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as **ALTER FUNCTION**, **COMMENT**, **DROP**, **GRANT**, and **REVOKE**) and must be used in DB2 commands (**START FUNCTION**, **STOP FUNCTION**, and **DISPLAY FUNCTION**). However, the function cannot be invoked by its specific name.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing **SELECT** and **SQL** data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. **NOT DETERMINISTIC** is the default.

DETERMINISTIC

The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for **SELECT** and **SQL** data change statements that refer to this function. **DETERMINISTIC** is not the default. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for **SQL** statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

Some **SQL** statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the **DISALLOW PARALLEL** clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from the function. For the data access classification of each statement, see Table 217 on page 2318.

MODIFIES SQL DATA

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

CALLED ON NULL INPUT or RETURNS NULL ON NULL INPUT

Specifies whether the function is invoked if any of the input arguments is null at execution time.

CALLED ON NULL INPUT

Specifies that the function is to be invoked if any, or if all, of the argument

values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

CALLED ON NULL INPUT is the default.

RETURNS NULL ON NULL INPUT

Specifies that the function is not invoked and returns the null value if any of the input argument values is null.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. **STATIC DISPATCH** is the default.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies if the function can be run in parallel. The default is DISALLOW PARALLEL, if you specify one or more of the following clauses:

- NOT DETERMINISTIC
- EXTERNAL ACTION
- MODIFIES SQL DATA

Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that the function can be run in parallel.

DISALLOW PARALLEL

Specifies that the function cannot be run in parallel.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE

Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

DISALLOW DEBUG MODE

Specifies that this version of the routine cannot be run in debugging mode.

You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

DISABLE DEBUG MODE

Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

PARAMETER CCSID

Specifies that the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that

is specified in the CCSID clauses of the parameter list or RETURNS clause, or in the DEF ENCODING SCHEME field on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause. This clause also specifies the encoding scheme that is used for system-generated parameters of the routine, such as message tokens and DBINFO.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

QUALIFIER *schema-name*

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the procedure body. See “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67 for information about how the default for this option is determined.

PACKAGE OWNER *authorization-name*

Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

The authorization ID must have the privileges that are required to execute the SQL statements that are contained in the routine body and must contain the necessary bind privileges. The value of PACKAGE OWNER is subject to translation when it is sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process or the authorization ID of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID that contains the necessary bind privileges.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

Specifies that there is no limit on the service units.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 43 on page 199.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 43 on page 199.

WLM ENVIRONMENT FOR DEBUG MODE *name*

Specifies the WLM (workload manager) application environment that is used by DB2 when debugging the routine. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

CURRENT DATA YES or CURRENT DATA NO

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

CURRENT DATA YES

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquires page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

CURRENT DATA NO

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of **CURRENT DATA NO** is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

CURRENT DATA NO is the default.

DEGREE

Specifies whether to attempt to run a query using parallel processing to maximize performance.

1 Specifies that parallel processing should not be used.

1 is the default.

ANY

Specifies that parallel processing can be used.

CONCURRENT ACCESS RESOLUTION

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

WAIT FOR OUTCOME

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

DYNAMICRULES

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

RUN

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND

Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

|
| **DEFINERUN**

| Specifies that dynamic SQL statements are to be processed using either
| define behavior or run behavior.

|
| **INVOKEBIND**

| Specifies that dynamic SQL statements are to be processed using either
| invoke behavior or bind behavior.

|
| **INVOKERUN**

| Specifies that dynamic SQL statements are to be processed using either
| invoke behavior or run behavior.

|
| See “Authorization IDs and dynamic SQL” on page 75 for information on the
| effects of these options.

| **APPLICATION ENCODING SCHEME**

| Specifies the default encoding scheme for SQL variables in static SQL
| statements in the routine body. The value is used for defining an SQL variable
| in a compound statement if the CCSID clause is not specified as part of the
| data type, and the PARAMETER CCSID routine option is not specified.

| **ASCII**

| Specifies that the data is encoded using the ASCII CCSIDs of the server.

| **EBCDIC**

| Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

| **UNICODE**

| Specifies that the data is encoded using the Unicode CCSIDs of the server.

|
| See the ENCODING bind option in *DB2 Command Reference* for information
| about how the default for this option is determined.

| **WITH EXPLAIN or WITHOUT EXPLAIN**

| Specifies whether information will be provided about how SQL statements in
| the routine will execute.

| **WITHOUT EXPLAIN**

| Specifies that information will not be provided about how SQL statements
| in the routine will execute.

|
| You can get EXPLAIN output for a statement that is embedded in a
| routine that is specified using WITHOUT EXPLAIN by embedding the
| SQL statement EXPLAIN in the routine body. Otherwise, the value of the
| EXPLAIN option applies to all explainable SQL statements in the routine
| body, and to the fullselect portion of any DECLARE CURSOR statements.

| **WITHOUT EXPLAIN** is the default.

| **WITH EXPLAIN**

| Specifies that information will be provided about how SQL statements in
| the routine will execute. Information is inserted into the table
| *owner.PLAN_TABLE*. *owner* is the authorization ID of the owner of the
| routine. Alternatively, the authorization ID of the owner of the routine can
| have an alias as *owner.PLAN_TABLE* that points to the base table,
| *PLAN_TABLE*. *owner* must also have the appropriate SELECT and INSERT
| privileges on that table. WITH EXPLAIN does not obtain information for
| statements that access remote objects. *PLAN_TABLE* must have a base
| table and can have multiple aliases with the same table name,
| *PLAN_TABLE*, but have different schema qualifiers. It cannot be a view or

a synonym and should exist before the version is added or replaced. In all inserts to *owner.PLAN_TABLE*, the value of *QUERYNO* is the statement number that is assigned by DB2.

The *WITH EXPLAIN* option also populates two optional tables if they exist: *DSN_STATEMNT_TABLE* and *DSN_FUNCTION_TABLE*. *DSN_STATEMNT_TABLE* contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. *DSN_FUNCTION_TABLE* contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.

For a description of the tables that are populated by the *WITH EXPLAIN* option, see “*EXPLAIN*” on page 1948.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The *IMMEDWRITE* subsystem parameter has no affect of this option. *DB2 Command Reference* shows the implied hierarchy of the *IMMEDWRITE* bind option (which is similar to this routine option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR

Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see *DB2 Performance Monitoring and Tuning Guide*.

RR Specifies repeatable read.

RS Specifies read stability.

CS Specifies cursor stability. **CS** is the default.

UR Specifies uncommitted read.

OPTHINT *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

string-constant is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the *PLAN_TABLE* for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *DB2 Installation Guide* for information about enabling optimization hints.

SQL PATH

Specifies the SQL path that the DB2 subsystem uses to resolve unqualified user-defined data types, functions, and procedure names (in CALL statements) in the body of the routine. The default value is "SYSIBM", "SYSFUN", "SYSPROC", and the value of the QUALIFIER option, which is the qualifier for the trigger that is the target of the statement. The maximum length of the SQL path is 2048 bytes. DB2 calculates the length by taking each *schema-name* that is specified and removing any trailing blanks from it, adding a delimiter on the left and right sides, and adding one comma after each schema name except for the last name. The length of the resulting string cannot exceed 2048 bytes.

schema-name

Identifies a schema. DB2 does not verify that the schema exists when the CREATE statement is processed. The same schema name should not appear more than one time in the list of schema names.

SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC".

SESSION_USER or USER

Specifies the value of the SESSION_USER (or USER) special register. At the time the CREATE statement is processed, the actual length is included in the total length of the list of schema names that is specified for the SQL PATH option.

REOPT

Specifies if DB2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE

Specifies that DB2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

ALWAYS

Specifies that DB2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

ONCE

Specifies that DB2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.

QUERY ACCELERATION

Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE

Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE

Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in DB2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and DB2 cannot route the static query to the accelerator for execution.

ENABLE WITH FAILBACK

Results in the same behavior as **ENABLE**, except if one of the error conditions occurs on the first **OPEN** of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, DB2 performs a temporary *statement-level* incremental bind of the query and runs the query in DB2. The application does not see the acceleration failure. Failback to DB2 is not possible after the application does a successful **OPEN** for the query on the accelerator.

ELIGIBLE

Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for **ENABLE**, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

ALL

Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If DB2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the **BIND** or **REBIND PACKAGE** operation fails with an error message for that query. (A failure exception is made for declared global temporary tables (DGTTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for **ENABLE**, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a *fullselect* or *WITH common-table-expression* that is specified in a **RETURN** statement for the routine, or in a **SET host-variable-assignment** that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

NO Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in DB2.

If the static query is bound for acceleration because the **QUERYACCELERATION** bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

YES

Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The QUERYACCELERATION bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a *fullselect* or *WITH common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

VALIDATE RUN or VALIDATE BIND

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN

Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

VALIDATE RUN is the default.

VALIDATE BIND

Specifies that if needed objects or privileges do not exist at the time the CREATE statement is processed, an error is issued and the CREATE statement fails.

ROUNDING

Specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in DECP.

DEC_ROUND_CEILING

Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN

Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR

Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN

Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

| **DEC_ROUND_HALF_UP**

| Specifies numbers are rounded to nearest; if equidistant, round up.

| **DEC_ROUND_UP**

| Specifies numbers are rounded away from 0.

| **DATE FORMAT ISO, EUR, USA, JIS, or LOCAL**

| Specifies the date format for result values that are string representations of
| date or time values. See “String representations of datetime values” on page
| 101 for more information.

| The default format is specified in the DATE FORMAT field of installation panel
| DSNTIP4 of the system where the routine is defined. You cannot use the
| LOCAL option unless you have a date exit routine.

| **DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)**

| Specifies the maximum precision that is to be used for decimal arithmetic
| operations. See “Arithmetic with two decimal operands” on page 231 for more
| information. The default format is specified in the DECIMAL ARITHMETIC
| field of installation panel DSNTIPF of the system where the routine is defined.
| If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents
| the minimum scale that is to be used for division.

| **FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED**

| Specifies whether the FOR UPDATE clause is required for a DECLARE
| CURSOR statement if the cursor is to be used to perform positioned updates.

| **FOR UPDATE CLAUSE REQUIRED**

| Specifies that a FOR UPDATE clause must be specified as part of the
| cursor definition if the cursor will be used to make positioned updates.

| **FOR UPDATE CLAUSE REQUIRED** is the default.

| **FOR UPDATE CLAUSE OPTIONAL**

| Specifies that the FOR UPDATE clause does not need to be specified in
| order for a cursor to be used for positioned updates. The routine body can
| include positioned UPDATE statements that update columns that the user
| is authorized to update.

| The FOR UPDATE clause with no column list applies to static or dynamic SQL
| statements. Even if you do not use this clause, you can specify FOR UPDATE
| OF with a column list to restrict updates to only the columns that are
| identified in the FOR UPDATE clause and to specify the acquisition of update
| locks.

| **TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**

| Specifies the time format for result values that are string representations of
| date or time values. See “String representations of datetime values” on page
| 101 for more information.

| The default format is specified in the TIME FORMAT field of installation panel
| DSNTIP4 of the system where the routine is defined. You cannot use the
| LOCAL option unless you have a date exit routine.

| **NOT SECURED or SECURED**

| Specifies if the function is considered secure for row access control and column
| access control. The SECURED or NOT SECURED option applies to all future
| versions of the function.

| **NOT SECURED**

| Specifies that the function is not considered secure for row access control
| and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body

Specifies a single SQL control statement, including a compound-statement. See Chapter 8, “SQL control statements for SQL routines,” on page 2251 for more information about defining SQL functions.

An error is issued if an SQL function calls a procedure and the procedure issues a COMMIT, ROLLBACK, CONNECT, RELEASE, or SET CONNECTION statement.

If the *SQL-routine-body* is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.

SQL-routine-body must not contain a period specification or period clause.

An ALTER FUNCTION (compiled SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION clause or a REPLACE clause is not allowed in an *SQL-routine-body*.

Notes

Choosing data types for parameters:

When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 108). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Identifier resolution:

See Chapter 8, “SQL control statements for SQL routines,” on page 2251 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, and the label name for SQL variables.

Determining the uniqueness of functions in a schema:

At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type. An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

Overriding a built-in function:

Giving a function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

Self-referencing function:

The body of an SQL function (that is, the *expression* or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Versions of a function:

The CREATE FUNCTION statement for an SQL function defines the initial version of the function. You can define additional versions using the ADD VERSION clause of the ALTER FUNCTION statement. All versions of a function share the same function signature and the same specific name. However, the parameters names can differ between versions of a functions. Only one version of the function can be considered to be the active version of the function.

Considerations for packages:

A package is generated for compiled SQL scalar functions. The package that is associated with the first version of a function is named as follows:

- *location* is set to the value of the CURRENT SERVER special register.
- *collection-id* (schema) for the package is the same as the schema qualifier of the function.
- *package-id* is the same as the specific name of the function.
- *version-id* is the same as the version identifier for the initial version of the function.

The package is generated using the bind options that correspond to the implicitly or explicitly specified function options. In addition to the corresponding bind options, the package is generated using the following bind options:

- FLAG(I)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

Correspondence of function options to bind command options:

The following table lists options for CREATE FUNCTION and ALTER FUNCTION and the corresponding bind command option. See BIND and REBIND options for packages and plans (DB2 Commands) for information about the BIND command options.

Table 162. Correspondence of function options to bind options

| CREATE FUNCTION or ALTER FUNCTION option | bind command option |
|--|--|
| APPLICATION ENCODING SCHEME | ENCODING(ASCII), ENCODING(EBCDIC), ENCODING(UNICODE) |
| CURRENT DATA NO | CURRENTDATA(NO) |
| CURRENT DATA YES | CURRENTDATA(YES) |

Table 162. Correspondence of function options to bind options (continued)

| CREATE FUNCTION or ALTER FUNCTION option | bind command option |
|---|--|
| DYNAMICRULES | DYNAMICRULES(RUN), DYNAMICRULES(BIND), DYNAMICRULES(DEFINEBIND), DYNAMICRULES(DEFINERUN), DYNAMICRULES(INVOKEBIND), DYNAMICRULES(INVOKERUN) |
| ISOLATION LEVEL | ISOLATION(RR), ISOLATION(RS), ISOLATION(CS), ISOLATION(UR) |
| OPTHINT | OPTHINT |
| PACKAGE OWNER | OWNER |
| QUALIFIER | QUALIFIER |
| REOPT ALWAYS | REOPT(ALWAYS) |
| REOPT NONE | REOPT(NONE) |
| REOPT ONCE | REOPT(ONCE) |
| ROUNDING DEC_ROUND_CEILING | ROUNDING(CEILING) |
| ROUNDING DEC_ROUND_DOWN | ROUNDING(DOWN) |
| ROUNDING DEC_ROUND_FLOOR | ROUNDING(FLOOR) |
| ROUNDING DEC_ROUND_HALF_DOWN | ROUNDING(HALFDOWN) |
| ROUNDING DEC_ROUND_HALF_EVEN | ROUNDING(HALFEVEN) |
| ROUNDING DEC_ROUND_HALF_UP | ROUNDING(HALFUP) |
| ROUNDING DEC_ROUND_UP | ROUNDING(UP) |
| SQL PATH | PATH |
| VALIDATE BIND | VALIDATE(BIND) |
| VALIDATE RUN | VALIDATE(RUN) |
| WITH EXPLAIN | EXPLAIN(YES) |
| WITHOUT EXPLAIN | EXPLAIN(NO) |
| WITH IMMEDIATE WRITE | IMMEDWRITE(YES) |
| WITHOUT IMMEDIATE WRITE | IMMEDWRITE(NO) |

Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see *Setting the SQL terminator character in a SPUFI input data set (DB2 Application programming and SQL)*.

Lines within definitions of an SQL function:

When a compiled SQL function is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

Considerations for functions defined with EXTERNAL ACTION or MODIFIES SQL DATA:

If a function is specified in the *select-list* of a *select-statement* and is the function specifies **EXTERNAL ACTION** or **MODIFIES SQL DATA**, the function will only be invoked for each row that is returned. Otherwise, the function might be invoked for rows that are not selected.

Error handling in SQL functions:

You should consider the possible exceptions that can occur for each SQL statement in the body of a compiled SQL function. Any exception SQLSTATE that is not handled within the function (using a handler), results in the exception SQLSTATE being returned for the SQL statement that caused the function to be invoked.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Considerations for a function that is defined using a TABLE LIKE name AS LOCATOR clause:

If a function is defined with a table parameter (the **TABLE LIKE name AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function cannot be changed with an ALTER FUNCTION statement if the change requires that the parameter list be specified. For example, to add or replace a version of an SQL scalar function, the function must be dropped and re-created.

Creating a secure function:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.

DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages. If the function is a compiled SQL function, DB2 assumes that such a control audit procedure is in place for all versions of the function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

Invoking other user-defined functions in a secure function:

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Deploying a compiled SQL scalar function:

When a BIND DEPLOY command is issued to deploy a compiled SQL scalar function to a target location, the SECURED and NOT SECURED options are included in the deployment process.

When deploying a compiled SQL scalar function, if a function with the same target name does not exist at the target location, the deployed function is created as a new function at the target location with the same SECURED or NOT SECURED option that is specified (or the default of NOT SECURED is used) in the source of the deployment.

When deploying a compiled SQL scalar function, if a function with the same target name already exists at the target location, the deployed function is either added as a new version of the function, or the deployed function is used to replace an existing version of the function. The SECURED or NOT SECURED option of the deployed function must be the same as that of the existing function at the target location.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example: Define a scalar function that returns the text of an input string, in reverse order:

```
CREATE FUNCTION REVERSE(INSTR VARCHAR(4000))
  RETURNS VARCHAR(4000)
  DETERMINISTIC NO EXTERNAL ACTION CONTAINS SQL
  BEGIN
  DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
  DECLARE LEN INT;
  IF INSTR IS NULL THEN
  RETURN NULL;
  END IF;
  SET (RESTSTR, LEN) = (INSTR, LENGTH(INSTR));
  WHILE LEN > 0 DO
  SET (REVSTR, RESTSTR, LEN)
    = (SUBSTR(RESTSTR, 1, 1) CONCAT REVSTR,
      SUBSTR(RESTSTR, 2, LEN - 1),
      LEN - 1);
  END WHILE;
  RETURN REVSTR;
END#
```

CREATE FUNCTION (external scalar)

This CREATE FUNCTION statement registers a user-defined external scalar function with a database server. A scalar function returns a single value each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

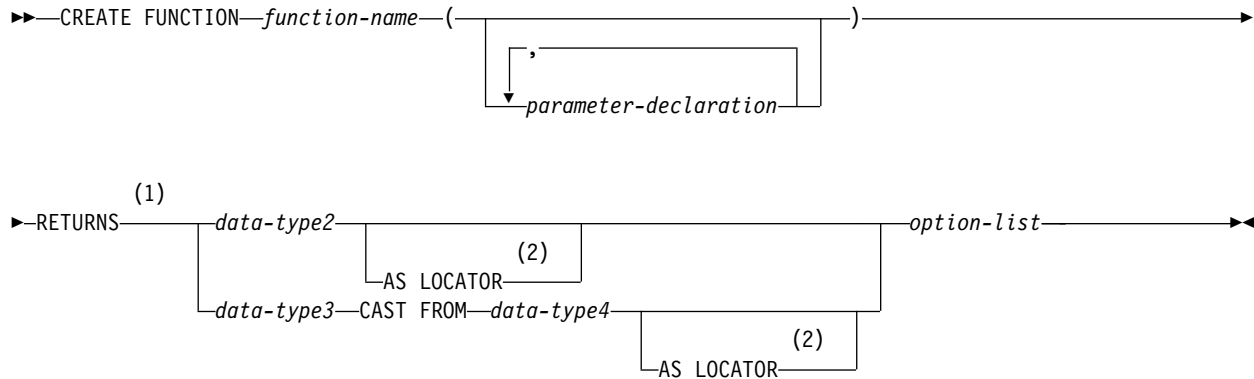

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.

- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

Notes:

- 1 This clause and the clauses that follow in the *option-list* can be specified in any order.
- 2 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

parameter-declaration:

Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

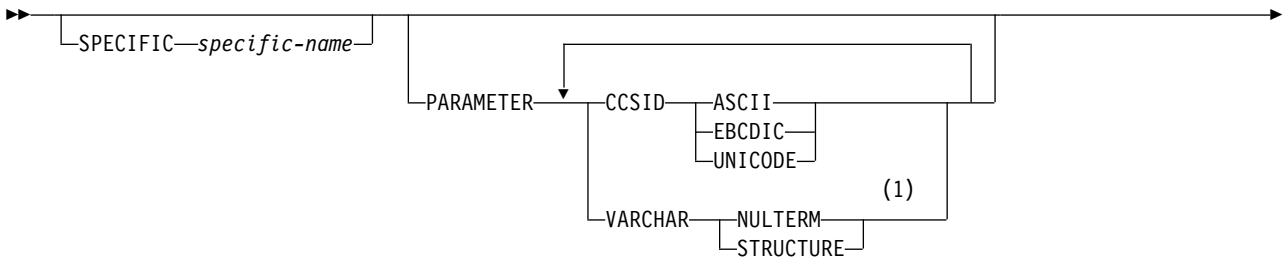

data-type:

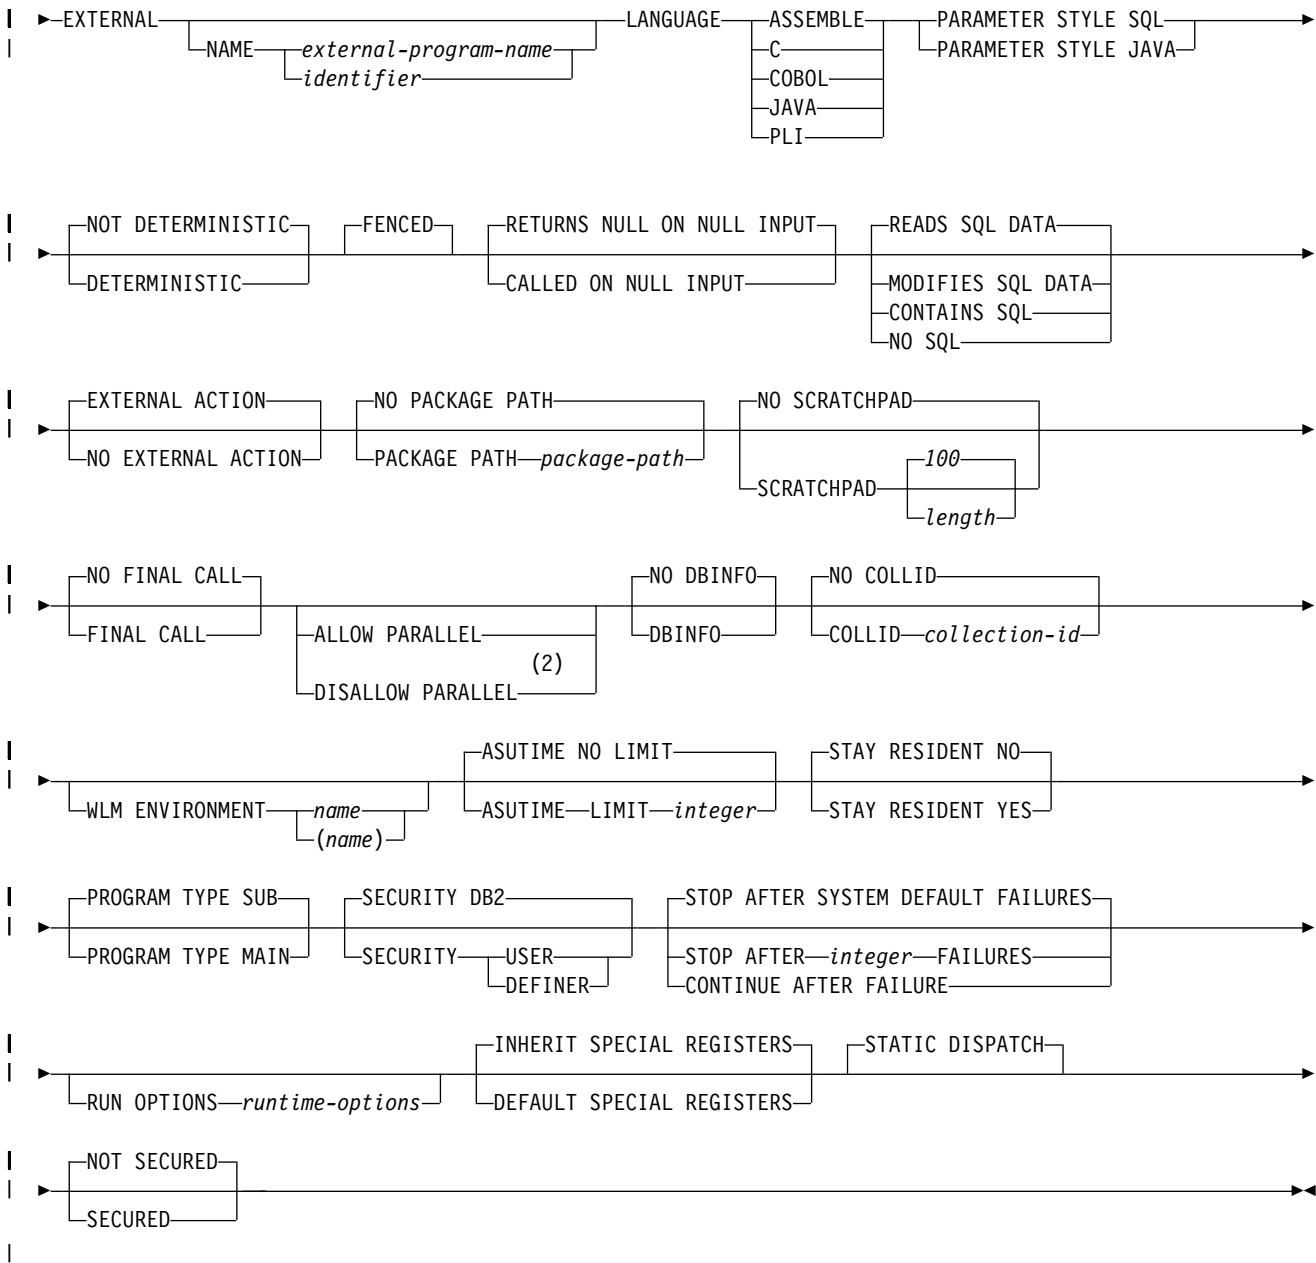

built-in-type:

option-list: (The clauses in the option list can be specified in any order)

Notes:

- 1 The same clause must not be specified more than one time.
- 2 If NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, DISALLOW PARALLEL is the default.

external-java-routine-name:

jar-name:

method-name:

method-signature:

Notes:

- 1 The slash (/) is supported for compatibility with previous release of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

Description

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

| | | |
|----------|-------|---------|
| ALL | LIKE | UNIQUE |
| AND | MATCH | UNKNOWN |
| ANY | NOT | = |
| BETWEEN | NULL | ≠ |
| DISTINCT | ONLY | < |

| | | |
|--------|----------|----|
| EXCEPT | OR | <= |
| EXISTS | OVERLAPS | ↖ |
| FALSE | SIMILAR | > |
| FOR | SOME | >= |
| FROM | TABLE | → |
| IN | TRUE | <> |
| IS | TYPE | |

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function

is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

TABLE LIKE *table-name* or *view-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

table-name or *view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option

when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.

- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

RETURNS

Specifies the data type for the result of the function. Consider this clause in conjunction with the optional CAST FROM clause.

data-type2

Specifies the data type of the output. The output parameter is nullable.

The same considerations that apply to the data type and nullability of input parameter, as described under *data-type*, apply to the data type of the result of the function.

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

data-type3 **CAST FROM** *data-type4*

Specifies the data type of the output of the function (*data-type4*) and the data type in which that output is returned to the invoking statement (*data-type3*). The two data types can be different. For example, for the following definition, the function returns a DOUBLE value, which DB2 converts to a DECIMAL value and then passes to the statement that invoked the function:

```
CREATE FUNCTION SQR(DECIMAL(15,0))
  RETURNS DECIMAL(15,0) CAST FROM DOUBLE
...
```

The value of *data-type4* can be any built-in data type and must be castable to *data-type3*. The value for *data-type3* can be any built-in data type. (For information on casting data types, see “Casting between data types” on page 109.) The encoding scheme of the parameters, if they are string data types, must be the same.

If the PARAMETER VARCHAR clause is specified, *data-type3* and *data-type4* should be specified as VARCHAR.

AS LOCATOR

Specifies that the function returns a locator to the value rather than the value. You can specify AS LOCATOR only if *data-type4* is a LOB data type or a distinct type based on a LOB data type.

SPECIFIC *specific-name*

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLXXXXXXXXXXXX

where 'XXXXXXXXXXXX' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

PARAMETER CCSID or VARCHAR

Specifies the encoding scheme for character and graphic string parameters, and in the case of LANGUAGE C, specifies that representation of variable length string parameters.

CCSID

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPE.

This clause provides a convenient way to specify the encoding scheme for *all* string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

VARCHAR

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as there is with the PARAMETER CCSID clause. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL

Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

DB2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

```
EXTERNAL  
EXTERNAL NAME PKJVSP1  
EXTERNAL NAME 'PKJVSP1'
```

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

```
EXTERNAL PKJVSP1
```

NAME *external-program-name* **or** *identifier*

Identifies the user-written code that implements the user-defined function.

If LANGUAGE is JAVA, *external-program-name* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *external-program-names* are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a JAVA function for which NO SQL is also specified.

An *external-java-routine-name* contains the following parts:

jar-name

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the CREATE FUNCTION statement is processed.

If *jar-name* is not specified, the function is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed function.

method-name

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

class-id

Identifies the class identifier of the Java object.

method-id

Identifies the method identifier with the Java class to be invoked.

method-signature

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the user-defined function involves any input or output parameters that can be NULL. When the function being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE FUNCTION statement.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for

load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

If you do not specify the NAME clause, 'NAME *function-name*' is implicit. In this case, *function-name* must not be longer than 8 characters.

LANGUAGE

Specifies the language interface convention to which the body of the function is written. All programs must be designed to run in IBM's Language Environment environment.

ASSEMBLE

The function is written in Assembler.

C The function is written in C or C++.

COBOL

The function is written in COBOL, including the object-oriented language extensions.

JAVA

The user-defined function is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must also be specified with a valid *external-java-routine-name* and PARAMETER STYLE must be specified with JAVA.

Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is in effect.

PLI

The function is written in PL/I.

PARAMETER STYLE

Specifies the conventions for passing parameters to and returning a value from the function.

SQL

Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- *n* parameters for the input parameters that are specified for the function
- A parameter for the result of the function
- *n* parameters for the indicator variables for the input parameters
- A parameter for the indicator variable for the result
- The SQLSTATE to be returned to DB2
- The qualified name of the function
- The specific name of the function
- The SQL diagnostic string to be returned to DB2
- The function can also pass from zero to three additional parameters:
 - The scratchpad, if SCRATCHPAD is specified
 - The call type, if FINAL CALL is specified
 - The DBINFO structure, if DBINFO is specified

JAVA

Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications.

PARAMETER STYLE JAVA can be specified only if LANGUAGE is specified as JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE JAVA is specified.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

Some functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

DETERMINISTIC

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

FENCED

Specifies that the external function runs in an external address space to prevent the function from corrupting DB2 storage.

FENCED is the default.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON NULL INPUT

The function is not called if any of the input arguments is null. The result is the null value. RETURNS NULL ON INPUT is the default.

CALLED ON NULL INPUT

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return a null or nonnull value.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies the classification of SQL statements that the function can execute. DB2 verifies that the SQL statements that the function issues are consistent with this specification. For the data access classification of each statement, see Table 217 on page 2318.

MODIFIES SQL DATA

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

READS SQL DATA

Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data. The default is READS SQL DATA.

CONTAINS SQL

Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

NO SQL

Specifies that the function can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA function that uses a JAR file.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for external functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

EXTERNAL ACTION

Specifies that the function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, DB2:

- Materializes the views and table expressions in SELECT or data change statements statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

Specifies that the function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

NO PACKAGE PATH or PACKAGE PATH *package-path*

Specifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

NO PACKAGE PATH

Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The *package-path* value that is provided when the function is created is checked when the function is invoked. If *package-path* contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

NO SCRATCHPAD or SCRATCHPAD

Specifies whether DB2 is to provide a scratchpad for the function. It is strongly recommended that external functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

NO SCRATCHPAD

Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

SCRATCHPAD *length*

Specifies that when the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- *length* must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00's).
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```
SELECT A, UDFX(A) FROM TABLEB
WHERE UDFX(A) > 103 OR UDFX(A) < 19;
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the `DISALLOW PARALLEL` clause for functions that will not work correctly with parallelism.

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2 initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.
- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify `FINAL CALL` to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify `SCRATCHPAD`, DB2:

- Does not move the function from one task control block (TCB) to another between `FETCH` operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared `WITH HOLD`.

Do not specify `SCRATCHPAD` when `LANGUAGE JAVA` is in effect.

NO FINAL CALL or FINAL CALL

Specifies whether a *final call* is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the `SCRATCHPAD` keyword and the function acquires system resource and anchors them in the scratchpad.

NO FINAL CALL

Specifies that a final call is not made to the function. The function does not receive an additional argument that specifies the type of call. `NO FINAL CALL` is the default.

FINAL CALL

Specifies that a final call is made to the function. To differentiate between final calls and other calls, the function receives an additional argument that specifies the type of call. The types of calls are:

First call

Specifies that the first call to the function for this reference to the function in this SQL statement. A first call is a normal call—SQL arguments are passed and the function is expected to return a result.

Normal call

Specifies that SQL arguments are passed and the function is expected to return a result.

Final call

Specifies that the last call to the function to enable the function to

free resources. A final call is not a normal call. If an error occurs, DB2 attempts to make the final call unless the function abended. A final call occurs at these times:

- *End of statement:* When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- *End of a parallel task:* When the function is executed by parallel tasks.
- *End of transaction:* When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends. If a commit occurs at the end of a parallel task, a final call is made regardless of whether a cursor defined as WITH HOLD is open.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

Some functions that use a final call can receive incorrect results if parallel tasks execute the function. For example, if a function sends a note for each final call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that have inappropriate actions when executed in parallel.

Do not specify FINAL CALL when LANGUAGE JAVA is in effect.

ALLOW or DISALLOW PARALLEL

For a single reference to the function, specifies whether parallelism can be used when the function is invoked. Although parallelism can be used for most scalar functions, some functions such as those that depend on a single copy of the scratchpad cannot be invoked with parallel tasks.

Consider these characteristics when determining which clause to use:

- If all invocations of the function are completely independent from one another, specify ALLOW PARALLEL.
- If each invocation of the function updates the scratchpad, providing values that are of interest to the next invocation, such as incrementing a counter, specify DISALLOW PARALLEL.
- If the scratchpad is used only so that some expensive initialization processing is performed a minimal number of times, specify ALLOW PARALLEL.
- If the function performs some external action that should apply to only one partition, specify DISALLOW PARALLEL.
- If the function is defined with MODIFIES SQL DATA, specify DISALLOW PARALLEL, not ALLOW PARALLEL.

ALLOW PARALLEL is the default unless NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, in which case, DISALLOW PARALLEL is the default.

ALLOW PARALLEL

Specifies that DB2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.

DISALLOW PARALLEL

Specifies that DB2 does not consider parallelism for the function.

NO DBINFO or DBINFO

Specifies whether additional status information is passed to the function when it is invoked.

NO DBINFO

No additional information is passed. NO DBINFO is the default.

DBINFO

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application runtime authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

Do not specify DBINFO when LANGUAGE JAVA is in effect.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

NO COLLID

The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

COLLID *collection-id*

The name of the package collection that is to be used when the function is executed.

WLM ENVIRONMENT

Identifies the WLM (workload manager) application environment in which the function is to run. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time. When LANGUAGE is JAVA, you must specify WLM ENVIRONMENT, and the WLM environment in which the function is to run must be Java-enabled.

name

The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, DB2 routes the function request to a different address space.

(name,*)

When an SQL application program directly invokes the function, the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see *Running external functions in WLM environments*.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the service units. NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the load module for the function is to remain resident in memory when the function ends. This option is ignored if LANGUAGE JAVA is specified.

NO The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

YES

The load module remains resident in memory after the function ends. Use YES for reentrant functions.

PROGRAM TYPE

Specifies whether the function program runs as a main routine or a subroutine.

SUB

The function runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option. SUB is the default.

MAIN

The function runs as a main routine.

SECURITY

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

DB2 is the default.

USER

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

DEFINER

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS *runtime-options*

Specifies the Language Environment runtime options to be used for the function. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Table 43 on page 199.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Table 43 on page 199.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is not considered as secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be defined with **SECURED** when it is referenced in a row permission or a column mask.

Notes

Owner privileges:

The owner is authorized to execute the function (EXECUTE privilege) and has the ability to grant these privileges to others. For more information, see “GRANT (function or procedure privileges)” on page 2008. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Choosing data types for parameters:

When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 108). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Determining the uniqueness of functions in a schema:

At the current server, the function signature of each function, which is the

qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type. An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

Character string representation considerations:

The PARAMETER VARCHAR clause is specific to LANGUAGE C functions because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external function. For example, a CREATE FUNCTION statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the function, the specific name of the function, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

Considerations for accessing message tokens and DBINFO:

DB2 returns system-generated parameters from a routine, such as message tokens and DBINFO. The message tokens and DBINFO are character string data. The CCSID for system-generated string parameters is determined from the CCSID that is in effect for string parameters that are defined for the routine. If the parameter list for the routine does not include any character or graphic string parameters, the CCSID for system-generated string parameters is determined from the PARAMETER CCSID option that is in effect for the routine. For example, with a Unicode database, you can specify PARAMETER CCSID EBCDIC to have the system-generated string parameters returned to the invoking application in EBCDIC.

Overriding a built-in function:

Giving a function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

Running external functions in WLM environments:

You can use the WLM ENVIRONMENT clause to identify the address space in which a function or is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with data, such as employee salaries.

To prevent a user from defining functions in sensitive WLM environments, DB2 invokes the external security manager to determine whether the user has authorization to issue CREATE FUNCTION statements that refer to the specified WLM environment. The following example shows the RACF command that authorizes DB2 user DB2USER1 to register a function on DB2 subsystem DB2A that runs in the WLM environment named PAYROLL.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Creating a secure function:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.

Invoking other user-defined functions in a secure function:

If a secure user-defined function invokes other user-defined functions, DB2 does not validate whether those nested user-defined functions have the SECURED attribute. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access the sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

If a row permission or a column mask definition references a user-defined function, the user-defined function must be secure because the sensitive data might be passed as arguments to the function. The column SECURE in the EXPLAIN table DSN_FUNCTION_TABLE indicates whether a user-defined function is considered secure.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Assume that you want to write an external function program in C that implements the following logic:

```
output = 2 * input - 4
```

The function should return a null value if and only if one of the input arguments is null. The simplest way to avoid a function call and get a null result when an input value is null is to specify RETURNS NULL ON NULL INPUT on the CREATE FUNCTION statement or allow it to be the default. Write the statement needed to register the function, using the specific name MINENULL1.

```
CREATE FUNCTION NTEST1 (SMALLINT)
  RETURNS SMALLINT
  EXTERNAL NAME 'NTESTMOD'
  SPECIFIC MINENULL1
  LANGUAGE C
  DETERMINISTIC
  NO SQL
  FENCED
  PARAMETER STYLE SQL
  RETURNS NULL ON NULL INPUT
  NO EXTERNAL ACTION;
```

Example 2: Assume that user Smith wants to register an external function named CENTER in schema SMITH. The function program will be written in C and will be reentrant. Write the statement that Smith needs to register the function, letting DB2 generate a specific name for the function.

```
CREATE FUNCTION CENTER (INTEGER, FLOAT)
  RETURNS FLOAT
  EXTERNAL NAME 'MIDDLE'
  LANGUAGE C
  DETERMINISTIC
```

```
NO SQL
FENCED
PARAMETER STYLE SQL
NO EXTERNAL ACTION
STAY RESIDENT YES;
```

Example 3: Assume that user McBride (who has administrative authority) wants to register an external function named CENTER in the SMITH schema. McBride plans to give the function specific name FOCUS98. The function program uses a scratchpad to perform some one-time only initialization and save the results. The function program returns a value with a FLOAT data type. Write the statement McBride needs to register the function and ensure that when the function is invoked, it returns a value with a data type of DECIMAL(8,4).

```
CREATE FUNCTION SMITH.CENTER (FLOAT, FLOAT, FLOAT)
  RETURNS DECIMAL(8,4) CAST FROM FLOAT
  EXTERNAL NAME 'CMOD'
  SPECIFIC FOCUS98
  LANGUAGE C
  DETERMINISTIC
  NO SQL
  FENCED
  PARAMETER STYLE SQL
  NO EXTERNAL ACTION
  SCRATCHPAD
  NO FINAL CALL;
```

Example 4: The following example registers a Java user-defined function that returns the position of the first vowel in a string. The user-defined function is written in Java, is to be run fenced, and is the FINDVWL method of class JAVAUDFS.

```
CREATE FUNCTION FINDV (CLOB(100K))
  RETURNS INTEGER
  FENCED
  LANGUAGE JAVA
  PARAMETER STYLE JAVA
  EXTERNAL NAME 'JAVAUDFS.FINDVWL'
  NO EXTERNAL ACTION
  CALLED ON NULL INPUT
  DETERMINISTIC
  NO SQL;
```

CREATE FUNCTION (external table)

This CREATE FUNCTION statement registers a user-defined external table function with a database server. A user-defined external table function can be used in the FROM clause of a subselect. It returns a table to the subselect by returning one row at a time each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

parameter-declaration:

parameter-type:

Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

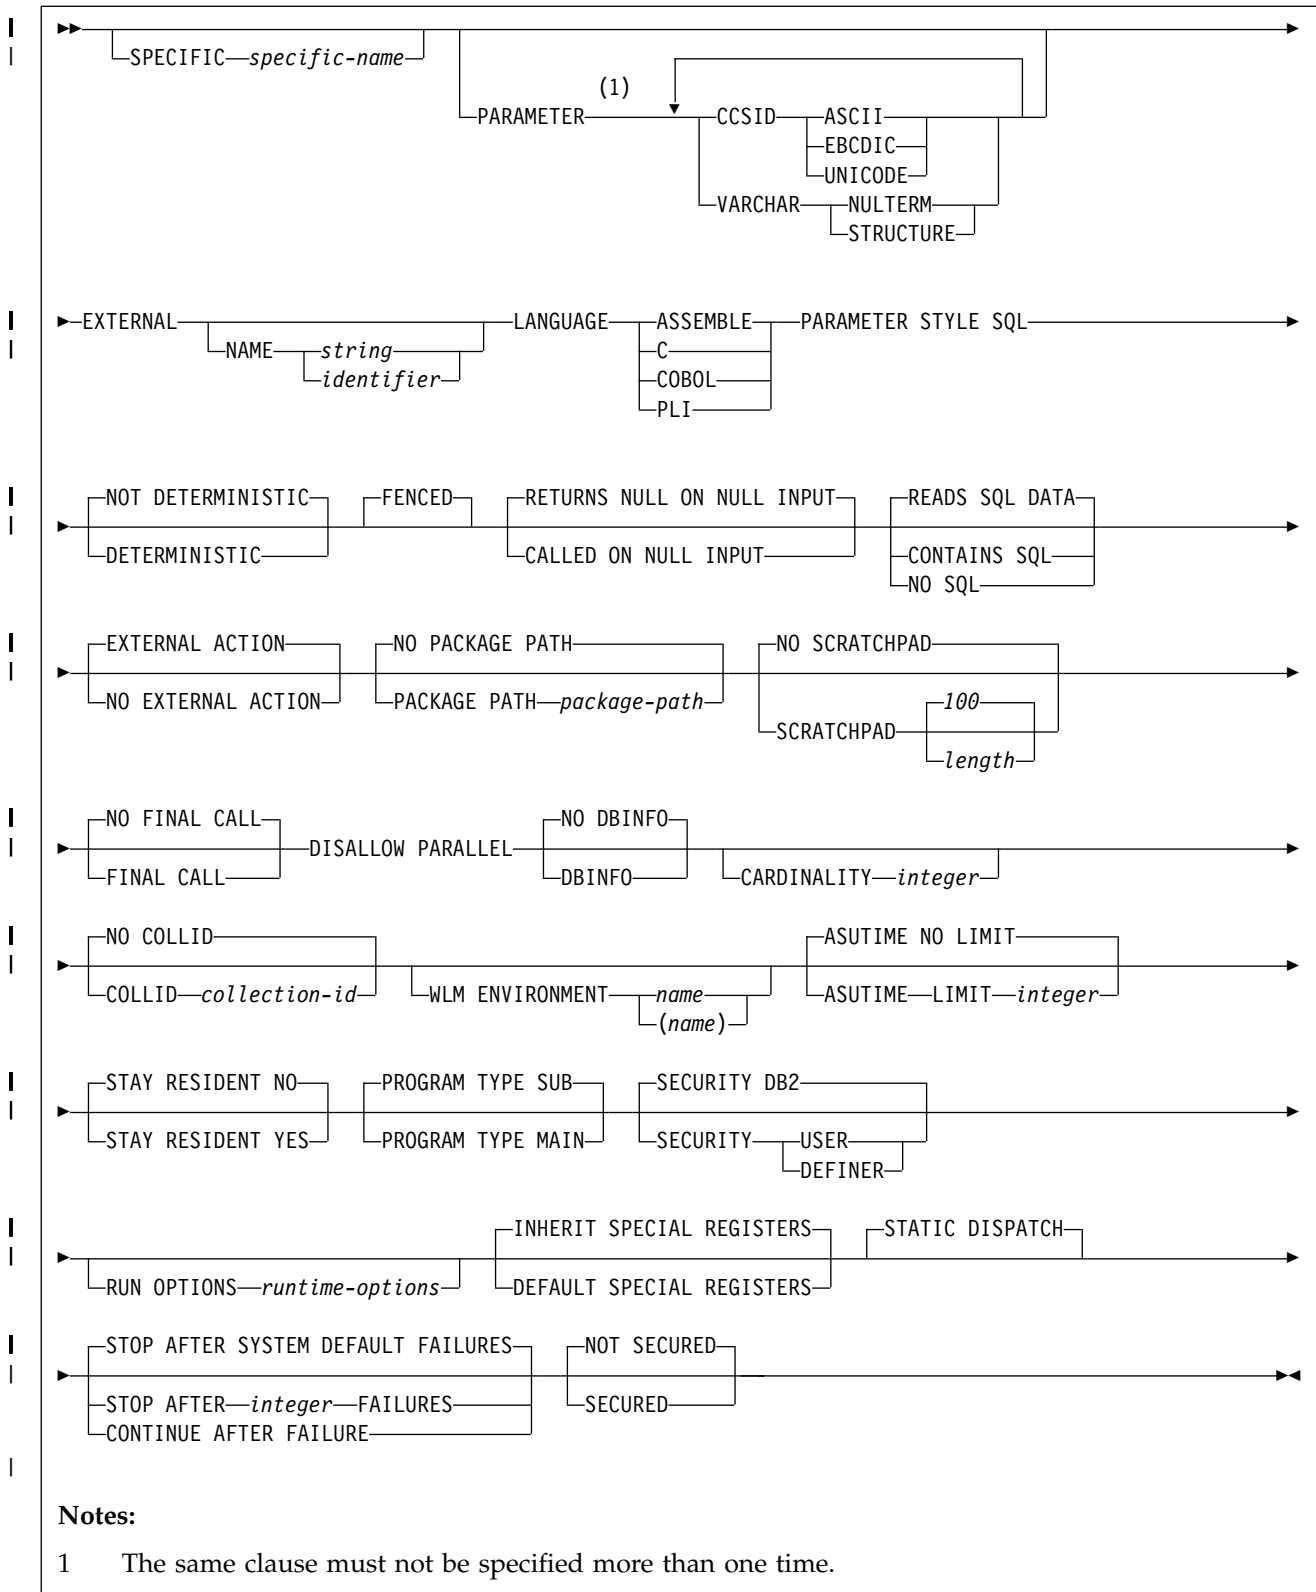

data-type:

built-in-type:

option-list: (The clauses in the *option-list* can be specified in any order.)

Description

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter²⁹ (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

| | | |
|----------|----------|---------|
| ALL | LIKE | UNIQUE |
| AND | MATCH | UNKNOWN |
| ANY | NOT | = |
| BETWEEN | NULL | ≠ |
| DISTINCT | ONLY | < |
| EXCEPT | OR | <= |
| EXISTS | OVERLAPS | << |
| FALSE | SIMILAR | > |
| FOR | SOME | >= |
| FROM | TABLE | >> |
| IN | TRUE | <> |
| IS | TYPE | |

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name. The same name cannot be used for a parameter name and a column name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length,

29. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type that is based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

TABLE LIKE *table-name* or *view-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

table-name or *view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

RETURNS TABLE(*column-name data-type ...*)

Identifies that the output of the function is a table. The parentheses that follow the keyword enclose the list of names and data types of the columns of the table.

column-name

Specifies the name of the column. The name is an SQL identifier and must be unique within the RETURNS TABLE clause for the function.

data-type

Specifies the data type of the column. The column is nullable.

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only for a LOB data type or a distinct type based on a LOB data type.

SPECIFIC *specific-name*

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

```
SQLXXXXXXXXXXXX
```

where 'XXXXXXXXXXXX' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

PARAMETER CCSID or VARCHAR

CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS TABLE clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

VARCHAR

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as there is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS TABLE clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the `PARAMETER VARCHAR` clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and `PARAMETER VARCHAR` is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL

Specifies that the function being registered is based on code that is written in an external programming language and adheres to the documented linkage conventions and interface of that language.

If you do not specify the `NAME` clause, `'NAME function-name'` is implicit. In this case, `function-name` must not be longer than 8 characters.

NAME *string or identifier*

Identifies the name of the load module that contains the user-written code that implements the logic of the function.

For other values of `LANGUAGE`, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

DB2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the `CREATE FUNCTION` statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the `EXTERNAL` clause in one of the following ways:

```
EXTERNAL  
EXTERNAL NAME PKJVSP1  
EXTERNAL NAME 'PKJVSP1'
```

If you specify an external program name, you must use the `NAME` keyword. For example, this syntax is not valid:

```
EXTERNAL PKJVSP1
```

LANGUAGE

Specifies the application programming language in which the function program is written. All programs must be designed to run in IBM's Language Environment environment.

ASSEMBLE

The function is written in Assembler.

C The function is written in C or C++. The `VARCHAR` clause can only be specified if `LANGUAGE C` is specified.

COBOL

The function is written in COBOL, including the object-oriented language extensions.

PLI

The function is written in PL/I.

PARAMETER STYLE SQL

Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

PARAMETER STYLE SQL specifies the parameter passing convention that supports passing null values both as input and for output.

If the RETURNS TABLE clause is specified, the parameters that are passed between the invoking SQL statement and the function include:

- n parameters for the input parameters that are specified for the function
- m parameters for the result columns of the function that are specified on the RETURNS TABLE clause
- n parameters for the indicator variables for the input parameters
- m parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause
- The SQLSTATE to be returned to DB2
- The qualified name of the function
- The specific name of the function
- The SQL diagnostic string to be returned to DB2
- The scratchpad, if SCRATCHPAD is specified
- The call type
- The DBINFO structure, if DBINFO is specified

For complete details about the structure of the parameter list that is passed, see *DB2 Application Programming and SQL Guide*.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same results each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

DETERMINISTIC

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function.

DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

FENCED

Specifies that the function runs in an external address space to prevent the function from corrupting DB2 storage.

FENCED is the default.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON NULL INPUT

The function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows. RETURNS NULL ON INPUT is the default.

CALLED ON NULL INPUT

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function. The default is READS SQL DATA. For the data access classification of each statement, see Table 217 on page 2318.

READS SQL DATA

Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

NO SQL

Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

If you specify EXTERNAL ACTION, DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

NO PACKAGE PATH or PACKAGE PATH *package-path*

Specifies the packagepath to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

NO PACKAGE PATH

Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The *package-path* value that is provided when the function is created is checked when the function is invoked. If *package-path* contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

NO SCRATCHPAD or SCRATCHPAD

Specifies whether DB2 provides a scratchpad for the function. It is strongly recommended that functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

NO SCRATCHPAD

Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

SCRATCHPAD *length*

Specifies that when the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- *length* must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00's).
- The scope of a scratchpad is the SQL statement. Each reference to the function in an SQL statement has a scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, two scratchpads are allocated for the two references to UDFX in the following SQL statement:

```
SELECT *  
FROM TABLE (UDFX(A)), TABLE (UDFX(B));
```

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2 initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.
- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify `FINAL CALL` to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify `SCRATCHPAD`, DB2:

- Does not move the function from one task control block (TCB) to another between `FETCH` operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared `WITH HOLD`.

NO FINAL CALL or FINAL CALL

Specifies whether a *first call* and a *final call* are made to the function.

NO FINAL CALL

A first call and final call are not made to the function. `NO FINAL CALL` is the default.

FINAL CALL

A first call and final call are made to the function in addition to one or more *open*, *fetch*, or *close calls*.

The types of calls are:

First call

A *first call* occurs only if the function was defined with `FINAL CALL`. Before a first call, the scratchpad is set to binary zeros. Argument values are passed to the function, and the function might acquire memory or perform other one-time only resource initialization. However, the function should not return any data to DB2, but it can set return values for the SQL-state and diagnostic-message arguments.

Open call

An *open call* occurs unless the function returns an error. The scratchpad is set to binary zeros only if the function was defined with `NO FINAL CALL`. Argument values are passed to the function, and the function might perform any one-time initialization actions that are required. However, the function should not return any data to DB2.

Fetch call

A *fetch call* occurs unless the function returns an error during the first call or open call. Argument values are passed to the function, and DB2 expects the function to return a row of data or the end-of-table condition. If a scratchpad is also passed to the function, it remains untouched from the previous call.

Close call

A *close call* occurs unless the function returns an error during the first call, open call, or fetch call. No SQL-argument or SQL-argument-ind values are passed to the function, and if the function attempts to examine these values, unpredictable results might occur. If a scratchpad is also passed to the function, it remains untouched from the previous call.

The function should not return any data to DB2, but it can set return values for the SQL-state and diagnostic-message arguments. Also on close call, a function that is defined with NO FINAL CALL should release any system resources that it acquired. (A function that is defined with FINAL CALL should release any acquired resources on the final call.)

Final The *final call* balances the first call, and like the first call, occurs only if the function was defined with FINAL CALL. The function can set return values for the SQL-state and diagnostic-message arguments. The function should also release any system resources that it acquired. A final call occurs at these times:

- *End of statement*: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- *End of transaction*: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

DISALLOW PARALLEL

Specifies that DB2 does not consider parallelism for the function.

NO DBINFO or DBINFO

Specifies whether additional status information is passed to the function when it is invoked.

NO DBINFO

No additional information is passed. NO DBINFO is the default.

DBINFO

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

CARDINALITY *integer*

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of *integer* must range from 0 to 2147483647.

If you do not specify CARDINALITY, DB2 assumes a finite value. The finite value is the same value that DB2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality—the function never returns the “end-of-table” condition and always returns a row, then a query that requires

the “end-of-table” to work correctly will need to be interrupted. Thus, avoid using such functions in queries that involve GROUP BY and ORDER BY.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

NO COLLID

The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

COLLID *collection-id*

The name of the package collection that is to be used when the external is executed.

WLM ENVIRONMENT

Identifies the WLM (workload manager) application environment in which the function is to run. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time.

name

The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, DB2 routes the function request to a different address space.

(name,*)

When an SQL application program directly invokes the function, the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see *Running external functions in WLM environments*.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the service units. NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the load module for the function is to remain resident in memory when the function ends.

NO The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

YES

The load module remains resident in memory after the function ends. Use YES for reentrant functions.

PROGRAM TYPE

Specifies whether the function program runs as a main routine or a subroutine.

SUB

The function runs as a subroutine. SUB is the default.

MAIN

The function runs as a main routine.

SECURITY

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

DB2 is the default.

USER

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

DEFINER

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

RUN OPTIONS *runtime-options*

Specifies the Language Environment run time options to be used for the function. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see *z/OS Language Environment Programming Reference*.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Table 43 on page 199.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Table 43 on page 199.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is not considered as secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be defined with SECURED when it is referenced in a row permission or a column mask.

Notes

See "Notes" on page 1521 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters

- Determining the uniqueness of functions in a schema
- Character string representation considerations
- Overriding a built-in function
- Scrollable cursors specified with user-defined functions
- Creating a secure function
- Invoking other user-defined functions in a secure function
- SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table

Example

Example 1: The following example registers a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.

Within the context of a single session, the table function always returns the same table; therefore, it is defined as DETERMINISTIC. In addition, the DISALLOW PARALLEL keyword is added because table functions cannot operate in parallel.

Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value and is specified to help DB2.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
    RETURNS TABLE (DOC_ID CHAR(16))
    EXTERNAL NAME ABC
    LANGUAGE C
    PARAMETER STYLE SQL
    NO SQL
    DETERMINISTIC
    NO EXTERNAL ACTION
    FENCED
    SCRATCHPAD
    FINAL CALL
    DISALLOW PARALLEL
    CARDINALITY 20;
```

CREATE FUNCTION (inlined SQL scalar)

The CREATE FUNCTION (inlined SQL scalar) statement defines an SQL scalar function at the current server and specifies an SQL procedural language RETURN statement for the body of the function. The function returns a single value each time it is invoked.

A package is not created for an inlined SQL scalar function.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

If a user-defined type is referenced (as the data type of a parameter), the privilege set must also include at least one of the following:

- Ownership of the user-defined type
- The USAGE privilege on the user-defined type
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified:

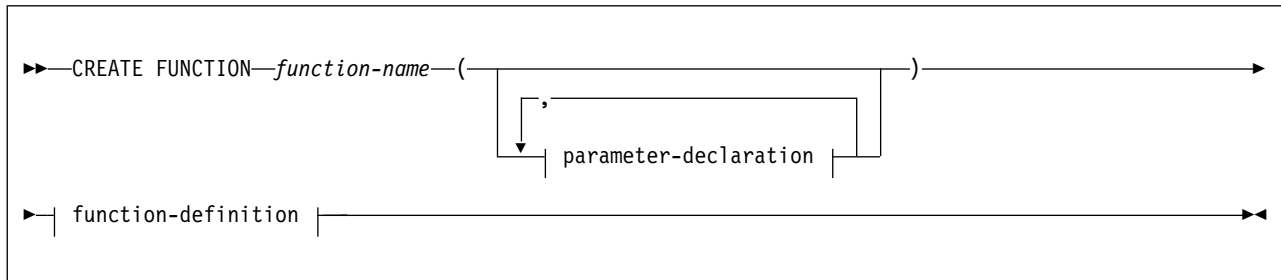

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

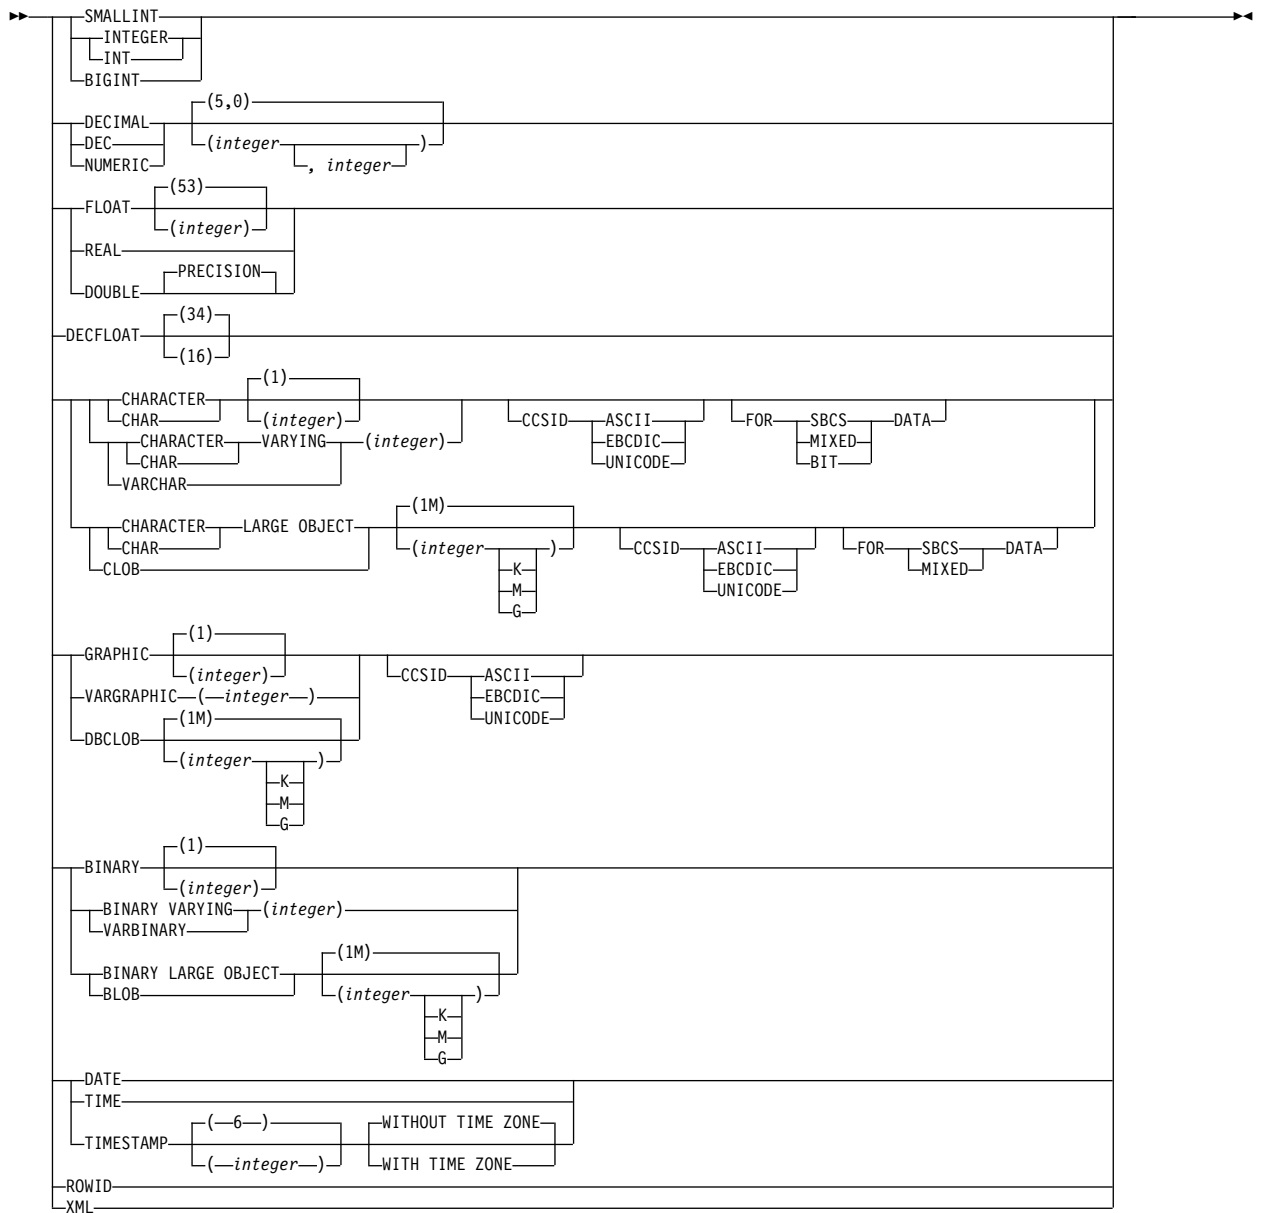

parameter-declaration:

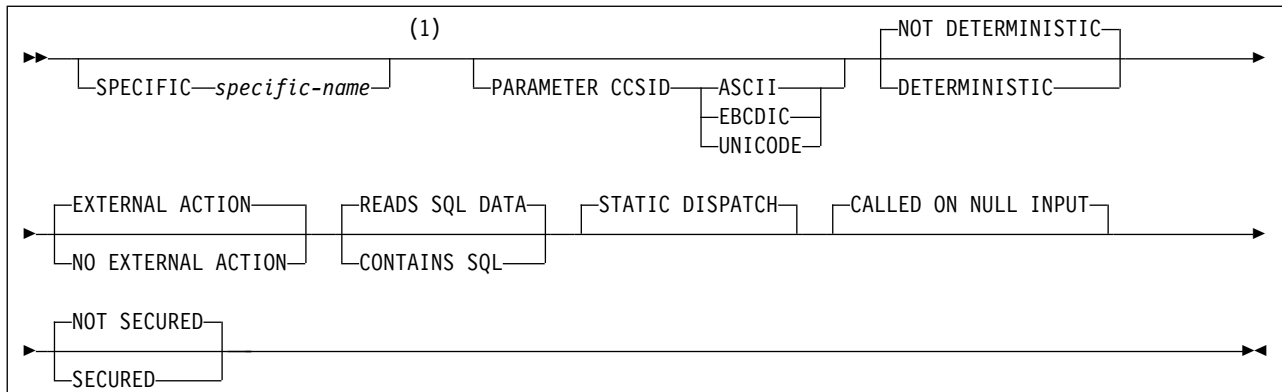

data-type:

built-in-type:

option-list:

Notes:

- 1 This clause and the other clauses in the *option-list* can be specified in any order. However, the same clause cannot be specified more than one time.

function-defintion

Notes:

- 1 The RETURNS clause, the *RETURN-statement*, and the clauses in the *option-list* can be specified in any order. However, the same clause cannot be specified more than one time.

SQL-routine-body

Description

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. The combination of name, schema name, the number of parameters, and the data type of each parameter³⁰ (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* is an SQL identifier.

The name must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

30. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

| | | |
|----------|----------|---------|
| ALL | LIKE | UNIQUE |
| AND | MATCH | UNKNOWN |
| ANY | NOT | = |
| BETWEEN | NULL | ≠ |
| DISTINCT | ONLY | < |
| EXCEPT | OR | <= |
| EXISTS | OVERLAPS | << |
| FALSE | SIMILAR | > |
| FOR | SOME | >= |
| FROM | TABLE | → |
| IN | TRUE | <> |
| IS | TYPE | |

The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the name and data type of each parameter. Each *parameter-declaration* specifies an input parameter for the function. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All of the parameters for a function are input parameters and are nullable. If the function has more than 30 parameters, only the first 30 parameters are used to determine if the function is unique.

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

If you specify the name of the distinct type without a schema name, DB2 resolves the distinct type by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program

can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

RETURNS

Identifies the output of the function.

data-type2

Specifies the data type of the output. The output is nullable.

The same considerations that apply to the data type of input parameter, as described under *data-type*, apply to the data type of the output of the function.

LANGUAGE SQL

Specifies that the function is written exclusively in SQL.

SPECIFIC *specific-name*

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

PARAMETER CCSID

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. NOT DETERMINISTIC is the default.

DETERMINISTIC

The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

READS SQL DATA or CONTAINS SQL

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from the function. For the data access classification of each statement, see Table 217 on page 2318.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

STATIC DISPATCH

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. **STATIC DISPATCH** is the default.

CALLED ON NULL INPUT

Specifies that the function is to be invoked if any, or if all, of the argument values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

CALLED ON NULL INPUT is the default.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

NOT SECURED

Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body

Specifies a single RETURN statement, see “RETURN statement” on page 2291.

Notes**Choosing data types for parameters:**

When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 108). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Determining the uniqueness of functions in a schema:

At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine

uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type. An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

Overriding a built-in function:

Giving a function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

Self-referencing function:

The body of an SQL function (that is, the *expression* or NULL in the RETURN clause of the CREATE FUNCTION (inlined SQL scalar) statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Creating a secure function:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires

the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.

DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages. If the function is a non-inline SQL function, DB2 assumes that such a control audit procedure is in place for all versions of the function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

Invoking other user-defined functions in a secure function:

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

For an inlined SQL scalar function, the RETURNS clause and the clauses in the *option-list* can be specified in any order.

Examples

Example 1: Define a scalar function that returns the tangent of a value using existing SIN and COS built-in functions:

```
CREATE FUNCTION TAN (X DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(X)/COS(X);
```

CREATE FUNCTION (sourced)

This CREATE FUNCTION statement registers a user-defined function that is based on an existing scalar or aggregate function with a database server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

Additional privileges are required for the source function, and other privileges are also needed if the function uses a table as a parameter, or refers to a distinct type. These privileges are:

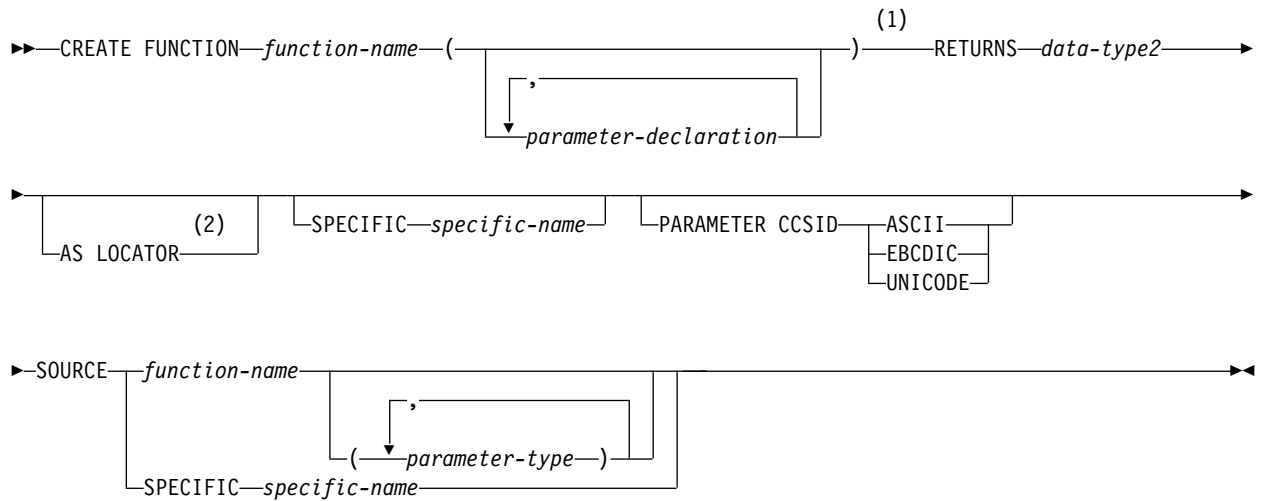

- The EXECUTE privilege for the function that the SOURCE clause references.
- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

Notes:

- 1 RETURNS, SPECIFIC, and SOURCE can be specified in any order.
- 2 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

parameter-declaration:

parameter-type:

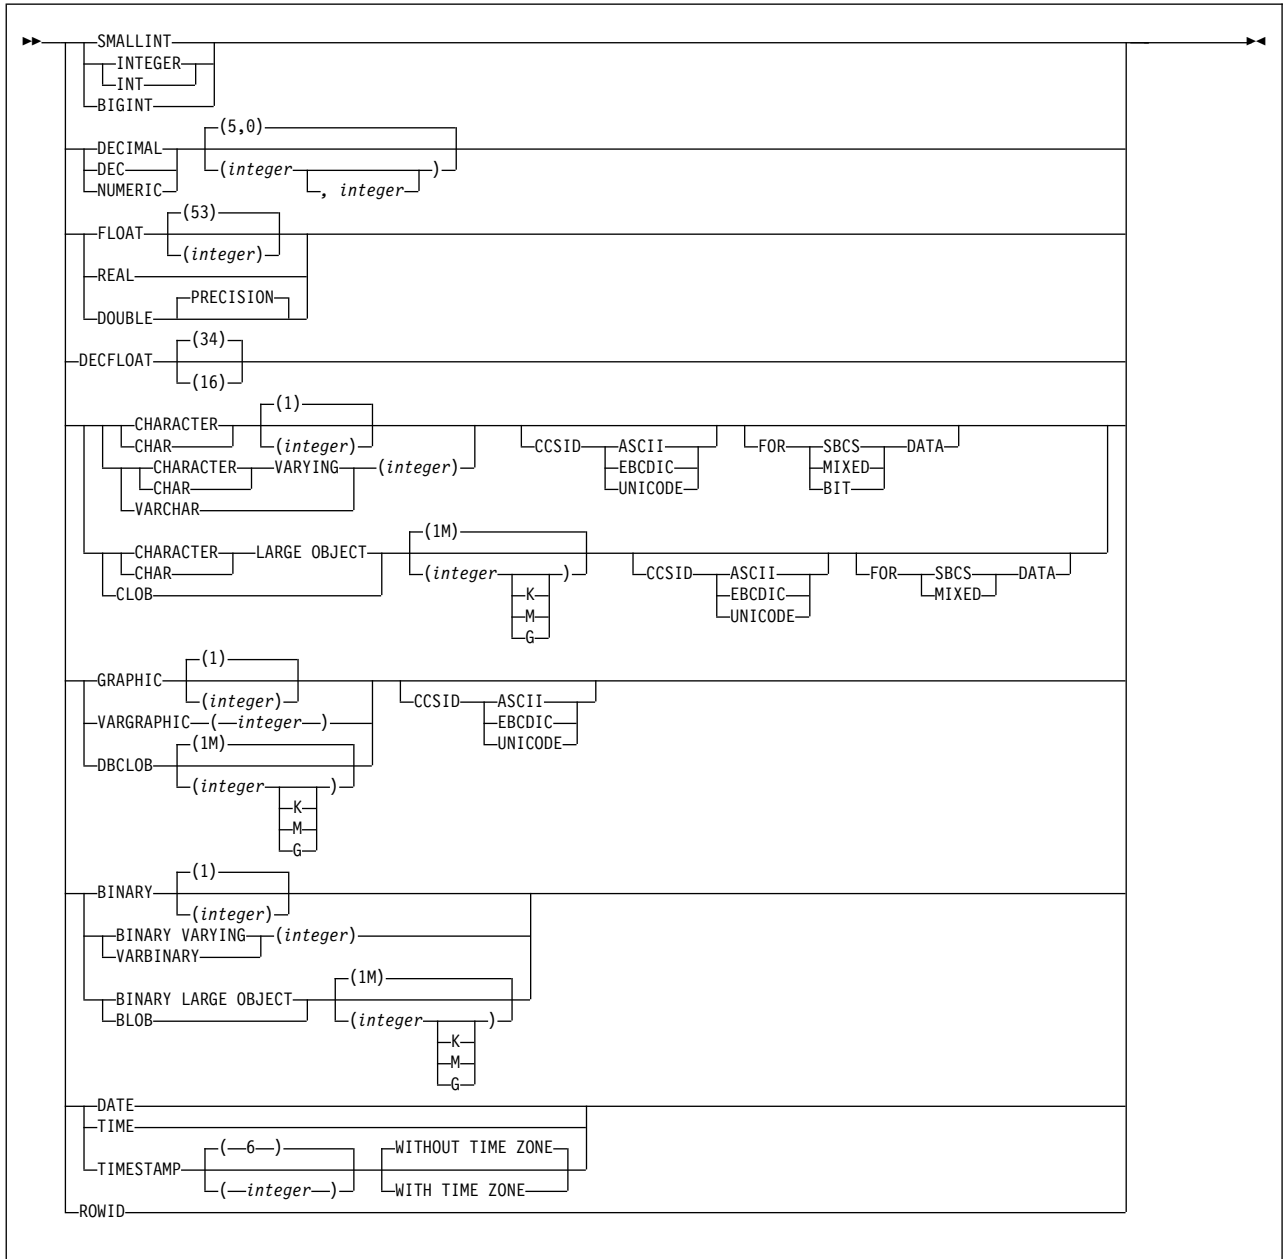

Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
- 2 The TABLE LIKE name AS LOCATOR clause can only be specified for the parameter list of the function that is being defined.

data-type:

built-in-type:

Description

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter³¹ (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

If the function is sourced on an existing function to enable the use of the existing function with a distinct type, the name can be the same name as the existing function. In general, more than one function can have the same name if the function signature of each function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

| | | |
|----------|----------|---------|
| ALL | LIKE | UNIQUE |
| AND | MATCH | UNKNOWN |
| ANY | NOT | = |
| BETWEEN | NULL | ≠ |
| DISTINCT | ONLY | < |
| EXCEPT | OR | ≤ |
| EXISTS | OVERLAPS | ≠ |
| FALSE | SIMILAR | > |
| FOR | SOME | ≥ |
| FROM | TABLE | → |
| IN | TRUE | <> |
| IS | TYPE | |

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the input parameter is a built-in data type.

31. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

You can specify any built-in data type or distinct type that matches or can be cast to the data type of the corresponding parameter of the source function (the function that is identified in the SOURCE clause). (For information on casting data types, see “Casting between data types” on page 109.) Length, precision, or scale attributes do not have to be specified for data types with these attributes. When specifying data types with these attributes, follow these rules:

- An empty set of parentheses can be used to indicate that the length, precision, or scale is the same as the source function.
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default values are used.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

TABLE LIKE *table-name* or *view-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

table-name or *view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

RETURNS

Identifies the output of the function.

data-type2

Specifies the data type of the output. The output is nullable.

You can specify any built-in data type or distinct type that can be cast from the data type of the result of the source function. (For information on casting data types, see “Casting between data types” on page 109.) For additional rules that apply to the data type that you can specify, see Rules for creating sourced functions.

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

SPECIFIC *specific-name*

Provides a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLXXXXXXXXXXXX

where 'XXXXXXXXXXXX' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

PARAMETER CCSID

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

SOURCE

Specifies that the new function is being defined as a sourced function. A *sourced function* is implemented by another function (the *source function*). The

source function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function. The source function must not be any of the built-in functions shown in Table 163 (if a particular syntax is shown, only the indicated form cannot be specified).

Table 163. Built-in functions that cannot be the source function. When listed with specific conditions, the function cannot be a source function under those conditions. Otherwise, the function cannot be a source function regardless of its arguments.

| Type of function | Restricted functions |
|------------------|------------------------------------|
| Aggregate | COUNT(*) COUNT_BIG(*) XMLAGG |

Table 163. Built-in functions that cannot be the source function (continued). When listed with specific conditions, the function cannot be a source function under those conditions. Otherwise, the function cannot be a source function regardless of its arguments.

| Type of function | Restricted functions |
|------------------|--|
| Scalar function | <p>CHAR(<i>datetime-expression</i>, <i>second-argument</i>) where <i>second-argument</i> is ISO, USA, EUR, JIS, or LOCAL or if CHAR is specified with OCTETS, CODEUNITS16, or CODEUNITS32.</p> <p>CHARACTER_LENGTH</p> <p>CLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>DBCLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>DECODE</p> <p>DECRYPT_BIT where second argument is DEFAULT</p> <p>DECRYPT_CHAR where second argument is DEFAULT</p> <p>DECRYPT_DB where second argument is DEFAULT</p> <p>EXTRACT</p> <p>GETVARIABLE where second argument is DEFAULT</p> <p>GRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>INSERT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>LEFT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>LOCAL</p> <p>LOCATE if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>MAX</p> <p>MIN</p> <p>NULLIF</p> <p>POSITION</p> <p>RID</p> <p>RIGHT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>STRIP where multiple arguments are specified</p> <p>SUBSTRING</p> <p>TRIM where the first argument is BOTH, B, LEADING, L, TRAILING, T, or the first or second argument is FROM</p> <p>VARCHAR if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>VARGRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>XMLCONCAT</p> <p>XMLELEMENT</p> <p>XMLFOREST</p> <p>XMLNAMESPACES</p> |

If you base the sourced function directly or indirectly on an external scalar function, the sourced function inherits the attributes of the external scalar function. This can involve several layers of sourced functions. For example,

assume that function A is sourced on function B, which in turn is sourced on function C. Function C is an external scalar function. Functions A and B inherit all of the attributes that are specified on the EXTERNAL clause of the CREATE FUNCTION statement for function C.

function-name

Identifies the function that is to be used as the source function. The source function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If you specify an unqualified *function-name*, DB2 searches the schemas of the SQL path. DB2 selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found or a schema has more than one function with this name.

function-name (parameter-type,...)

Identifies the function that is to be used as the source function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. DB2 uses the number of data types and the logical concatenation of the data types to identify the specific function instance. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name()* is specified, the identified function must have zero parameters.

function-name

Identifies the function name of the source function. If you specify an unqualified name, DB2 searches the schemas of the SQL path. Otherwise, DB2 searches for the function in the specified schema.

parameter-type,...

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision, or scale attribute, use one of the following specifications:

- Empty parentheses indicate that DB2 ignores the attribute when determining whether the data types match. For example, DEC() is considered a match for a parameter of a function that is defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parentheses because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the

data type is FLOAT, the precision does not need to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

If you omit the FOR *subtype* DATA clause or the CCSID clause for data types with a subtype or encoding scheme attribute, DB2 is to ignore the attribute when determining whether the data types match. An exception to ignoring the attribute is FOR BIT DATA. A character FOR BIT DATA parameter of the new function cannot correspond to a parameter of the source function that is not defined as character FOR BIT DATA. Likewise, a character parameter of the new function that is not FOR BIT DATA cannot correspond to a parameter of the source function that is defined as character FOR BIT DATA.

The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or distinct type that is based on a LOB.

SPECIFIC *specific-name*

Identifies the function to be used as the source function by its specific name.

If you specify an unqualified *specific-name*, DB2 searches the SQL path to locate the schema. DB2 selects the first schema that contains a function with this specific name for which the user has EXECUTE authority. DB2 returns an error if it cannot find a function with the specific name in one of the schemas in the SQL path.

If you specify a qualified *specific-name*, DB2 searches the named schema for the function. DB2 returns an error if it cannot find a function with the specific name.

Notes

Owner privileges:

The owner is authorized to execute the function (EXECUTE privilege) in the following cases:

- If the underlying function is a user-defined function, and the owner is authorized with the grant option to execute the underlying function, the privilege on the new function includes the grant option. Otherwise, the owner can execute the new function but cannot grant others the privilege to do so.
- If the underlying function is a built-in function, the owner is authorized with the grant option to execute the underlying built-in function and the privilege on the new function includes the grant option.

For more information, see “GRANT (function or procedure privileges)” on page 2008. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Choosing data types for parameters:

When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 108). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Determining the uniqueness of functions in a schema:

At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type.

An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

Rules for creating sourced functions:

Assume that the function that is being created is named NEWF and the source function is named SOURCEF. Consider the following rules when creating a sourced function:

- The unqualified names of the sourced function and source function can be different (NEWF and SOURCEF).
- The number of input parameters for NEWF and SOURCEF must be the same.
- When specifying the input parameters and output for NEWF, you can specify a value for the precision, scale, subtype, or encoding scheme for a data type with any of these attributes or use empty parentheses.

Empty parentheses, such as VARCHAR(), indicate that the value of the attribute is the same as the attribute for the corresponding parameter of SOURCEF, or that is determined by data type promotion. If you specify any values for the attributes, DB2 checks the values against the corresponding input parameters and returned output of SOURCEF as described next.

- When the CREATE FUNCTION statement is executed, DB2 checks the input parameters of NEWF against those of SOURCEF. The data type of each input parameter of NEWF function must be either the same as, or promotable to, the data type of the corresponding parameter of SOURCEF. (For information on the promotion of data types, see “Casting between data types” on page 109.)

This checking does not guarantee that an error will not occur when NEWF is invoked. For example, an argument that matches the data type and length or precision attributes of a NEWF parameter might not be promotable if the corresponding SOURCEF parameter has a shorter length or less precision. In general, do not define the parameters of a sourced function with length or precision attributes that are greater than the attributes of the corresponding parameters of the source function.

- When the CREATE FUNCTION statement is executed, DB2 checks the data type identified in the RETURNS clause of NEWF against the data type that SOURCEF returns. The data type that SOURCEF returns must be either the same as, or promotable to, the RETURNS data type of NEWF.

This checking does not guarantee that an error will not occur when NEWF is invoked. For example, the value of a result that matches the data type and length or precision attributes of those specified for SOURCEF's result might not be promotable if the RETURNS data type of NEWF has a shorter length or less precision. Consider the possible effects of defining the RETURNS data type of a sourced function with

length or precision attributes that are less than the attributes defined for the data type returned by source function.

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

SECURED functions:

The sourced user-defined function inherits the SECURED or NOT SECURED attribute from the source function in which only the topmost user-defined function is considered. If the topmost user-defined function is secure, any nested user-defined functions are also considered secure. DB2 does not validate whether those nested user-defined functions are secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

If the sourced function is using the VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER function as its source, the sourced function must specify only two input parameters.

Examples

Example 1: Assume that you created a distinct type HATSIZE, which you based on the built-in data type INTEGER. You want to have an AVG function to compute the average hat size of different departments. Create a sourced function that is based on built-in function AVG.

```
CREATE FUNCTION AVE (HATSIZE) RETURNS HATSIZE
SOURCE SYSIBM.AVG (INTEGER);
```

When you created distinct type HATSIZE, two cast functions were generated, which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to be cast to HATSIZE for the result of the function.

Example 2: After Smith registered the external scalar function CENTER in his schema, you decide that you want to use this function, but you want it to accept two INTEGER arguments instead of one INTEGER argument and one FLOAT argument. Create a sourced function that is based on CENTER.

```
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
RETURNS FLOAT
SOURCE SMITH.CENTER (INTEGER, FLOAT);
```

CREATE FUNCTION (SQL table)

The CREATE FUNCTION (SQL table) statement creates an SQL table function at the current server. The function returns a set of rows.

Invocation

This statement can only be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following privileges or authorities:

- The CREATEIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

If a distinct type is referenced (i.e. as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following:

- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority
- SYSDBADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:

- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the owner is a role, matching of the implicit schema name does not apply and the role must include one of the previously listed privileges or authorities.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the

set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

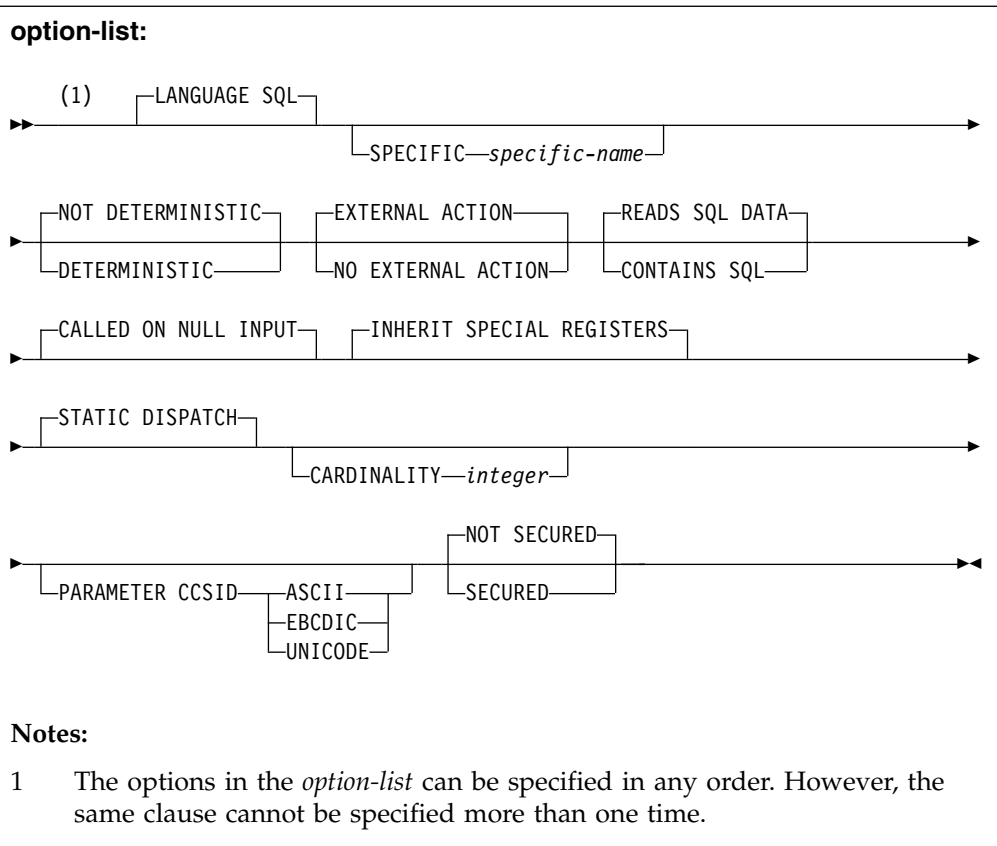

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the CREATEIN privilege on the schema

Syntax

built-in-type:

function-definition

Description

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. The combination of the name, the schema name, the number of parameters, and the data type of each parameter (without regard to any length, precision, scale, subtype, or encoding scheme attribute of the data type) must not identify a user-defined function that exists at the current server.

| *(parameter-declaration,...)*

| Identifies the number of input parameters of the function, and specifies the
| name and data type of each parameter. All of the parameters for a function are
| input parameters and are nullable. There must be one entry in the list for each
| parameter that the function expects to receive.

| *parameter-name*

| Specifies the name of the input parameter. Each name in the parameter list
| must not be the same as any other name.

| *data-type1*

| Specifies the data type of the input parameter. The data type can be a
| built-in data type or a distinct type.

| *built-in-type*

| The data type of the parameter is a built-in data type.

| For more information on the data types, including the subtype of
| character data types (the FOR subtype DATA clause), see built-in types.
| However, the varying length string data types have different maximum
| lengths for this statement than for the CREATE TABLE statement. The
| maximum lengths for parameters (and SQL variables) are as follows:

- | • VARCHAR or VARBINARY: 32704
- | • VARGRAPHIC: 16352

| For parameters with a character or graphic data type, the
| PARAMETER CCSID clause or the CCSID clause indicates the
| encoding scheme of the parameter. If you do not specify either of the
| CCSID clauses, the encoding scheme is the value of the DEF
| ENCODING SCHEME field on installation panel DSNTIPF.

| Although an input parameter with a character data type has an
| implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the
| value that is actually passed in the input parameter can have any
| subtype. Therefore, conversion of the input data to the subtype of the
| parameter might occur when the function is invoked. With ASCII or
| EBCDIC, an error occurs if mixed data that actually contains DBCS
| characters is used as the value for an input parameter that is declared
| with an SBCS subtype.

| *distinct-type-name*

| The data type of the parameter is a distinct type. Any length, precision,
| scale, subtype, or encoding scheme attributes for the parameter are
| those of the source type for the distinct type.

| **TABLE LIKE *table-name* AS LOCATOR**

| Specifies that the parameter is a transition table. However, when the
| function is invoked, the actual values in the transition table are not
| passed to the function. A single value is passed instead. This value is a
| locator for the table, which the function uses to access the columns of
| the transition table. The table that is identified can contain XML
| columns; however, the function cannot reference those XML columns.

| A function with a table parameter can only be invoked from the
| triggered action of a trigger.

| **RETURNS TABLE**

| Specifies that the output of the function is a table. The RETURN statement in
| an SQL table function must return a table result. The parentheses that follow

the RETURNS TABLE keyword delimit a list of name and data type pairs of the columns of the output table. All columns of the output table are nullable.

column-name

Specifies the name of the column. The name cannot be qualified, and must be unique within the RETURNS TABLE clause for the function.

data-type2

Specifies the data type and attributes of the column of the output table.

For SQL table functions, the result table of the function might include multiple encoding schemes – similar to what a view definition can include.

LANGUAGE SQL

Specifies that the function is written exclusively in SQL.

SPECIFIC *specific-name*

Specifies a unique name for the function.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. DB2 does not verify that the function program is consistent with the specification of NOT DETERMINISTIC or DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result table each time that the function is invoked with the same input arguments, even when the referenced data in the database has not changed. The function depends on some state values that might affect the results. When the MATERIALIZE_NODET_SQLTUDF subsystem parameter is set to YES, DB2 disables the merging of SQL table functions that are defined with this option. An example of a table function that is not deterministic is one which references special registers, other functions that are not deterministic, or a sequence in a way that affects the table function's result table. **NOT DETERMINISTIC** is the default.

DETERMINISTIC

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments (provided that the referenced data in the database has not changed). DB2 enables the merging of SQL table functions that are defined with this option.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function contains an external action. DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

EXTERNAL ACTION

The function performs some external action (outside the scope of the function program). Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION must be specified if the function invokes another function that has external actions.

EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not perform any external action. It need not be called with each successive function invocation. Functions that are defined with NO EXTERNAL ACTION might perform better than functions that are defined with EXTERNAL ACTION because the function might not be invoked for each successive function invocation.

| **READS SQL DATA or CONTAINS SQL**

| Specifies the classification of SQL statements that the function (any routine that
| is invoked from this function) can execute. DB2 verifies that the SQL
| statements that the function issues are consistent with this specification.

| **READS SQL DATA**

| Specifies that the function can execute statements with a data access
| indication of READS SQL DATA or CONTAINS SQL. The function cannot
| execute SQL statements that modify data.

| READS SQL DATA is the default.

| **CONTAINS SQL**

| Specifies that the function can execute only SQL statements with a data
| access indication of CONTAINS SQL. The function cannot execute
| statements that read or modify data.

| **CALLED ON NULL INPUT**

| Specifies that the function is called regardless of whether any of the input
| arguments are null, making the function responsible for testing for null
| argument values. The function can return an empty table, depending on its
| logic.

| CALLED ON NULL INPUT is the default.

| **INHERIT SPECIAL REGISTERS**

| Specifies that existing values of special registers are inherited upon entry to the
| function. INHERIT SPECIAL REGISTERS is the default.

| **STATIC DISPATCH**

| At function resolution time, DB2 chooses a function based on the static (or
| declared) types of the function parameters. **STATIC DISPATCH** is the default.

| **CARDINALITY** *integer*

| Specifies an estimate of the expected number of rows that the function returns.
| The number is used for optimization purposes. The value of *integer* must be
| between 0 and 2147483647.

| If you do not specify CARDINALITY, DB2 assumes a finite value. The finite
| value is the same value that DB2 assumes for tables for which the RUNSTATS
| utility has not gathered statistics.

| If a function has an infinite cardinality (the function never returns the
| end-of-table condition and always returns a row), a query that requires the
| end-of-table condition to work correctly will need to be interrupted.

| **PARAMETER CCSID**

| Specifies the encoding scheme for character and graphic string parameters is
| ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that
| is specified in the CCSID clauses of the parameter list or RETURNS clause, or
| in the DEF ENCODING SCHEME field on installation panel DSNTIPF. This
| clause provides a convenient way to specify the encoding scheme for character
| and graphic string parameters. If individual CCSID clauses are specified for
| individual parameters in addition to this PARAMETER CCSID clause, the
| value specified in all of the CCSID clauses must be the same value that is
| specified in this clause. This clause also specifies the encoding scheme that is
| used for system-generated parameters of the routine such as message tokens
| and DBINFO.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

NOT SECURED

Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body***RETURN-statement***

Specifies the return value of the function. A RETURN statement must be specified for an SQL table function.

ATOMIC

ATOMIC indicates that an unhandled exception condition within the RETURN statement causes the statement to be rolled back.

Notes**Identifier resolution:**

See Chapter 8, "SQL control statements for SQL routines," on page 2251 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, and the label name for SQL variables.

Referencing date and time special registers:

If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. In addition, this value is the same value that is returned by the register invocation in the statement that invoked the function.

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Considerations for columns that are defined with a field procedure:

The body of an SQL table function must not reference a column that is defined with a field procedure, and the RETURNS clause of an SQL table function must not reference a column that is defined with a field procedure. An SQL table function must not be invoked with an expression that is derived from a column that is defined with a field procedure.

Creating a secure function:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.

DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages. If the function is a compiled SQL function, DB2 assumes that such a control audit procedure is in place for all versions of the function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

Invoking other user-defined functions in a secure function:

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Alternative syntax and synonyms:

To provide compatibility with previously releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

Examples

Example 1: Define a table function, JTABLE, to return a table with 3 columns:

```
CREATE FUNCTION JTABLE (COLD_VALUE CHAR(9), T2_FLAG CHAR(1))
  RETURNS TABLE (COLA INT, COLB INT, COLC INT)
  LANGUAGE SQL
  SPECIFIC DEPTINFO
  NOT DETERMINISTIC
  READS SQL DATA
  RETURN
  SELECT A.COLA, B.COLB, B.COLC
  FROM TABLE1 AS A
```

```
|      LEFT OUTER JOIN
|      TABLE2 AS B
|      ON A.COL1 = B.COL1 AND T2_FLAG = 'Y'
|      WHERE A.COLD = COLD_VALUE;
```

Example 2: Define a table function that returns the employees in a specified department number. The function simply returns the employees for the requested department:

```
| CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
| RETURNS TABLE (EMPNO CHAR(6), LASTNAME VARCHAR(15), FIRSTNAME VARCHAR(12))
| LANGUAGE SQL
| READS SQL DATA
| NO EXTERNAL ACTION
| DETERMINISTIC
| RETURN
| SELECT EMPNO, LASTNAME, FIRSTNAME
| FROM YEMP
| WHERE YEMP.WORKDEPT = DEPTEMPLOYEES.DEPTNO;
```

CREATE GLOBAL TEMPORARY TABLE

The CREATE GLOBAL TEMPORARY TABLE statement creates a description of a temporary table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETMTAB system privilege
- The CREATETAB database privilege for any database
- DBADM, DBCTRL, or DBMAINT authority for any database
- SYSADM or SYSCtrl authority
- System DBADM

However, DBADM, DBCTRL, or DBMAINT authority is not sufficient authority if you are creating a temporary table for someone else and the table qualifier is not your authorization ID.

Additional privileges might be required when the data type of a column is a distinct type or the LIKE clause is specified. See the description of *distinct-type* and LIKE for the details.

Privilege set: The privilege set is the same as the privilege set for the CREATE TABLE statement. See information about CREATE TABLE Authorization for details.

Syntax

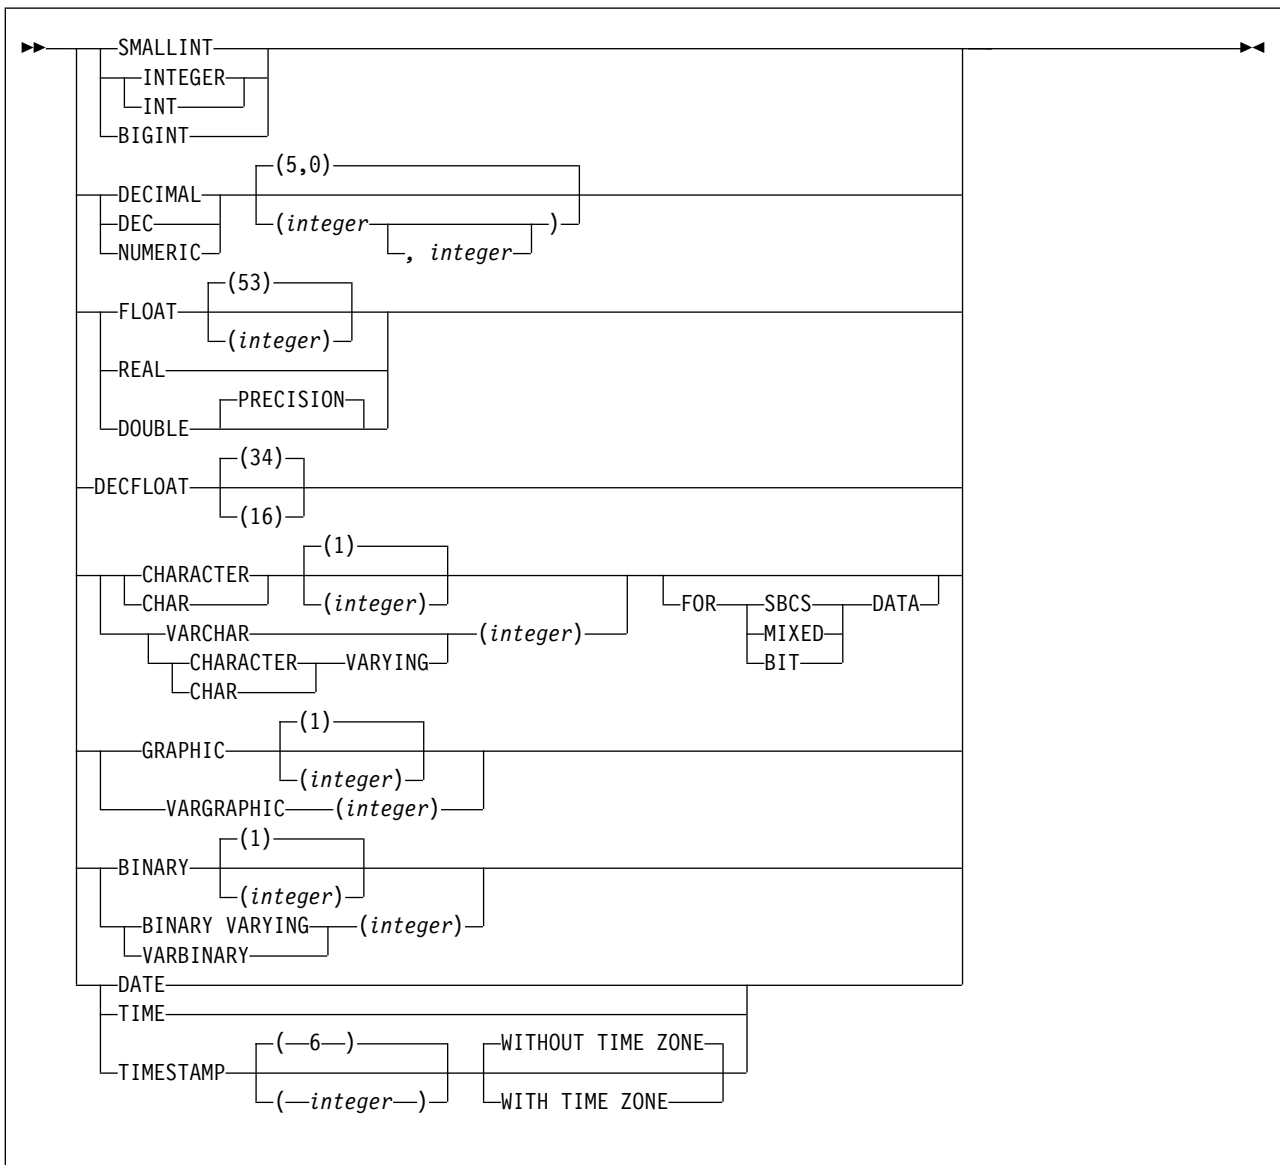

column-definition:

data-type:

built-in-type:

Description

table-name

Names the temporary table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, synonym, or temporary table that exists at the database server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

The qualification rules for a temporary table are the same as for other tables.

The owner acquires ALL PRIVILEGES on the table WITH GRANT OPTION and the authority to drop the table.

column-definition

Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32714 bytes. The maximum row size must not exceed 32706 bytes (8 bytes less than the maximum record size).

column-name

Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

data-type

Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the column is a built-in data type.

For more information on and the rules that apply to the data types, see built-in-type.

distinct-type

Any distinct type except one that is based on a LOB or ROWID data type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

NOT NULL

Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

LIKE *table-name* or *view-name*

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view. The name specified after LIKE must identify a table, view, or temporary table that exists at the current server. The identified table must not be an accelerator-only table. A view cannot contain columns of length 0.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If any column of the identified table or view has an attribute value that is not allowed for a column in a temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.
- If any column of the identified table or view allows a default value other than null, that default value is ignored and the corresponding column in the new temporary table has no default value. A default value other than null is not allowed for any column in a temporary table.

CCSID encoding-scheme

Specifies the encoding scheme for string data stored in the table.

ASCII Specifies that the data must be encoded by using the ASCII CCSIDs of the server.

An error occurs if a valid ASCII CCSID has not been specified for the installation.

EBCDIC

Specifies that data must be encoded by using the EBCDIC CCSIDs of the server.

An error occurs if a valid EBCDIC CCSID has not been specified for the installation.

UNICODE

Specifies that data must be encoded by using the CCSIDs of the server for Unicode.

An error occurs if a valid CCSID for Unicode has not been specified for the installation.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used. An error occurs if CCSIDs have not been defined.

For the creation of temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause.

Notes

Owner privileges: The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 2026) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Instantiation and termination: Let T be a temporary table defined at the current server and let P denote an application process:

- An empty instance of T is created as a result of the first implicit or explicit reference to T in an OPEN, SELECT INTO or SQL data change operation that is executed by any program in P.
- Any program in P can reference T and any reference to T by a program in P is a reference to that instance of T.

When a commit operation terminates a unit of work in P and no program in P has an open WITH HOLD cursor that is dependent on T, the commit includes the operation DELETE FROM T.

- When a rollback operation terminates a unit of work in P, the rollback includes the operation DELETE FROM T.
- When the connection to the database server at which an instance of T was created terminates, the instance of T is destroyed. However, the definition of T remains. A DROP TABLE statement must be executed to drop the definition of T.

Restrictions and extensions: Let T denote a temporary table:

- Columns of T cannot have default values other than null.

- A column of T cannot have a LOB or ROWID data type (or a distinct type based on one).
- T cannot have unique constraints, referential constraints, or check constraints.
- T cannot be defined as the parent in a referential constraint.
- T cannot be referenced in:
 - A CREATE INDEX statement.
 - A LOCK TABLE statement.
 - As the object of an UPDATE statement in which the object is T or a view of T. However, you can reference T in the WHERE clause of an UPDATE statement (including the update operation of the MERGE statement).
 - DB2 utility commands.
- If T is referenced in the *fullselect* of a CREATE VIEW statement, you cannot specify a WITH CHECK OPTION clause in the CREATE VIEW statement.
- ALTER TABLE T is valid only if the statement is used to add a column to T. Any column that you add to T must have a default value of null.

When you alter T, any packages that refer to the table are invalidated, and DB2 automatically rebinds the packages the next time they are run.
- DELETE FROM T or a *view of T* is valid only if the statement does not include a WHERE or WHERE CURRENT OF clause. In addition, DELETE FROM *view of T* is valid only if the view was created (CREATE VIEW) without the WHERE clause. A DELETE FROM statement deletes all the rows from the table or view.
- You can refer to T in the FROM clause of any subselect. If you refer to T in the first FROM clause of a *select-statement*, you cannot specify a FOR UPDATE clause.
- You cannot use a DROP DATABASE statement to implicitly drop T. To drop T, reference T in a DROP TABLE statement.
- A temporary table instantiated by an SQL statement using a three-part table name can be accessed by another SQL statement using the same name in the same application process for as long as the DB2 connection which established the instantiation is not terminated.
- GRANT ALL PRIVILEGES ON T is valid, but you cannot grant specific privileges on T.

Of the ALL privileges, only the ALTER, INSERT, DELETE, and SELECT privileges can actually be used on T.
- REVOKE ALL PRIVILEGES ON T is valid, but you cannot revoke specific privileges from T.
- A COMMIT operation deletes all rows of every temporary table of the application process, but the rows of T are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on T. In addition, if RELEASE(COMMIT) is in effect and no open WITH HOLD cursors are dependent on T, all logical work files for T are also deleted.
- A ROLLBACK operation deletes all rows and all logical work files of every temporary table of the application process.
- You can reuse threads when using a temporary table, and a logical work file for a temporary table name remains available until deallocation. A new logical work file is not allocated for that temporary table name when the thread is reused.
- You can refer to T in the following statements:

| | | |
|-----------------|-------------------|---|
| ALTER FUNCTION | CREATE PROCEDURE | DECLARE TABLE |
| ALTER PROCEDURE | CREATE SYNONYM | DELETE (if it does not include a WHERE clause) |
| COMMENT | CREATE TABLE LIKE | DROP TABLE |
| CREATE ALIAS | CREATE VIEW | INSERT |
| CREATE FUNCTION | DESCRIBE TABLE | LABEL |
| | | SELECT INTO |

Alternative syntax and synonyms: For compatibility with previous releases of DB2, you can specify LONG VARCHAR as a synonym for VARCHAR(*integer*) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(*integer*) when defining the data type of a column. However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

Examples

Example 1: Create a temporary table, CURRENTMAP. Name two columns, CODE and MEANING, both of which cannot contain nulls. CODE contains numeric data and MEANING has character data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, column MEANING has a subtype of SBCS:

```
CREATE GLOBAL TEMPORARY TABLE CURRENTMAP
(CODE INTEGER NOT NULL, MEANING VARCHAR(254) NOT NULL);
```

Example 2: Create a temporary table, EMP:

```
CREATE GLOBAL TEMPORARY TABLE EMP
(TMPDEPTNO CHAR(3) NOT NULL,
TMPDEPTNAME VARCHAR(36) NOT NULL,
TMPMGRNO CHAR(6) ,
TMPLOCATION CHAR(16) );
```

CREATE INDEX

The CREATE INDEX statement creates a partitioning index or a secondary index and an index space at the current server. The columns included in the key of the index are columns of a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The INDEX privilege on the table
- Ownership of the table
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the index is created using an expression, the EXECUTE privilege is required on any user-defined function that is invoked in the index expression.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the specified index name includes a qualifier that is not the same as this owner, the privilege set must include SYSADM or SYSCTRL authority, or DBADM or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

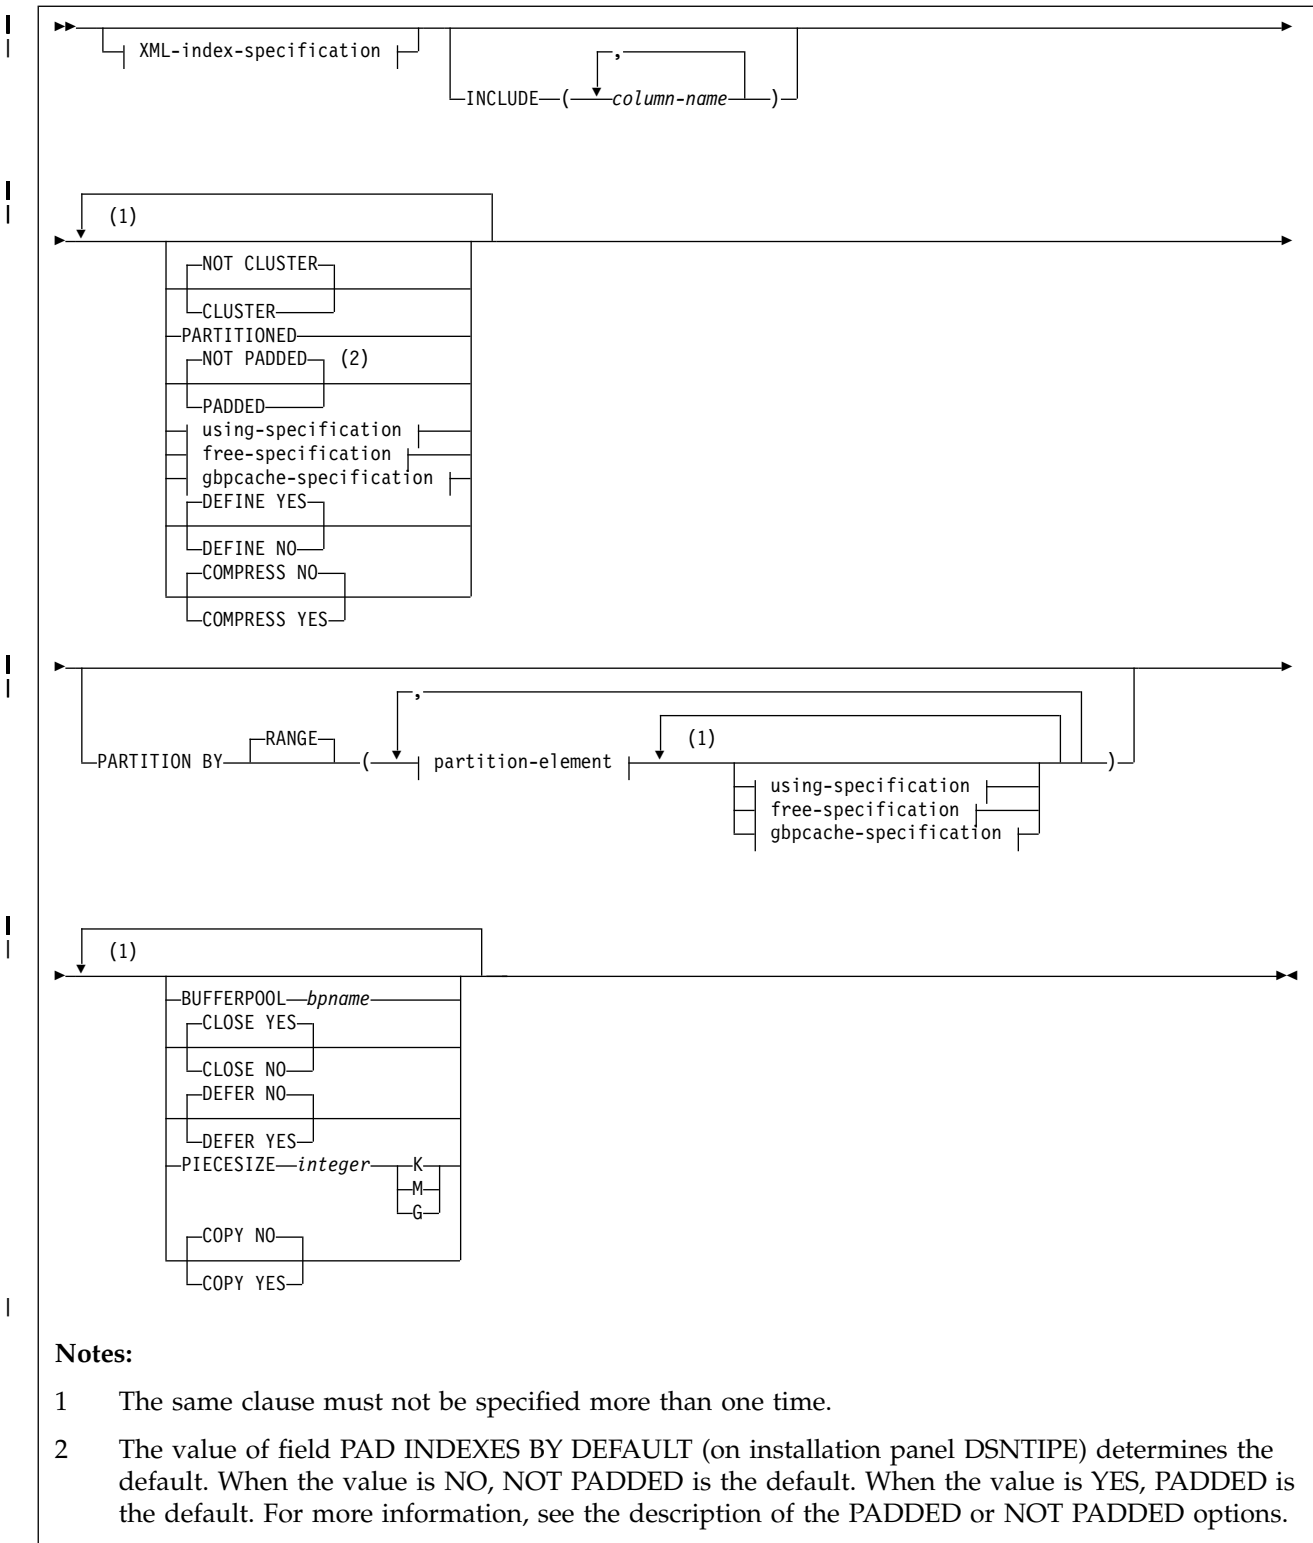

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. However, if the specified index name includes a qualifier that is not the same as this authorization ID, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
- If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all privileges needed to create the index. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

Description

UNIQUE

Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

UNIQUE WHERE NOT NULL

Prevents the table from containing two or more rows with the same value of the index key where all null values for a column are not considered equal. Multiple null values are allowed. Otherwise, this is identical to UNIQUE.

INDEX *index-name*

Names the index. The name must not identify an index that exists at the current server, or is listed in the SYSIBM.SYSPENDINGOBJECTS catalog table, or is in an accelerator-only table.

The associated index space also has a name. That name appears as a qualifier in the names of data sets defined for the index. If the data sets are managed by the user, the name is the same as the second (or only) part of *index-name*. If this identifier consists of more than eight characters, only the first eight are used. The name of the index space must be unique among the names of the index spaces and table spaces of the database for the identified table. If the data sets are defined by DB2, DB2 derives a unique name.

If the index is an index on a declared temporary table, the qualifier, if explicitly specified, must be SESSION. If the index name is unqualified, DB2 uses SESSION as the implicit qualifier.

ON *table-name* or *aux-table-name*

Identifies the table on which the index is created. The name can identify a base table, a materialized query table, a declared temporary table, or an auxiliary table.

table-name

Identifies the base table, materialized query table, or declared temporary table on which the index is created. The name must identify a table that exists at the current server. (The name of a declared temporary table must be qualified with SESSION.)

The name must not identify a clone table. The name must not identify a created temporary table or a table that is implicitly created for an XML column. If the index that is being created is for XML values, the table can contain an XML column, otherwise, the table must not contain an XML column. The name must not identify a catalog table or declared temporary table if the index is created using expressions. The name must not identify an accelerator-only table.

If the table has enforced row or column access controls, the row permissions and column masks are not applied during key generation.

column-name,...

Specifies the columns of the index key.

Each *column-name* must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. Do not qualify *column-name*.

Do not specify a column for *column-name* that is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- a BINARY or VARBINARY column (or a column with a distinct type that is based on a BINARY or VARBINARY data type) when the PARTITION BY RANGE clause is also specified
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type) when the PADDED clause is also specified
- a row change timestamp column when the PARTITION BY RANGE clause is also specified.
- a timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) when the PARTITION or PARTITION BY RANGE clause is also specified.

A column with an XML type can only be specified if the XMLPATTERN clause is also specified. If the XMLPATTERN clause is specified, only one column can be identified and the column must be an XML type. The resulting index is an XML index.

The sum of the length attributes of the columns must not be greater than the following limits, where n is the number of columns that can contain null values and m is the number of varying-length columns in the key:

- $2000 - n$ for a padded, nonpartitioning index
- $2000 - n - 2m$ for a nonpadded, nonpartitioning index
- $255 - n$ for a partitioning index (padded or nonpadded)
- $255 - n - 2m$ for a nonpadded, partitioning index

key-expression

Specifies an expression that returns a scalar value. An index with a key that includes one or more expressions consisting of more than just a column name is an *expression-based index*. *key-expression* cannot be specified with the GENERATE KEY USING clause or the INCLUDE clause. *key-expression* has the following restrictions:

- Each *key-expression* must contain at least one reference to a column of *table-name*.

All references to columns of *table-name* must be unqualified.

Referenced columns cannot be LOB, XML, or DECFLOAT data types or a distinct type that is based on one of these data types.

Referenced columns cannot include any FIELDPROCs or a SECURITY LABEL. Referenced columns cannot be implicitly hidden (that is, defined with the IMPLICITLY HIDDEN attribute).

- *key-expression* must not include any of the following:
 - A subquery
 - An aggregate function
 - A function that is not deterministic function
 - A function that has an external action
 - A user-defined function

- The VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER functions
 - A sequence reference
 - A host variable
 - A parameter marker
 - A special register
 - An expression for which implicit time zone value apply (or example, cast a timestamp to a timestamp with time zone)
 - A CASE expression
 - An OLAP specification
- If *key-expression* references a cast function, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type.
 - If *key-expression* references the LOWER or UPPER functions, the input *string-expression* cannot be FOR BIT DATA, and the function invocation must contain the *locale-name* argument.
 - If *key-expression* references the TRANSLATE function, the function invocation must contain the *to-string* argument.
 - If *key-expression* references the SUBSTR function, the function can reference the inline portion of a LOB column.
 - The same expression cannot be used more than one time in the same index.
 - The data type of the result of the expression cannot be a LOB, XML, or DECFLOAT value. However, the data type of the intermediate result can be a LOB value, but not an XML or DECFLOAT value.
 - The encoding scheme of the result of a *key-expression* must be the same encoding scheme as the table.

The maximum length of the text string of each *key-expression* is 4000 bytes after conversion to UTF-8. The maximum number of *key-expression* in an extended index is 64.

ASC

Puts the index entries in ascending order by the column. ASC cannot be specified with the GENERATE KEY USING clause.

ASC is the default.

DESC

Puts the index entries in descending order by the column. DESC cannot be specified with the GENERATE KEY USING clause or if the ON clause contains *key-expression*.

RANDOM

Index entries are put in a random order by the column. RANDOM cannot be specified in the following cases:

- A varying length column is part of the index key and the index is defined with the NOT PADDED option
- A column of the index key is defined as TIMESTAMP WITH TIME ZONE
- The index is an XML index. An XML index is defined with the GENERATE KEY USING clause
- The index is part of the partitioning key
- The index is an expression-based index

BUSINESS_TIME WITHOUT OVERLAPS

Specifies that the columns of the BUSINESS_TIME period are automatically added to the end of the index key in the following order:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. The list must also include at least one *column-name* or *key-expression*. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as *column-name* or a *key-expression*, or as columns in the partitioning key.

WITH OR WITHOUT OVERLAPS

Indicates whether multiple rows may exist with the same values for the non-period columns and expressions of the index key for a row, with overlapping time periods.

WITHOUT OVERLAPS

Indicates that the values for the non-period columns and expressions of the index key for a row must be unique with respect to the time represented by the BUSINESS_TIME period for the row. DB2 enforces that multiple rows do not exist with the same key values for the columns or expressions of the index, with overlapping time periods.¹⁴ The BUSINESS_TIME WITHOUT OVERLAPS clause is intended for use in defining a unique index to enforce a primary key or unique constraint.

BUSINESS_TIME WITHOUT OVERLAPS can only be specified for an index that is defined as UNIQUE.

aux-table-name

Identifies the auxiliary table on which the index is created. The name must identify an auxiliary table that exists at the current server. If the auxiliary table already has an index, do not create another one. An auxiliary table can only have one index.

Do not specify any columns for the index key. The key value is implicitly defined as a unique 19 byte value that is system generated.

If qualified, *table-name* or *aux-table-name* can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.) Whether the name is two-part or three-part, the authorization ID that qualifies the name is the owner of the index.

The table space that contains the named table must be available to DB2 so that its data sets can be opened. If the table space is EA-enabled, the data sets for the index must be defined to belong to a DFSMS data class that has the extended format and addressability attributes.

GENERATE KEY USING

Along with XMLPATTERN, GENERATE KEY USING is required to generate an XML index.

XMLPATTERN

When an XML column is indexed, only parts of the documents will be indexed. To identify those parts, a path expression that follows the

XMLPATTERN clause is specified. Only values of those element, attribute, or text nodes which match the specified pattern are indexed. An XML pattern can be specified using an optional namespace declaration where namespace prefixes are mapped to namespace URIs and by providing a path expression. The path expression is similar to a path expression in XQuery except that the paths that are specified for the XML index can support child axis, self-or-descendant axis, wildcard expressions, or attribute only. The maximum length of an XML pattern text is 4000 bytes after being converted to UTF-8. Refer to *DB2 XML Guide* for more information about XQuery.

prolog

To use qualified names in the *pattern-expression*, namespace prefixes need to be declared. A default namespace can also be declared for use with unqualified names.

declare namespace *NCName=StringLiteral*

The namespace prefix, *NCName*, is mapped to a namespace URI that is identified in *StringLiteral*. Multiple namespaces can be declared, but each namespace prefix must be unique within the list of namespace declarations. *NCName* is an XML name as defined by the XML 1.0 standard. *NCName* cannot include a colon character. The namespace URI cannot be `http://www.w3.org/XML/1998/namespace` or `http://w3.org/2000/xmlns/`.

declare default element namespace *StringLiteral*

Specifies the default namespace URI for unqualified names of elements and types. *StringLiteral* is a namespace URI. If no default element namespace is declared, unqualified names of element and types are in no namespace. Only one default namespace can be declared.

pattern-expression

Pattern-expression is used to identify those nodes in an XML document that are indexed. *Pattern-expression* cannot be an empty or invalid string, and the XQuery expression cannot be nested more than 50 levels. *pattern-expression* cannot be an XQuery updating expression.

/ (forward slash)

Separates path expression steps.

// (double forward slash)

Abbreviated syntax for `/descendant-or-self::node()/`

. (dot)

Abbreviated syntax for `/self::node()/`

child::

Specifies children of the context node. `child::` is the default if no forward axis is specified.

descendant::

Specifies the descendants of the context node.

self::

Specifies the current context node.

descendant-or-self::

Specifies the context node and the descendents of the context node.

element-name

Identifies an element in an XML document. *element-name* is an XML QName that can have one of the following forms:

nsprefix:NCName

nsprefix explicitly specifies a namespace prefix that must be declared.

NCName

An unqualified XML name that uses the default namespace.

*** (an asterisk)**

Indicates any element name. If * is prefixed by *attribute::* or *@*, * indicates any attribute name.

*nsprefix:**

Indicates any NCName within the specified namespace.

**:NCName*

Indicates a specific XML name in any of the currently declared namespaces.

attribute:: or @

Specifies attributes of the context node.

attribute-name

Identifies an attribute in an XML document. *attribute-name* is an XML QName that can have one of the following forms:

nsprefix:NCName

nsprefix explicitly specifies a namespace prefix that must be declared.

NCName

An unqualified XML name that uses the default namespace.

text()

Matches any text node.

fn:upper-case(.)

Specifies an element node or an attribute node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to *fn:upper-case*).

The context step of *fn:upper-case()* must specify an element node or an attribute node. The argument of *fn:upper-case()* must be a self step. The key values of an XML value index must be specified as the SQL data type VARCHAR. The length of the VARCHAR value can be any value that is allowed in DB2.

fn:exists()

Specifies an element node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to *fn:exists*).

The context step of *fn:exists()* must specify an element node. The argument of *fn:exists()* must be either a single step of a child element node or an attribute node. The name test part can be a wildcard character for either the namespace prefix or NCName. The key values of an XML value index for an XPath expression that ends with *fn:exists()* must be specified as the SQL data type VARCHAR(1). The key value will be "T" or "F". "T" implies that *fn:exists()* evaluates to true and "F" implies that *fn:exists()* evaluates to false.

AS SQL data-type

Specifies that indexed values are stored as an instance of the specified SQL data type. Casting to the specified data type can result in a loss of precision of

the values. For example, a loss of precision can occur when an XML integer value is cast to the SQL data type DECFLOAT. If the cast causes a loss of precision, the result will be rounded to the approximate value when it is stored in the index. The cast result cannot be outside of the range that is supported by the SQL data type. If the value cannot be cast to the specified data type, the document is still inserted into the table, but the index entry for that value is not created. No error or warning code is returned.

If the index is unique, the uniqueness is enforced on the value after it is cast to the specified type. Because rounding can occur during the cast to the SQL data type, if a value is cast to the same key value as a document that the table already contains, DB2 will return duplicate key errors at insert time, or fail to create the index.

VARCHAR (*integer*)

The length *integer* is a value in the range of 1 to 1000 bytes. If VARCHAR is specified with a length, the specified length is treated as a constraint. If documents are inserted into a table (or exist in the table at create index time) that have nodes with values that are longer than the specified length, the insert or index creation will fail.

DECFLOAT

DECFLOAT can be specified to index numeric values. For the cast to succeed, the string must be a valid XML numeric type. Otherwise the value will be ignored and no insert to the index will occur. The result of the cast cannot be outside of the range that DECFLOAT can represent. Because the XML Schema data type for numeric values allows greater precision than the SQL data type, the result might be rounded to fit into the SQL data type. The DECFLOAT values that are stored in the index are the normalized numeric values.

DATE

The SQL DATE data type values will be normalized to UTC (Coordinated Universal Time) before being stored in the index. For invalid *xs:date* values, the value will be ignored without being inserted into the index. The XML schema data type for DATE allows for greater precision than the SQL data type. If an out-of-range value is encountered, an error is returned.

TIMESTAMP (12)

The SQL TIMESTAMP data type values will be normalized to UTC (Coordinated Universal Time) before being stored in the index. If the value that is specified in the document does not specify the time zone, DB2 will use the implicit time zone to normalize the value to UTC. For invalid *xs:dateTime* values, the value will be ignored without being inserted into the index. The XML schema data type for timestamps allows for greater precision than the SQL data type. If an out-of range value is encountered, an error is returned. Only a precision of 12 fractional digits is allowed for an SQL TIMESTAMP index key.

INCLUDE (*column-name*)

Specifies additional columns to append to the set of index key columns of a unique index. Any column that is specified using **INCLUDE** *column-name* is not used to enforce uniqueness. The included columns might improve performance for some queries using index only access.

The **UNIQUE** clause must be specified when **INCLUDE** is specified. Columns that are specified in the **INCLUDE** clause count towards the limits for the

number of columns and the limits on the sum of the length attributes of the columns that are specified in the index. The total number of columns for the index cannot exceed 64.

column-name must be distinct from the columns that are used to enforce uniqueness and from other columns specified in the INCLUDE clause. *column-name* must be unqualified, must identify a column of the specified table, and must not be one of the existing columns of the index. *column-name* must not identify a LOB or DECFLOAT column (or a distinct type that is based on one of those types).

The INCLUDE clause cannot be specified for the following types of indexes:

- A non-unique index
- A partitioning index when index-controlled partitioning is used
- An auxiliary index
- An XML index
- An extended index
- An expression-based index

Columns in the INCLUDE list that are defined as character or graphic string data types must be defined with the same encoding scheme as other key columns with character or graphic string data types.

CLUSTER or NOT CLUSTER

Specifies whether the index is the clustering index for the table. This clause must not be specified for an index on an auxiliary table, or on a table that is defined to use hash organization.

CLUSTER

The index is to be used as the clustering index of the table. CLUSTER cannot be specified if XMLPATTERN or *key-expression* is specified.

NOT CLUSTER

The index is not to be used as the clustering index of the table.

PARTITIONED

Specifies that the index is data partitioned (that is, partitioned according to the partitioning scheme of the underlying data). A partitioned index can be created only on a partitioned table space, not on a partition-by-growth table space. PARTITIONED cannot be specified if XMLPATTERN is specified. The types of partitioned indexes are partitioning and secondary.

An index is considered a partitioning index if the specified index key columns match or comprise a superset of the columns specified in the partitioning key, are in the same order, and have the same ascending or descending attributes.

If PARTITION BY was not specified when the table was created, the CREATE INDEX statement must have the ENDING AT clause specified to define a partitioning index and use index-controlled partitioning. This index is created as a partitioned index even if the PARTITIONED keyword is not specified. When a partitioning index is created, if both the PARTITIONED and ENDING AT keywords are omitted, the index will be non-partitioned. If PARTITIONED is specified, the USING specification with PRIQTY and SECQTY specifications are optional. If these space parameters are not specified, default values are used.

A secondary index is any index defined on a partitioned table space that does not meet the definition of the partitioning index. For partitioned secondary indexes (data-partitioned secondary indexes), the ENDING AT clause is not

allowed because the partitioning scheme of the index is predetermined by that of the underlying data. UNIQUE and UNIQUE WHERE NOT NULL are allowed only if the columns in the index are a superset of the partitioning columns. All of the index columns must be specified in a *table-name(column-name)* clause, and not in an INCLUDE clause. If a partitioned secondary index is created on a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning.

Index-controlled partitioning cannot be used if the PREVENT_NEW_IXCTRL_PART subsystem parameter is set to YES.

Related information:

Subsystem parameters that are not on installation panels (DB2 Installation and Migration)

NOT PADDED or PADDED

Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned. Indexes that do not have varying-length string columns are always created as physically padded indexes.

NOT PADDED

Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key.

NOT PADDED is ignored and has no effect if the index is being created on an auxiliary table. Indexes on auxiliary tables are always padded.

PADDED

Specifies that varying-length string columns within the index are always padded with the default pad character to their maximum length. PADDED cannot be specified if XMLPATTERN is specified. PADDED cannot be specified for indexes that are defined on VARBINARY columns.

When the index contains at least one varying-length column, the default for the option depends on the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE:

- When the value of this field is NO, new indexes are not padded unless PADDED is specified.
- When the value of this field is YES, new indexes are padded unless NOT PADDED is specified.

The components of the USING clause are discussed below, first for non-partitioned indexes and then for partitioned indexes.

Using clause for non-partitioned indexes

For non-partitioned indexes, the USING clause indicates whether the data sets for the index are to be managed by the user or managed by DB2. If DB2 definition is specified, the clause also gives space allocation parameters (PRIQTY and SECQTY) and an erase rule (ERASE).

If you omit USING, the data sets will be managed by DB2 on volumes listed in the default storage group of the database that is associated with the table. That default storage group must exist. With no USING clause, PRIQTY, SECQTY, and ERASE assume their default values.

VCAT *catalog-name*

Specifies that the first data set for the index is managed by the user, and that following data sets, if needed, are also managed by the user.

The data sets defined for the index are linear VSAM data sets cataloged in an integrated catalog facility catalog identified by *catalog-name*. An alias³² must be used if *catalog-name* is longer than eight characters.

Conventions for index data set names are given in Data set naming conventions (DB2 Administration Guide). *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

Do not specify VCAT in any of the following circumstances:

- For an index on a declared temporary table.
- If the table space is partition-by-growth, and the table space is not part of the DB2 catalog.

STOGROUP *stogroup-name*

Specifies that DB2 will define and manage the data sets for the index. Each data set will be defined on a volume listed in the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. If $PRIQTY + 118 \times SECQTY$ is 2 gigabytes or greater, more than one data set could eventually be used, but only the first is defined during execution of this statement.

To use USING STOGROUP, the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. Moreover, *stogroup-name* must identify a storage group that exists at the current server and includes in its description at least one volume serial number. The description can indicate that the choice of volumes will be left to Storage Management Subsystem (SMS). Each volume specified in the storage group must be accessible to z/OS for dynamic allocation of the data set, and all these volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must *not* contain an entry for the first data set of the index. If the catalog is password protected, the description of the storage group must include a valid password.

The storage group supplies the data set name. The first level qualifier is also the name of, or an alias for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming convention for the data set is the same as if the data set is managed by the user.

PRIQTY *integer*

Specifies the minimum primary space allocation for a DB2-managed data set. *integer* must be a positive integer, or -1. When you specify PRIQTY with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is:

- 12 If *integer* is greater than 0 and less than 12.

32. The alias of an integrated catalog facility catalog

integer

If *integer* is between 12 and 4194304.

2097152

If both of the following conditions are true:

- *integer* is greater than 2097152.
- The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.

4194304

If *integer* is greater than 4194304.

If you do not specify PRIQTY, or you specify a PRIQTY value of -1, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of 4KB not less than *n*. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

When determining a suitable value for PRIQTY, be aware that two of the pages of the primary space could be used by DB2 for purposes other than storing index entries.

SECQTY *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set. *integer* must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify a SECQTY value of -1, DB2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify **SECQTY**, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of 4KB not less than *integer*. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE

Indicates whether the DB2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index.

NO Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2. This is the default.

YES

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

USING clause for partitioned indexes:

If the index is partitioned, there is a PARTITION clause for each partition.

Within a PARTITION clause, a USING clause is optional. If a USING clause is present, it applies to that partition in the same way that a USING clause for a secondary index applies to the entire index.

When a USING specification is absent from a PARTITION clause, the USING clause parameters for the partition depend on whether a USING clause is specified before the PARTITION clauses.

- If the USING clause is specified, it applies to every PARTITION clause that does not include a USING clause.
- If the USING clause is not specified, the following defaults apply to the partition:
 - Data sets are managed by DB2
 - The default storage group for the database is used
 - A value of 12 is used for PRIQTY and SECQTY
 - A value of NO is used for ERASE

VCAT *catalog-name*

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify an alias for the integrated catalog facility catalog if the name of the integrated catalog facility catalog is longer than eight characters.

If *n* is the number of the partition, the identified integrated catalog facility catalog must already contain an entry for the *n*th data set of the index, conforming to the DB2 naming convention for data sets set forth in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

STOGROUP *stogroup-name*

If USING STOGROUP is used, explicitly or by default, for a partition *n*, DB2 defines the data set for the partition during the execution of the CREATE INDEX statement, using space from the named storage group. The privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. The integrated catalog facility catalog used for the storage group must NOT contain an entry for the *n*th data set of the index.

stogroup-name must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group.

If you omit PRIQTY, SECQTY, or ERASE from a USING STOGROUP clause for some partition, their values are given by the next USING STOGROUP clause that governs that partition: either a USING clause that is not in any PARTITION clause, or a default USING clause. DB2 assumes one and only one data set for each partition.

FREEPAGE *integer*

Specifies how often to leave a page of free space when index entries are created as the result of executing a DB2 utility or when creating an index for a table with existing rows. One free page is left for every *integer* pages. The value of *integer* can range from 0 to 255. The default is 0, leaving no free pages.

Do not specify FREEPAGE for an index on a declared temporary table.

PCTFREE *integer*

Determines the percentage of free space to leave in each nonleaf page and leaf page when entries are added to the index or index partition as the result of executing a DB2 utility or when creating an index for a table with existing rows. The first entry in a page is loaded without restriction. When additional entries are placed in a nonleaf or leaf page, the percentage of free space is at least as great as *integer*.

The value of *integer* can range from 0 to 99, however, if a value greater than 10 is specified, only 10 percent of free space will be left in nonleaf pages. The default is 10.

Do not specify PCTFREE for an index on a declared temporary table.

If the index is partitioned , the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that applies:

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition. Do not use more than one *free-specification* in any PARTITION clause.
- The values given in a *free-specification* that is not in any PARTITION clause.
- The default values FREEPAGE 0 and PCTFREE 10.

GBPCACHE

In a data sharing environment, specifies what index pages are written to the group buffer pool. In a non-data-sharing environment, the option is ignored unless the index is on a declared temporary table. Do not specify GBPCACHE for an index on a declared temporary table in either environment (data sharing or non-data-sharing).

CHANGED

Specifies that updated pages are written to the group buffer pool, when there is inter-DB2 R/W interest on the index or partition. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the index or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), CHANGED is ignored and no pages are written to the group buffer pool.

ALL

Indicates that pages are written to the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating DB2 subsystem when no other DB2 subsystems have any interest in the page set, no pages are written to the group buffer pool.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), ALL is ignored and no pages are written to the group buffer pool.

NONE

Indicates that no pages are written to the group buffer pool. DB2 uses the group buffer pool only for cross-invalidation.

If the index is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one *gbpcache-specification* in any PARTITION clause.
2. The value given in a *gbpcache-specification* that is not in any PARTITION clause.
3. GBPCACHE CHANGED is the default value.

DEFINE

Specifies when the underlying data sets for the index are physically created. The SPACE column in catalog table SYSINDEXPART is used to record the status of the data sets (undefined or allocated). If the DEFINE keyword is not specified, the define attribute is inherited from the current state of the base table space.

YES

The data sets are created when the index is created (the CREATE INDEX statement is executed).

NO The data sets are not created until data is inserted into the index.

DEFINE NO is applicable only for DB2-managed data sets (USING STOGROUP is specified). Use DEFINE NO especially when performance of the CREATE INDEX statement is important or DASD resource is constrained.

Do not use DEFINE NO on an index if you use a program outside of DB2 to propagate data into a table on which that index is defined. If you use DEFINE NO on an index of a table and data is then propagated into the table from a program that is outside of DB2, the index space data sets are allocated, but the DB2 catalog will not reflect this fact. As a result, DB2 treats the data sets for the index space as if they have not yet been allocated. The resulting inconsistency causes DB2 to deny application programs access to the data until the inconsistency is resolved.

DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DEFINE NO is also ignored if the index is being created on a table that is not empty or on an auxiliary table.

Do not specify DEFINE NO if the index is created on a base table that is involved in a clone relationship.

Do not specify DEFINE NO for an index on a declared temporary table.

COMPRESS NO or COMPRESS YES

Specifies whether compression for index data will be used. If the index is partitioned, the clause will apply to all partitions.

COMPRESS NO

Specifies that no index compression will be used.

COMPRESS NO is the default.

COMPRESS YES

Specifies that index compression will be used. The bufferpool that is used to create the index must be 8K, 16K, or 32K in size. The physical page size on disk will be 4K. The index compression will take place immediately.

Index compression is recommended for applications that do sequential insert operations with few or no delete operations. Random inserts and deletes can adversely effect compression. Index compress is also recommended for applications where the indexes are created primarily for scan operations.

PARTITION BY RANGE

Specifies the partitioning index for the table, which determines the partitioning scheme for the data in the table.

PARTITION BY RANGE should only be specified if the table space is partitioned and the partitioning schema has not already been established.

PARTITION BY RANGE must not be specified if the index is an extended index, is defined with the **BUSINESS_TIME WITHOUT OVERLAPS**, or if the table is in a universal table space (ranged-partitioned or partition-by-growth table space).

partition-element

Specifies the range for each partition.

PARTITION integer

A **PARTITION** clause specifies the highest value of the index key in one partition of a partitioning index. In this context, highest means highest in the sorting sequences of the index columns. In a column defined as *ascending* (**ASC**), highest and lowest have their usual meanings. In a column defined as *descending* (**DESC**), the lowest actual value is highest in the sorting sequence.

If you use **CLUSTER**, and the table is contained in a partitioned table space, you must use exactly one **PARTITION** clause for each partition (defined with **NUMPARTS** on **CREATE TABLESPACE**). If there are *p* partitions, the value of *integer* must range from 1 through *p*.

The length of the highest value of a partition (also called the limit key) is the same as the length of the partitioning index.

ENDING AT(*constant*, **MAXVALUE**, or **MINVALUE**...)

Specifies that this is the partitioning index and indicates how the data will be partitioned. The table space is marked complete after this partitioning index is created. You must use at least one value (*constant*, **MAXVALUE**, or **MINVALUE**) after **ENDING AT** in each **PARTITION** clause. You can use as many as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index unless the **VALUES** statement was already specified when the table or previous index was created.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is **X'FF'**. If the column is descending, the padding character is **X'00'**. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (**GX**) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all **X'FF'** regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the **MINVALUE**

clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MAXVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- The highest value of the key in the last partition depends on how the table space is defined. For table spaces that are created without the LARGE or DSSIZE options, the values that you specify after VALUES are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

For large partitioned table space, the values you specify are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value that is specified for the last partition are out of range.

ENDING AT can be specified only if the ENDING AT clause was not specified on a previous CREATE or ALTER TABLE statement for the underlying table.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

BUFFERPOOL *bpname*

Identifies the buffer pool that is to be used for the index. The *bpname* must identify an activated 4KB, 8KB, 16KB, or 32KB buffer pool and the privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

The default is the default 4KB buffer pool for indexes in the database. A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

See “Naming conventions” on page 59 for more details about *bpname*. See *DB2 Command Reference* for a description of active and inactive buffer pools.

CLOSE

Specifies whether or not the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached.

YES

Eligible for closing. This is the default unless the index is on a declared temporary table.

NO Not eligible for closing.

If the limit on the number of open data sets is reached and there are no page sets that specify CLOSE YES to close, page sets that specify CLOSE NO will be closed.

For an index on a declared temporary table, DB2 uses CLOSE NO regardless of the value specified.

DEFER

Indicates whether the index is built during the execution of the CREATE INDEX statement. Regardless of the option specified, the description of the index and its index space is added to the catalog. If the table is determined to be empty and DEFER YES is specified, the index is neither built nor placed in a rebuild-pending status. Refer to *DB2 Administration Guide* for more information about using DEFER. Do not specify DEFER for an index on a declared temporary table or an auxiliary table.

NO The index is built. This is the default.

YES

The index is not built. If the table is populated, the index is placed in a rebuild-pending status and a warning message is issued; the index must be rebuilt by the REBUILD INDEX utility.

PIECESIZE *integer*

Specifies the maximum addressability of each data set for a non-partitioned index. The subsequent keyword K, M, or G, indicates the units of the value that is specified in *integer*.

K Indicates that the *integer* value is to be multiplied by 1024 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 268435456.

M Indicates that the *integer* value is to be multiplied by 1048576 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 262144.

G Indicates that the *integer* value is to be multiplied by 1073741824 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 256.

Table 164 shows the valid values for the data set size, which depend on the size of the table space.

Table 164. Valid values of PIECESIZE clause

| K units | M units | G units | Size attribute of table space |
|----------------|----------------|----------------|--------------------------------------|
| 256K | | | |
| 512K | | | |
| 1024K | 1M | | |

Table 164. Valid values of PIECESIZE clause (continued)

| K units | M units | G units | Size attribute of table space |
|------------|---------|---------|-------------------------------|
| 2048K | 2M | | |
| 4096K | 4M | | |
| 8192K | 8M | | |
| 16384K | 16M | | |
| 32768K | 32M | | |
| 65536K | 64M | | |
| 131072K | 128M | | |
| 262144K | 256M | | |
| 524288K | 512M | | |
| 1048576K | 1024M | 1G | |
| 2097152K | 2048M | 2G | |
| 4194304K | 4096M | 4G | LARGE, DSSIZE 4G (or greater) |
| 8388608K | 8192M | 8G | DSSIZE 8G (or greater) |
| 16777216K | 16384M | 16G | DSSIZE 16G (or greater) |
| 33554432K | 32768M | 32G | DSSIZE 32G (or greater) |
| 67108864K | 65536M | 64G | DSSIZE 64G (or greater) |
| 134217728K | 131072M | 128G | DSSIZE 128G (or greater) |
| 268435456K | 262144M | 256G | DSSIZE 256G |

PIECESIZE has no effect on primary and secondary space allocation as it is only a specification of the maximum amount of data that a data set can hold and not the actual allocation of storage.

If you change the PIECESIZE value with the ALTER INDEX statement, the index is put into REBUILD-pending status.

See the following for additional information:

- Number of pieces and maximum piece size for non-partitioned indexes and data-partitioned secondary indexes
- Choosing a value for PIECESIZE

COPY

Indicates whether the COPY utility is allowed for the index. Do not specify COPY for an index on a declared temporary table.

NO Does not allow full image or concurrent copies or the use of the RECOVER utility on the index. NO is the default.

YES

Allows full image or concurrent copies and the use of the RECOVER utility on the index.

Notes

Owner privileges:

The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 2026) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Effects of the DEFER clause:

If DEFER NO is implicitly or explicitly specified, the CREATE INDEX statement cannot be executed while a DB2 utility has control of the table space that contains the identified table.

If the identified table already contains data and if the index build is not deferred, CREATE INDEX creates the index entries for it. If the table does not yet contain data, CREATE INDEX creates a description of the index; the index entries are created when data is inserted into the table.

Errors evaluating the expressions for an index:

Errors that occur during the evaluation of an expression for an index are returned when the expression is evaluated. This can occur on an SQL data change statement, SELECT from an SQL data change statement, or the REBUILD INDEX utility. For example, the evaluation of the expression $10 / column_1$ returns an error if the value in *column_1* is 0. The error is returned during CREATE INDEX processing if the table is not empty and contains a row with a value of zero in *column_1*, otherwise the error is returned during the processing of the insert or update operation when a row with a value of zero in *column_1* is inserted or updated.

Result length of expressions that return a string type:

If the result data type of *key-expression* is a string type and the result length cannot be calculated at bind time, the length is set to the maximum allowable length of that data type or the largest length that DB2 can estimate. In this case, the CREATE INDEX statement can fail because the total key length might exceed the limit of an index key.

For example, the result length of the expression REPEAT('A', CEIL(1.1)) is VARCHAR(32767) and the result length of the expression SUBSTR(DESCRIPTION, 1, INTEGER(1.2)) is the length of the DESCRIPTION column. Therefore, a CREATE INDEX statement that uses any of these expressions as a *key-expression* might not be created because the total key length might exceed the limit of an index key.

Use of ASC or DESC on key columns:

There are no restrictions on the use of ASC or DESC for the columns of a parent key or foreign key. An index on a foreign key does not have to have the same ascending and descending attributes as the index of the corresponding parent key.

EBCDIC, ASCII, and UNICODE encoding schemes for an index:

An index has the same encoding scheme as its associated table.

Maximum partition size of a partitioned index

The size of a partitioned index depends on whether the corresponding partitioned table space is created with or without the LARGE or DSSIZE keywords, and on the number of partitions.

The following table provides information about partitioned indexes on table spaces that are created without the LARGE or DSSIZE keywords and with 64 or fewer partitions.

Table 165. Maximum number of pieces and the default size of a partitioned index on a partitioned table space that is created without the LARGE or DSSIZE clauses and with a Numparts value of less than or equal to 64

| Definition of partitioned table space (non-large) | Maximum number of pieces for a partitioned index | Default size of a partitioned index, per data set |
|---|--|---|
| Numparts <= 16 | 16 | 4G |

Table 165. Maximum number of pieces and the default size of a partitioned index on a partitioned table space that is created without the LARGE or DSSIZE clauses and with a Numparts value of less than or equal to 64 (continued)

| Definition of partitioned table space (non-large) | Maximum number of pieces for a partitioned index | Default size of a partitioned index, per data set |
|---|--|---|
| NUMPARTS >= 17 but NUMPARTS <= 32 | 32 | 2G |
| NUMPARTS >= 33 | 64 | 1G |

The following table shows information about partitioned indexes on table spaces that are created with the LARGE or DSSIZE keywords and with more than 64 partitions.

Table 166. Maximum number of pieces and the default partitioned index size for a partitioned table space that is created with the LARGE or DSSIZE clauses or with a Numparts value of greater than 64

| Definition of partitioned table space (large) | Maximum number of pieces for a partitioned index | Default index piece size for a partitioned index |
|--|---|--|
| One or more of the following conditions are true: <ul style="list-style-type: none"> LARGE clause - specified NUMPARTS greater than 64 but less than 256 | Maximum number of partitions in the partitioned table space | 4G |
| One or more of the following conditions are true: <ul style="list-style-type: none"> DSSIZE clause - specified NUMPARTS greater than or equal to 256 | Maximum number of partitions in the partitioned table space | MIN(table space DSSIZE, 2 ³² / (Maximum number of partitions in the table space) * index page size) |

To calculate the maximum data set size for a partitioned index, you need to first calculate the maximum number of partitions in the table space by using the following formula:

$$\text{MIN}(4096, 2^{32} / (\text{table space DSSIZE} / \text{table space page size}))$$

After you calculate the maximum number of partitions in the table space, you can calculate the maximum data set size for a partitioned index with the following formula, using the number of partitions that you calculated above:

$$\text{MIN}(\text{table space DSSIZE}, 2^{32} / (\text{Maximum number of partitions in the table space}) * \text{index page size})$$

Example: Suppose that a table space and an index on that table space have the following characteristics:

- DSSIZE: 64 GB
- Page size: 32 KB
- Index page size: 4 KB
- Maximum number of partitions: 2048

Given those characteristics, you can begin by calculating the maximum number of partitions in the table space:

$$\text{MIN}(4096, 2^{32} / (64\text{GB} / 32\text{KB})) = \mathbf{2048}$$

You can then use the value of 2048 to calculate the maximum data set size for the partitioned index:

$$\begin{aligned} & \text{MIN}(64 \text{ GB}, 2^{32} / 2048 * 4\text{KB}) \\ & = \text{MIN}(64\text{GB}, 8\text{GB}) \\ & = 8\text{GB} \end{aligned}$$

Number of pieces and maximum piece size for non-partitioned indexes

The largest amount of data that an index can hold is the maximum number of pieces for the index times the maximum amount of data that a piece can hold.

For a non-partitioned index, the maximum amount of data that an index can hold is defined by using the PIECESIZE parameter.

The default piece size for an index is as follows:

- 2 GB (PIECESIZE 2 G) for indexes of table spaces created without the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for indexes of table spaces created with the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for auxiliary indexes

The following tables list the maximum number of pieces and the default index piece size for various table spaces.

Table 167. Maximum number of pieces and the default index piece size for a partitioned table space that is created without the LARGE or DSSIZE clauses and has a NUMPART value of less than or equal to 64.

| Definition of partitioned table space (non-large), NUMPART value | Maximum number of pieces in a non-partitioned index | Default index piece size for a non-partitioned index |
|--|---|--|
| NUMPARTS <= 16 | 32 | 2G |
| NUMPARTS >= 17 but NUMPARTS <= 32 | 32 | 2G |
| NUMPARTS >= 33 | 32 | 2G |

Table 168. Maximum number of pieces and the default index piece size for a partitioned table space that is created with the LARGE or DSSIZE clauses or has a NUMPARTS value of greater than or equal to 65.

| Definition of partitioned table space (large) | Maximum number of pieces for a non-partitioned index | Default index piece size for a non-partitioned index |
|--|--|--|
| <ul style="list-style-type: none"> • LARGE clause - specified • DSSIZE clause - not specified | $\text{MIN}(4096, 2^{32} / (x/y))$ - see 1 on page 1612 | 4G |
| <ul style="list-style-type: none"> • LARGE clause - not specified • DSSIZE clause - not specified • NUMPARTS clause - greater than 64 but less than 256 | $\text{MIN}(4096, 2^{32} / (x/y))$ - see 1 on page 1612 | 4G |
| <ul style="list-style-type: none"> • LARGE clause - not specified • DSSIZE clause - specified or NUMPARTS clause - greater than or equal to 256 | $\text{MIN}(4096, 2^{32} / (x/y))$ - see 1 on page 1612 | 4G |

Table 168. Maximum number of pieces and the default index piece size for a partitioned table space that is created with the LARGE or DSSIZE clauses or has a Numparts value of greater than or equal to 65 (continued).

| Definition of partitioned table space (large) | Maximum number of pieces for a non-partitioned index | Default index piece size for a non-partitioned index |
|--|--|--|
| Note: | | |
| 1. For a non-partitioned index, the formula $\text{MIN}(4096, 2^{32} / (x / y))$, determines the maximum number of pieces for the non-partitioned index, where x and y have the following values: | | |
| x is the piece size of the index (stored in the PIECESIZE column of the SYSIBM.SYSINDEXES catalog table) | | |
| y is the page size of the index (stored in the PGSIZE column of the SYSIBM.SYSINDEXES catalog table) | | |

Table 169. Maximum number of pieces and the default index piece size for a non-partitioned table space

| Type of non-partitioned table space | Maximum number of pieces | Default index piece size |
|-------------------------------------|--------------------------|--------------------------|
| non-segmented table space | 32 | 2G |
| segmented table space | 32 | 2G |
| LOB, auxiliary, or XML table space | 32 | 4G |

Choosing a value for PIECESIZE:

To choose a value for PIECESIZE, divide the size of the non-partitioned index by the number of data sets that you want. For example, to ensure that you have five data sets for the non-partitioned index, and your index is 10MB (and not likely to grow much), specify PIECESIZE 2 M. If your non-partitioned index is likely to grow, choose a larger value.

Remember that 32 data sets is the limit if the underlying table space is not defined as LARGE or with a DSSIZE parameter and that the limit is 4096 for objects with greater than 254 parts. For a non-partitioned index on a table space that is defined as LARGE or with a DSSIZE parameter, the maximum is $\text{MIN}(4096, 2^{32} / (\text{index piece size} / \text{index page size}))$.

Keep the PIECESIZE value in mind when you are choosing values for primary and secondary quantities. Ideally, the value of your primary quantity plus the secondary quantities should be evenly divisible into PIECESIZE.

Dropping an index:

Partitioning indexes can be dropped. If the table space is using index-controlled partitioning, the table space is converted to table-controlled partitioning. Secondary indexes that are not indexes on auxiliary tables can be dropped simply by dropping the indexes. An empty index on an auxiliary table can be explicitly dropped; a populated index can be dropped only by dropping other objects. For details, see Dropping an index on an auxiliary table and an auxiliary table.

If the index is a unique index that enforces a primary key, unique key, or referential constraint, the constraint must be dropped before the index is dropped. See "DROP" on page 1918.

Unique indexes and enforcement of UNIQUE or PRIMARY KEY specifications for a table:

A table requires a unique index (that is not defined as UNIQUE WHERE NOT NULL) if you use the UNIQUE or PRIMARY KEY clause in the CREATE or ALTER TABLE statements, or if there is a ROWID column that

is defined as GENERATED BY DEFAULT. DB2 implicitly creates those unique indexes if the table space is explicitly created and the CREATE or ALTER TABLE statement is processed by the schema processor or if the table space is implicitly created; otherwise, you must explicitly create them. If any of the unique indexes that must be explicitly defined do not exist, the definition of the table is incomplete, and the following rules apply:

- Let K denote a key for which a required unique index does not exist and let n denote the number of unique indexes that remain to be created before the definition of the table is complete. (For a new table that has no indexes, K is its primary key or any of the keys defined in the CREATE or ALTER TABLE statement as UNIQUE and n is the number of such keys. After the definition of a table is complete, an index cannot be dropped if it is enforcing a primary key or unique key.)
- The creation of the unique index reduces n by one if the index key is identical to K. The keys are identical only if they have the same columns in the same order.
- If n is now zero, the creation of the index completes the definition of the table.
- If K is a primary key, the description of the index indicates that it is a primary index. If K is not a primary key, the description of the index indicates that it enforces the uniqueness of a key defined as UNIQUE in the CREATE or ALTER TABLE statement.

A unique index cannot be created on a materialized query table.

Unique indexes and XML columns:

If the index is an XML index on a unique XML column, the uniqueness applies to values of the specified pattern across all documents of that column, and the uniqueness is enforced on the value after the value is cast to the specified SQL data type. Because the data type conversion might result in a loss of precision and normalization, multiple values that appear unique in the XML document might still result in duplicate errors. If the index is defined using an expression, the uniqueness is enforced against the values that are stored in the index, not against the original values of the columns. The **WHERE NOT NULL** specification is ignored with a warning if XMLPATTERN is also specified, and the index is treated as if **UNIQUE** had been specified.

Defining an XML index using an XPath pattern-expression that includes functions:

An XPath *pattern-expression* that includes functions (including fn:exists() or fn:upper-case()) will have two parts. The first part is referred to as the *context step* and specifies the XPath of the element node or attribute node for which an index entry will be created (the element or attributes NodeID will be included in the index). The context step follows the same syntax as the XPath *pattern-expression* for an XML index, except that for fn:exists() it has to specify an element node, and for fn:upper-case() it has to specify an element node or an attribute node.

The second part is referred to as the *function expression step* and specifies the fn:exists() or fn:upper-case() XPath function. The function expression step is the right-most part of an XPath *pattern-expression*. For each node specified by the context step, the function expression step specifies the key value for the index. For example, in the XPath *pattern-expression* /purchaseOrder/items/item/fn:exists(shipDate), the context step is /purchaseOrder/items/item, and the function expression step is fn:exists(shipDate).

Use of PARTITIONED keyword:

When a partitioned index is created and no additional keywords are specified, the index is non-partitioned. If the keyword PARTITIONED is specified, the index is partitioned. If PARTITION BY RANGE is specified, the index is both data-partitioned and key-partitioned because it is defined on the partitioning columns of the table. Any index on a partitioned table space that does not meet the definition of a partitioning index is a secondary index. When a secondary index is created and no additional keywords are specified, the secondary index is non-partitioned (NPSI). If the keyword PARTITIONED is specified, the index is a data-partitioned secondary index (DPSI).

Creating a partitioning index for a table created without partition boundaries:

When a table is created without specifying partition boundaries using the ENDING AT clause, the table is incomplete until a partitioning index is created. The first index that is created for a table must specify both the PARTITION and the ENDING AT clauses.

When the PARTITION clause is specified while creating an index, either the PARTITIONED clause, or the ENDING AT clause must also be specified.

Considerations for tables that are involved in a clone relationship:

If an index is created on a base table that is involved in a clone relationship, an index with the same name is also created on the clone table. The index on the clone table will be placed in rebuild-pending status unless the clone table is empty when the index is created.

Considerations for tables that contain a row change timestamp column:

To create an index that refers to a row change timestamp column in the table, values must already exist in the column for all rows. Values are stored in row change timestamp columns whenever a row is inserted or updated in the table. If the row change timestamp column is added to an existing table that contains rows, the values for the row change timestamp column is not materialized and stored at the time of the ALTER TABLE statement. Values are materialized for these rows when they are updated, or when a REORG or a LOAD REPLACE utility is run on the table or table space.

Restriction on table spaces when there are pending changes to the definition:

A CREATE INDEX statement is not allowed if there are pending changes to the definition of the table space or to any objects in the table space. In addition, an index that references an expression cannot be created on a table where the inline length of a LOB column has been changed and the table space has not been reorganized.

Creating indexes on DB2 catalog tables:

For details on creating indexes on catalog tables, see "SQL statements allowed on the catalog" on page 2697.

EA-enabled index data sets:

If an index is created for an EA-enabled table space, the data sets for the index must be set up to belong to a DFSMS data class that has the extended format and extended addressability attributes.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords when creating a partitioned index:

- **PART integer VALUES** as an alternative syntax for **PARTITION integer ENDING**. The **PARTITION BY RANGE** keyword that precedes the *partition-element* clause is optional.

Although these keywords are supported as alternatives, they are not the preferred syntax.

User-defined indexes on catalog tables:

If you issue CREATE INDEX for an index on a catalog table, and you specify the USING clause, DB2 ignores that clause. Instead, DB2 defines and manages the index data sets. The data sets are defined in the same SMS environment that is used for the catalog data sets with default space attributes.

Examples

Example 1: Create a unique index, named DSN8A10.XDEPT1, on table DSN8A10.DEPT. Index entries are to be in ascending order by the single column DEPTNO. DB2 is to define the data sets for the index, using storage group DSN8G100. Each data set should hold 1 megabyte of data at most. Use 512 kilobytes as the primary space allocation for each data set and 64 kilobytes as the secondary space allocation. These specifications enable each data set to be extended up to 8 times before a new data set is used—512KB + (8*64KB)= 1024KB. Make the index padded.

The data sets can be closed when no one is using the index and do not need to be erased if the index is dropped.

```
CREATE UNIQUE INDEX DSN8A10.XDEPT1
ON DSN8A10.DEPT
(DEPTNO ASC)
PADDED
USING STOGROUP DSN8G100
PRIQTY 512
SECQTY 64
ERASE NO
BUFFERPOOL BP1
CLOSE YES
PIECESIZE 1M;
```

For the above example, the underlying data sets for the index will be created immediately, which is the default (DEFINE YES). Assuming that table DSN8A10.DEPT is empty, if you wanted to defer the creation of the data sets until data is first inserted into the index, you would specify DEFINE NO instead of accepting the default behavior. Specifying PADDED ensures that the varying-length character string columns in the index are padded with blanks.

Example 2: Create a cluster index, named XEMP2, on table EMP in database DSN8A10. Put the entries in ascending order by column EMPNO. Let DB2 define the data sets for each partition using storage group DSN8G100. Make the primary space allocation be 36 kilobytes, and allow DB2 to use the default value for SECQTY, which for this example is 12 kilobytes (3 times 4KB). If the index is dropped, the data sets need not be erased.

There are to be 4 partitions, with index entries divided among them as follows:

- Partition 1: entries up to H99
- Partition 2: entries above H99 up to P99
- Partition 3: entries above P99 up to Z99
- Partition 4: entries above Z99

Associate the index with buffer pool BP1 and allow the data sets to be closed when no one is using the index. Enable the use of the COPY utility for full image or concurrent copies and the RECOVER utility.

```
CREATE INDEX DSN8A10.XEMP2
ON DSN8A10.EMP
(EMPNO ASC)
USING STOGROUP DSN8G100
PRIQTY 36
ERASE NO
CLUSTER
PARTITION BY RANGE
(PARTITION 1 ENDING AT('H99'),
PARTITION 2 ENDING AT('P99'),
PARTITION 3 ENDING AT('Z99'),
PARTITION 4 ENDING AT('999'))
BUFFERPOOL BP1
CLOSE YES
COPY YES;
```

Example 3: Create a secondary index, named DSN8A10.XDEPT1, on table DSN8A10.DEPT. Put the entries in ascending order by column DEPTNO. Assume that the data sets are managed by the user with catalog name DSNCAT and each data set is to hold 1GB of data, at most, before the next data set is used.

```
CREATE UNIQUE INDEX DSN8A10.XDEPT1
ON DSN8A10.DEPT
(DEPTNO ASC)
USING VCAT DSNCAT
PIECESIZE 1048576K;
```

Example 4: Assume that a column named EMP_PHOTO with a data type of BLOB(110K) was added to the sample employee table for each employee's photo and auxiliary table EMP_PHOTO_ATAB was created in LOB table space DSN8D10A.PHOTOLTS to store the BLOB data for the column. Create an index named XPHOTO on the auxiliary table. The data sets are to be user-managed with catalog name DSNCAT.

```
CREATE UNIQUE INDEX DSN8A10.XPHOTO
ON DSN8A10.EMP_PHOTO_ATAB
USING VCAT DSNCAT
COPY YES;
```

In this example, no columns are specified for the key because auxiliary indexes have implicitly generated keys.

CREATE MASK

The CREATE MASK statement creates a column mask at the current server. A *column mask* is used for column access control and specifies the value that should be returned for a specified column.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

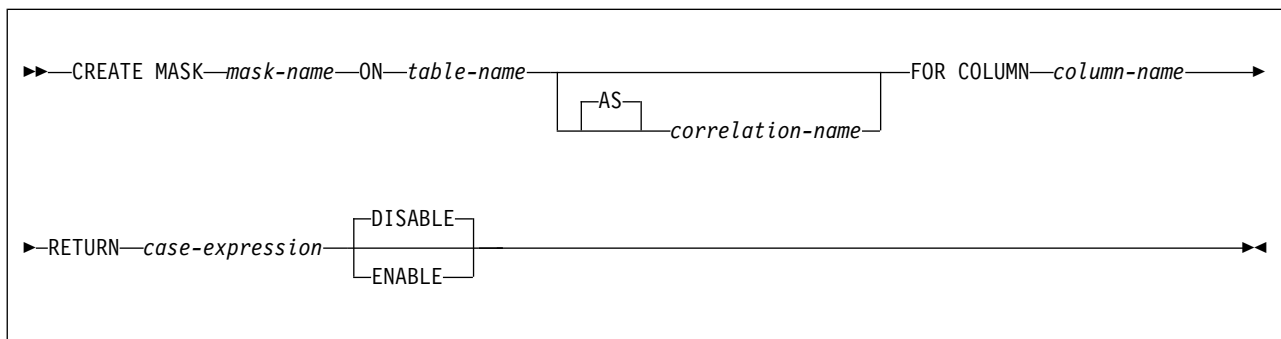

The privilege set that is defined below must include the following authority:

SECADM authority

SECADM authority can create a column mask in any schema. Additional privileges are not needed to reference other objects in the mask definition. For example, the SELECT privilege is not needed query a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role that is in effect.

Syntax

Description

mask-name

Specifies the names the column mask. The name, including the implicit or explicit qualifier, must not identify a column mask or a row permission that already exists at the current server.

ON *table-name*

Identifies the table for which the column mask is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:

- An auxiliary table

- A created or declared temporary table
- A view
- A catalog table
- An alias
- A synonym
- A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
- A table that was implicitly created for an XML column
- A table that contains a period
- A history table
- An accelerator-only table

correlation-name

Specifies a correlation name that can be used within *case-expression* to designate the table. For information about *correlation-name*, see “Correlation names” on page 202.

FOR COLUMN *column-name*

Identifies the column to which the mask applies. *column-name* must be an unqualified name that identifies a column of the specified table. A mask must not already exist for the column. The column must not be:

- a LOB column or a distinct type column that is based on a LOB
- an XML column
- defined with a FIELDPROC

RETURN *case-expression*

Specifies a CASE expression that determines the value that is returned for the column. The result of the CASE expression is returned in place of the column value in a row. The result data type, null attribute, data length, subtype, encoding scheme, and CCSID of the CASE expression must be identical to those attributes of the column that is specified by *column-name*. If the data type of *column-name* is a user-defined data type, the result data type of the CASE expression must be the same user-defined type. The CASE expression must not reference any of the following objects:

- A remote object
- The table for which the column mask is being defined
- A created global temporary table or a declared global temporary table
- An auxiliary table
- A table that was implicitly created for an XML column
- A column that is defined with a FIELDPROC
- A LOB column or a distinct type column that is based on a LOB
- An XML column
- A select list notation * or *name.** in the SELECT clause
- A user-defined external table function or a user-defined SQL table function
- A user-defined function that is defined as not secure
- A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
- An aggregate function, unless it is specified in a subquery
- A built-in table function
- An XMLTABLE table function

- An XMLEXISTS predicate
- An OLAP specification
- A ROW CHANGE expression
- A sequence reference
- A host variable, SQL variable, SQL parameter, or trigger transition variable
- A parameter marker
- A table reference that contains a period specification
- A view that includes any of the preceding restrictions in its definition
- An accelerator-only table

The encoding scheme of the specified table is used to evaluate the CASE expression. Tables and language elements that require multiple encoding scheme evaluation must not be referenced in the CASE expression. See “Determining the encoding scheme and CCSID of a string” on page 51 for language elements that require multiple evaluation.

If the CASE expression references tables for which row or column access control is active, access controls for those tables are not cascaded.

DISABLE or ENABLE

Specifies that the column mask is to be enabled or disabled for column access control.

DISABLE

Specifies that the column mask is to be disabled for column access control. The column mask will remain disabled regardless of whether column access control is activated for the table.

DISABLE is the default.

ENABLE

Specifies that the column mask is to be enabled for column access control. If column access control is not currently active for the table, the column mask will become enabled when column access control is activated for the table. If column access control is currently active for the table, the column mask becomes enabled immediately and all packages and statements in the dynamic statement cache that reference the table are invalidated.

Notes

How column masks affect queries:

The application of enabled column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, or ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY clause with a *sort-key* expression, the order is based on the original values of the column and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT statement. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, a column mask on column SSN might change the result of the aggregate function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values.

However, if the expression in the query is the same as the expression that is used to mask the column value in the definition of the column mask, the result of the expression might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression appears in the definition of the column mask. In this particular example, you can replace the expression in the query with column SSN to avoid the same expression being evaluated twice.

Conflicts between the definition of a column mask and SQL:

A column mask is created as a stand alone object, without knowing all of the contexts in which it might be used. To mask the value of a column in the final result table, the definition of the column mask is merged into a query by DB2. When the definition of the column mask is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of the column mask can return an error. When this happens, either the statement needs to be modified or the column mask must be dropped or re-created with a different definition. See "ALTER TABLE" on page 1304 for those situations in which a bind time error might be issued for the statement.

Column masks and null columns:

If the column is not nullable, the definition of its column mask will not, most likely, consider a null value for the column. After the column access control is activated for the table, if the table is the null-padded table in an outer join, the value of the column in the final result table might be a null. To ensure that the column mask can mask a null value, if the table is the null-padded table in an outer join, DB2 will add "WHEN *target-column* IS NULL THEN NULL" as the first WHEN clause to the column mask definition. This forces a null value to always be masked as a null value. For a nullable column, this removes the ability to mask a null value as something else. Example 5 shows this added WHEN clause.

Column mask values for SQL data change statements

When columns are used to derive new values for an INSERT, UPDATE, MERGE, or a SET *transition-variable* assignment statement, the original values of the column, not the masked values, are used to derive the new values. If the columns have column masks, those column masks are applied to ensure that the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure that the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time. The rules that are used to apply column masks in order to derive the new values follow the same rules for the final result table of a query.

Column masks that are created before column access control is activated:

The CREATE MASK statement is an independent statement that can be used to create a column access control mask before column access control is activated for a table. The only requirement is that the table and the columns exist before the mask is created. Multiple column masks can be created for a table but a column can have one mask only.

The definition of a mask is stored in the DB2 catalog. Dependency on the table for which the mask is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A column mask can be created as enabled or disabled for column access control. An enabled column mask does not

take effect until the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for the table. SECADM authority is required to issue such an ALTER TABLE statement. A disabled column mask remains ineffective even when column access control is activated for the table. The ALTER MASK statement can be used to alter between ENABLE and DISABLE.

After column access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are implicitly applied by DB2 to mask the values returned for the columns referenced in the final result table of the queries or to determine the new values used in the data change statements.

Creating column masks before activating column access control for a table is the recommended sequence to avoid multiple invalidations of packages and dynamic cached statements that reference the table.

Column masks that are created after column access control is activated:

The enabled column masks become effective as soon as they are committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled column masks are implicitly applied by DB2 to the statement. Any disabled column mask remains ineffective even when column access control is activated for the table.

No cascaded effect when column or row access control enforced tables are referenced in column mask definitions:

A column mask definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables and columns are ignored when the table for which the column mask is being created is referenced in a data manipulation statement.

Multiple column masks and row permissions sharing the same environment variables:

Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

Table 170. Environment Variables in SYSIBM.SYSENVIRONMENT

| Environment variables shown as SYSENVIRONMENT columns | Description | Static create statement | Dynamic create statement | Must be the same among multiple column masks and row permissions? |
|---|---|-------------------------|--|---|
| ENVID | Internal identifier of the environment | Assigned by DB2 | Assigned by DB2 | Yes |
| CURRENT_SCHEMA | The qualifier used to qualify unqualified objects such as tables, views, etc. | Package owner | Value of CURRENT_SCHEMA special register | Yes |

Table 170. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

| Environment variables shown as SYSENVIRONMENT columns | Description | Static create statement | Dynamic create statement | Must be the same among multiple column masks and row permissions? |
|---|---|---|--|---|
| PATHSCHEMAS | The schema path used to qualify unqualified object such as user-defined functions and CAST functions for distinct types. | PATH bind option | Value of CURRENT_PATH special register | Yes |
| APPLICATION_ENCODING_CCSID | The CCSID of the application environment | ENCODING bind option | CURRENT APPLICATION_ENCODING_SCHEME special register | Yes |
| ORIGINAL_ENCODING_CCSID | The original CCSID of the statement text string | CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel | CCSID based on DEF_ENCODING_SCHEME on DSNTIPF installation panel | Yes |
| DECIMAL_POINT | The decimal point indicator | COMMA or PERIOD precompiler option or DECIMAL POINT IS on DSNTIPF installation panel | DECIMAL POINT IS on DSNTIPF installation panel | Yes |
| MIN_DIVIDE_SCALE | The minimum divide scale | MINIMUM DIVIDE SCALE on DSNTIP4 installation panel | MINIMUM DIVIDE SCALE on DSNTIP4 installation panel | Yes |
| STRING_DELIMITER | The string delimiter that is used in COBOL string constants | APOST precompiler option or STRING_DELIMITER on DSNTIPF installation panel | STRING DELIMITER on DSNTIPF installation panel | No |
| SQL_STRING_DELIMITER | The SQL string delimiter that is used in constants | APOSTSQL pre-compiler option or SQL STRING_DELIMITER on DSNTIPF installation panel | SQL STRING_DELIMITER on DSNTIPF installation panel | Yes |
| MIXED_DATA | Uses mixed DBCS data | MIXED DATA on DSNTIPF installation panel | MIXED DATA on DSNTIPF installation panel | Yes |
| DECIMAL_ARITHMETIC | The rules that are to be used for CURRENT_PRECISION and when both operands in a decimal operation have a precision of 15 or less. | DEC(15) or DEC(31) precompiler option or DECIMAL_ARITHMETIC on DSNTIP4 installation panel | DECIMAL_ARITHMETIC on DSNTIP4 installation panel | Yes |

Table 170. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

| Environment variables shown as SYSENVIRONMENT columns | Description | Static create statement | Dynamic create statement | Must be the same among multiple column masks and row permissions? |
|---|---|--|---|---|
| DATE_FORMAT | The date format | DATE pre-compiler option or DATE FORMAT on DSNTIP4 installation panel | DATE FORMAT on DSNTIP4 installation panel | Yes |
| TIME_FORMAT | The time format | TIME pre-compiler option or TIME FORMAT on DSNTIP4 installation panel | TIME FORMAT on DSNTIP4 installation panel | Yes |
| FLOAT_FORMAT | The floating point format | FLOAT (S390 IEEE) pre-compiler option or default of FLOAT S390 | Default of FLOAT S390 | No |
| HOST_LANGUAGE | The host language | HOST pre-compiler option or LANGUAGE DEFAULT on DSNTIPF installation panel | LANGUAGE DEFAULT on DSNTIPF installation panel | No |
| CHARSET | The character set | CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel | EBCDIC CCSID on DSNTIPF installation panel | No |
| FOLD | FOLD is only applicable when HOST_LANGUAGE is C or CPP. Otherwise FOLD is blank. | HOST(C(FOLD)) precompiler option or default of NO FOLD | default of NO FOLD | No |
| ROUNDING | The rounding mode that is used when arithmetic and casting operations are performed on DECFLOAT data. | ROUNDING bind option | CURRENT DECFLOAT ROUNDING MODE special register | Yes |

Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

Ordinary SQL identifiers specified in a static CREATE MASK statement in a COBOL application:

If the CREATE MASK statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the column mask definition must not follow the rules for naming COBOL words. They must follow the rules for naming "SQL identifiers" on page 57. For example, the COBOL word 1ST-TIME is not allowed as an ordinary SQL identifier in a column mask definition; change it to FIRST_TIME or put it in the delimiters.

Encoding scheme and CCSIDs of the data manipulation statement after column masks are applied:

The encoding scheme and CCSIDs of the data manipulation statement is not affected by the column masks that are implicitly applied by DB2 for the column access control. The column mask definition is evaluated using its target table's encoding scheme and CCSIDs.

Consideration for DB2 limits:

If the data manipulation statement already approaches some DB2 limits in the statement, it should be noted that the more enabled column masks and enabled row permissions are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in DB2 for z/OS" in SQL Reference for the limits of a statement.

Examples

Example 1:

After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary who is a manager can see the last four characters only of the social security number. Peter who is neither cannot see the social security number.

```
CREATE MASK SSN_MASK ON EMPLOYEE
FOR COLUMN SSN RETURN
CASE
    WHEN (VERIFY_GROUP_FOR_USER(SSESSION_USER, 'PAYROLL') = 1)
    THEN SSN
    WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR') = 1)
    THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
    ELSE NULL
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SSN FROM EMPLOYEE
WHERE EMPNO = 123456;
```

Example 2:

In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression gets evaluated twice.

```
CREATE MASK SSN_MASK ON EMPLOYEE
FOR COLUMN SSN RETURN
CASE
    WHEN (1 = 1)
```

```

        THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
        ELSE NULL
    END
    ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT 'XXX-XX-' || SUBSTR(SSN,8,4) FROM EMPLOYEE
    WHERE EMPNO = 123456;

```

Example 3:

A state government conducted a survey for the library usage of the households in each city. Fifty households in each city were sampled in the survey. Each household was given an option, opt-in or opt-out, whether to show their usage in any reports generated from the result of the survey.

A SELECT statement is used to generate a report to show the average hours used by households in each city. Column mask CITY_MASK is created to mask the city name based on the opt-in or opt-out information chosen by the sampled households. However, after column access control is activated for table LIBRARY_USAGE, the SELECT statement receives a bind time error. This is because column mask CITY_MASK references another column LIBRARY_OPT and LIBRARY_OPT does not identify a grouping column.

```

CREATE MASK CITY_MASK ON LIBRARY_USAGE
    FOR COLUMN CITY RETURN
    CASE
        WHEN (LIBRARY_OPT = 'OPT-IN')
            THEN CITY
        ELSE ' '
    END
    ENABLE;

COMMIT;

ALTER TABLE LIBRARY_USAGE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT CITY, AVG(LIBRARY_TIME) FROM LIBRARY_USAGE
    GROUP BY CITY;

```

Example 4:

Employee with EMPNO 123456 earns bonus \$8000 and salary \$80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS_MASK is defined.

```

CREATE MASK SALARY_MASK ON EMPLOYEE
    FOR COLUMN SALARY RETURN
    CASE
        WHEN (BONUS < 10000)
            THEN SALARY
        ELSE NULL
    END
    ENABLE;

COMMIT;

```

```

CREATE MASK BONUS_MASK ON EMPLOYEE
FOR COLUMN BONUS RETURN
CASE
    WHEN (BONUS > 5000)
    THEN NULL
    ELSE BONUS
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
WHERE EMPNO = 123456;

```

Example 5:

This example shows DB2 adds "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition then merges the column mask definition into the statement.

```

CREATE EMPLOYEE (EMPID INT,
                DEPTID CHAR(8),
                SALARY DEC(9,2) NOT NULL,
                BONUS DEC(9,2));

CREATE MASK SALARY_MASK ON EMPLOYEE
FOR COLUMN SALARY RETURN
CASE
    WHEN SALARY < 10000
    THEN CAST(SALARY*2 AS DEC(9,2))
    ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
END
ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
FOR COLUMN BONUS RETURN
CASE
    WHEN BONUS > 1000
    THEN BONUS
    ELSE NULL
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM DEPT
LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

/* When SALARY_MASK is merged into the above statement,
 * 'WHEN SALARY IS NULL THEN NULL' is added as the
 * first WHEN clause, as follows:
 */

SELECT CASE WHEN SALARY IS NULL THEN NULL
           WHEN SALARY < 10000 THEN CAST(SALARY*2 AS DEC(9,2))

```

```
|           ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
|           END SALARY
|           FROM DEPT
|           LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;
```

```
|
```

CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission for row access control at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

- SECADM authority

SECADM authority can create a row permission in any schema. Additional privileges are not needed to reference other objects in the permission definition. For example, the SELECT privilege is not needed to retrieve from a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if it is running in a trusted context defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role in effect.

Syntax

Description

permission-name

Names the row permission for row access control. The name, including the implicit or explicit qualifier, must not identify a row permission or a column mask that already exists at the current server

ON *table-name*

Identifies the table on which the row permission is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:

- An auxiliary table
- A created or declared temporary table
- A view

- A catalog table
- An alias
- A synonym
- A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
- A table that was implicitly created for an XML column
- A table that contains a period
- A history table
- An accelerator-only table
- A table that has a security label column.

correlation-name

Can be used within *search-condition* to designate the table. For the explanation of *correlation-name*, see “Correlation names” on page 202.

FOR ROWS WHERE

Indicates that a row permission is created. A row permission specifies a search condition under which rows of the table can be accessed.

search-condition

Specifies a condition that can be true, false, or unknown for a row of the table. *search-condition* follows the same rules that are used by the search condition in a WHERE clause of a subselect. In addition, the search condition must not reference any of the following objects:

- A remote object
- The table for which the row permission is being defined
- A table that has a security label column
- A created global temporary table or a declared global temporary table
- An auxiliary table
- A table that was implicitly created for an XML column
- A user-defined external table function or a user-defined SQL table function
- An XMLTABLE table function
- A built-in table function, such as ADMIN_TASK_LIST and ADMIN_TASK_STATUS
- A host variable, SQL variable, SQL parameter, or trigger transition variable
- A user-defined function that is defined as not secure
- A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
- A parameter marker
- A column that is defined with a FIELDPROC
- A LOB column or a distinct type column that is based on a LOB
- An XML column
- An XMLEXISTS predicate
- An OLAP specification
- A ROW CHANGE expression
- A sequence reference
- A select list notation * or *name.** in the SELECT clause
- A table reference that contains a period specification
- A view that includes any of the preceding restrictions in its definition

The encoding scheme of the table is used to evaluate the *search-condition*. Tables and language elements that require multiple encoding scheme evaluation must not be referenced in the *search-condition*. See “Determining the encoding scheme and CCSID of a string” on page 51 for those language elements.

If the *search-condition* references tables for which row or column access control is activated, access control from those tables is not cascaded.

ENFORCED FOR ALL ACCESS

Specifies that the row permission applies to all references of the table. If row access control is activated for the table, when the table is referenced in a data manipulation statement, DB2 implicitly applies the row permission to control the access of the table. If the reference of the table is for a fetch operation such as SELECT, the application of the row permission determines what set of rows can be retrieved by the user who requested the fetch operation. If the reference of the table is for a data change operation such as INSERT, the application of the row permission determines whether all rows to be changed are insertable or updatable by the user who requested the data change operation.

DISABLE or ENABLE

Specifies that the row permission is to be enabled or disabled for row access control.

DISABLE

Specifies that the row permission is to be disabled for row access control. The row permission will remain ineffective regardless the row access control is activated for the table or not.

DISABLE is the default.

ENABLE

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

Notes

How row permission are applied and how they affect certain statements:

See the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause for information on how to activate row access control and how row permissions are applied. See the description of subselect for information on how the application of row permissions affects the fetch operation. See the data change statements for information on how the application of row permissions affects the data change operation.

Row permissions that are created before row access control is activated for a table:

The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.

The definition of the row permission is stored in the DB2 catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A row permission can be created as enabled or disabled for row access control. An enabled row

permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by DB2 to control access to the table.

Creating row permissions before activating row access control for a table is the recommended sequence to avoid multiple invalidations of packages and dynamic cached statements that reference the table.

Row permissions that are created after row access control is activated for a table:

An enabled row permission becomes effective as soon as it is committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permission remains ineffective even when row access control is activated for the table.

No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:

A row permission definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables are ignored when the table for which the row permission is being created is referenced in a data manipulation statement.

Multiple column masks and row permissions sharing the same environment variables:

Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

Table 171. Environment Variables in SYSIBM.SYSENVIRONMENT

| Environment variables shown as SYSENVIRONMENT columns | Description | Static create statement | Dynamic create statement | Must be the same among multiple column masks and row permissions? |
|---|--|-------------------------|--|---|
| ENVID | Internal identifier of the environment | Assigned by DB2 | Assigned by DB2 | Yes |
| CURRENT_SCHEMA | The qualifier used to qualify unqualified objects such as tables, views. etc. | Package owner | Value of CURRENT_SCHEMA special register | Yes |
| PATHSCHEMAS | The schema path used to qualify unqualified object such as user-defined functions and CAST functions for distinct types. | PATH bind option | Value of CURRENT_PATH special register | Yes |

Table 171. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

| Environment variables shown as SYSENVIRONMENT columns | Description | Static create statement | Dynamic create statement | Must be the same among multiple column masks and row permissions? |
|---|---|---|--|---|
| APPLICATION_ENCODING_CCSID | The CCSID of the application environment | ENCODING bind option | CURRENT APPLICATION_ENCODING_SCHEME special register | Yes |
| ORIGINAL_ENCODING_CCSID | The original CCSID of the statement text string | CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel | CCSID based on DEF_ENCODING_SCHEME on DSNTIPF installation panel | Yes |
| DECIMAL_POINT | The decimal point indicator | COMMA or PERIOD precompiler option or DECIMAL_POINT_IS on DSNTIPF installation panel | DECIMAL_POINT_IS on DSNTIPF installation panel | Yes |
| MIN_DIVIDE_SCALE | The minimum divide scale | MINIMUM_DIVIDE_SCALE on DSNTIP4 installation panel | MINIMUM_DIVIDE_SCALE on DSNTIP4 installation panel | Yes |
| STRING_DELIMITER | The string delimiter that is used in COBOL string constants | APOST precompiler option or STRING_DELIMITER on DSNTIPF installation panel | STRING_DELIMITER on DSNTIPF installation panel | No |
| SQL_STRING_DELIMITER | The SQL string delimiter that is used in constants | APOSTSQL pre-compiler option or SQL_STRING_DELIMITER on DSNTIPF installation panel | SQL_STRING_DELIMITER on DSNTIPF installation panel | Yes |
| MIXED_DATA | Uses mixed DBCS data | MIXED_DATA on DSNTIPF installation panel | MIXED_DATA on DSNTIPF installation panel | Yes |
| DECIMAL_ARITHMETIC | The rules that are to be used for CURRENT_PRECISION and when both operands in a decimal operation have a precision of 15 or less. | DEC(15) or DEC(31) precompiler option or DECIMAL_ARITHMETIC on DSNTIP4 installation panel | DECIMAL_ARITHMETIC on DSNTIP4 installation panel | Yes |
| DATE_FORMAT | The date format | DATE pre-compiler option or DATE_FORMAT on DSNTIP4 installation panel | DATE_FORMAT on DSNTIP4 installation panel | Yes |
| TIME_FORMAT | The time format | TIME pre-compiler option or TIME_FORMAT on DSNTIP4 installation panel | TIME_FORMAT on DSNTIP4 installation panel | Yes |

Table 171. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

| Environment variables shown as SYSENVIRONMENT columns | Description | Static create statement | Dynamic create statement | Must be the same among multiple column masks and row permissions? |
|---|---|--|---|---|
| FLOAT_FORMAT | The floating point format | FLOAT (S390 IEEE) pre-compiler option or default of FLOAT S390 | Default of FLOAT S390 | No |
| HOST_LANGUAGE | The host language | HOST pre-compiler option or LANGUAGE DEFAULT on DSNTIPF installation panel | LANGUAGE DEFAULT on DSNTIPF installation panel | No |
| CHARSET | The character set | CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel | EBCDIC CCSID on DSNTIPF installation panel | No |
| FOLD | FOLD is only applicable when HOST_LANGUAGE is C or CPP. Otherwise FOLD is blank. | HOST(C(FOLD)) precompiler option or default of NO FOLD | default of NO FOLD | No |
| ROUNDING | The rounding mode that is used when arithmetic and casting operations are performed on DECFLOAT data. | ROUNDING bind option | CURRENT DECFLOAT ROUNDING MODE special register | Yes |

Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

Ordinary SQL identifiers specified in a static CREATE PERMISSION statement in a COBOL application:

If the CREATE PERMISSION statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the row permission definition must not follow the rules for naming COBOL words (DSNH20474, reason code 14). They must follow the rules for naming SQL identifiers as described in the topic "SQL identifiers" in DB2 SQL Reference. For example, the COBOL word 1ST-TIME is not allowed as an ordinary SQL identifier in a row permission definition; change it to FIRST_TIME or put it in the delimiters.

Encoding scheme and CCSIDs of the data manipulation statement after row permissions are applied:

The encoding scheme and CCSIDs of the data manipulation statement are not affected by the row permissions that are implicitly applied by DB2 for the row access control. The row permission definition is evaluated using its target table's encoding scheme and CCSIDs.

Consideration for DB2 limits:

If the data manipulation statement already approaches some DB2 limits in

the statement, it should be noted that the more enabled row permissions and enabled column masks are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in DB2 for z/OS" in SQL Reference for the limits of a statement.

Examples

Example 1:

Secure user-defined function ACCOUNTING_UDF in row permission SALARY_ROW_ACCESS processes the sensitive data in column SALARY. After row access control is activated for table EMPLOYEE, Accountant Paul retrieves the salary of employee with EMPNO 123456 who is making \$100,000 a year. Paul may or may not see the row depending on the output value from user-defined function ACCOUNTING_UDF.

```
CREATE PERMISSION SALARY_ROW_ACCESS ON EMPLOYEE
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR', 'ACCOUNTING') = 1
  AND
  ACCOUNTING_UDF(SALARY) < 120000
  ENFORCED FOR ALL ACCESS
  ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE ROW ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
  WHERE EMPNO = 123456;
```

Example 2:

The tellers in a bank can only access customers from their branch. All tellers have secondary authorization ID TELLER. The customer service representatives are allowed to access all customers of the bank. All customer service representatives have secondary authorization ID CSR. A row permission is created for each group of personnel in the bank accordingly to the access rule defined by SECADM authority. After row access control is activated for table CUSTOMER, in the SELECT statement the search conditions of both row permissions are merged into the statement and they are combined with the logic OR operator to control the set of rows accessible by each group.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'TELLER') = 1
  AND
  BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
  WHERE EMP_ID = SESSION_USER)
  ENFORCED FOR ALL ACCESS
  ENABLE;

COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'CSR') = 1
  ENFORCED FOR ALL ACCESS
  ENABLE;
```

CREATE PROCEDURE

The CREATE PROCEDURE statement registers a stored procedure with a database server. You can register the following types of procedures with this statement, each of which is described separately.

External

The procedure is written in a programming language such as C, COBOL, or Java. The external executable is referenced by a procedure defined at the server along with various attributes of the procedure.

See “CREATE PROCEDURE (external)” on page 1637.

SQL

The procedure is written exclusively in SQL statements. The body of an SQL procedure is written in the SQL procedural language. The procedure body is defined at the current server along with various attributes of the procedure.

See “CREATE PROCEDURE (SQL - external)” on page 1656 and “CREATE PROCEDURE (SQL - native)” on page 1668.

CREATE PROCEDURE (external)

The CREATE PROCEDURE statement defines an external stored procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is specified implicitly or explicitly.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure.

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file, the Java archive file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

The authorization ID that is used to create the stored procedure must have authority to define programs that run in the specified WLM environment. In addition, if the stored procedure uses a distinct type as a parameter, this authorization ID must have the USAGE privilege on each distinct type that is a parameter.

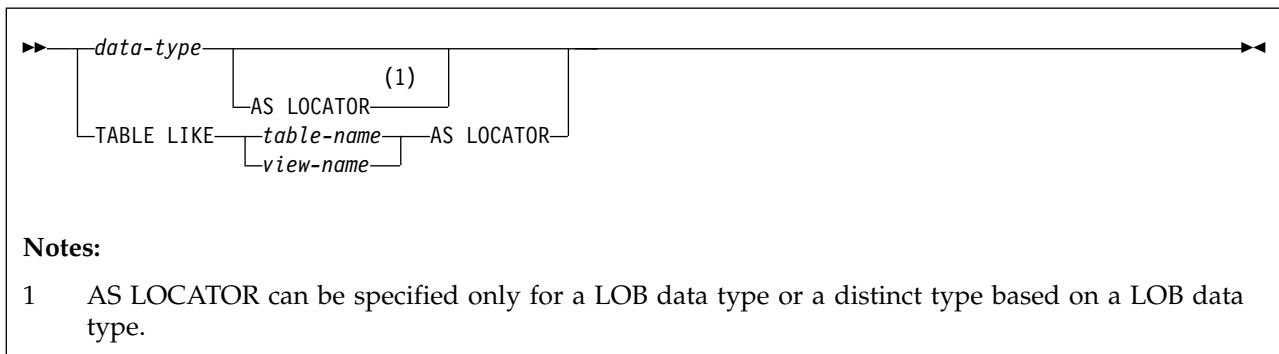

Syntax

parameter-declaration:

parameter-type:

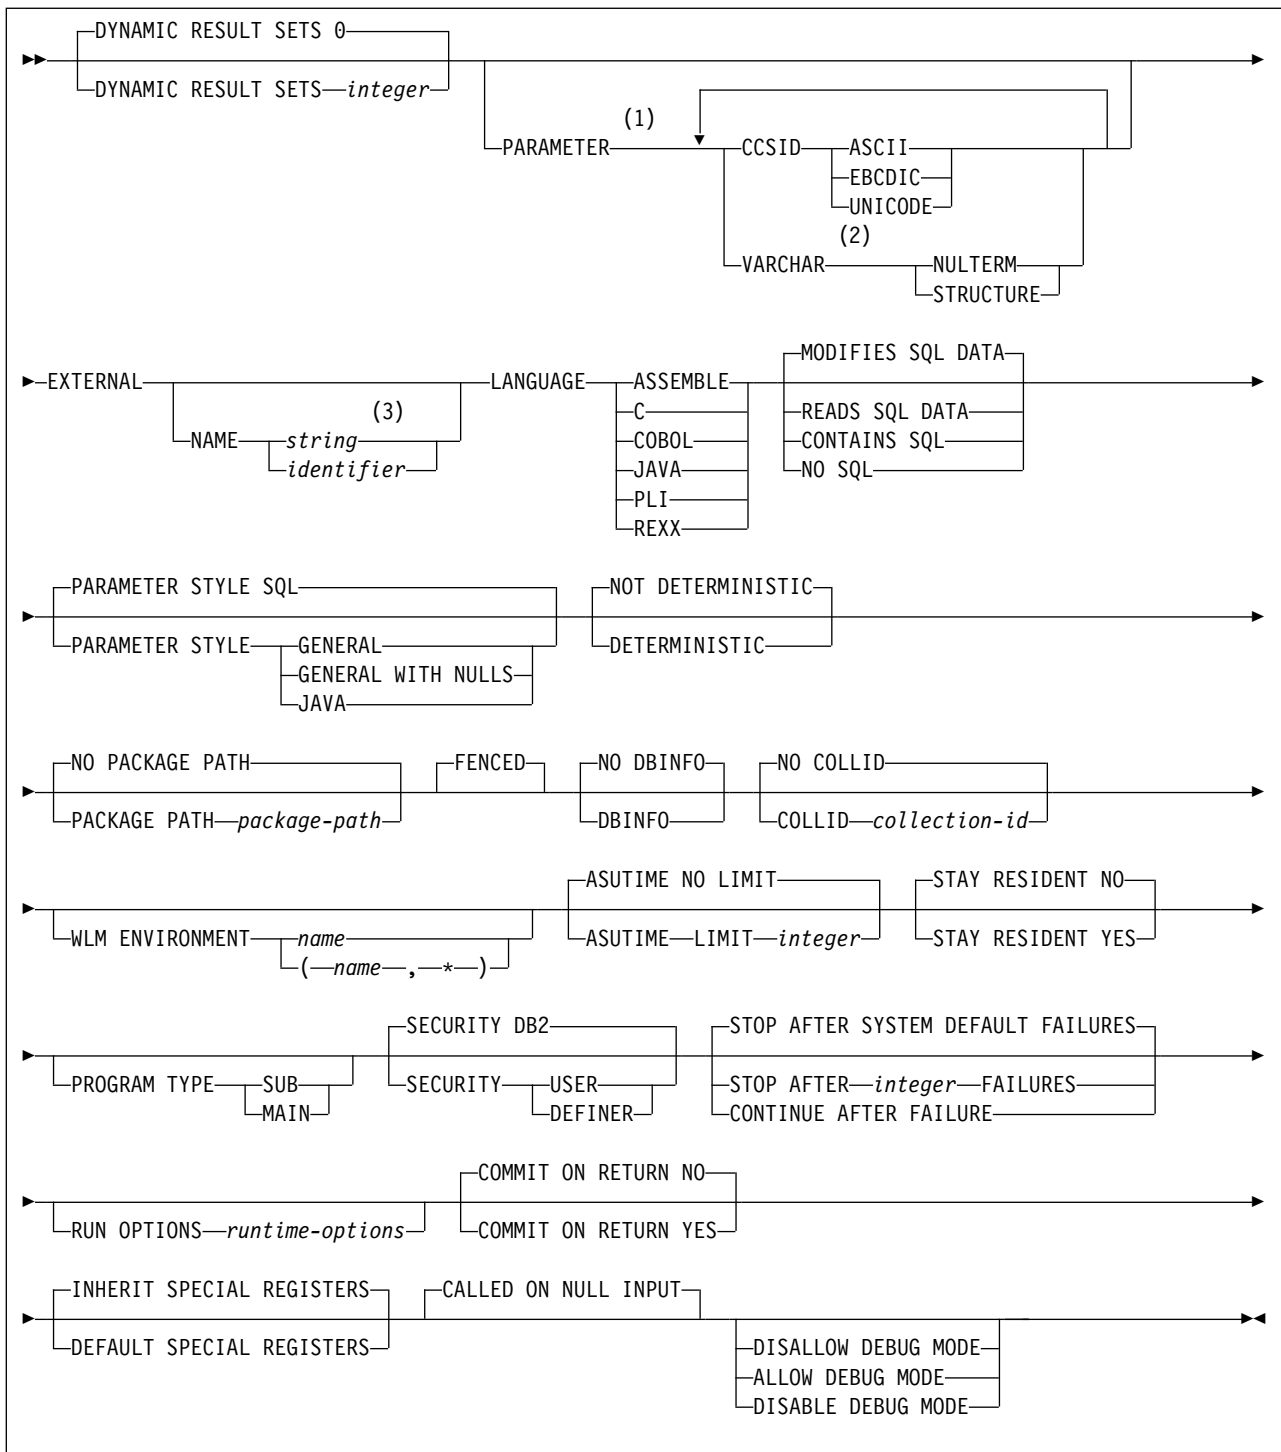

data-type:

built-in-type:

option-list: (The options can be specified in any order.)

Notes:

- 1 The same clause must not be specified more than one time.
- 2 The VARCHAR clause can only be specified is LANGUAGE C is specified.
- 3 With LANGUAGE JAVA, use a valid *external-java-routine-name*.

external-java-routine-name:

jar-name:

method-name:

method-signature:

Notes:

- 1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

Description

procedure-name

Names the stored procedure. The name cannot be a single asterisk, even if you specify it as a delimited identifier ("*"). The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

The schema name can be 'SYSIBM' or 'SYSPROC'. It can also be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Specifies the number of parameters of the stored procedure and the data type of each parameter, and optionally, the name of each parameter. A parameter for a stored procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined and INOUT parameters are unchanged.

All parameters are nullable except for numeric parameters in Java procedures, where numeric parameters, other than the DECIMAL types are not nullable in order to conform to the SQL/JRT standard.

IN Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the stored procedure.

INOUT

Identifies the parameter as both an input and output parameter for the stored procedure.

parameter-name

Names the parameter for use as an SQL variable. The name cannot be the same as any other *parameter-name* for the procedure.

data-type

Specifies the data type of the parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input argument on the CALL statement can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

TABLE LIKE *table-name* or *view-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the stored procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACES. The number of columns and the attributes of those columns are determined at the time the CREATE PROCEDURE statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the procedure.

table-name or *view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE PROCEDURE statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE PROCEDURE statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the procedure is called, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length,

precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE PROCEDURE statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE PROCEDURE statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

FENCED

Specifies that the procedure runs in an external address space.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the stored procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether the procedure can be run in debugging mode. When DYNAMICRULES run behavior is in effect, the default is determined by using the value of the CURRENT DEBUG MODE special register. Otherwise the default is DISALLOW DEBUG MODE.

Do not specify this option unless LANGUAGE JAVA is in effect.

ALLOW DEBUG MODE

Specifies that the JAVA procedure can be run in debugging mode.

DISALLOW DEBUG MODE

Specifies that the JAVA procedure cannot be run in debugging mode.

You can use an ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE

Specifies that the JAVA procedure can never be run in debugging mode.

The procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE once the procedure has been created or altered using DISABLE DEBUG MODE. To change this option, you must drop and re-create the procedure using the option that you want.

PARAMETER CCSID or PARAMETER VARCHAR

Specifies the encoding scheme for string parameters, and in the case of LANGUAGE C, specifies the representation of variable length string parameters.

CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER

CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

VARCHAR

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as there is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL

Specifies that the CREATE PROCEDURE statement is being used to define a new procedure that is based on code written in an external programming language. If the NAME clause is not specified, 'NAME *procedure-name*' is assumed. The NAME clause is required for a LANGUAGE JAVA procedure because the default name is not valid for a Java procedure. In some cases, the default name will not be valid. To avoid invalid names, specify the NAME clause for the following types of procedures:

- A procedure that is defined as LANGUAGE JAVA
- A procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

NAME *string or identifier*

Identifies the user-written code that implements the stored procedure.

If LANGUAGE is JAVA, *string* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *strings* are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break.

An *external-java-routine-name* contains the following parts:

jar-name

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified

with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the CREATE PROCEDURE statement is processed. Do not specify a *jar-name* for a JAVA procedure for which NO SQL is also specified.

If *jar-name* is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

method-name

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

class-id

Identifies the class identifier of the Java object.

method-id

Identifies the method identifier with the Java class to be invoked.

method-signature

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE PROCEDURE statement.

For other values of LANGUAGE, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

LANGUAGE

This mandatory clause is used to specify the language interface convention to which the procedure body is written. All programs must be designed to run in the server's environment. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM's Language Environment.

ASSEMBLE

The stored procedure is written in Assembler.

C The stored procedure is written in C or C++.

COBOL

The stored procedure is written in COBOL, including the OO-COBOL language extensions.

JAVA

The stored procedure is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must be specified with a valid *external-java-routine-name* and PARAMETER STYLE must be specified with JAVA. The procedure must be a public static method of the specified Java class.

Do not specify LANGUAGE JAVA when DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is specified.

PLI

The stored procedure is written in PL/I.

REXX

The stored procedure is written in REXX. Do not specify LANGUAGE REXX when PARAMETER STYLE SQL is in effect. When REXX is specified, the procedure must use PARAMETER STYLE GENERAL or GENERAL WITH NULLS.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies which SQL statements, if any, can be executed in the procedure or any routine that is called from this procedure. The default is MODIFIES SQL DATA. For the data access classification of each statement, see Table 217 on page 2318.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The procedure cannot execute statements that read or modify data.

NO SQL

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA procedure that uses a JAR file.

PARAMETER STYLE

Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to

the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see *DB2 Application Programming and SQL Guide*.

SQL

Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first *n* parameters that are specified on the CREATE PROCEDURE statement.
- *n* parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to DB2.
- If DBINFO is specified, the DBINFO structure.

PARAMETER STYLE SQL is the default. Do not specify PARAMETER STYLE SQL when LANGUAGE REXX or LANGUAGE JAVA is in effect.

GENERAL

Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

GENERAL WITH NULLS

Specifies that, in addition to the parameters on the CALL statement as specified in GENERAL, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short INTS. The indicator array enables the stored procedure to accept or return null parameter values.

JAVA

Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. PARAMETER JAVA can be specified only if LANGUAGE is JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

INOUT and OUT parameters are passed as single-entry arrays. The INOUT and OUT parameters are declared in the Java method as single-element arrays of the Java type.

For REXX stored procedures (LANGUAGE REXX), GENERAL and GENERAL WITH NULLS are the only valid values for PARAMETER STYLE; therefore, specify one of these values and do not allow PARAMETER STYLE to default to SQL.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same IN and INOUT arguments.

DETERMINISTIC

The stored procedure always returns the same results each time the stored

procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

NOT DETERMINISTIC

The stored procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed. NOT DETERMINISTIC is the default.

DB2 does not verify that the stored procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

NO PACKAGE PATH or PACKAGE PATH *package-path*

Specifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

NO PACKAGE PATH

Specifies that the list of package collections for the procedure is the same as the list of package collection IDs for the calling program. If the calling program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the routine is invoked.

The *package-path* value that is provided when the procedure is created is checked when the CALL statement is prepared. If *package-path* contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

NO DBINFO or DBINFO

Specifies whether additional status information is passed to the stored procedure when it is invoked.

NO DBINFO

Additional information is not passed. NO DBINFO is the default.

DBINFO

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the name of the current server, the application run time authorization ID and identification of the version and release of the database manager that invoked the procedure. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

DBINFO can be specified only if PARAMETER STYLE SQL is specified.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.

NO COLLID

The package collection for the stored procedure is the same as the package

collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

COLLID *collection-id*

The package collection for the stored procedure is the one specified.

For REXX stored procedures, *collection-id* can be DSNREXRR, DSNREXRS, DSNREXCR, or DSNREXCS.

WLM ENVIRONMENT

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the stored procedure runs in the default WLM-established stored procedure address space specified at installation time.

name

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the stored procedure request to a different address space.

(name,*)

When an SQL application program directly calls a stored procedure, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To define a stored procedure that is to run in a specified WLM environment, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the service units. NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than

|
|

the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends. This option is ignored if LANGUAGE JAVA is specified.

NO The load module is deleted from memory after the stored procedure ends. NO is the default.

YES

The load module remains resident in memory after the stored procedure ends.

PROGRAM TYPE

Specifies whether the stored procedure runs as a main routine or a subroutine.

SUB

The stored procedure runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option.

MAIN

The stored procedure runs as a main routine. With LANGUAGE REXX, PROGRAM TYPE MAIN is always in effect.

The default for PROGRAM TYPE is:

- MAIN with LANGUAGE REXX
- SUB with LANGUAGE JAVA
- For other languages, the default depends on the value of the CURRENT RULES special register:
 - MAIN when the value is DB2
 - SUB when the value is STD

SECURITY

Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space. DB2 is the default.

USER

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

DEFINER

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS *runtime-options*

Specifies the Language Environment run time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run time options to be passed to the REXX language interface to DB2. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

For a description of the Language Environment run time options, see *z/OS Language Environment Programming Reference*.

COMMIT ON RETURN

Indicates whether DB2 commits the transaction immediately on return from the stored procedure.

NO DB2 does not issue a commit when the stored procedure returns. NO is the default.

YES

DB2 issues a commit when the stored procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine. The default is INHERIT SPECIAL REGISTERS.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Table 43 on page 199.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Table 43 on page 199.

CALLED ON NULL INPUT

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values. CALLED ON NULL INPUT is the default.

Notes

Owner privileges: The owner is authorized to call the procedure (EXECUTE privilege) and grant others the privilege to call the procedure. See “GRANT (function or procedure privileges)” on page 2008. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Choosing data types for parameters: When you choose the data types of the parameters for your stored procedure, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 108). For example, a constant that is one of the input arguments to the stored procedure might have a built-in data type that is different from the data type that the procedure expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters: The encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE. If you specify the encoding scheme on the individual parameters, instead of using the PARAMETER CCSID to specify it for all parameters at once or allowing the encoding scheme to default to the system value, ensure that they all agree.

Character string representation considerations: The PARAMETER VARCHAR clause is specific to LANGUAGE C routines because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external procedure. For example, a CREATE PROCEDURE statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the procedure, the specific name of the procedure, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

Running stored procedures: You can use the WLM ENVIRONMENT clause to identify the address space in which a stored procedure is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with sensitive data, such as employee salaries.

Regardless of where the stored procedure is to run, DB2 invokes RACF to determine whether you have appropriate authorization. You must have authorization to issue CREATE PROCEDURE statements that refer to the specified WLM environment or the DB2-established stored procedure address space. For example, the following RACF command authorizes DB2 user DB2USER1 to define stored procedures on DB2 subsystem DB2A that run in the WLM environment named PAYROLL.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

Accessing result sets from nested stored procedures: When another stored procedure or a user-defined function calls a stored procedure, only the calling routine can access the result sets that the stored procedure returns. The result sets are not returned to the application that contains the outermost stored procedure or user-defined function in the sequence of nested calls.

When a stored procedure is nested, the result sets that are returned by the stored procedure are accessible only by the calling routine. The result sets are not returned to the application that contains the outermost stored procedure or user-defined function in the sequence of nested calls.

Restrictions for nested stored procedures: A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN clause.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET as a synonym for DYNAMIC RESULT SET
- RESULT SETS as a synonym for DYNAMIC RESULT SETS
- STANDARD CALL as a synonym for DB2SQL
- SIMPLE CALL as a synonym for GENERAL
- SIMPLE CALL WITH NULLS as a synonym for GENERAL WITH NULLS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

Examples

Example 1: Create the definition for a stored procedure that is written in COBOL. The procedure accepts an assembly part number and returns the number of parts that make up the assembly, the total part cost, and a result set. The result set lists the part numbers, quantity, and unit cost of each part. Assume that the input parameter cannot contain a null value and that the procedure is to run in a WLM environment called PARTSA.

```
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
  LANGUAGE COBOL
  EXTERNAL NAME MYMODULE
  PARAMETER STYLE GENERAL
  WLM ENVIRONMENT PARTSA
  DYNAMIC RESULT SETS 1;
```

Example 2: Create the definition for the stored procedure described in Example 1, except use the linkage convention that passes more information than the parameter specified on the CALL statement. Specify Language Environment run time options HEAP, BELOW, ALL31, and STACK.

```
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
  LANGUAGE COBOL
  EXTERNAL NAME MYMODULE
  PARAMETER STYLE SQL
  WLM ENVIRONMENT PARTSA
  DYNAMIC RESULT SETS 1
  RUN OPTIONS 'HEAP(,,ANY),BELOW(4K,,),ALL31(ON),STACK(,,ANY,)' ;
```

Example 3: Create the procedure definition for a stored procedure, written in Java, that is passed a part number and returns the cost of the part and the quantity that is currently available.

```
CREATE PROCEDURE PARTS_ON_HAND(IN PARTNUM INT,
                                OUT COST DECIMAL(7,2),
                                OUT QUANTITY INT)
  LANGUAGE JAVA
  EXTERNAL NAME 'PARTS.ONHAND'
  PARAMETER STYLE JAVA;
```

CREATE PROCEDURE (SQL - external)

The CREATE PROCEDURE statement defines an external SQL procedure at the current server and specifies the source statements for the procedure. This is the only type of SQL procedure that is available for versions of DB2 prior to Version 9.

For information about the SQL control statements that are supported in external SQL procedures, refer to “SQL control statements for external SQL procedures” on page 2320.

Invocation

This statement can only be dynamically prepared, but the DYNAMICRULES run behavior must be specified implicitly or explicitly. It is intended to be processed using one of the following methods:

- JCL
- The DB2 for z/OS SQL procedure processor (DSNTPSMP) (IBM Optim™ Development Studio uses this method.)

Issuing the CREATE PROCEDURE statement from another context will result in an incomplete procedure definition even though the statement processing returns without error. For more information on preparing SQL procedures for execution, see *DB2 Application Programming and SQL Guide*.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

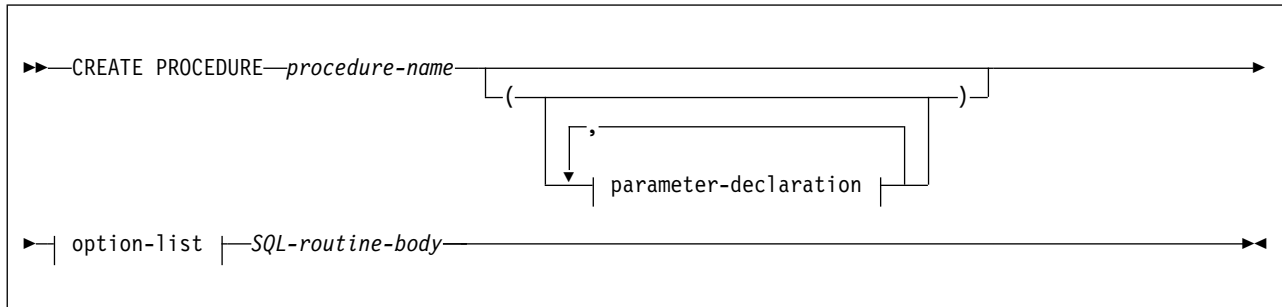

The authorization ID that is used to create the stored procedure must have authority to create programs that are to be run in the specified WLM environment.

The owner of the procedure is determined by how the CREATE PROCEDURE statement is invoked:

- If the statement is embedded in a program, the owner is the authorization ID of the owner of the plan or package.
- If the statement is dynamically prepared, the owner is the SQL authorization ID in the CURRENT SQLID special register.

The owner is implicitly given the EXECUTE privilege with the GRANT option for the procedure.

Syntax

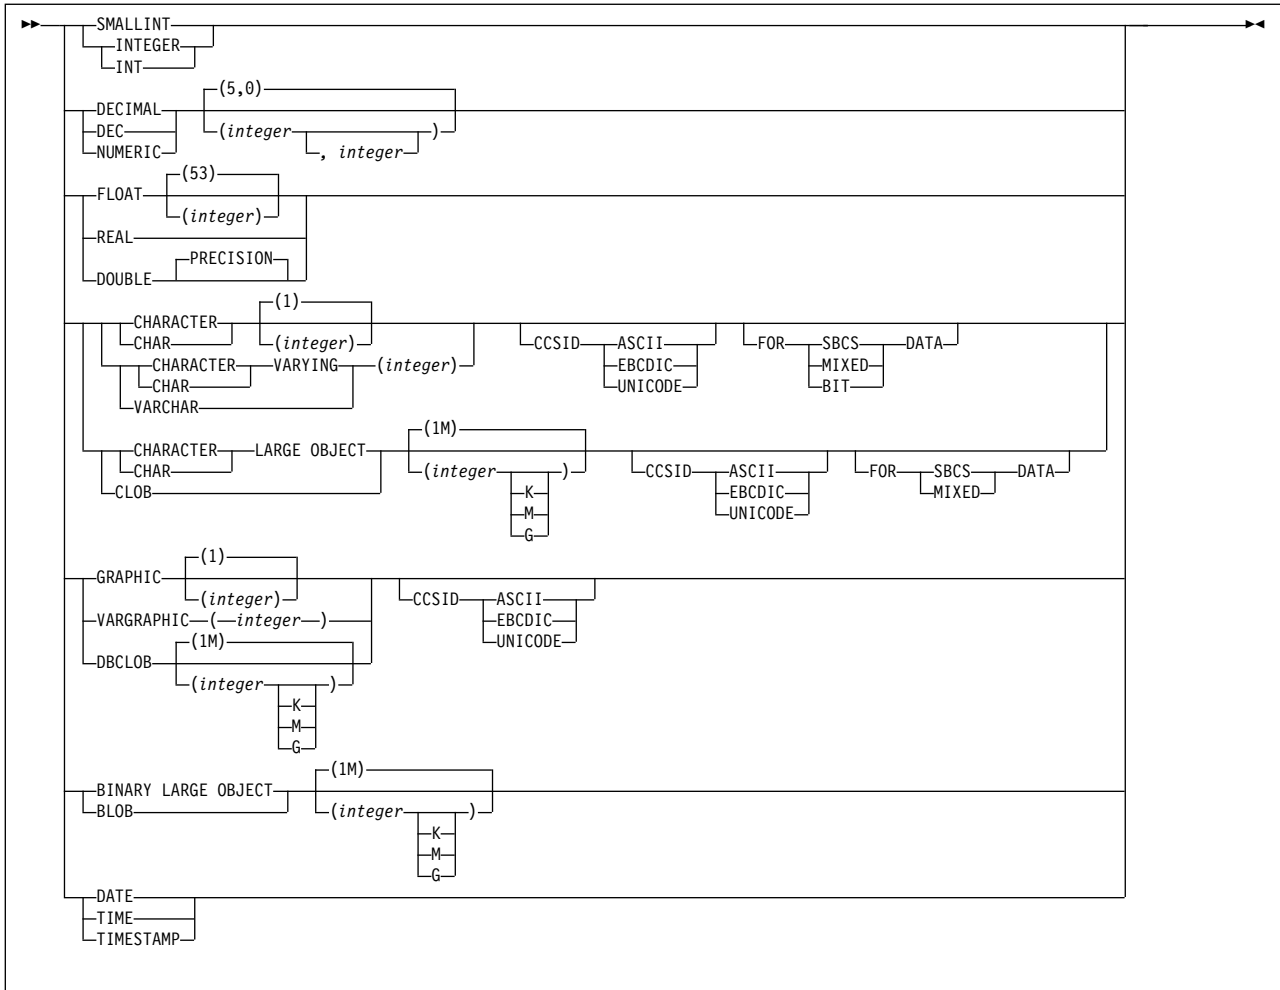

parameter-declaration:

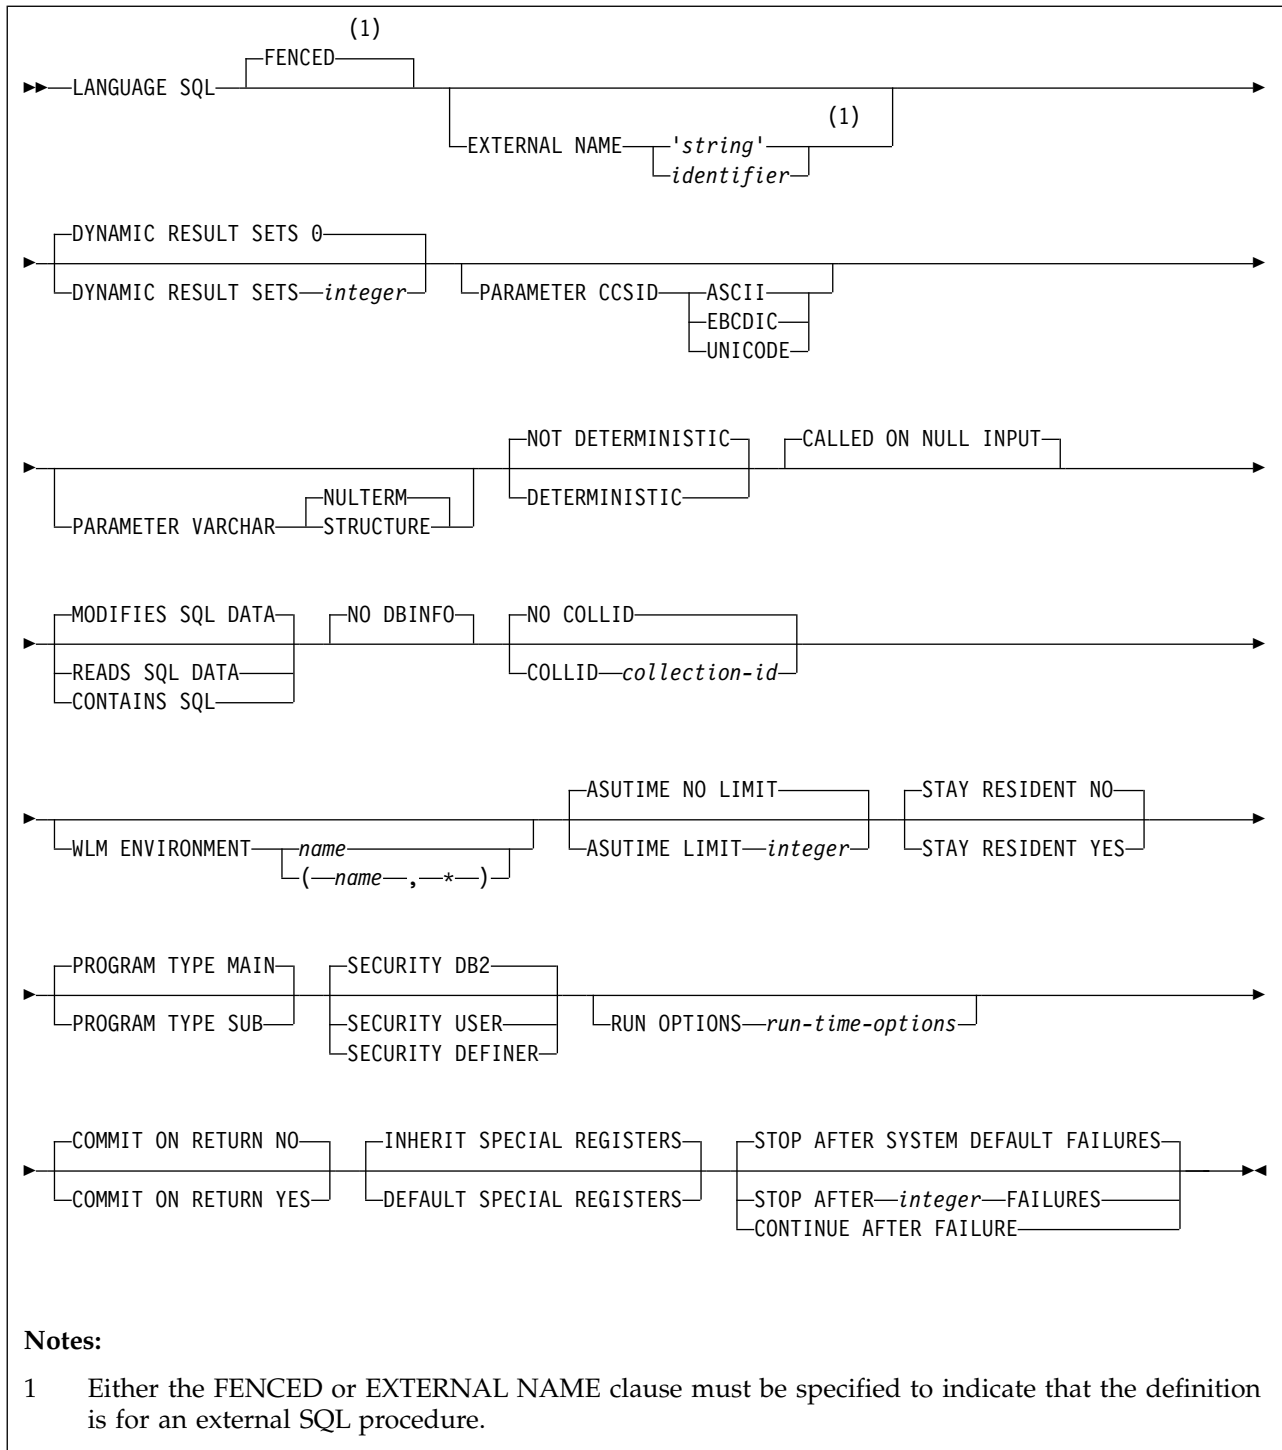

parameter-type:

built-in-type:

option-list: (The options can be specified in any order, but each option can be specified only one time)

Description

procedure-name

Names the procedure. The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

The schema name can be 'SYSIBM' or 'SYSPROC'. It can also be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Specifies the number of parameters of the procedure, the data type of each parameter, and the name of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined, and INOUT parameters are unchanged. All of the parameters are nullable.

IN Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

parameter-name

Names the parameter for use as an SQL variable. *parameter-name* is an SQL identifier and must not be a delimited identifier that includes lowercase letters or special characters. A parameter name cannot be the same as the name of any other parameter for this version of the procedure.

parameter-type

Specifies the data type of the parameter.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR *subtype* DATA clause), see built-in-type. For external SQL procedures, the maximum limit for VARCHAR is 32767 and for VARGRAPHIC is 16382.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

A parameter with a datetime data type is passed to the SQL procedure as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is determined as follows:

- If there are one or more parameters with a character or graphic data type, the encoding scheme of the datetime type parameter is the same as the encoding scheme of the character or graphic parameters.
- Otherwise, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

TABLE LIKE *table-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The transition table includes columns that are defined as implicitly hidden in the table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns.

For more information about the TABLE LIKE clause, see TABLE LIKE. For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

LANGUAGE

Specifies the application programming language in which the procedure is written.

SQL

The procedure is written in DB2 SQL procedural language.

FENCED

Specifies that the procedure runs in an external address space. FENCED also specifies that the SQL procedure program is an MVS load module with an external name.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that the procedure can return no result sets. The value of *integer* must be between 0 and 32767.

PARAMETER CCSID

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme that is to be used for system-generated parameters of the routine such as message tokens and DBINFO.

PARAMETER VARCHAR

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

NULTERM is the default.

STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL NAME 'string' or identifier

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

EXTERNAL NAME *procedure-name* is the default. In some cases, the default name will not be valid. To avoid an invalid name, specify EXTERNAL NAME for a procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

NOT DETERMINISTIC

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

NOT DETERMINISTIC is the default.

DETERMINISTIC

The procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

CALLED ON NULL INPUT

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or non-null values.

CALLED ON NULL INPUT is the default.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements that the procedure can execute.

For the data access classification of each statement, see Table 217 on page 2318. Statements that are not supported in any procedure return an error.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

NO DBINFO

Specifies that no additional status information that is known by DB2 is passed to the procedure when it is invoked.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

NO COLLID

Specifies that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

COLLID *collection-id*

Specifies the package collection for the procedure.

WLM ENVIRONMENT *name* or (*name*,*)

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the procedure runs in the default WLM-established stored procedure address space that is specified at installation time.

name

The WLM environment in which the procedure must run. If another procedure or a user-defined function calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the procedure request to a different address space.

(*name*,*)

When an SQL application program directly calls a procedure, *name* specifies the WLM environment in which the procedure runs.

If another procedure or a user-defined function calls the stored procedure, the procedure runs in the same WLM environment that the calling routine uses.

To define a procedure that is to run in a specified WLM environment, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

There is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the load module for the procedure remains resident in memory when the procedure ends.

NO The load module is deleted from memory after the procedure ends.

NO is the default.

YES

The load module remains resident in memory after the procedure ends.

PROGRAM TYPE

Specifies whether the procedure runs as a main routine or a subroutine.

MAIN

The procedure runs as a main routine.

MAIN is the default.

SUB

The procedure runs as a subroutine.

SECURITY

Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2

The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.

DB2 is the default.

USER

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

DEFINER

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

RUN OPTIONS *run-time-options*

Specifies the Language Environment run time options that are to be used for the procedure. You must specify *run-time-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see *z/OS Language Environment Programming Reference*.

COMMIT ON RETURN

Indicates whether DB2 commits the transaction immediately on return from the procedure.

NO DB2 does not issue a commit when the procedure returns.

NO is the default.

YES

DB2 issues a commit when the procedure returns if the following statements are true:

- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 43 on page 199.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 43 on page 199.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies the routine is stopped after failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

STOP AFTER SYSTEM DEFAULT FAILURES is the default.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

SQL-routine-body

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in external SQL procedures, see "SQL control statements for external SQL procedures" on page 2320.

Notes

See "Notes" on page 1653 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters
- Environments for running stored procedures
- Accessing result sets from nested stored procedures

Error handling in SQL procedures: You should consider the possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound statement results in the exception SQLSTATE being returned to the caller of the procedure.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC

Examples

Example 1: Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATESALARY
  (IN EMPLOYEE_NUMBER CHAR(10),
  IN RATE DECIMAL(6,2))
LANGUAGE SQL
FENCED
EXTERNAL NAME 'USALARY1'
```

```
MODIFIES SQL DATA
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 2: Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The procedure runs in a WLM environment called PARTSA.
- The same input always produces the same output.
- SQL work is committed on return to the caller.
- The Language Environment run time options to be used when the SQL procedure executes are 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'.

```
CREATE PROCEDURE UPDATESALARY
(IN EMPLOYEE_NUMBER CHAR(10),
IN RATE DECIMAL(6,2))
LANGUAGE SQL
FENCED
EXTERNAL NAME 'USALARY2'
MODIFIES SQL DATA
WLM ENVIRONMENT PARTSA
DETERMINISTIC
RUN OPTIONS 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'
COMMIT ON RETURN YES
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

For more examples of SQL procedures, see “SQL control statements for external SQL procedures” on page 2320.

CREATE PROCEDURE (SQL - native)

The CREATE PROCEDURE statement defines an SQL procedure at the current server and specifies the source statements for the procedure.

You can define multiple versions of the procedure. CREATE PROCEDURE is used to define the initial version, and ALTER PROCEDURE is used to define subsequent versions.

For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 8, "SQL control statements for SQL routines," on page 2251.

Invocation

This statement can only be dynamically prepared, and the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema and the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If a distinct type is referenced (as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following privileges or authorities:

- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority

If the procedure uses a table as a parameter, the privilege set must also include at least one of the following privileges or authorities:

- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

If the authorization ID that is used to create the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure.

Privilege set: The privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process and the owner is that role.

If the statement is not running in a trusted context for which the `ROLE AS OBJECT OWNER` clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes `SYSADM` or `SYSCTRL` authority.
- The SQL authorization ID of the process has the `CREATEIN` privilege on the schema.

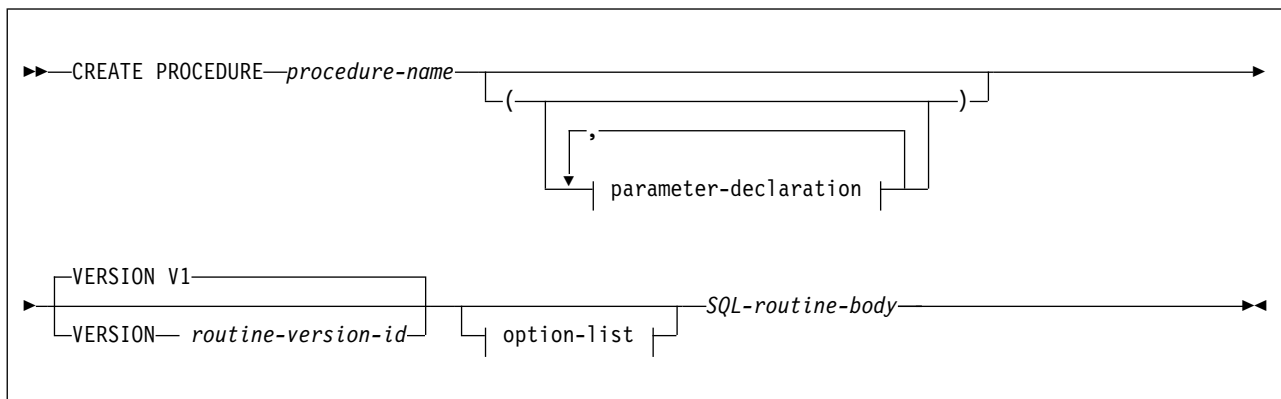

The privilege set must also include the privileges required to execute the statements in *SQL-routine-body*.

If the `WLM ENVIRONMENT FOR DEBUG MODE` clause is specified, the privilege set must have authority to define programs that run in the specified WLM environment.

The owner of the procedure is the SQL authorization ID in the `CURRENT SQLID` special register unless the process is running within a trusted context and the `ROLE AS OBJECT OWNER` clause is specified. In that case, the owner of the procedure is the role that is associated with the primary authorization ID of the process.

The owner is implicitly given the `EXECUTE` privilege with the `GRANT` option for the procedure.

Syntax

parameter-declaration:

parameter-type:

|
| **data-type:**

|
built-in-type:

option-list: (The options can be specified in any order, but each one can only be specified one time.)

SQL-routine-body:

| SQL-control-statement | (1) |
|--|-----|
| ALTER DATABASE statement | |
| ALTER FUNCTION statement (external scalar, external table, sourced, SQL scalar, or SQL table) | |
| ALTER INDEX statement | |
| ALTER PROCEDURE statement (external, SQL - external, or SQL - native) | |
| ALTER SEQUENCE statement | |
| ALTER STOGROUP statement | |
| ALTER TABLE statement | |
| ALTER TABLESPACE statement | |
| ALTER TRUSTED CONTEXT statement | |
| ALTER VIEW statement | |
| COMMENT statement | |
| COMMIT statement | |
| CONNECT statement | |
| CREATE ALIAS statement | |
| CREATE DATABASE statement | |
| CREATE FUNCTION statement (external scalar, external table, or sourced) | |
| CREATE GLOBAL TEMPORARY TABLE statement | |
| CREATE INDEX statement | |

| LOCK TABLE statement | |
| MERGE statement | |
| REFRESH TABLE statement | |
| RELEASE statement | |
| RELEASE SAVEPOINT statement | |
| RENAME statement | |
| REVOKE statement | |
| ROLLBACK statement | |
| SAVEPOINT statement | |
| SELECT INTO statement | |
| SET CONNECTION statement | |
| SET special-register statement | |
| TRUNCATE statement | |
| UPDATE statement | |
| VALUES INTO statement | |

Notes:

- 1 An ALTER FUNCTION statement (SQL scalar) or an ALTER PROCEDURE statement (SQL native) with an ADD VERSION or REPLACE clause are not allowed in an *SQL-routine-body*.

Description

procedure-name

Names the procedure. If *procedure-name* already exists, an error is returned even if VERSION is specified with a *version-id* that is different from any existing version identifier for the procedure that is specified in *procedure-name*.

The schema name can be 'SYSIBM' or 'SYSPROC'. It can also be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the procedure that is being defined. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match. All parameters are nullable.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

IN Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

parameter-name

Names the parameter for use as an SQL variable. A parameter name cannot be the same as the name of any other parameter for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR *subtype* DATA clause), see built-in-type. However, the varying length string data types have different maximum lengths than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows: 32704 for VARCHAR or VARBINARY, and 16352 for VARGRAPHIC.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore,

conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format. The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.
- A distinct type parameter is passed as the source type of the distinct type.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

TABLE LIKE *table-name* **AS LOCATOR**

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

VERSION *routine-version-id*

Specifies the version identifier for the first version of the procedure that is to be generated. See “Naming conventions” on page 59 for information about specifying *routine-version-id*. You can use an ALTER PROCEDURE statement with the ADD VERSION clause or the BIND DEPLOY command to create additional versions of the procedure.

V1 is the default version identifier.

Important: Do not create additional versions of procedures that are supplied with DB2 by specifying the VERSION keyword. Only versions that are supplied with DB2 are supported. Additional versions of such routines cause the installation and configuration of the supplied routines to fail.

See Versions of a procedure for more information about the use of versions for procedures.

LANGUAGE SQL

Specifies that the procedure is written in the DB2 SQL procedural language.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.

DETERMINISTIC

The procedure always returns the same results each time it is called with the same IN and INOUT arguments if the data that is referenced in the database has not changed.

NOT DETERMINISTIC

The procedure might not return the same result each time it is called with the same IN and INOUT arguments, even when the data that is referenced in the database has not changed.

NOT DETERMINISTIC is the default.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements that the procedure can execute.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

CALLED ON NULL INPUT

Specifies that the procedure will be called if any, or even if all parameter values are null.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE

Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

DISALLOW DEBUG MODE

Specifies that this version of the routine cannot be run in debugging mode.

You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

DISABLE DEBUG MODE

Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

PARAMETER CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

QUALIFIER *schema-name*

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the procedure body. See “Unqualified alias, index, JAR file, sequence, table, trigger, and view names” on page 67 for information about how the default for this option is determined.

PACKAGE OWNER *authorization-name*

Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

The authorization ID must have the privileges that are required to execute the SQL statements that are contained in the routine body and must contain the necessary bind privileges. The value of PACKAGE OWNER is subject to translation when it is sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process or the authorization ID of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID that contains the necessary bind privileges.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

NO LIMIT

Specifies that there is no limit on the service units.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

COMMIT ON RETURN NO or COMMIT ON RETURN YES

Indicates whether DB2 commits the transaction immediately on return from the procedure.

COMMIT ON RETURN NO

DB2 does not issue a commit when the procedure returns. NO is the default.

COMMIT ON RETURN YES,

DB2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 43 on page 199.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 43 on page 199.

WLM ENVIRONMENT FOR DEBUG MODE *name*

Specifies the WLM (workload manager) application environment that is used by DB2 when debugging the routine. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application

environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

DEFER PREPARE or NODEFER PREPARE

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value in effect for the REOPT option. If REOPT NONE is in effect, the default is inherited from the plan at run time. Otherwise, the default is DEFER PREPARE.

DEFER PREPARE

Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

Refer to the DEFER(PREPARE) option in *DB2 Command Reference* for considerations with distributed processing.

NODEFER PREPARE

Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

CURRENT DATA YES or CURRENT DATA NO

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

CURRENT DATA YES

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquires page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

CURRENT DATA NO

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of **CURRENT DATA NO** is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

CURRENT DATA NO is the default.

DEGREE

Specifies whether to attempt to run a query using parallel processing to maximize performance.

1 Specifies that parallel processing should not be used.

1 is the default.

ANY

Specifies that parallel processing can be used.

CONCURRENT ACCESS RESOLUTION

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

WAIT FOR OUTCOME

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

DYNAMICRULES

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

RUN

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND

Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

DEFINERUN

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

INVOKEBIND

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

INVOKERUN

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See “Authorization IDs and dynamic SQL” on page 75 for information on the effects of these options.

APPLICATION ENCODING SCHEME

Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

ASCII

Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN

Specifies whether information will be provided about how SQL statements in the routine will execute.

WITHOUT EXPLAIN

Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN

Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table *owner.PLAN_TABLE*. *owner* is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as *owner.PLAN_TABLE* that points to the base table, *PLAN_TABLE*. *owner* must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. *PLAN_TABLE* must have a base table and can have multiple aliases with the same table name, *PLAN_TABLE*, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to *owner.PLAN_TABLE*, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables if they exist: DSN_STATEMNT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMNT_TABLE contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. DSN_FUNCTION_TABLE contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see “EXPLAIN” on page 1948.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDIATEWRITE subsystem parameter has no effect of this option. *DB2 Command Reference* shows the implied hierarchy of the IMMEDIATEWRITE bind option (which is similar to this routine option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR

Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see *DB2 Performance Monitoring and Tuning Guide*.

RR Specifies repeatable read.

RS Specifies read stability.

CS Specifies cursor stability. CS is the default.

UR Specifies uncommitted read.

WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC

Specifies whether DB2 keeps dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC

Specifies that DB2 does not keep dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC is the default.

WITH KEEP DYNAMIC

Specifies that DB2 keeps dynamic SQL statements after commit points. If you specify WITH KEEP DYNAMIC, the application does not need to prepare an SQL statement after every commit point. DB2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs

- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify WITH KEEP DYNAMIC, and the prepared statement cache is active, the DB2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread timeouts, as described in *DB2 Installation Guide* for installation panel DSNTIPR.

If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The DB2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

OPHTINT *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

string-constant is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *DB2 Installation Guide* for information about enabling optimization hints.

SQL PATH

Specifies the SQL path that DB2 uses to resolve unqualified user-defined type, function, and procedure names in the procedure body. The default value is "SYSIBM", "SYSFUN", "SYSPROC", and the value of the QUALIFIER option, which is the qualifier for the procedure that is the target of the statement.

Schemas "SYSIBM", "SYSFUN", "SYSPROC" do not need to be explicitly specified. If any of these schemas is not explicitly specified, it is implicitly assumed at the beginning the SQL path.

DB2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed the length of the CURRENT_SCHEMA special register. If you do not specify the "SYSIBM", "SYSFUN", "SYSPROC", schemas, they are not included in the length of the SQL path. If the total length of the SQL path exceeds the length of the CURRENT_PATH special register, DB2 returns an error for the CREATE statement.

Related information:

"SQL path" on page 65

“CURRENT SCHEMA” on page 189

“CURRENT PATH” on page 181

schema-name

Specifies a schema. DB2 does not validate that the specified schema actually exists when the CREATE statement is processed.

schema-name-list

Specifies a comma separated list of schema names. The same schema name should not appear more than one time in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.

SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC".

SESSION_USER or USER

Specifies the value of the SESSION_USER or USER special register, which represents a maximum 8 byte (in EBCDIC) *schema-name*. At the time the CREATE statement is processed, this length is included in the total length of the list of schema names that is specified for the PATH bind option.

RELEASE AT

Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

COMMIT

Specifies that resources will be released at each commit point.

COMMIT is the default.

DEALLOCATE

Specifies that resources will be released only when the thread terminates. DEALLOCATE has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package or plan size because additional items become resident in the package or plan.

Related information:

Choosing a RELEASE option (DB2 Performance)

REOPT

Specifies if DB2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE

Specifies that DB2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

ALWAYS

Specifies that DB2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

ONCE

Specifies that DB2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.

QUERY ACCELERATION

Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE

Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE

Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in DB2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and DB2 cannot route the static query to the accelerator for execution.

ENABLE WITH FAILBACK

Results in the same behavior as ENABLE, except if one of the error conditions occurs on the first OPEN of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, DB2 performs a temporary *statement-level* incremental bind of the query and runs the query in DB2. The application does not see the acceleration failure. Failback to DB2 is not possible after the application does a successful OPEN for the query on the accelerator.

ELIGIBLE

Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

ALL

Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If DB2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the BIND or REBIND PACKAGE operation fails with an error message for that query. (A failure exception is made for declared global temporary tables (DGTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a *fullselect* or *WITH common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

NO Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in DB2.

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

YES

Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The QUERYACCELERATION bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a *fullselect* or *WITH common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

VALIDATE RUN or VALIDATE BIND

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN

Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

VALIDATE RUN is the default.

VALIDATE BIND

Specifies that if needed objects or privileges do not exist at the time the CREATE statement is processed, an error is issued and the CREATE statement fails.

ROUNDING

Specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in DECP.

DEC_ROUND_CEILING

Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN

Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR

Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN

Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

DEC_ROUND_HALF_UP

Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP

Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the date format for result values that are string representations of date or time values. See "String representations of datetime values" on page 101 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)

Specifies the maximum precision that is to be used for decimal arithmetic operations. See "Arithmetic with two decimal operands" on page 231 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 101 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

SQL-routine-body

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 8, “SQL control statements for SQL routines,” on page 2251. If an *SQL-procedure-statement* is the only statement in the procedure body, the statement must not end with a semicolon.

Notes

Additional Notes:

See “Notes” on page 1653 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters
- Environments for running stored procedures
- Accessing result sets from nested stored procedures

Versions of a procedure:

The CREATE PROCEDURE statement for an SQL procedure defines the initial version of the procedure. You can define additional versions using the ADD VERSION clause of the ALTER PROCEDURE statement. All versions of a procedure share the same procedure signature and the same specific name. However, the parameters names can differ between versions of a procedure. Only one version of the procedure can be considered to be the active version of the procedure.

Important: Do not create additional versions of procedures that are supplied with DB2 by specifying the VERSION keyword. Only versions that are supplied with DB2 are supported. Additional versions of such routines cause the installation and configuration of the supplied routines to fail.

Characteristics of the package that is generated for a procedure:

The package that is associated with the first version of a procedure is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the procedure.
- *package-id* is the same as the specific name of the procedure
- *version-id* is the same as the version identifier for the initial version of the procedure.

If you want to change the *collection-id* for the name of the package, you need to make a copy of the package.

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See "Implicit rebinding and regeneration that occurs because of an ALTER PROCEDURE statement" in Chapter 8, "SQL control statements for SQL routines," on page 2251 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:

- DBPROTOCOL(DRDA)
- FLAG(1)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

See Table 151 on page 1289 for additional information about the correspondence of procedure options to bind options.

Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see *DB2 Application Programming and SQL Guide*.

Identifier resolution:

See Chapter 8, "SQL control statements for SQL routines," on page 2251 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, and the label name for SQL variables.

Lines within the SQL procedure definition:

When a procedure is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

Error handling in SQL procedures:

You should consider the possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound

statement or a compound statement that is nested within that compound statement results in the exception SQLSTATE being returned to the caller of the procedure.

Compatibilities:

For compatibility with previous versions of DB2, the following clauses can be specified, but they will be ignored and a warning will be issued:

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER *n*m FAILURES
- CONTINUE AFTER FAILURES
- PARAMETER VARCHAR

If the FENCED or EXTERNAL clause is specified, an external SQL procedure will be generated. See “CREATE PROCEDURE (SQL - external)” on page 1656 for more information.

If WLM ENVIRONMENT is specified without the FOR DEBUG MODE keywords, an error is returned. If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL

Examples

Example 1: Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATE_SALARY_1
  (IN EMPLOYEE_NUMBER CHAR(10),
  IN RATE DECIMAL(6,2))
LANGUAGE SQL
MODIFIES SQL DATA
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 2: Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The same input always produces the same output.
- SQL work is committed on return to the caller.

```
CREATE PROCEDURE UPDATE_SALARY_1
  (IN EMPLOYEE_NUMBER CHAR(10),
  IN RATE DECIMAL(6,2))
LANGUAGE SQL
MODIFIES SQL DATA
DETERMINISTIC
COMMIT ON RETURN YES
  UPDATE EMP
  SET SALARY = SALARY * RATE
  WHERE EMPNO = EMPLOYEE_NUMBER
```

For more examples of SQL procedures, see Chapter 8, “SQL control statements for SQL routines,” on page 2251.

CREATE ROLE

The CREATE ROLE statement creates a role at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following authorities:

- SYSADM authority
- SYSCTRL authority
- SECADM

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process or by the role that is associated with the primary authorization ID, if the statement is run in a trusted context and the ROLE AS OBJECT OWNER clause is specified.

Syntax

►►—CREATE ROLE—*role-name*—————►◄

Description

role-name

Names the role. The name must not identify a role that exists at the current server. The name must not begin with the characters 'SYS' and must not be 'DBADM', 'NONE', 'NULL', 'PUBLIC', or 'SECADM'.

Examples

The following statement creates a role named TELLER.

```
CREATE ROLE TELLER;
```

CREATE SEQUENCE

The CREATE SEQUENCE statement creates a sequence at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

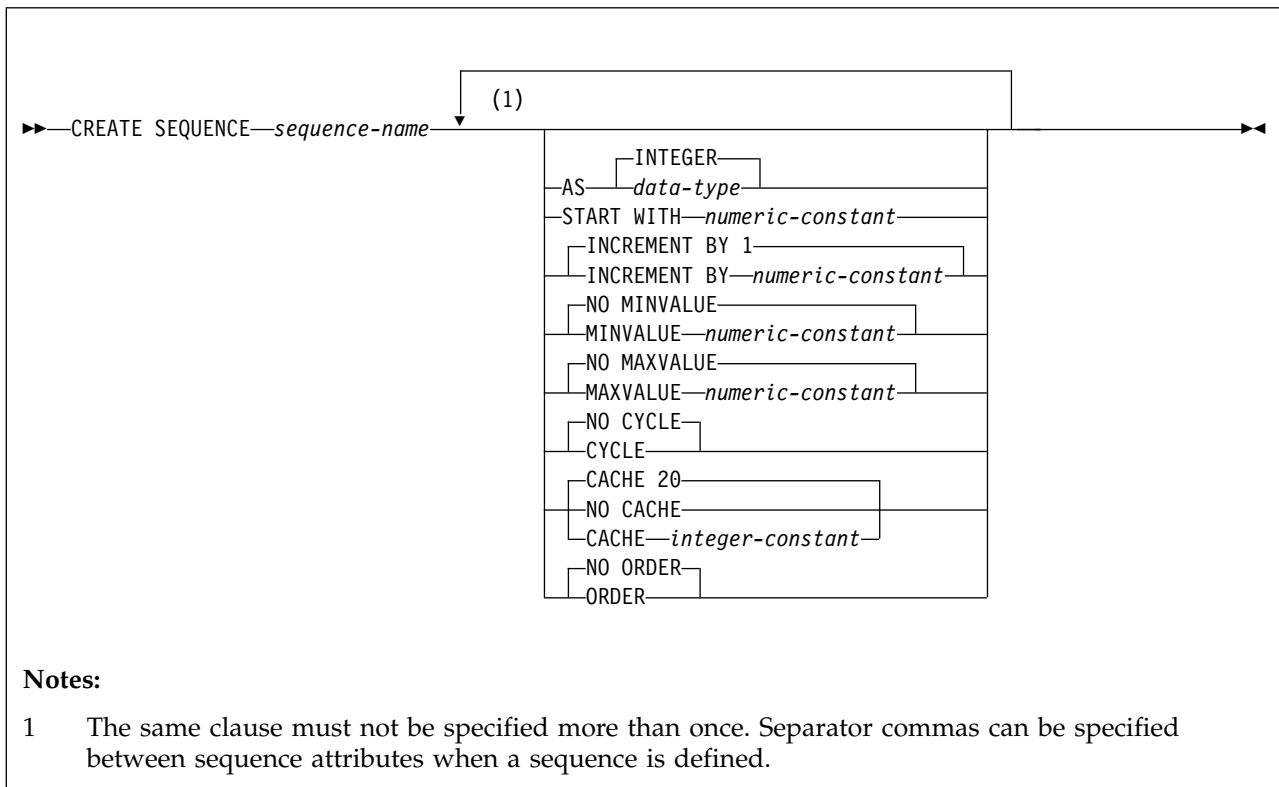

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

If the data type of the sequence is a distinct type, the privilege set must include the USAGE privilege on the distinct type.

Syntax

data-type:

built-in-type:

Description

sequence-name

Names the sequence. The name, including the implicit or explicit qualifiers, must not identify an existing sequence at the current server, including the sequence names that are generated by DB2.

The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

AS *data-type*

Specifies the data type to be used for the sequence value. The data type can be any exact numeric data type (SMALLINT, INTEGER, BIGINT, or DECIMAL with a scale of zero), or a user-defined distinct type for which the source type is an exact numeric data type with a scale of zero. The default, when AS is not specified, is INTEGER. If DECIMAL is specified, the default is DECIMAL(5,0).

START WITH *numeric-constant*

Specifies the first value for the sequence. The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If the START WITH clause is not explicitly specified with a value, the default is the MINVALUE for ascending sequences and MAXVALUE for descending sequences.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point. The default is 1.

If INCREMENT BY is positive, the sequence ascends. If INCREMENT BY is negative, the sequence descends. If INCREMENT is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

MINVALUE or NO MINVALUE

Specifies the minimum value at which a descending sequence either cycles or stops generating values or an ascending sequence cycles to after reaching the maximum value. The default is NO MINVALUE.

MINVALUE *numeric-constant*

Specifies the minimum end of the range of values for the sequence. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

For the effects of defining MINVALUE and MAXVALUE with the same value, see Defining a constant sequence.

NO MINVALUE

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending sequence, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending sequence, the value is the minimum value of the data type that is associated with the sequence.

MAXVALUE or NO MAXVALUE

Specifies the maximum value at which an ascending sequence either cycles or stops generating values or an descending sequence cycles to after reaching the minimum value. The default is NO MAXVALUE.

MAXVALUE *numeric-constant*

Specifies the maximum end of the range of values for the sequence. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

For the effects of defining MAXVALUE and MINVALUE with the same value, see Defining a constant sequence.

NO MAXVALUE

Specifies the maximum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence.
- For a descending sequence, the value is the START WITH value or -1 if START WITH is not specified.

To find the maximum possible value for a given data type, see “Limits in DB2 for z/OS” on page 2300.

CYCLE or NO CYCLE

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it. The default is NO CYCLE.

CYCLE

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application conversion tools for converting applications from other vendor platforms to DB2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

NO CYCLE

Specifies that the sequence cannot generate more values once the

maximum or minimum value for the sequence has been reached. The NO CYCLE option (the default) can be altered to CYCLE at any time during the life of the sequence.

When the next value is being generated for a sequence if the maximum value (for an ascending sequence) or the minimum value (for a descending sequence) of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, an error occurs.

CACHE or NO CACHE

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

CACHE *integer-constant*

Specifies the maximum number of values of the sequence that DB2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that DB2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

The minimum value is 2. The default is CACHE 20.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

NO CACHE

| Specifies that values of the sequence are not to be preallocated. This option
| ensures that there is not a loss of values in the case of a system failure.
| When NO CACHE is specified, the values of the sequence are not stored in
| the cache. In this case, every request for a new value for the sequence
| results in synchronous I/O to the log.

ORDER or NO ORDER

Specifies whether the sequence numbers must be generated in order of request. The default is NO ORDER.

ORDER

Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

NO ORDER

Specifies that the sequence numbers do not need to be generated in order of request.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to

20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested for next value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple DB2 members using the same sequence concurrently, specify the ORDER option.

Notes

Owner privileges: The owner is authorized to change (ALTER privilege) or use (USAGE privilege) the sequence and grant others these privileges. See "GRANT (sequence privileges)" on page 2019. For more information about ownership of the object see "Authorization, privileges, permissions, masks, and object ownership" on page 70.

Relationship of MINVALUE and MAXVALUE: MINVALUE must not be greater than MAXVALUE. Although MINVALUE is typically less than MAXVALUE, MINVALUE can equal MAXVALUE. If START WITH were the same value as MINVALUE and MAXVALUE, the sequence would be constant. The request for the next value in a constant sequence appears to have no effect because all of the values that are generated by the sequence are in fact the same value.

Defining sequences that cycle: When you define a sequence, you can choose to have it cycle automatically or not when the maximum or minimum value for the sequence has been reached.

- Implicitly or explicitly defining a sequence with NO CYCLE causes the sequence to not cycle automatically after the boundary is reached. However, you can use the ALTER SEQUENCE statement to cycle the sequence manually. ALTER SEQUENCE allows you to restart or extend the sequence, which causes sequence values to continue to be generated.
- Explicitly defining a sequence with CYCLE causes the sequence to cycle automatically after the boundary is reached. Sequence values continue to be generated after the sequence cycles.

When a sequence is defined to cycle automatically, the maximum or minimum value that is generated for a sequence might not be the actual MAXVALUE or MINVALUE value that is specified if the increment is a value other than 1 or -1. For example, the sequence defined with START WITH=1, INCREMENT=2, MAXVALUE=10 will generate a maximum value of 9, and will not generate the value 10.

When a sequence is defined with CYCLE, any application conversion tools (for converting applications from other vendor platforms to DB2) should also explicitly specify MINVALUE, MAXVALUE, and START WITH.

Defining a constant sequence: You can define a sequence such that it always returns the same (or a constant) value. To create a constant sequence, use either of these techniques when defining the sequence:

- Specify an INCREMENT value of zero and a START WITH value that does not exceed MAXVALUE.
- Specify the same value for START WITH, MINVALUE, and MAXVALUE, and specify CYCLE.

A constant sequence can be used as a numeric global variable. You can use ALTER SEQUENCE to adjust the values that are generated for a constant sequence.

Consumed values of a sequence: After DB2 generates a value for a sequence, that value can be said to be "consumed" regardless of whether or not that value is used

by the application or not. The value is not reused within the current cycle. A consumed value might not be used when the statement that caused the value to be generated fails for some reason or is rolled back after the value was generated. Generated but unused values can constitute gaps in a sequence.

Gaps in a sequence: Consecutive values in a sequence differ by the constant INCREMENT BY value specified for the sequence. However, gaps can occur in the values that are assigned to a sequence object by DB2.

The following situations are some examples of how gaps can be introduced in the sequence values:

- A transaction has advanced the sequence and then rolls back.
- The SQL statement leading to the generation of the next value fails after the value was generated.
- The NEXT VALUE expression is used in the SELECT statement of a cursor in a DRDA environment where the client uses block-fetch and not all retrieved rows are fetched by the application.
- The sequence is altered and then the alteration is rolled back.
- The sequence (or an identity column table) is dropped and then the drop is rolled back.
- The SYSIBM.SYSSEQ table space is stopped or closed for any reason (including when DSMAX is reached)
- The DB2 subsystem is stopped or goes down

Values of such gaps are not available for the current cycle, unless the sequence is altered and restarted in a specific way to make them available.

A sequence is incremented independently of a transaction. Thus, a given transaction increments the sequence two times might see a gap in the two numbers that it receives if other transactions concurrently increment the same sequence. Most applications can tolerate these instances as these are not really gaps.

Duplicate sequence values: It is possible the duplicate values can be generated for a sequence. Duplicate values are most likely to occur when a sequence is defined with the CYCLE option, is defined as a constant sequence, or is altered. For example, the following situations could cause duplicate sequence values:

- A sequence is defined with the attributes START WITH=2, INCREMENT BY 2, MINVALUE=2, MAXVALUE=10, and CYCLE.
- The ALTER SEQUENCE statement is used to restart the sequence with a value that has already been generated.
- The ALTER SEQUENCE statement is used to reverse the ascending direction of a sequence by changing the INCREMENT BY value from a positive to a negative.

Using sequences: A sequence can be referenced using a *sequence-reference*. A sequence reference can appear in most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value or the previously generated value. A NEXT VALUE sequence expression is used to generate a new value. A PREVIOUS VALUE sequence expression is used to obtain the last assigned value of a sequence. For more information, see “Sequence reference” on page 274.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOCACHE (single key word) as a synonym for NO CACHE
- NOORDER (single key word) as a synonym for NO ORDER

Examples

Example 1: Create a sequence names "org_seq" that starts at 1 increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORDER_SEQ
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 24;
```

INCREMENT 1, NO MAXVALUE, and NO CYCLE are defaults and do not need to be specified.

Example 2: The following example shows how to create and use a sequence named "order_seq" in a table named "orders":

```
CREATE SEQUENCE ORDER_SEQ
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 20;
INSERT INTO ORDERS (ORDERNO, CUSTNO)
  VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
```

or to update the orders:

```
UPDATE ORDERS
  SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
  WHERE CUSTNO = 123456;
```

Example 3: The following example shows how to use the same sequence number as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row to generate the sequence value and with a PREVIOUS VALUE expression for the other rows to refer to the sequence value most recently generated.

```
INSERT INTO ORDERS (ORDERNO, CUSTNO)
  VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
INSERT INTO LINE_ITEMS (ORDERNO, PARTNO, QUANTITY)
  VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 100);
```

If NEXT VALUE is invoked in the same statement as the PREVIOUS VALUE, then regardless of their order in the statement, PREVIOUS VALUE returns the previous (unincremented) value and NEXT VALUE returns the next value.

CREATE STOGROUP

The CREATE STOGROUP statement creates a storage group at the current server. Storage from the identified volumes can later be allocated for table spaces and index spaces.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

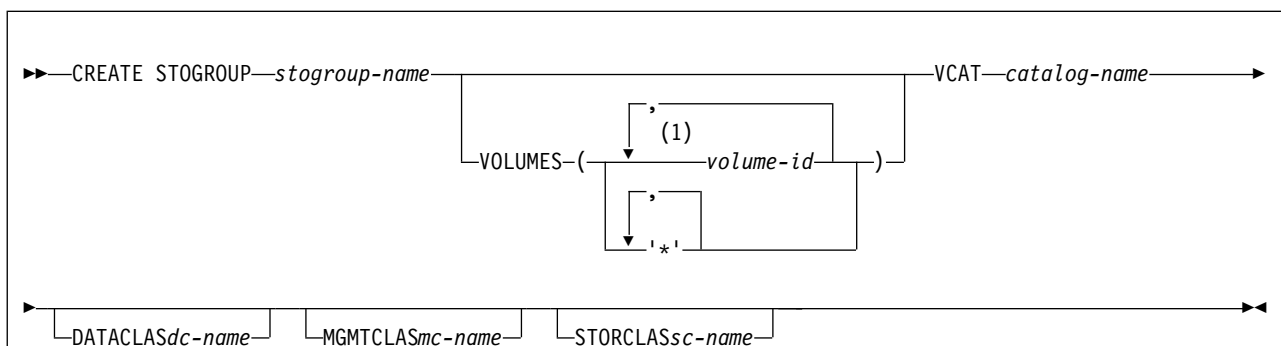

The privilege set that is defined below must include at least one of the following:

- The CREATESG privilege
- SYSADM or SYSCTRL authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax

Notes:

- 1 The same *volume-id* must not be specified more than once.

Description

stogroup-name

Names the storage group. The name must not identify a storage group that exists at the current server.

VOLUMES(*volume-id*,...) or **VOLUMES**('*',...)

Defines the volumes of the storage group. Each *volume-id* is a volume serial number of a storage volume. The volume serial number can have a maximum of six characters and is specified as an identifier or a string constant.

If the data set that is associated with the storage group is not managed by Storage Management Subsystem (SMS), **VOLUMES** must be specified. Asterisks are recognized only by SMS. SMS usage is recommended, rather than using DB2 to allocate data to specific volumes. Having DB2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended. If one or more of the **DATACLAS**, **MGMTCLAS**, or **STORCLAS** clauses are specified, **VOLUMES** can be omitted. If the **VOLUMES** clause is omitted, the volume selection is controlled by SMS.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

VCAT *catalog-name*

Identifies the integrated catalog facility catalog for the storage group. You must specify an alias³³ if the name of the integrated catalog facility catalog is longer than 8 characters.

The designated catalog is the one in which entries are placed for the data sets created by DB2 with the aid of the storage group. These are linear VSAM data sets for associated table or index spaces or for their partitions. For each such space or partition, association is made through a **USING** clause in a **CREATE TABLESPACE**, **CREATE INDEX**, **ALTER TABLESPACE**, or **ALTER INDEX** statement. For more on the association, see the descriptions of those statements in this chapter.

Conventions for data set names are given in *DB2 Administration Guide*. *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DATACLAS *dc-name*

Identifies the name of the SMS data class to associate with the DB2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. **DATACLAS** must not be specified more than one time.

MGMTCLAS *mc-name*

Identifies the name of the SMS management class to associate with the DB2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. **MGMTCLAS** must not be specified more than one time.

STORCLAS *sc-name*

Identifies the name of the SMS storage class to associate with the DB2 storage group. The SMS storage class name must be from 1-8 characters in length. The

33. The alias of an integrated catalog facility catalog.

SMS storage administrator defines the storage class that can be used. STORCLAS must not be specified more than one time.

Notes

Device types: When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

Number of volumes: There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

z/OS imposes a limit on the number of volumes that can be allocated per data set (currently, 59 volumes). For the latest information on that restriction, see z/OS DFSMS Access Method Services for Catalogs.

Storage group owner: If the statement is embedded in an application program, the owner of the plan or package is the owner of the storage group. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the storage group. The owner has the privilege of altering and dropping the storage group.

Specifying volume IDs: A new storage group must have either specific volume IDs or non-specific volume IDs. You cannot create a storage group that contains a mixture of specific and non-specific volume IDs.

| **Verifying the existence of volumes and classes:** When processing the VOLUMES,
| DATACLAS, MGMTCLAS, or STORCLAS clauses, DB2 does not check the
| existence of the volumes or classes or determine the types of devices that are
| identified or if SMS is active. Later, when the storage group allocates data sets, the
| list of volumes is passed to Data Facilities (DFSMSdftp) in the physical order of the
| rows in the SYSIBM.SYSVOLUMES catalog table.

Related information:

| Implementing DB2 storage groups (DB2 Administration Guide)

Example

Create storage group, DSN8G100, of volumes ABC005 and DEF008. DSNCAT is the integrated catalog facility catalog name.

```
CREATE STOGROUP DSN8G100
VOLUMES (ABC005,DEF008)
VCAT DSNCAT;
```

CREATE SYNONYM

The CREATE SYNONYM statement defines a synonym for a table or view at the current server.

Important: Use aliases instead of synonyms. Synonyms are similar to aliases but are supported only for compatibility with previous releases. Aliases behave the same for the DB2 family of products. **Recommendation:** When writing new SQL statements or creating portable applications, use aliases instead. IBM has no current plans to remove support for synonyms from DB2 for z/OS; however the use of synonyms is discouraged.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified. The statement cannot be processed in a trusted context that is defined with a role as the object owner.

Authorization

None required.

Syntax

```
▶▶ CREATE SYNONYM synonym FOR authorization-name. table-name ▶▶  
└──────────────────┬──────────────────┘  
                  view-name
```

Description

synonym

Names the synonym. The name must not identify a synonym, table, view, or alias that exists at the current server and that is owned by the owner of the synonym that is being created and must not identify a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

FOR *authorization-name.table-name* **or** *authorization-name.view-name*

Identifies the object to which the synonym applies. The name must consist of two parts and must identify a table, view, or alias that exists at the current server. If a table is identified, it must not be an auxiliary table or a declared temporary table. If an alias is identified, it must be an alias for a table or view at the current server and the synonym is defined for that table or view. The name must not identify a table that was implicitly created for an XML column, or an accelerator-only table.

Notes

Owner privileges: There are no specific privileges on a synonym.

The owner of the synonym is determined as follows:

- If the CURRENT SCHEMA special register contains a value that is not the same as the CURRENT SQLID special register, the owner of the synonym is the value of the CURRENT SCHEMA special register.
- Otherwise, the owner of the schema is the value of the CURRENT SQLID special register.

For more information about ownership of an object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

If an alias is used to denote the table or view, the name of that table or view, not the alias, is recorded in the catalog as the definition of the synonym. That severs the connection between the synonym and alias, and even if the alias is dropped and redefined, the synonym is still in effect and names the original table or view.

Example

Define DEPT as a synonym for the table DSN8A10.DEPT.

```
CREATE SYNONYM DEPT
FOR DSN8A10.DEPT;
```

CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database explicitly specified by the IN clause. If the IN clause is not specified, the CREATETAB privilege on database DSNDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDB04 is required.
- SYSADM or SYSCTRL authority
- System DBADM

If the table space is created implicitly, the privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database explicitly specified by the IN clause. If the IN clause is not specified, the CREATETS privilege on database DSNDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDB04 is required.
- SYSADM or SYSCTRL authority

The privilege set must also have the USE privilege for the following objects:

- For the table space if one is specified in the IN clause
- For the default buffer pool and default storage group of the database if a database is specified in the IN clause

If you specify a table space name, you must also have the SYSADM or SYSCTRL authority or the DBADM authority for the database.

For tables that are created in an implicit database, the database authority must be held on DSNDB04.

Additional privileges might be required in the following conditions:

- The clause IN, LIKE or FOREIGN KEY is specified.
- The data type of a column is a distinct type.
- The table space is implicitly created.
- A *fullselect* is specified.
- A column is defined as a security label column.

See the description of the appropriate clauses for details about these privileges.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the application is bound in a trusted context with the `ROLE AS OBJECT OWNER` clause specified:

- A role is the owner of the table that is being created
- The privilege set is the set of privileges that are held by that role
- The schema qualifier (implicit or explicit) must be the same as the role, unless the role has the `CREATEIN` privilege on the schema, or `SYSADM`, `SYSCTRL`, or system `DBADM` authority

Otherwise, an authorization ID is the owner of the package, and the following rules apply:

- If the privilege set lacks the `CREATEIN` privilege on the schema, `SYSADM` authority, `SYSCTRL` authority, and System `DBADM` authority, the schema qualifier (implicit or explicit) must be the same as the authorization ID of the owner of the package.
- If the privilege set lacks `SYSADM` authority, `SYSCTRL` authority, and System `DBADM` authority, and the table is explicitly qualified, the authorization ID that is the same as the schema name must have all the necessary privileges to create the table, and that authorization ID is the owner of the table. Otherwise, the authorization ID of the owner of the package must have all the necessary privileges to create the table, and that authorization ID is the owner of the table.
- If the privilege set includes `SYSADM` authority, `SYSCTRL` authority, or system `DBADM` authority, the schema qualifier (implicit or explicit) can be any schema name. However, if the table is explicitly qualified, the authorization ID that is the same as the schema name is the owner of the table. Otherwise, the authorization ID of the owner of the package is the owner of the table.
- If the privilege set includes `DBADM` authority and `DBCTRL` authority for the database, the schema qualifier (implicit or explicit) can be any schema name. However, if the table is explicitly qualified, the authorization ID that is the same as the schema name is the owner of the table. Otherwise, the authorization ID of the owner of the package is the owner of the table.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the `ROLE AS OBJECT OWNER` clause is in effect. When `ROLE AS OBJECT OWNER` is in effect, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process, and the owner of the table is that role. The schema qualifier (implicit or explicit) must be the same as that role, unless the role has `CREATEIN` privilege on the schema, or `SYSADM` authority, `SYSCTRL` authority, or System `DBADM` authority.

For the case where the SQL authorization ID of the process holds the privileges, the following rules apply:

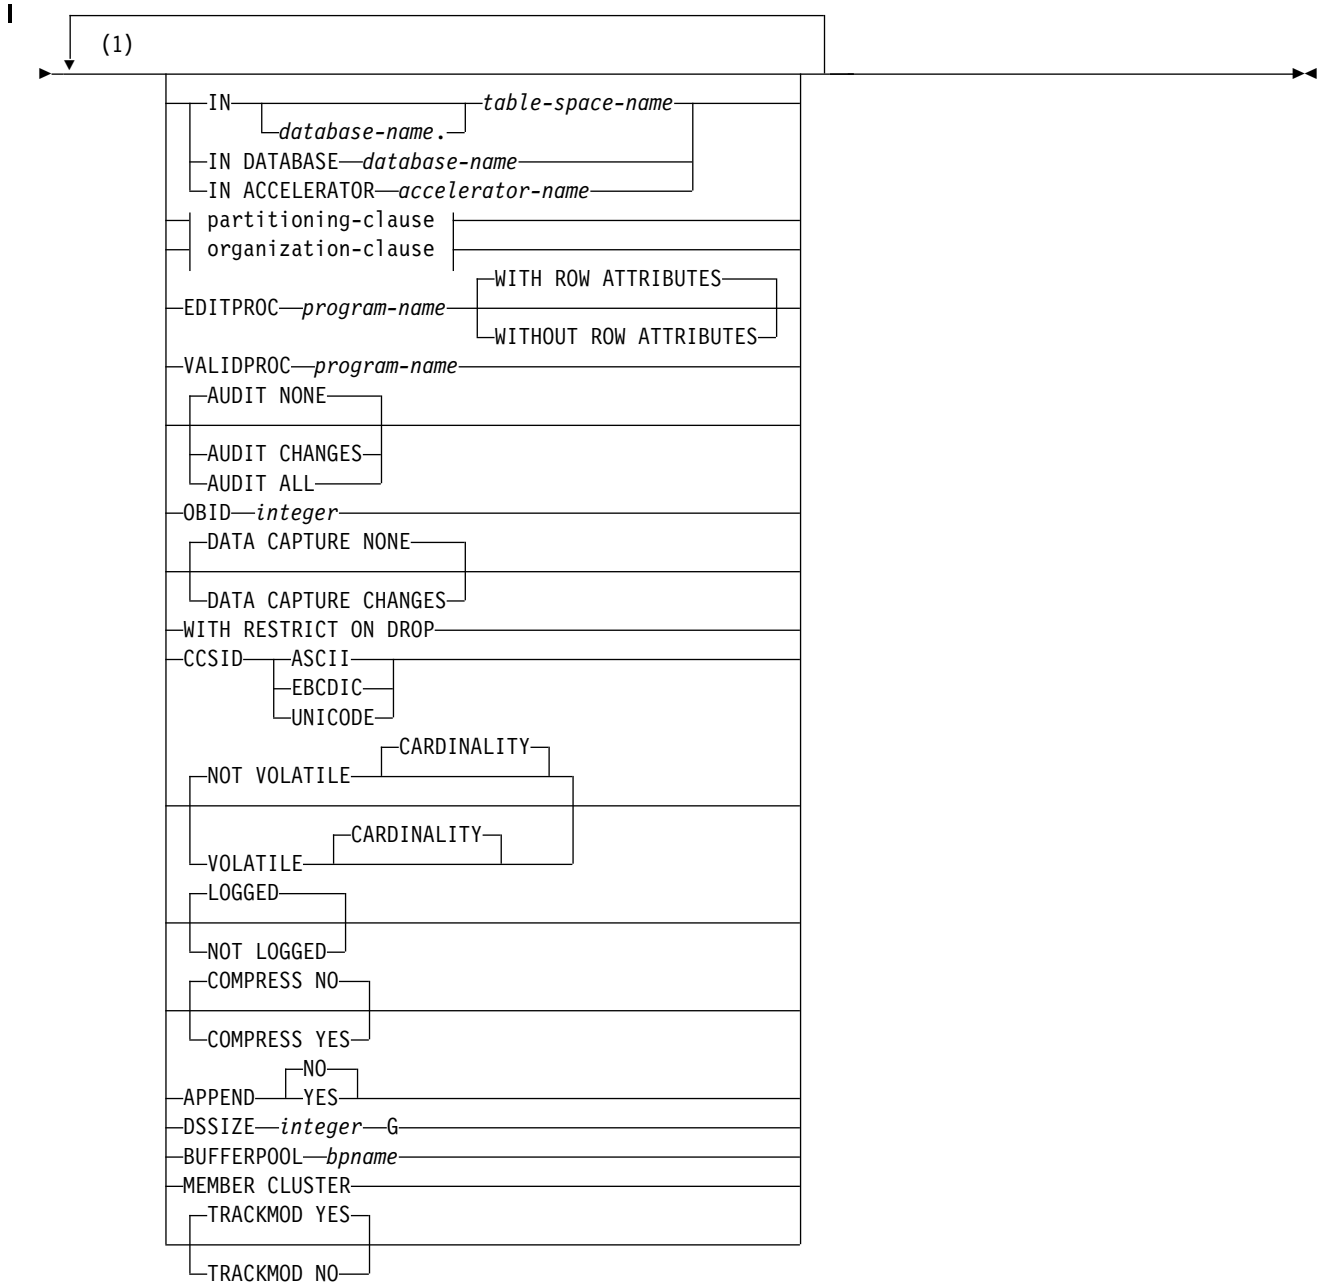

- If the privilege set lacks `CREATEIN` privilege on the schema, `SYSADM` authority, `SYSCTRL` authority, and System `DBADM` authority, the schema qualifier must be the same as one of the authorization IDs of the process.
- If the privilege set lacks `SYSADM` authority, `SYSCTRL` authority, and System `DBADM` authority, and the table is explicitly qualified, then the authorization ID that is the same as the schema name must have all the necessary privileges to create the table, and that authorization ID is the owner of the table. Otherwise,

the SQL authorization ID of the process must include all privileges that are needed to create the table, and that authorization ID is the owner of the table.

- If the privilege set includes SYSADM authority, SYSCTRL authority, or System DBADM authority, the schema qualifier can be any schema name. However, if the table is explicitly qualified, then the authorization ID that is the same as the schema name is the owner of the table. Otherwise, the SQL authorization ID of the process is the owner of the table.

Syntax

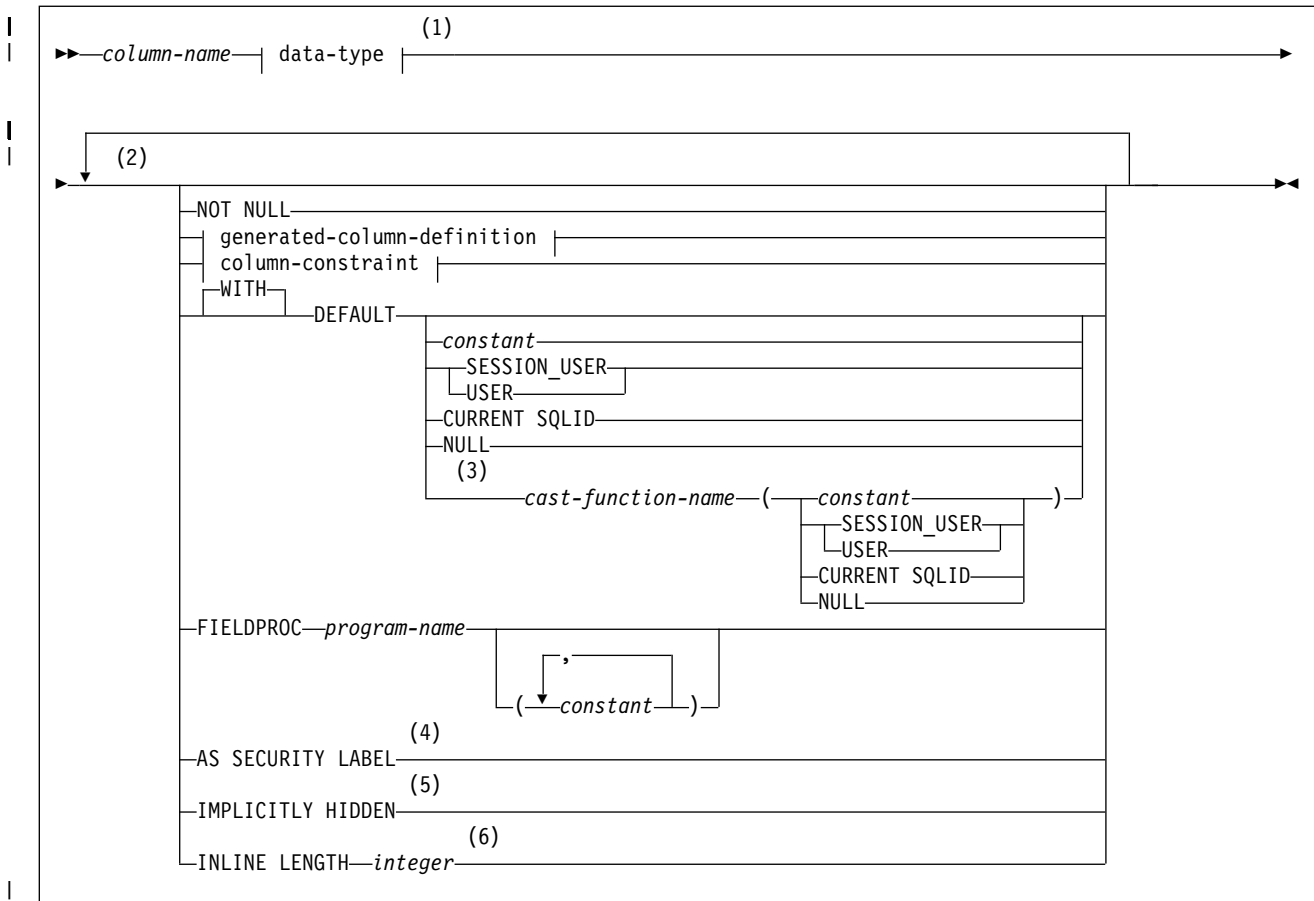

Notes:

- 1 The same clause must not be specified more than once.

column-definition:

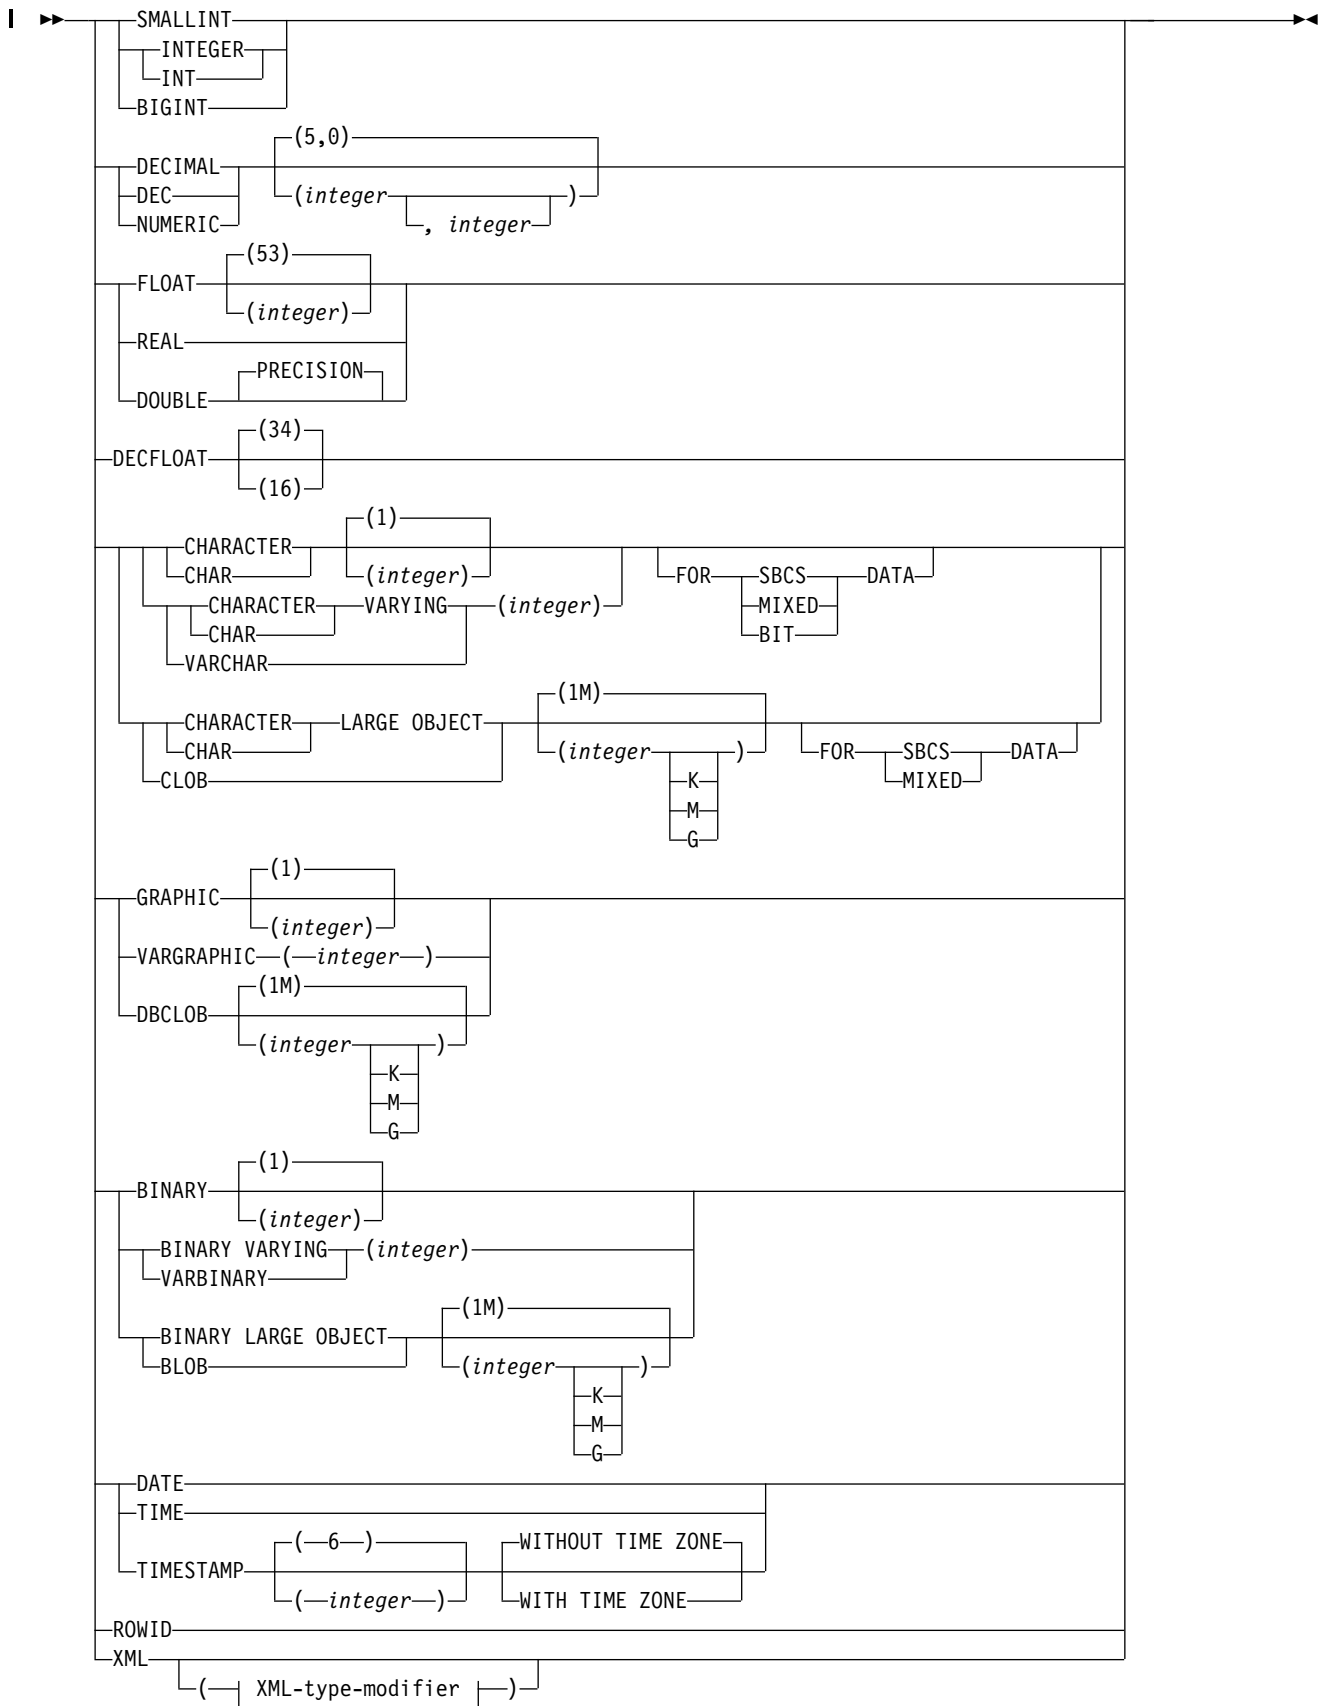

Notes:

- 1 Data type is optional if *as-row-change-timestamp-clause* is specified
- 2 The same clause must not be specified more than one time.
- 3 This form of the DEFAULT value can only be used with columns that are defined as a distinct type.
- 4 AS SECURITY LABEL can be specified only for a CHAR(8) data type and requires that the NOT NULL and WITH DEFAULT clauses be specified.
- 5 IMPLICITLY HIDDEN must not be specified for a column defined as a ROWID, or a distinct type that is based on a ROWID.
- 6 INLINE LENGTH only applies to a column with a LOB data type or a distinct type that is based on a LOB data type.

organization-clause

Description

table-name

Names the table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

column-definition

column-name

Names a column of the table. For a dependent table, up to 749 columns can be named. For a table that is not a dependent, this number is 750. Do not qualify *column-name* and do not use the same name for more than one column of the table.

built-in-type

Specifies the data type of the column as one of the following built-in data types, and for character string data types, specifies the subtype. For more information about defining a table with a LOB column (CLOB, BLOB, or DBCLOB), see *Creating a table with LOB columns*.

If IN ACCELERATOR is specified, not all data types are supported. For example, DECFLOAT, LOB, ROWID, TIMESTAMP WITH TIME ZONE, and XML are not supported. The *IBM DB2 Analytics Accelerator for z/OS: Stored Procedures Reference* has a complete list of supported data types.

SMALLINT

For a small integer.

INTEGER or INT

For a large integer.

BIGINT

For a big integer.

DECIMAL(*integer*, *integer*) or DEC(*integer*, *integer*)**DECIMAL(*integer*) or DEC(*integer*)****DECIMAL or DEC**

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p*,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

DECFLOAT(*integer*)

For a decimal floating-point number. The value of *integer* must be either 16 or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

FLOAT(*integer*)**FLOAT**

For a floating-point number. If *integer* is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

REAL

For single precision floating-point.

DOUBLE or DOUBLE PRECISION

For double precision floating-point

CHARACTER(*integer*) or CHAR(*integer*)**CHARACTER or CHAR**

For a fixed-length character string of length *integer*, which can range from 1 to 255. If the length specification is omitted, a length of 1 character is assumed.

VARCHAR(*integer*), CHAR VARYING(*integer*), or CHARACTER VARYING(*integer*)

For a varying-length character string of maximum length *integer*, which can range from 1 to the maximum record size minus 10 bytes. See Table 174 on page 1768 to determine the maximum record size.

FOR *subtype* DATA

Specifies a subtype for a character string column, which is a column with a data type of CHAR, VARCHAR, or CLOB. Do not use the FOR *subtype* DATA clause with columns of any other data type (including any distinct type). *subtype* can be one of the following:

SBCS

Column holds single-byte data.

MIXED

Column holds mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified, or the table is being created in a Unicode table space or database.

BIT

Column holds BIT data. Do not specify BIT for a CLOB column.

Only character strings are valid when subtype is BIT.

If you do not specify the FOR clause, the column is defined with a default subtype. For ASCII or EBCDIC data:

- The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO.
- The default is MIXED when the value is YES.

For Unicode data, the default subtype is MIXED.

A security label column is always considered SBCS data, regardless of the encoding scheme of the table.

CLOB(*integer* [K|M|G]), CHAR LARGE OBJECT(*integer* [K|M|G]), or CHARACTER LARGE OBJECT(*integer* [K|M|G])
CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 to 2 147 483 647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 97.

When *integer* is not specified, the default length is **1M**. The maximum value that can be specified for *integer* depends on whether a units indicator is also specified as shown in the following list.

integer The maximum value for *integer* is 2 147 483 647. The maximum length of the string is *integer*.

integer **K**

The maximum value for *integer* is 2 097 152. The maximum length is 1024 times *integer*.

integer **M**

The maximum value for *integer* is 2048. The maximum length is 1 048 576 times *integer*.

integer **G**

The maximum value for *integer* is 2. The maximum length is 1 073 741 824 times *integer*.

If you specify a value that evaluates to 2 gigabytes (2 147 483 648), DB2 uses a value that is one byte less, or 2 147 483 647.

GRAPHIC(*integer*)
GRAPHIC

For a fixed-length graphic string of length *integer*, which can range from 1 to 127. If the length specification is omitted, a length of 1 character is assumed.

VARGRAPHIC(*integer*)

For a varying-length graphic string of maximum length *integer*, which must range from 1 to $n/2$, where n is the maximum row size minus 2 bytes.

DBCLOB(*integer* [K|M|G])**DBCLOB**

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1 through 1 073 741 823. A DBCLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 97.

When *integer* is not specified, the default length is **1M**. The meaning of *integer* K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

BINARY(*integer*)

A fixed-length binary string of length *integer*. The *integer* can range from 1 through 255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(*integer*) or VARBINARY(*integer*)

A varying-length binary string of maximum length *integer*, which can range from 1 through 32704. The length is limited by the page size of the table space.

BLOB (*integer* [K|M|G] or BINARY LARGE OBJECT(*integer* [K|M|G])**BLOB or BINARY LARGE OBJECT**

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2 147 483 647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 97.

When *integer* is not specified, the default length is **1M**. The meaning of *integer* K|M|G is the same as for CLOB.

DATE

For a date.

TIME

For a time.

TIMESTAMP(*integer*) WITHOUT TIME ZONE

For a timestamp. *integer* specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(*integer*) WITH TIME ZONE

For a timestamp with time zone. *integer* specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

ROWID

For a row ID type.

A table can have only one ROWID column. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

XML

For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.

XMLSCHEMA

Specifies one or more XML schemas that are used to validate the XML value. The same XML schema can not be specified more than one time.

If the XML value has already been validated, for example, the XML value is the result of the DSN_XMLVALIDATE function or from an XML column with a type modifier, and the XML schema against which the XML value is validated is one of the schemas specified in the *XML-type-modifier*, DB2 accepts the XML value without revalidation.

XML-schema-specification

Specifies one XML schema. The XML schema can be identified by using either the registered XML-schema-name or the schema's target namespace followed by an optional schema location. Any XML schema that is referenced in this clause must be registered in the XML schema repository prior to use.

ID *registered-XML-schema-name*

Identifies an XML schema by using its *registered-XML-schema-name*. The name must uniquely identify an existing XML schema in the XML schema repository at the current server. If no XML schema by this name exists, an error is returned.

The schema qualifier must be SYSXSR.

URI *target-namespace*

Specifies the target namespace URI of the XML schema. The value for the target-namespace URI is a character string constant which is not empty. The URI must be the target namespace of a registered XML schema and, if no LOCATION clause is specified, it must uniquely identify the registered XML schema.

NO NAMESPACE

Specifies that the XML schema has no target namespace. There must be a registered XML schema that has no target namespace. If no LOCATION clause is specified, there must be only one such registered XML schema.

LOCATION *schema-location*

Specifies the XML schema location URI of the XML schema. The value of *schema-location* is a character string constant that is not empty. The schema location URI, combined with the target namespace URI, must identify a registered XML schema.

ELEMENT *element-name*

Specifies the name of the global element declaration. *element-name* must match the local name of the root element node in the instance XML document. The namespace name of the root element node must be the same as the target namespace URI.

distinct-type-name

Specifies the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the

length, precision, and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table. The subtype for the distinct type, if it has the attribute, is the subtype with which the distinct type was created.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

NOT NULL

Prevents the column from containing null values. Omission of NOT NULL implies that the column can contain null values.

column-constraint

The *column-constraint* of a *column-definition* provides a shorthand method of defining a constraint composed of a single column. Thus, if a *column-constraint* is specified in the definition of column C, the effect is the same as if that constraint were specified as a *unique-constraint*, *referential-constraint*, or *check-constraint* in which C is the only identified column.

CONSTRAINT *constraint-name*

Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If the name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

PRIMARY KEY

Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. PRIMARY KEY cannot be specified more than one time in a column definition, and must not be specified if the UNIQUE clause is specified in the definition. This clause must also not be specified if the definition is for one of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- an XML column
- a row change timestamp column
- a column in an accelerator-only table

The table is marked as unavailable until its primary index is explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, DB2 implicitly creates an index to enforce the uniqueness of the primary key and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

UNIQUE

Provides a shorthand method of defining a unique key composed of a

single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. UNIQUE cannot be specified more than one time in a column definition and must not be specified if the PRIMARY KEY clause is specified in the column definition or if the definition is for one of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- an XML column
- a row change timestamp column
- a column in an accelerator-only table

The table is marked as unavailable until all the required indexes are explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, DB2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

references-clause

The *references-clause* of a *column-definition* provides a shorthand method of defining a foreign key composed of a single column. Thus, if *references-clause* is specified in the definition of column C, the effect is the same as if the *references-clause* were specified as part of a FOREIGN KEY clause in which C is the only identified column.

Do not specify *references-clause* in the definition of the following types of columns because these types of columns cannot be a foreign key:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- an XML column
- a row change timestamp column
- a security label column

CHECK (*check-condition*)

CHECK (*check-condition*) provides a shorthand method of defining a check constraint that applies to a single column. For conformance with the SQL standard, if CHECK is specified in the column definition of column C, no columns other than C should be referenced in the check condition of the check constraint. The effect is the same as if the check condition were specified as a separate clause.

DEFAULT

Specifies the default value that is assigned to the column in the absence of a value specified on an insert or update operation or LOAD. DEFAULT must not

be specified more than one time in the same *column-definition*. Do not specify DEFAULT for the following types of columns because DB2 generates default values:

- An identity column (a column that is defined AS IDENTITY)
- A ROWID column (or a distinct type that is based on a ROWID)
- A row change timestamp column
- A row-begin column
- A row-end column
- A *transaction-start-id* column
- An XML column

If IN ACCELERATOR is specified, do not specify DEFAULT for a column.

Do not specify a value after the DEFAULT keyword for a security label column. DB2 provides the default value for a security label column.

If a value is not specified after DEFAULT, the default value depends on the data type of the column, as follows:

Data Type

Default Value

Numeric

0

Big integer

0

Fixed-length character string

Blanks

Fixed-length graphic string

Blanks

Fixed-length binary string

Hexadecimal zeros

Varying-length string

A string of length 0

Inline BLOB

Hexadecimal zeros

Inline CLOB

Blanks

Inline DBCLOB

Blanks

Date CURRENT DATE

Time CURRENT TIME

TIMESTAMP(*integer*) WITHOUT TIME ZONE

CURRENT TIMESTAMP(*p*) WITHOUT TIME ZONE where *p* is the corresponding timestamp precision.

TIMESTAMP(*integer*) WITH TIME ZONE

CURRENT TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

If the column is defined as timestamp with time zone the default value must include a time zone.

Distinct type

The default of the source data type

A default value other than the one that is listed above can be specified in one of the following forms:

- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

Omission of NOT NULL and DEFAULT from a *column-definition*, for a column other than an identity column, is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and DB2 generates default values.

constant

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or graphic string constant must be short enough so that its UTF-8 representation requires no more than 1536. A hexadecimal graphic string constant (GX) cannot be specified.

In addition, the length of the constant value cannot be greater than the INLINE LENGTH attribute for LOB columns.

SESSION_USER or USER

Specifies the value of the SESSION_USER (USER) special register at the time of an SQL data change statement or LOAD as the default value for the column. If SESSION_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to 8 characters when the value is expressed as CCSID 37.

CURRENT SQLID

Specifies the value of the SQL authorization ID of the process at the time of an insert or update operation or LOAD as the default value for the column. If CURRENT SQLID is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT SQLID special register. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL

Specifies null as the default value for the column. If NOT NULL is specified, DEFAULT NULL must not be specified with the same *column-definition*.

cast-function-name

The name of the cast function that matches the name of the distinct type for the column. A cast function can only be specified if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.

constant

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type. The length of the constant cannot be greater than the INLINE LENGTH attribute for LOB columns.

SESSION_USER or USER

Specifies the value of the SESSION_USER (USER) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline

CLOB with a length attribute (inline length attribute for CLOB) that is greater than or equal to the length attribute of the SESSION_USER special register.

CURRENT SQLID

Specifies the value of the CURRENT SQLID special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (or inline length attribute for CLOB) that is greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL

Specifies the NULL value as the argument.

In a given column definition:

- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.

Table 172 summarizes the effect of specifying the various combinations of the NOT NULL and DEFAULT clauses on the CREATE TABLE statement *column-description* clause.

Table 172. Effect of specifying combinations of the NOT NULL and DEFAULT clauses

| If NOT NULL is: | And DEFAULT is: | The effect is: |
|------------------------|------------------------------|---|
| Specified ¹ | Omitted | An error occurs if a value is not provided for the column on an insert or update operation or LOAD. |
| | Specified without an operand | The system defined nonnull default value is used. |
| | <i>constant</i> | The specified constant is used as the default value. |
| | SESSION_USER | The value of the SESSION_USER special register at the time of an insert or update operation or LOAD is used as the default value. |
| | CURRENT SQLID | The SQL authorization ID of the process at the time of an insert or update operation or LOAD is used as the default value. |
| | NULL | An error occurs during the execution of CREATE TABLE. |
| Omitted | Omitted | Equivalent to an implicit specification of DEFAULT NULL. |
| | Specified without an operand | The system defined nonnull default value is used. |
| | <i>constant</i> | The specified constant is used as the default value. |
| | SESSION_USER | The value of the SESSION_USER special register at execution time is used as the default value. |
| | CURRENT SQLID | The SQL authorization ID of the process is used as the default value. |
| | NULL | Null is used as the default value. |

Table 172. Effect of specifying combinations of the NOT NULL and DEFAULT clauses (continued)

| If NOT NULL is: | And DEFAULT is: | The effect is: |
|--|-----------------|----------------|
| Note: The table does not apply to a column with a ROWID data type or to an identity column. | | |

GENERATED

Specifies that DB2 generates values for the column. GENERATED must be specified if the column is to be considered one of the following types of columns:

- An identity column
- A row change timestamp column.
- A ROWID column
- A row-begin column
- A row-end column
- A *transaction-start-id* column

GENERATED must only be specified for these types of columns. GENERATED must not be specified with *default-clause* in a column definition.

ALWAYS

Specifies that DB2 always generates a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the default and recommended value.

BY DEFAULT

Specifies that DB2 will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a row change timestamp column, DB2 inserts or updates a specified value but does not verify that the value is unique for the column unless the row change timestamp column has a unique constraint or a unique index that specifies only the row change timestamp column.

For a ROWID column, DB2 uses a specified value only if it is a valid row ID value that was previously generated by DB2 and the column has a unique, single-column index. Until this index is created on the ROWID column, the SQL insert or update operation and the LOAD utility cannot be used to add rows to the table. If the table space is explicitly created and the value of the CURRENT RULES special register is 'STD' when the CREATE TABLE statement is processed, or if the table space is implicitly created, DB2 implicitly creates the index on the ROWID column. The name of this index is 'I' followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, DB2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, DB2 inserts a specified value but does not verify that it a unique value for the column unless the identity column has a unique, single-column index.

BY DEFAULT is the recommended value only when you are using data propagation.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp column for the table. DB2 generates a value for the column for each row as the row is inserted, and for any row in which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the insert or update time of the row. If multiple rows are inserted or updated with a single statement, the value for the row change timestamp column might be different for each row.

A table can only have one row change timestamp column.

If *data-type* is specified, it must be `TIMESTAMP WITHOUT TIME ZONE` with a precision of 6.

A row change timestamp column cannot have a `DEFAULT` clause. `NOT NULL` must be specified for a row change timestamp column.

AS TRANSACTION START ID

Specifies that the value is assigned by DB2 whenever a row is inserted into the table or any column in the row is updated. DB2 assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated using the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or when a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

A transaction-start-ID column is required for a system-period temporal table.

A table can have only one transaction-start-ID column. If a data type is not specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. If a data type is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP WITH TIME ZONE`, the values are stored in UTC, with a time zone of `+00:00`. A transaction-start-ID column cannot have a `DEFAULT` clause. A transaction-start-ID column is not updatable.

A value for a transaction-start-ID column is composed of a `TIMESTAMP(9)` value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

AS ROW BEGIN

Specifies that the column contains timestamp data and that the values are generated by DB2. DB2 generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL unit of work, the values for the transaction start timestamp column are the same.

A *row-begin* column is intended to be used for a system-period temporal table.

For a system-period temporal table, DB2 ensures the uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted or updated within a single SQL transaction, the values

for the row-begin column are the same for all the rows and are unique from the values that are generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period.

A table can have only one column defined as AS ROW BEGIN. If a data type is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP(12) WITH TIME ZONE`, the values are stored in UTC, with a time zone of +00:00. If no data type is specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. A column defined as a row-begin column cannot have a `DEFAULT` clause, and must be defined as `NOT NULL`.

A row-begin column is not updatable.

A value for a row-begin column is composed of a `TIMESTAMP(9)` value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

AS ROW END

Specifies that a value for the data type of the column is assigned by DB2 whenever a row is inserted or any column in the row is updated. The value that is assigned for a `TIMESTAMP WITHOUT TIME ZONE` column is the `TIMESTAMP` value '9999-12-30-00.00.00.000000000000'. The value that is assigned for a `TIMESTAMP WITH TIME ZONE` column is the `TIMESTAMP` value '9999-12-30-00.00.00.000000000000 +00:00'.

A row-end column is required as the second column of a SYSTEM_TIME period.

A table can have only one row-end column. If a data type is not specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. If a data type is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP WITH TIME ZONE`, the values are stored in UTC, with a time zone of +00:00. A row-end column cannot have a `DEFAULT` clause and must be defined as `NOT NULL`. A row-end column is not updatable.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. `AS IDENTITY` can be specified only if the data type for the column is an exact numeric type with a scale of zero (`SMALLINT`, `INTEGER`, `BIGINT`, `DECIMAL` with a scale of zero, or a distinct type based on one of these types).

An identity column is implicitly `NOT NULL`. An identity column cannot have a `WITH DEFAULT` clause.

Defining a column `AS IDENTITY` does not necessarily ensure the uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

If `IN ACCELERATOR` is specified, `AS IDENTITY` must not be specified.

START WITH *numeric-constant*

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after reaching the maximum or minimum value for the identity column. The START WITH clause can be used to start the generation of values outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant, and could be assigned to the column without any non-zero digits existing to the right of the decimal point.

If this value is negative, the values for the identity column descend. If this value is 0 or positive, the values for the identity column ascend. The default is 1.

MINVALUE or NO MINVALUE

Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

NO MINVALUE

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

The default is NO MINVALUE.

MINVALUE *numeric-constant*

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

MAXVALUE or NO MAXVALUE

Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

NO MAXVALUE

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending identity column, the value is the maximum value of the data type associated with the column.
- For a descending identity column, the value is the START WITH value -1 if START WITH is not specified.

The default is NO MAXVALUE.

MAXVALUE *numeric-constant*

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

CYCLE or NO CYCLE

Specifies whether this identity column should continue to generate values after reaching either its maximum or minimum value. The default is **NO CYCLE**.

NO CYCLE

Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached.

CYCLE

Specifies that values continue to be generated for the identity column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When **CYCLE** is in effect, duplicate values can be generated by DB2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

CACHE *integer-constant* or **NO CACHE**

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is **CACHE 20**.

NO CACHE

Specifies that values for the identity column and sequences are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column or sequence results in synchronous I/O.

In a data sharing environment, use **NO CACHE** if you need to guarantee that the identity column and sequence values are generated in the order in which they are requested.

CACHE *integer-constant*

Specifies the maximum number of values of the identity column sequence that DB2 can preallocate and keep in memory.

During a DB2 shutdown, all cached identity column values and sequence values that are yet to be assigned will be lost and will not be used. Therefore, the value that is specified for **CACHE** also represents the maximum number of identity column values and sequence values that will be lost during a DB2 shutdown.

The minimum value is 2.

In a data sharing environment, you can use the **CACHE** and **NO ORDER** options to allow multiple DB2 members to cache sequence values simultaneously.

ORDER or NO ORDER

Specifies whether the identity column values must be generated in order of request. The default is **NO ORDER**.

NO ORDER

Specifies that the values do not need to be generated in order of request.

ORDER

Specifies that the values are generated in order of request. Specifying **ORDER** might disable the caching of values. **ORDER** applies only to a single-application process.

In a data sharing environment, if the **CACHE** and **NO ORDER** options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the identity column, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested a value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that identity values are generated in strict numeric order among multiple DB2 members using the same identity column, specify the **ORDER** option.

FIELDPROC *program-name*

Designates *program-name* as the field procedure exit routine for the column. A field procedure can be specified only for a column with a length attribute that is not greater than 255 bytes. **FIELDPROC** can only be specified for columns that are a built-in character string or graphic string data types. The column must not be one of the following:

- a LOB column
- a security label column
- a row change timestamp column
- a column with the **TIMESTAMP WITH TIME ZONE** data type
- a column in an accelerator-only table

The field procedure encodes and decodes column values: before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the **CREATE TABLE** statement. When so invoked, the procedure provides DB2 with the column's *field description*. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the **CREATE TABLE** statement defines the data characteristics of the decoded values.

Related information:

Field procedures (DB2 Administration Guide)

“Character and graphic string comparisons” on page 134

constant

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The *n*th parameter specified in the FIELDPROC clause on CREATE TABLE corresponds to the *n*th parameter of the specified field procedure. The maximum length of the parameter list is 254 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

If you omit FIELDPROC, the column has no field procedure.

AS SECURITY LABEL

Specifies that the column will contain security label values. This also indicates that the table is defined with multilevel security with row level granularity. A table can have only one security label column. A security label column cannot be defined for an accelerator-only table. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column must be defined with the NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not specify a default value (DB2 determines the default value)
- No field procedures, check constraints, or referential constraints are defined on the column.
- No edit procedure for the table can be defined with row attribute sensitivity.

For information about using multilevel security, see *DB2 Administration Guide*.

IMPLICITLY HIDDEN

Specifies that the column is not visible in the result for SQL statements unless you explicitly refer to the column by name. For example, assuming that the table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT * would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID. IMPLICITLY HIDDEN must not be specified for all columns of a table. If IN ACCELERATOR is specified, IMPLICITLY HIDDEN must not be specified.

INLINE LENGTH *integer*

Specifies the maximum length for the column, if the column is a LOB column and the table is in a universal table space. INLINE LENGTH cannot be specified if the column is not a LOB column (or a distinct type that is based on a LOB), if the table is not in a universal table space, or if the table is an accelerator-only table.

For BLOB and CLOB columns, *integer* specifies the maximum number of bytes that are stored in the base table space for the column. *integer* must be between 0 and 32680 (inclusive) for a BLOB or CLOB column.

For a DBCLOB column, *integer* specifies the maximum number of double-byte characters that are stored in the table space for the column. *integer* must be between 0 and 16340 (inclusive) for a DBCLOB column.

If `INLINE LENGTH` is specified, the value of *integer* cannot be greater than the maximum length of the LOB column.

If the `INLINE LENGTH` clause is not specified, the maximum length of the LOB column depends on the following conditions:

- If a distinct type is not used or the distinct type that is used has been created without the `INLINE LENGTH` attribute, the LOB column will use the value of the `LOB INLINE LENGTH` parameter on installation panel `DSNTIPD` as the default inline length when the value of `LOB INLINE LENGTH` does not exceed the maximum length of the LOB column. If the value of `LOB INLINE LENGTH` exceeds the maximum length of the LOB column, the maximum length is the inline length of this LOB column.
- If a distinct type that has been created with the `INLINE LENGTH` attribute is used, the LOB column inherits the inline length from the distinct type.

Regardless of how the length is determined, the inline length of the LOB cannot be greater than its maximum length.

period-definition

PERIOD

Defines a period for the table. *begin-column-name* must not be the same as *end-column-name*. The data type, length, precision, and scale for *begin-column-name* must be the same as for *end-column-name*.

If `IN ACCELERATOR` is specified, `PERIOD` must not be specified.

SYSTEM_TIME (*begin-column-name*,*end-column-name*)

Defines a system period with the name `SYSTEM_TIME`. There must not be a column in the table with the name `SYSTEM_TIME`. A table can have only one `SYSTEM_TIME` period. *begin-column-name* must be defined as `AS ROW BEGIN` and *end-column-name* must be defined as `AS ROW END`.

BUSINESS_TIME (*begin-column-name*,*end-column-name*)

Defines an application period with the name `BUSINESS_TIME`. There must not be a column in the table with the name `BUSINESS_TIME`. A table can have only one `BUSINESS_TIME` period. *begin-column-name* and *end-column-name* must be defined as `DATE` or `TIMESTAMP(6) WITHOUT TIME ZONE`, and the columns must be defined as `NOT NULL`. *begin-column-name* and *end-column-name* must not identify a column that is defined with a `GENERATED` clause.

An implicit check constraint is generated to ensure that the value of *end-column-name* is greater than the value of *begin-column-name*. The name of the implicitly created check constraint is `DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME`, and that name must not be defined as the name of an existing check constraint.

begin-column-name

Identifies the column that records the beginning of the period of time in which a row is valid. The name must identify a column that exists in the table and must not be the same as a column that is used in the definition of another period for the table. *begin-column-name* must not be the same as *end-column-name*. The data type and precision for *begin-column-name* must be the same as for *end-column-name*.

For a `SYSTEM_TIME` period, *begin-column-name* must be defined as `AS ROW BEGIN`.

For a BUSINESS_TIME period, the column must not be defined with a GENERATED clause.

end-column-name

Identifies the column that records the end of the period of time in which a row is valid. In the history table that is associated with a system-period temporal table, the history table column that corresponds to *end-column-name* in the system-period temporal table is set to reflect the deletion of the row. The name must identify a column that exists in the table and must not be the same as a column that is used in the definition of another period for the table.

For a SYSTEM_TIME period, *end-column-name* must be defined as AS ROW END.

For a BUSINESS_TIME period, the column must not be defined with a GENERATED clause.

unique-constraint

CONSTRAINT *constraint-name*

Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

PRIMARY KEY(*column-name*,...)

Defines a primary key composed of the identified columns. The clause must not be specified more than one time and the same column must not be identified more than one time. The identified columns must be defined as NOT NULL. Each *column-name* must be an unqualified name that identifies a column of the table except for the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT
- an XML column
- a row change timestamp column

The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than $2000 - 2m$, where m is the number of varying-length columns in the key.

The table is marked as unavailable until its primary index is explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In that case, DB2 implicitly creates an index to enforce the uniqueness of the primary key and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name* or *key-expression*. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the

BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

UNIQUE(*column-name*,...)

Defines a unique key composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. Each identified column must be defined as NOT NULL. The same column must not be identified more than one time. The following types of columns cannot be identified:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT
- a row change timestamp column

The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than $2000 - 2m$, where m is the number of varying-length columns in the key.

A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table is marked as unavailable until all the required indexes are explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In these cases, DB2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name* or *key-expression*. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

referential-constraint

CONSTRAINT *constraint-name*

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

FOREIGN KEY (*column-name*,...) **references-clause**

Each specification of the FOREIGN KEY clause defines a referential constraint. The table being created is the child table for the referential constraint.

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than one time. The column cannot be any of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a row change timestamp column
- a security label column
- a column in an accelerator-only table

The number of identified columns must not exceed 64. The sum of the column length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and parent table are the same as the FOREIGN KEY and parent table of a previously defined referential constraint. The specification of a duplicate referential constraint is ignored with a warning.

The foreign key of the referential constraint cannot reference a parent key that contains BUSINESS_TIME WITHOUT OVERLAPS.

REFERENCES *table-name (column-name,...)*

The table name that is specified after REFERENCES must identify a table that exists at the current server³⁴. The table name must not identify one of the following tables:

- A catalog table
- A declared global temporary table
- A history table

In the following discussion, let T2 denote an identified table and let T1 denote the table that you are creating (T1 and T2 cannot be the same table³⁴).

T2 must have a unique index. The privilege set must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key.

The parent key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than one time. The identified column cannot be any of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a row change timestamp column
- a security label column

The list of column names in the parent key must match the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the same order as in the primary key or unique

34. This restriction is relaxed when the statement is processed by the schema processor and the other table is created within the same CREATE SCHEMA.

key. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme.

If a list of column names is not specified, T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2 and, except for their names, default values, null attributes and check constraints, the description of the n th column of the foreign key must be identical to the description of the n th column of the nominated parent key. If the foreign key includes a column defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A *field description* is a description of the encoded value as it is stored in the database for a column that has been defined to have an associated field procedure.

The table space that contains T1 must be available to DB2. If T1 is populated, its table space is placed in a check pending status. A table in a segmented table space is populated if the table is not empty. A table in a table space that is not segmented is considered populated if the table space has ever contained any records.

The referential constraint that is specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

ON DELETE

The delete rule of the relationship is determined by the ON DELETE clause. For more on the concepts used here, see "Referential constraints" on page 25.

SET NULL must not be specified unless some column of the foreign key allows null values. The default value for the rule depends on the value of the CURRENT RULES special register when the CREATE TABLE statement is processed. If the value of the register is 'DB2', the delete rule defaults to RESTRICT; if the value is 'STD', the delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let p denote such a row of T2. Then:

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of p in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of p in T1 is set to null.

Let T3 denote a table identified in another FOREIGN KEY clause (if any) of the CREATE TABLE statement. The delete rules of the relationships involving T2 and T3 must be the same and must not be SET NULL if:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendents of the same table and the deletion of rows from that table cascades to both T2 and T3.

ENFORCED or NOT ENFORCED

Indicates whether or not the referential constraint is enforced by DB2 during normal operations, such as insert, update, or delete.

ENFORCED

Specifies that the referential constraint is enforced by the DB2 during normal operations (such as insert, update, or delete) and that it is guaranteed to be correct. This is the default.

NOT ENFORCED

Specifies that the referential constraint is not enforced by DB2 during normal operations, such as insert, update, or delete. This option should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on the database manager.

ENABLE QUERY OPTIMIZATION

Specifies that the constraint can be used for query optimization. DB2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

check-constraint**CONSTRAINT** *constraint-name*

Names the check constraint. The constraint name must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

If *constraint-name* is not specified, a unique constraint name is derived from the name of the first column in the *check-condition* specified in the definition of the check constraint.

CHECK (*check-condition*)

Defines a check constraint. At any time, the *check-condition* must be true or unknown for every row of the table. A *check-condition* can evaluate to unknown if a column that is an operand of the predicate is null. A *check-condition* that evaluates to unknown does not violate the check constraint. A *check-condition* is a search condition, with the following restrictions:

- It can refer only to columns of table *table-name*.
- The columns cannot be the following types of columns:
 - LOB columns
 - ROWID columns
 - DECFLOAT columns
 - distinct type columns that are based on LOB, ROWID, and DECFLOAT data types
 - XML columns
 - security label columns
 - columns in an accelerator-only table
- It can be up to 3800 bytes long, not including redundant blanks.
- It must not contain any of the following:
 - Subselects
 - Built-in or user-defined functions
 - CAST specifications
 - Cast functions other than those created when the distinct type was created

- Host variables
- Parameter markers
- Special registers
- Columns that include a field procedure
- CASE expressions
- ROW CHANGE expressions
- Row expressions
- DISTINCT predicates
- GX constants (hexadecimal graphic string constants)
- Sequence references
- OLAP specifications
- If a *check-condition* refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the *check-condition* must be either a constant or a column name of a column in the table.
 - If the second operand of a predicate is a constant, and if the constant is:
 - A floating-point number, then the column data type must be floating point.
 - A decimal number, then the column data type must be either floating point or decimal.
 - An integer number, then the column data type must not be a small integer.
 - A small integer number, then the column data type must be small integer.
 - A decimal constant, then its precision must not be larger than the precision of the column.
 - If the second operand of a predicate is a column, then both columns of the predicate must have:
 - The same data type.
 - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes.

LIKE

table-name **or** *view-name*

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view.

The name that is specified after LIKE must identify a table or view that exists at the current server or a declared temporary table. A view cannot contain columns of length 0.

LIKE must not reference an accelerator-only table or be used with the IN ACCELERATOR clause.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view. If the identified table or view contains a column with a distinct type, the USAGE privilege on the distinct type is also needed. An identified table must not be an auxiliary table or a clone table. An identified view must not include a column that is an explicitly defined ROWID column (including a distinct type that is based on a ROWID), an identity column, or a row change timestamp column.

The use of LIKE is an implicit definition of n columns, where n is the number of columns in the identified table (including implicitly hidden columns) or view. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition includes all attributes of the n columns as they are described in SYSCOLUMNS with the following exceptions:

- When a table is identified in the LIKE clause and a column in the table has a field procedure, the corresponding column of the new table has the same field procedure and the field description. However, the field procedure is not invoked during the execution of the CREATE TABLE statement. When a view is identified in the LIKE clause, none of the columns of the new table will have a field procedure. This is true even in the case that a column of a base table underlying the view has a field procedure defined.
- When a table is identified in the LIKE clause and a column in the table is an identity column, the corresponding column of the new table inherits only the data type of the identity column; none of the identity attributes of the column are inherited unless the INCLUDING IDENTITY clause is specified.
- When a table is identified in the LIKE clause and a column in the table is a security label column, the corresponding column of the new table inherits only the data type of the security label column; none of the security label attributes of the column are inherited.
- When a table is identified in the LIKE clause and the table contains a ROWID column (explicitly-defined or implicitly hidden), the corresponding columns of the new table inherits the ROWID columns.
- When a table is identified in the LIKE clause and the table contains row change timestamp column, a transaction-start-ID column, a row-begin column, or a row-end column, the corresponding column of the new table inherits only the data type of the original column. The new column is not considered a generated column.
- When a table is identified in the LIKE clause and the table contains an inline LOB column, the corresponding columns of the new table will inherit the inline attribute if the table is in an universal table space. Otherwise, the inline attribute of the table identified in the LIKE clause is ignored.
- When a view is identified in the LIKE clause, the default value that is associated with the corresponding column of the new table depends on the column of the underlying base table for the view. If the column of the base table does not have a default, the new column does not have a default. If the column of the base table has a default, the default of the new column is:
 - Null if the column of the underlying base table allows nulls.
 - The default for the data type of the underlying base table if the underlying base table does not allow nulls.

The above defaults are chosen regardless of the current default of the base table column. The existence of an INSTEAD OF trigger does not affect the inheritance of default values.

- When a table that uses table-controlled partitioning is identified in the LIKE clause, the new table does not inherit partitioning scheme of that table. You can add these partition boundaries by specifying ALTER TABLE with the ADD PARTITION BY RANGE clause.
- The CCSID of the column is determined by the implicit or explicit CCSID clause. For more information, see the CCSID clause.
- When a table is identified in the LIKE clause and the table includes a period, the new table does not inherit the period.
- When the table that is identified in the LIKE clause is a system-period temporal table, the new table is not a system-period temporal table.
- When the table that is identified in the LIKE clause has row access controls or column access controls activated, the new table does not inherit the row access controls or the column access controls.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

copy-options

copy-options

Specifies whether identity column attributes, row change timestamp attributes, and column defaults are inherited from the definition of the source of the result table.

EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies whether identity column attributes are inherited from the definition of the source of the result table.

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that identity column attributes are not inherited from the definition of the source of the result table. This is the default.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that, if available, identity column attributes (such as START WITH, INCREMENT BY, and CACHE values) are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or *fullselect* is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table with the identity attribute. In other cases, the columns of the new temporary table do not inherit the identity attributes. The columns of the new table do not inherit the identity attributes in the following cases:

- The select list of the *fullselect* includes multiple instances of an identity column name (that is, selecting the same column more than one time).
- The select list of the *fullselect* includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The *fullselect* includes a set operation.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies whether row change timestamp column attributes are inherited from the definition of the source of the result table.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that row change timestamp column attributes are not inherited from the source result table definition. This is the default.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that, if available, row change timestamp column attributes are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or *fullselect* is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table defined as a row change timestamp column. In other cases, the columns of the new temporary table do not inherit the row change timestamp column attributes. The columns of the new table do not inherit the row change timestamp attributes in the following cases:

- The select list of the *fullselect* includes multiple instances of a row change timestamp column name (that is, selecting the same column more than one time).
- The select list of the *fullselect* includes multiple row change timestamp column names (that is, it involves a join).
- The row change timestamp column is included in an expression in the select list.
- The *fullselect* includes a set operation (such as union).

EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS

Specifies whether column defaults are inherited from the source result table definition. **EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS** must not be specified if the **LIKE** clause is specified.

EXCLUDING COLUMN DEFAULTS

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert or update operation, or **LOAD** for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that column defaults for each updatable column of the definition of the source table are inherited. Columns that are not updatable do not have a default defined in the corresponding column of the created table. The existence of an **INSTEAD OF** trigger for a view does not affect the inheritance of default values.

USING TYPE DEFAULTS

Specifies that the default values for the table depend on data type of the columns that result from *fullselect*, as follows:

| Data type | Default value |
|------------------|----------------------|
| Numeric | 0 |

Fixed-length character string

Blanks

Fixed-length graphic string

Blanks

Fixed-length binary string

Hexadecimal zeros

Varying-length string

A string of length 0

Fixed-length char or fixed-length graphic

A string of blanks

Fixed-length binary

Hexadecimal zeros

Date CURRENT DATE

Time CURRENT TIME

Timestamp(*integer*) without time zone

CURRENT_TIMESTAMP(*p*) WITHOUT TIME ZONE where *p* is the corresponding timestamp precision.

Timestamp(*integer*) with time zone

CURRENT_TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

as-result-table

as-result-table

Specifies that the column definitions of the table are based on the result of the *fullselect*.

column-name

Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the *fullselect*. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *fullselect*.

A list of column names must be specified if the result table of the *fullselect* has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause.

AS (*fullselect*)

Specifies that the table definition is based on the column definitions from the result of the *fullselect*. The use of AS (*fullselect*) is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of *fullselect*. The length of each column must not be 0. Other column attributes, such as DEFAULT and IDENTITY, are not inherited from the *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. The generated column attributes are not inherited from the *fullselect*. That is, a new column of the table is not considered as a generated column. A FIELDPROC is inherited for a column if the corresponding select item of the *fullselect* is a column that can be mapped

to a column of a base table or a view. The new table contains a security label column if only one table in the *fullselect* contains a security label column and the primary authorization ID of the statement has a valid security label.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

If IN ACCELERATOR is specified, AS (*fullselect*) cannot be specified.

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the fullselect, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the fullselect reside. Having SELECT privilege means that the owner has at least one of the following authorizations.

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the tables of the fullselect reside

Additional privileges might be necessary for accessing other objects that are referenced in the fullselect.

The fullselect must not:

- Result in a column having a ROWID, BLOB, CLOB, DBCLOB, or XML data type or a distinct type based on these data types.
- Include multiple security label columns.
- Include a PREVIOUS VALUE or a NEXT VALUE expression.
- Refer to host variables or include parameter markers.
- Include an SQL data change statement in the FROM clause.
- Reference data that is encoded with different CCSID sets.
- Reference a remote object.
- Reference an accelerator-only table.

WITH NO DATA

Specifies that the query is used only to define the attributes of the new table. The table is not populated using the results of the *fullselect* and the REFRESH TABLE statement cannot be used.

If the tables that are specified in the use row access controls or column access controls, the row access controls and the column access controls are not defined for the new table.

materialized-query-definition

materialized-query-definition

Specifies that the column definitions of the materialized query table are based on the result of a *fullselect*. If *materialized-query-table-options* are specified, the REFRESH TABLE statement can be used to populate the table with the results of the *fullselect*.

column-name

Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the *fullselect*. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *fullselect*.

A list of column names must be specified if the result table of the *fullselect* has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

AS (*fullselect*)

Specifies that the table definition is based on the column definitions from the result of the *fullselect*. The use of AS (*fullselect*) is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of *fullselect*. The length of each column must not be a 0. Other column attributes, such as DEFAULT, IDENTITY, and unique constraints, are not inherited from the *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. The generated column attributes are not inherited from the *fullselect*. That is, the new column of the materialized query table is not considered as a generated column. A FIELDPROC is inherited for a column if the corresponding select item of the *fullselect* is a column that can be directly mapped to a column of a base table or a view in the FROM clause of the *fullselect*. The materialized query table contains a security label column if only one table in the *fullselect* contains a security label column and the primary authorization ID of the statement has a valid security label.

Authorization for creating materialized query tables:

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the *fullselect*, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the *fullselect* reside. Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the *fullselect*
- The SELECT privilege on the tables and views referenced in the *fullselect*
- SYSADM authority
- DBADM authority for the database in which the tables of the *fullselect* reside

Additional privileges might be necessary for accessing other objects that are referenced in the *fullselect*.

The rules for establishing the qualifiers for names used in the *fullselect* are the same as the rules used to establish the qualifiers for *table-name*.

The following restrictions apply when creating materialized query tables. When *fullselect* does not satisfy the restrictions, an error occurs:

General restrictions: The following restrictions apply:

- The length of each result column of the fullselect must not be 0.
- The fullselect cannot contain a column of a LOB or XML data type.
- No more than one table in the fullselect can contain a security label column.
- The fullselect must not contain a period specification.
- The object that is specified in the FROM clause of the fullselect cannot be a view with columns of length 0.
- The fullselect cannot contain a reference to a created global temporary table, a declared global temporary table, an accelerator-only table, or another materialized query table.
- If IN ACCELERATOR is specified, *materialized-query-definition* cannot be specified.
- The fullselect cannot directly or indirectly reference a base table that has been activated for the row or column access control or a base table for which a row permission or a column mask has been defined.
- The fullselect must not refer to host variables or include parameter markers.

Additional restrictions when ENABLE QUERY OPTIMIZATION is in effect:

- The fullselect must be a subselect.
- The outermost SELECT list of the subselect must not reference data that is encoded with different CCSID sets.
- The subselect cannot include the following:
 - A special register
 - A scalar fullselect
 - A row change timestamp column
 - A ROW CHANGE expression
 - An expression for which implicit time zone values apply (for example, cast a timestamp to a timestamp with time zone)
 - The RAND built-in function
 - The RID built-in function
 - A user-defined scalar or table function that is not deterministic or that has external actions
 - Any predicates that include a subquery
 - A row expression predicate
 - A join using the INNER JOIN syntax, or an outer join
 - A lateral correlation
 - A nested table expression or view that requires temporary materialization
 - A direct or indirect reference to a table that uses activated row or column access controls, or a table for which row or column access controls have been defined.
 - A FETCH FIRST clause

- If a table with a security label is referenced, the security label column must be referenced in the outer select list of the subselect.
- If the subselect references a view, the fullselect in the view definition must satisfy all other restrictions.

refreshable-table-options

Specifies the options for a refreshable materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

DATA INITIALLY DEFERRED

Specifies that the data is not inserted into the materialized query table when it is created. Use the REFRESH TABLE statement to populate the materialized query table, or use the INSERT statement to insert data into a user-maintained materialized query table.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated for a user-maintained materialized query table.

MAINTAINED BY SYSTEM or MAINTAINED BY USER

Specifies how the data in the materialized query table is maintained.

MAINTAINED BY SYSTEM

Specifies that the materialized query table is maintained by the system. Only the REFRESH statement is allowed on the table. This is the default.

MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user, who can use the LOAD utility, an SQL data change statement, a SELECT from data change statement, or REFRESH TABLE SQL statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for optimization.

ENABLE QUERY OPTIMIZATION

Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the restrictions for query optimization, an error occurs.

ENABLE QUERY OPTIMIZATION is the default.

The fullselect must not contain a period specification.

DISABLE QUERY OPTIMIZATION

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

IN

IN *database-name.table-space-name* or **IN DATABASE** *database-name*

Identifies the database and table space in which the table is created. Both forms are optional.

If you specify both a database and a table space, the database must be described in the catalog on the current server. The database must not be DSNDB06 or a work file database. The table space must belong to the database that you specify and must not be an XML table space.

If you specify a database but not a table space, a table space is implicitly created in *database-name*. The name of the table space is derived from the name of the table. The qualifier of the table space is the same as the qualifier of the table. The buffer pool that is used is the default buffer pool for user data that is specified on installation panel DSNTIP1. If you specify a table space but not a database, the database that contains the table space is used.

If you specify neither a table space or a database, a database is implicitly created with the name DSNxxxx, where xxxxx is a five-digit number. A table space is also implicitly created.

If you specify a table space, it cannot be one of the following table spaces:

- A table space that was created implicitly
- A partitioned or a partition-by-growth table space that already contains a table
- A LOB table space
- A table space that already contains a system-period temporal table or a history table

If you specify a partitioned table space, you cannot load or use the table until its partitioned scheme is created.

You cannot specify the name of an implicitly created database. That is, you specify a database name that is eight characters, DSNxxxxx, where xxxxx is a five-digit number.

To create a table space implicitly, the privilege set must have: SYSADM or SYSCTRL authority; DBADM, DBCTRL, or DBMAINT authority for the database; or the CREATETS privilege for the database. You must also have the USE privilege for the default buffer pool in the database and default storage group.

IN ACCELERATOR *accelerator-name*

Specifies that the table is an accelerator-only table. *accelerator-name* identifies the accelerator in which the table will be defined.

You can specify an alias (logical name) for *accelerator-name*. For more information, see Using an alias for an accelerator (DB2 Performance).

If you specify an accelerator-only table, the table and the data of the table exists only in the accelerator, not in DB2. However, the table and column definition of the accelerator-only table are contained in DB2 catalog tables.

partitioning-clause block

PARTITION BY RANGE or PARTITION BY SIZE

Specifies the partitioning scheme for the table.

PARTITION BY RANGE

Specifies the range partitioning scheme for the table (the columns that are used to partition the data). When this clause is specified, the table space is complete, and it is not necessary to create a partitioned index on the table. If this clause is used, the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

If this clause is specified, the *IN database-name.table-space-name* clause is required. This clause applies only to tables in a partitioned table space. **PARTITION BY RANGE** must not be specified for a table that is created in a partition-by-growth table space. If **IN ACCELERATOR** is specified, **PARTITION BY RANGE** must not be specified.

partition-expression

Specifies the key data over which the range is defined to determine the target data partition of the data.

column-name

Specifies the columns of the key. Each *column-name* must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. The sum of length attributes of the columns must not be greater than 255 - *n*, where *n* is the number of columns that can contain null values. Do not specify a qualified column name.

A timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) can only be specified as the last column in a partitioning key.

Do not specify a column for *column-name* if the column is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a BINARY column (or a column with a distinct type that is based on a BINARY data type)
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- an XML column
- a row change timestamp column

NULLS LAST

Specifies that null values are treated as positive infinity for purposes of comparison.

ASC

Puts the entries in ascending order by the column. **ASC** is the default.

DESC

Puts the entries in descending order by the column.

partition-element

Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

PARTITION integer

integer is the physical number of a partition in the table space. A **PARTITION** clause must be specified for every partition of the table space. In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (**ASC**), highest and lowest have their usual meanings. In a column defined as descending (**DESC**), the lowest actual value is highest in the sorting sequence.

ENDING AT (*constant*, MAXVALUE, or MINVALUE, ...)

Defines the limit key for a partition boundary. Specify at least one value (*constant*, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all values is the highest value of the key for ascending and the lowest for descending.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition for ascending cases.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value specified for the last partition are out of range.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.

- If a null value is specified for the partitioning key and the key is ascending, an error is returned unless MAXVALUE is specified. If the key is descending, an error is returned unless MINVALUE is specified..

HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the partition that is associated with the *partition-element*. If HASH SPACE is omitted from the partition element, the HASH SPACE value from the ORGANIZE BY clause is used. If IN ACCELERATOR is specified, HASH SPACE must not be specified.

If HASH SPACE is not specified, each partition will use the HASH SPACE value specified in *organization-clause*.

The HASH SPACE keyword in *partition-element* must only be specified if *organization-clause* is also specified.

K Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

M Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

G Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

PARTITION BY SIZE

Specifies that the table is created in a partition-by-growth table space. If the IN clause is also specified, the IN clause must identify a partition-by-growth table space.

If IN ACCELERATOR is specified, PARTITION BY SIZE must not be specified.

EVERY *integer* G

Specifies that the table is to be partitioned by growth, every *integer* G bytes. *integer* must not be greater than 256. If the IN clause identifies a table space, *integer* must be the same as the DSSIZE value that is in effect for the table space that will contain the table.

organization-clause

ORGANIZE BY HASH

Specifies that a hash is to be used for the data organization of the table.

If PARTITION BY RANGE is specified, and the IN clause specifies a table space, the table space must be a partition by range universal table space, and cannot be a table space with PAGENUM RELATIVE.

If PARTITION BY RANGE is not specified, and an IN clause is specified, the IN clause must identify a partition-by-growth universal table space.

ORGANIZE BY HASH must not be specified if the table is defined with APPEND YES.

ORGANIZE BY HASH must not be specified if the table is using basic row format.

If IN ACCELERATOR is specified, ORGANIZE BY HASH must not be specified.

UNIQUE

Specifies that DB2 enforces uniqueness of the hash key columns, preventing the table from containing two or more rows with the same value of the hash key.

(*column-name*,...)

The list of column names defines the hash key that is used to determine where a row will be placed. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be specified more than once and the specified columns must be defined as NOT NULL. The number of specified columns must not exceed 64, and the sum of their length attributes must not exceed 255. A specified column cannot be any of the following types:

- a LOB column
- a DECFLOAT column
- a XML column
- a distinct type column that is based on one of the preceding data types

If PARTITION BY RANGE is also specified, the list of column names must specify all of the column names that are specified in *partition-expression* for the table, and must specify the column names in the same order as *partition-expression*. If the ORGANIZE BY clause contains more columns than *partition-expression*, *partition-expression* determines the partition number.

HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the table. If the table is partitioned by range, this is the space for each partition.

The default is 64M for a table in a partition-by-growth universal table space or 64M for each partition of a partition by range universal table space.

K Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

M Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

G Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

Other options

EDITPROC *program-name*

Identifies the user-written code that implements the edit procedure for the table. The edit procedure must exist at the current server. The procedure is invoked during the execution of an SQL data change statement or LOAD and all row retrieval operations on the table.

An edit routine receives an entire table row, and can transform that row in any way. Also, it receives a transformed row and must change the row back to its original form.

You must not specify an edit routine for a table with a LOB column.

For information on writing an EDITPROC exit routine, see *Edit procedures (DB2 Administration Guide)*.

WITH ROW ATTRIBUTES

Specifies that the edit procedure parameter list contains an address for the description of a row. WITH ROW ATTRIBUTES must not be specified for a table with an identity, LOB, XML, ROWID, or SECURITY LABEL column. WITH ROW ATTRIBUTES is the default. When WITH ROW ATTRIBUTES is specified, the column names in the table must not be longer than 18 EBCDIC SBCS characters in length.

WITHOUT ROW ATTRIBUTES

Specifies that the description of the row is not provided to the edit procedure. On entry to the edit procedure, the address for the row description in the parameter list contains a value of zero.

VALIDPROC *program-name*

Designates *program-name* as the validation exit routine for the table. Writing a validation exit routine is described in *Validation routines (DB2 Administration Guide)*.

The validation routine can inhibit a load, insert, update, or delete operation on any row of the table: before the operation takes place, the procedure is passed the row. The values that are represented by any LOB or XML columns in the table are not passed to the validation routine. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns. If IN ACCELERATOR is specified, VALIDPROC must not be specified.

A table can have only one validation procedure at a time. In an ALTER TABLE statement, you can designate a replacement procedure or discontinue the use of a validation procedure.

If you omit VALIDPROC, the table has no validation routine.

AUDIT

Identifies the types of access to this table that causes auditing to be performed. For information about audit trace classes, see *DB2 Administration Guide*.

If a materialized query table is refreshed with the REFRESH TABLE statement, the auditing also occurs during the REFRESH TABLE operation. **AUDIT** works as usual for LOAD and SQL data change operations on a user-maintained materialized query table.

NONE

Specifies that no auditing is to be done when this table is accessed. This is the default.

CHANGES

Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

ALL

Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

If the table is subsequently altered with an ALTER TABLE statement, the ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- **AUDIT** attribute is changed to **NONE**, **CHANGES**, or **ALL** on an audited or non-audited table.
- **AUDIT CHANGES** or **AUDIT ALL** is in effect.

If IN ACCELERATOR is specified, **AUDIT NONE**, **CHANGES**, and **ALL** must not be specified.

OBID *integer*

Identifies the OBID to be used for this table. An OBID is the identifier for an object's internal descriptor. The integer must be greater than 1 and must not identify an existing or previously used OBID of the database. If you omit OBID, DB2 generates a value.

The following statement retrieves the value of OBID:

```
SELECT OBID
FROM SYSIBM.SYSTABLES
WHERE CREATOR = 'ccc' AND NAME = 'nnn';
```

Here, *nnn* is the table name and *ccc* is the creator of the table.

DATA CAPTURE

Specifies whether the logging of the following actions on the table is augmented by additional information:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause of the ALTER TABLE statement)
- Changing columns (using the ALTER COLUMN clause of the ALTER TABLE statement)

For guidance on intended uses of the expanded log records, see:

- The description of data propagation to IMS in *IMS DataPropagator: An Introduction*
- The instructions for using Remote Recovery Data Facility (RRDF) in *Remote Recovery Data Facility Program Description and Operations*
- The instructions for reading log records in *DB2 Administration Guide*

If a materialized query table is refreshed with the REFRESH TABLE statement, the logging of the augmented information occurs during the REFRESH TABLE operation. DATA CAPTURE works as usual for insert, update, and delete operations on a user-maintained materialized query table.

A table with data that is stored only in an accelerator-only table cannot be defined with this attribute.

NONE

Do not record additional information to the log. This is the default.

CHANGES

Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available. Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

WITH RESTRICT ON DROP

Indicates that the table can be dropped only by using REPAIR DBD DROP. In addition, the database and table space that contain the table can be dropped only by using REPAIR DBD DROP.

The WITH RESTRICT ON DROP clause can be removed using the ALTER TABLE statement with the DROP RESTRICT ON DROP clause. After the WITH RESTRICT ON DROP clause is removed from the definition of the table, the table, the database, and the containing table space can be dropped using the DROP statement.

CCSID *encoding-scheme*

Specifies the encoding scheme for string data stored in the table. If the IN clause is specified with a table space, the value must agree with the encoding scheme that is already in use for the specified table space. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the table space or database specified in the IN clause. If the IN clause is not specified, the value specified is used for the table being created as well as for the table space that DB2 implicitly creates. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

If IN ACCELERATOR is specified, a column cannot be defined as ASCII mixed or graphic. The *IBM DB2 Analytics Accelerator for z/OS: Stored Procedures Reference* contains a complete description of encoding schemes allowed in an accelerator.

If the CCSID clause is not specified, the encoding scheme for the table depends on the IN clause:

- If the IN clause is specified, the encoding scheme already in use for the table space or database specified in the IN clause is used.
- If the IN clause is not specified, the encoding scheme of the new table is the same as the scheme for the table that is specified in the LIKE clause.

If the CCSID clause is specified for a materialized query table, the encoding scheme specified in the clause must be the same as the scheme for the result CCSID of the fullselect. The CCSID must also be the same as the CCSID of the table space for the table being created.

VOLATILE or NOT VOLATILE

Specifies how DB2 is to choose access to the table.

VOLATILE

Specifies that DB2 is to use index access to the table whenever possible for

SQL operations. However, be aware that list prefetch and certain other optimization techniques might be disabled when VOLATILE is used.

One instance in which you might want to use VOLATILE is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows.

Another instance in which you might want to use VOLATILE is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation. If IN ACCELERATOR is specified, VOLATILE must not be specified. For this usage, the primary index must be the only index that is defined on the table, and list prefetch is disabled to ensure the sequence in which the rows are locked.

NOT VOLATILE

Specifies that SQL access to this table should be based on the current statistics. NOT VOLATILE is the default.

CARDINALITY

An optional keyword that currently has no effect, but that is provided for DB2 family compatibility.

LOGGED or NOT LOGGED

Specifies whether changes that are made to the data in the implicitly created table space are recorded in the log. This parameter applies to the implicitly created table space and to all indexes of this table. XML table spaces and indexes associated with the XML table spaces inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

Do not specify **LOGGED** or **NOT LOGGED** if the table space name is specified by using the **IN** *table-space-name* clause or if the IN ACCELERATOR clause is specified.

LOGGED

Specifies that changes that are made to the data in the implicitly created table space are recorded in the log.

LOGGED is the default.

NOT LOGGED

Specifies that changes that are made to data in the implicitly created table space are not recorded in the log.

NOT LOGGED prevents undo and redo information from being recorded in the log. However, control information for the implicitly created table space will continue to be recorded in the log.

COMPRESS YES or COMPRESS NO

Specifies whether data compression applies to the rows of the implicitly created table space. The default is specified by the value of the subsystem parameter USE DATA COMPRESSION.

If the **IN** *table-space-name* clause or the **IN ACCELERATOR** clause is specified, **COMPRESS YES** or **COMPRESS NO** must not be specified.

| **COMPRESS YES**

| Specifies that data compression applies to the rows of the implicitly created
| table space. The rows are not compressed until the LOAD or REORG
| utility is run on the table in the implicitly created table space.

| **COMPRESS NO**

| Specifies that data compression is not used for the rows of the implicitly
| created table space.

| **APPEND NO or APPEND YES**

| Specifies whether append processing is used for the table. The APPEND clause
| must not be specified for a table that is created in a work file table space.

| **NO** Specifies that append processing is not used for the table. For insert and
| LOAD operations, DB2 will attempt to place data rows in a well clustered
| manner with respect to the value in the row's cluster key column.

| NO is the default.

| **YES**

| Specifies that data rows are to be placed into the table by disregarding the
| clustering during insert and LOAD operations.

| **DSSIZE integer G**

| Specifies the maximum size for the implicitly created partition-by-growth or
| range-partitioned universal table space. This value is only applied to the
| implicitly created base table space, not to any associated implicitly created
| XML or LOB table spaces.

| Do not specify **DSSIZE integer G** if any of the following conditions are true:

- | • The table space name is specified by using the **IN table-space-name** clause.
| • The **PARTITION BY** clause includes the **EVERY integer-constant G** clause.
| • The statement contains an accelerator-only table.

| The default is specified by the value of the subsystem parameter MAXIMUM
| PARTITION SIZE.

| For more detailed information about the DSSIZE clause, refer to "CREATE
| TABLESPACE" on page 1775.

| **BUFFERPOOL bpname**

| Specifies the buffer pool to use for the implicitly created table space and
| determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB
| page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB,
| respectively.

| *bpname* must identify an activated buffer pool. The privilege set must include
| SYSADM authority, SYSCTRL authority, or the USE privilege on the buffer
| pool.

| Do not specify **BUFFERPOOL bpname** if the table space name is specified by
| using the **IN table-space-name** clause or the **IN ACCELERATOR** clause is
| specified.

| If you do not specify the BUFFERPOOL clause for an implicitly created table
| space, the default buffer pool of the database is used unless the record length
| exceeds the page size. If the record length exceeds the page size, do not specify
| the BUFFERPOOL clause. In this case, DB2 will choose a suitable buffer pool
| for the implicitly table space.

| Refer to "Naming conventions" on page 59 for more information about *bpname*.

MEMBER CLUSTER

Specifies that data that is inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. DB2 places the data in the implicitly created table space based on available space.

Do not specify **MEMBER CLUSTER** if the table space name is specified by using the **IN *table-space-name*** clause or if **IN ACCELERATOR** clause is specified.

TRACKMOD YES or TRACKMOD NO

Specifies whether DB2 tracks modified pages in the space map pages of the implicitly created table space. The default is specified by the value of the subsystem parameter **TRACK MODIFIED PAGES**.

Do not specify **TRACKMOD YES** or **TRACKMOD NO** if the table space name is specified by using the **IN *table-space-name*** clause or if using the **IN ACCELERATOR** clause.

TRACKMOD YES

Changed pages are tracked in the space map pages to help improve performance of incremental image copies.

TRACKMOD NO

Changed pages are not tracked in the space map pages. DB2 uses the LRSN value in each page to determine whether a page has been changed.

Notes

Owner privileges:

The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 2026) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Table design:

Designing tables is part of the process of database design. For information on design, see *Introduction to DB2 for z/OS*.

Creating a table in a segmented table space:

A table cannot be created in a segmented table space if any of the following conditions are true:

- The available space in the data set is less than the segment size specified for the table space, and
- The data set cannot be extended.

Creating a table with graphic and mixed data columns:

You cannot create an ASCII or EBCDIC table with a **GRAPHIC**, **VARGRAPHIC**, or **DBCLOB** column or a **CHAR**, **VARCHAR**, or **CLOB** column defined as **FOR MIXED DATA** when the setting for installation option **MIXED DATA** is **NO**.

Creating a table with distinct type columns based on LOB, ROWID, and DECFLOAT columns:

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB columns (**CLOB**, **DBCLOB**, and **BLOB**), ROWID columns, and DECFLOAT columns apply to distinct type columns that are based on LOBs, row IDs, and DECFLOATs. For example, a table cannot have both an explicitly defined ROWID column and a column with a distinct type that is based on a row ID.

Tables with inline LOB columns:

If the 32K page size is exceeded for a table in an universal table space, DB2 recalculates the record size using 0 as the inline length for LOB columns that do not specify the INLINE LENGTH clause. After the recalculation, if the 32K page size is still exceeded, the CREATE TABLE statement returns an error.

You cannot create a table with an inline LOB column in a table space that has basic row format.

Creating a table with LOB columns:

A table with a LOB column (CLOB, DBCLOB, or BLOB) must also have a ROWID column and one or more auxiliary tables. When you create the table, DB2 implicitly generates a ROWID column for you. This is called an *implicitly hidden ROWID column*, and DB2:

- Creates the column with a name of DB2_GENERATED_ROWID_FOR_LOBS nn .
DB2 appends nn only if the column name already exists in the table, replacing nn with 00 and incrementing by 1 until the name is unique within the row.
- Defines the column as GENERATED ALWAYS.
- Appends the implicitly hidden ROWID column to the end of the row after all the other explicitly defined columns.

For example, assume that DB2 generated an implicitly hidden ROWID column named DB2_GENERATED_ROWID_FOR_LOBS for table MYTABLE. The result table for a SELECT * statement for table MYTABLE would not contain that ROWID column. However, the result table for SELECT COL1, DB2_GENERATED_ROWID_FOR_LOBS would include the implicitly hidden ROWID column.

If the MIXED DATA subsystem parameter is set to yes, and a lowercase or mixed case hexadecimal constant is specified as the default value for a LOB column, the CREATE TABLE statement returns an error.

The definition of the table is marked incomplete until an auxiliary table is created in a LOB table space for each LOB column in the base table and index is created on each auxiliary table. The auxiliary table stores the actual values of a LOB column. If you create a table with a LOB column in a partitioned table space, there must be one auxiliary table defined for each partition of the base table space.

Unless DB2 implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in the base table, you need to create these objects using the CREATE TABLESPACE, CREATE AUXILIARY TABLE, and CREATE INDEX statements.

If the table space that contains the table is explicitly created and the value of the CURRENT RULES special register is 'STD' when the CREATE TABLE statement is processed, or the table space that contains the table is implicitly created, DB2 implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in the base table.

The privilege set must include the following privileges:

- The USE privilege on the buffer pool and the storage group that is used by the XML objects

- If the base table space is explicitly created, CREATETS is also required on the database that contains the table (DSNDB04 if the database is implicitly created)

DB2 chooses the names of implicitly created objects using these conventions:

LOB table space

Name is 8 characters long, consisting of an 'L' followed by 7 random characters.

auxiliary table

Name is 18 characters long. The first five characters of the name are the first five characters of the name of the base table. The second five characters are the first five characters of the name of the LOB column. The last eight characters are randomly generated. If a base table name or a LOB column name is less than five characters, DB2 adds underscore characters to the name to pad it to a length of five characters.

index on the auxiliary table

Name is 18 characters long. The first character of the name is an 'I'. The next ten characters are the first ten characters of the name of the auxiliary table. The last seven characters are randomly generated. The index has the COPY NO attribute.

The other attributes of these implicitly created objects are those that would have been created by their respective CREATE statements with all optional clauses omitted, with the following exceptions:

- The database name is the database name of the base table.
- If the LOB table space is implicitly created, the buffer pool is determined by the DEFAULT BUFFER POOL FOR USER LOB DATA fields of installation panel DSNTIP1. The appropriate USE privilege is required on that buffer pool.

Utility REPORT TABLESPACESET identifies the LOB table spaces that DB2 implicitly created.

Creating a table with an XML column:

When a table is created with an XML column, an XML table space, XML table, and a node ID index and document ID index are implicitly created.

The privilege set must include the following privileges:

- The USE privilege on the buffer pool and the storage group that is used by the XML objects
- If the base table space is explicitly created, CREATETS is also required on the database that contains the table (DSNDB04 if the database is implicitly created)

The buffer pool for the XML table space is determined by the DEFAULT BUFFER POOL FOR USER XML DATA fields of installation panel DSNTIP1. The appropriate USE privilege is required on that buffer pool.

The XML table space will have a larger DSSIZE than the base table space if the base table space is partitioned by range. If the base table space is partitioned by growth, the default DSSIZE of 4GB will be used for the XML table space. The DSSIZE for an XML table space that is associated with a partitioned by range base table space is determined as follows.

Table 173. Default DSSIZE for XML table spaces, given base table space DSSIZE and page size

| Base table space DSSIZE | 4KB base page size | 8KB base page size | 16KB base page size | 32KB base page size |
|-------------------------|--------------------|--------------------|---------------------|---------------------|
| 1GB - 4GB | 4GB | 4GB | 4GB | 4GB |
| 8GB | 32GB | 16GB | 16GB | 16GB |
| 16GB | 64GB | 32GB | 16GB | 16GB |
| 32GB | 64GB | 64GB | 32GB | 16GB |
| 64GB | 64GB | 64GB | 64GB | 32GB |
| 128GB | 256GB | 256GB | 128GB | 64GB |
| 256GB | 256GB | 256GB | 256GB | 128GB |

For example: for a base table space that has a DSSIZE of 8GB and a page size of 8KB, the XML table space will have a DSSIZE of 16GB.

Naming convention for implicitly created XML objects:

Implicitly created XML table spaces names will be *Xyyyynnnn*, where *yyy* is derived from the first three bytes of the base table name (if the name is shorter than 3, *yyy* is padded with X). *nnnn* is a numeric string that will start at 0000 and be incremented by 1 until a unique number is found.

Implicitly created XML table names will be *Xyyyyyyyyyyyyyyyyynnnn*, where *yyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the base table name or of the entire name if it is less than 18. *nnn* will only be appended if the name already exists in the table. If the name already exists, *nnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Implicitly created document ID index names will be *I_DOCIDyyyyyyyyyyyyyyyyynnnn*, where *yyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the base table name or the entire name if it is less than 18. *nnn* will only be appended if the index already exists in the table. If the index already exists, *nnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Implicitly created node ID index names will be *I_NODEIDyyyyyyyyyyyyyyyyynnnn*, where *yyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the XML table name or the entire name if it is less than 18. *nnn* will only be appended if the index already exists in the table. If the index already exists, *nnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Creating a table with an identity column:

When a table has an identity column, DB2 can automatically generate sequential numeric values for the column as rows are inserted into the table. Thus, identity columns are ideal for primary keys. Identity columns and ROWID columns are similar in that both types of columns contain values that DB2 generates. ROWID columns are used in large object (LOB) table spaces and can be useful in direct-row access. ROWID columns contain values of the ROWID data type, which returns a 40 byte VARCHAR value that is not regularly ascending or descending. ROWID data values are therefore not well suited to many application uses, such as generating employee numbers or product numbers. For data that is not LOB data and that does not require direct-row access, identity columns are usually a better approach, because identity columns contain existing

numeric data types and can be used in a wide variety of uses for which ROWID values would not be suitable.

When a table is recovered to a point-in-time, it is possible that a large gap in the generated values for the identity column might result. For example, assume a table has an identity column that has an incremental value of 1 and that the last generated value at time T1 was 100 and DB2 subsequently generates values up to 1000. Now, assume that the table space is recovered back to time T1. The generated value of the identity column for the next row that is inserted after the recovery completes will be 1001, leaving a gap from 100 to 1001 in the values of the identity column.

If you want to ensure that an identity column has unique values, create a unique index on the column.

Creating a table with a LONG VARCHAR or LONG VARGRAPHIC column:

Although the syntax LONG VARCHAR and LONG VARGRAPHIC is allowed for compatibility with previous releases of DB2, its use is not encouraged. VARCHAR(*integer*) and VARGRAPHIC(*integer*) is the recommended syntax, because after the CREATE TABLE statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

When a column is defined using the LONG VARCHAR or LONG VARGRAPHIC syntax, DB2 determines the length attribute of the column. You can use the following information, which is provided for existing applications that require the use of the LONG VARCHAR or LONGVARGRAPHIC syntax, to calculate the byte count and the character count of the column.

To calculate the byte count, use this formula:

$$2*(\text{INTEGER}((\text{INTEGER}((m-i-k)/j))/2))$$

Where:

- m* Is the maximum row size (8 less than the maximum record size)
- i* Is the sum of the byte counts of all columns in the table that are not LONG VARCHAR or LONG VARGRAPHIC
- j* is the number of LONG VARCHAR and LONG VARGRAPHIC columns in the table
- k* k is the number of LONG VARCHAR and LONG VARGRAPHIC columns that allow nulls

To find the character count:

1. Find the byte count.
2. Subtract 2.
3. If the data type is LONG VARGRAPHIC, divide the result by 2. If the result is not an integer, drop the fractional part.

If the IN DATABASE clause is specified:

If you specify IN DATABASE (either explicitly or by default), but do not specify a table space, a table space is implicitly created in *database-name*. The name of the table space is derived from the table name. The qualifier of the table space is the same as the qualifier of the table. The owner of the table space is SYSIBM.

If range-partitioning is not specified, the implicitly created table space is a partition-by-growth table space with MAXPARTITIONS 256, SEGSIZE 32, and DSSIZE 4G.

If range-partitioning is specified, the table space will be partitioned based on the number of parts specified on the CREATE TABLE statement with defaults of SEGSIZE 32, LOCKSIZE ROW, and LOCKMAX SYSTEM.

If the IN clause is not specified:

If you do not specify the IN clause, the DB2 subsystem will implicitly create a table space as described previously, but the DB2 subsystem will also choose a database. The DB2 subsystem creates a name in the form of DSN*nnnnn*, where *nnnnn* is between 00001 and the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, which has a default of 10000, inclusive. The owner of the database is SYSIBM.

- If DSN*nnnnn* already exists and is an implicitly created database, the DB2 subsystem creates the table in that database.
- If DSN*nnnnn* does not exist, the DB2 subsystem creates a database with the name DSN*nnnnn*.

If DSN*nnnnn* cannot be created because of a deadlock, timeout, or resource unavailable condition, the DB2 subsystem increments *nnnnn* by one and tries the resultant database name. If the DB2 subsystem reaches the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, and the corresponding database name is not available, the DB2 subsystem sets *nnnnn* to 00001 and tries the resultant database name. If the DB2 subsystem attempts to create the table a number of times that is equal to the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB without success, an error occurs.

Implicitly created table space attributes:

The attributes of the implicitly created table space can be changed by using the "ALTER TABLESPACE" on page 1389 statement.

Defining a system-period temporal table:

A system-period temporal table definition includes the following:

- A system period named SYSTEM_TIME which is defined using a row-begin column and a row-end column.
- A transaction-start-ID column.
- A system-period data versioning definition which includes the name of the associated history table.

To ensure that the history table cannot be implicitly dropped when a system-period temporal table is dropped, use the WITH RESTRICT ON DROP clause in the definition of the history table.

Defining an application-period temporal table:

An application-period temporal table definition includes an application period named BUSINESS_TIME. The application period is defined using a begin timestamp column and an end timestamp column.

Data change operations on an application-period temporal table might result in an automatic insert of one or two additional rows when a row is updated or deleted. When an update or delete of a row in an application-period temporal table is specified for a portion of the period that is represented by that row, the row is updated or deleted and one or two rows are automatically inserted to represent the portion of the row that is not changed. New values are generated for each generated column in an application-period temporal table for each row that is automatically

inserted as a result of an update or delete operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert will violate a constraint or index, in which case an error is returned.

Bitemporal tables:

A table that is defined for system-period data versioning and contains a BUSINESS_TIME period is referred to as a bitemporal table.

Considerations for transaction-start-ID columns:

A transaction-start-ID column contains a null value if the column allows null values. A row-begin column which is unique from other row-begin column values that are generated for other transactions exists with the transaction-start-ID column. Given that the column might contain null values, consider using one of the following methods when retrieving a value from the column:

```
COALESCE ( transaction_start_id_col, row_begin_col)
CASE WHEN transaction_start_id_col IS NOT NULL
      THEN transaction_start_id_col
      ELSE row_begin_col
END
```

If the IN clause is specified with ORGANIZE BY HASH:

If you specify IN DATABASE (either explicitly or by default), and ORGANIZE BY HASH, DB2 will calculate an optimum buffer pool for hash organization based on the definition of the table and validate the calculated buffer pool with the buffer pool of the explicitly created table space. If the buffer pool sizes are different, DB2 will return an error.

If the table is in a range-partitioned universal table space, the DSSIZE value for the table space must be large enough to fit the HASH SPACE specification for each partition.

If the table is in a partition-by-growth table space, the total space calculated from the DSSIZE and MAXPARTITIONS values for the table space must be large enough for the implicitly or explicitly specified HASH SPACE.

If the IN clause is not specified with ORGANIZE BY HASH:

If you do not specify IN DATABASE (either explicitly or by default), DB2 will use the default DSSIZE of 4G for each partition for a range-partition universal table space or use the value that is specified in the partitioning clause. The hash space value that is specified on CREATE TABLE will be validated, per part, to ensure that the specified DSSIZE is adequate. If the DSSIZE is not adequate, an error will be returned.

If the maximum number of partitions needed for the specified hash space is more than the maximum number of partitions allowed, DB2 will return an error.

If the selected buffer pool is not available, an error will be returned.

Creating a table with hash organization and LOB columns:

If the table space is a partition-by-growth universal table space, DB2 will preallocate as many partitions as needed depending on the value specified for HASH SPACE. If DB2 needs to implicitly create the LOB object in a new partition, the privilege set for the implicitly created LOB objects must include the USE privilege on the buffer pool for the LOB table space.

Hash space and DB2 page size:

If the specified hash space is less than or equal to 64 MB (the DB2 default),

DB2 will add extra space for DB2 system pages. If the specified hash space is greater than 64 MB, DB2 will use part of the hash space for DB2 system pages. The amount of space needed for DB2 system pages depends on SEGSIZE and PAGESIZE. The larger the SEGSIZE and/or PAGESIZE becomes, the larger the requirement for DB2 system pages. DB2 can reserve up to 5 MB for system pages for the highest SEGSIZE value (64) and PAGESIZE value (32K).

Hash space and DSSIZE:

Depending on certain table space characteristics, DB2 needs to reserve space for the hash overflow area. Therefore, the amount of hash space cannot be equal to the DSSIZE value. The maximum amount of hash space that can be specified is approximately 20% less than the DSSIZE value. DB2 returns an error if the amount of hash space is too large. If the amount of hash space is too large, specify a larger value of DSSIZE, or decrease the amount of hash space.

Specifying APPEND with ORGANIZE BY HASH:

Append processing is not applicable to tables with hash organization since there is no key clustering in hash organization. For insert operations into tables with hash organization, DB2 will use the internal hash algorithm to determine the location of the row.

Restrictions for tables with hash organization:

Tables that use hash organization are subject to the following restrictions:

- A table that is defined to use hash organization cannot be created in a LOB table space or XML table space.
- ORGANIZE BY HASH must not be specified if the table space is defined with the MEMBER CLUSTER clause.
- The MAXROWS clause is applicable only to the hash overflow area of the table space for tables with hash organization. The fixed hash area of each page will contain as many rows as it can hold, up to a maximum of 255.
- The ORGANIZE BY HASH UNIQUE (*column-list*) clause is required when specifying HASH SPACE *integer K|M|G* in the *partition-element*. The *organization-clause* applies to the entire table and the *partition-element* clause applies at the partition level.
- DB2 will automatically create a hash overflow index when a table is created with hash organization.

Implicitly created table spaces:

If the table space is implicitly created, all of the following required system objects will also be implicitly created:

- The enforcing primary key index
- The enforcing unique key index
- Any necessary LOB table spaces, auxiliary table spaces, and auxiliary indexes
- The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

When DB2 implicitly creates a base table space for a table with LOB columns that can have inline LOBs, DB2 creates the base table space in reordered row format, regardless of the value of the RRF subsystem parameter.

When DB2 implicitly creates a table space for a table with hash organization, DB2 creates the table space in reordered row format, regardless of the value of the RRF subsystem parameter.

Implicitly created indexes:

When the PRIMARY KEY or UNIQUE clause is used in the CREATE TABLE statement and the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created, DB2 implicitly creates the unique indexes used to enforce the uniqueness of the primary or unique keys.

When a ROWID column is defined as GENERATED BY DEFAULT in the CREATE TABLE statement, and the CREATE TABLE statement is processed by SET CURRENT RULES = 'STD' or the table space that contains the table is implicitly created, DB2 implicitly creates the unique indexes used to enforce the uniqueness of the ROWID column.

The privilege set must include the USE privilege of the buffer pool.

Each index is created as if the following CREATE INDEX statement were issued:

```
CREATE UNIQUE INDEX xxx ON table-name (column1,...)
```

Where:

- *xxx* is the name of the index that DB2 generates.
- *table-name* is the name of the table specified in the CREATE TABLE statement.
- (*column1,...*) is the list of column names that were specified in the UNIQUE or PRIMARY KEY clause of the CREATE TABLE statement, or the column is a ROWID column that is defined as GENERATED BY DEFAULT.

For more information about the schema processor, see *DB2 Administration Guide*.

In addition, if the table space that contains the table is implicitly created, DB2 will check the DEFINE DATA SET subsystem parameter to determine whether to define the underlying data set for the index space of the implicitly created index on the base table.

If DEFINE DATA SET is NO, the index is created as if the following CREATE INDEX statement is issued:

```
CREATE UNIQUE INDEX xxx ON table-name (column1,...) DEFINE NO
```

Maximum record size:

The maximum record size of a table depends on the page size of the table space, whether the table space is organized for hash access, and whether the EDITPROC clause is specified, as shown in Table 174 on page 1768.

The initial page size of the table space is the size of its buffer, which is determined by the BUFFERPOOL clause that was explicitly or implicitly specified when the table space was created. When the record size reaches 90 percent of the maximum record size for the page size of the table space, the next largest page size is automatically used.

Table 174. Maximum record size, in bytes

| | Page Size = 4KB | Page Size = 8KB | Page Size = 16KB | Page Size = 32KB |
|--|--------------------|--------------------|---------------------|---------------------|
| Non-hash table | 4056 | 8138 | 16330 | 32714 |
| Non-hash table with EDITPROC=YES | 4046 | 8128 | 16320 | 32704 |
| Hash table (hash home page) | 3817 | 7899 | 16091 | 32475 |
| Hash table with EDITPROC=YES (hash home page) | 3807 | 7889 | 16081 | 32465 |

The maximum record size corresponds to the maximum length of a VARCHAR column if that column is the only column in the table.

If the table space that contains the table is implicitly created, the proper buffer pool size is chosen according to the actual record size. If the record size reaches 90% of the maximum record size for the page size of the table space, the next largest page size will be used. Table 175 shows 90% of the maximum record size:

Table 175. 90% of Maximum record size, in bytes

| | Page Size = 4KB | Page Size = 8KB | Page Size = 16KB | Page Size = 32KB |
|--|--------------------|--------------------|---------------------|---------------------|
| Non-hash table | 3650 | 7324 | 14697 | 29443 |
| Non-hash table with EDITPROC=YES | 3641 | 7315 | 14688 | 29434 |
| Hash table (hash home page) | 3435 | 7109 | 14482 | 29228 |
| Hash table with EDITPROC=YES (hash home page) | 3426 | 7100 | 14473 | 29219 |

Byte counts:

The sum of the byte counts of the columns must not exceed the maximum row size of the table. The maximum row size is eight less than the maximum record size.

For columns that do not allow null values, Table 176 gives the byte counts of columns by data type. For columns that allow null values, the byte count is one more than shown in the table.

Table 176. Byte counts of columns by data type

| Data Type | Byte Count |
|-----------|------------|
| INTEGER | 4 |
| SMALLINT | 2 |
| BIGINT | 8 |

Table 176. Byte counts of columns by data type (continued)

| Data Type | Byte Count |
|---|--|
| FLOAT(<i>n</i>) | If <i>n</i> is between 1 and 21, the byte count is 4. If <i>n</i> is between 22 and 53, the byte count is 8. |
| DECIMAL | INTEGER($(p/2)+1$), where <i>p</i> is the precision |
| DECFLOAT(16) | 9 |
| DECFLOAT(34) | 17 |
| CHAR(<i>n</i>) | <i>n</i> |
| VARCHAR(<i>n</i>) | <i>n</i> +2 |
| CLOB | 6 |
| Inline CLOB | 6 + inline byte count |
| GRAPHIC(<i>n</i>) | 2 <i>n</i> |
| VARGRAPHIC(<i>n</i>) | 2 <i>n</i> +2 |
| DBCLOB | 6 |
| Inline DBCLOB | 6 + (inline char count * 2) |
| BINARY(<i>n</i>) | <i>n</i> |
| VARBINARY(<i>n</i>) | <i>n</i> +2 |
| BLOB | 6 |
| Inline BLOB | 6 + inline byte count |
| DATE | 4 |
| TIME | 3 |
| TIMESTAMP(<i>p</i>) WITHOUT TIME ZONE | INTEGER($(p+1)/2$) + 7 where <i>p</i> is the precision |
| TIMESTAMP(<i>p</i>) WITH TIME ZONE | INTEGER($(p+1)/2$) + 9 where <i>p</i> is the precision |
| ROWID | 19 |
| distinct type | The length of the source data type upon which the distinct type was based |
| XML | 6 - If column cannot contain multiple versions of an XML document. 14 - If column can contain multiple versions of an XML document. |

Related information:

See XML versions (DB2 Programming for XML).

Creating a materialized query table:

If the fullselect in the CREATE TABLE statement contains a SELECT *, the select list of the subselect is determined at the time the materialized query table is created. In addition, any references to user-defined functions are resolved at the same time. The isolation level at the time when the CREATE TABLE statement is executed is the isolation level for the materialized query table. After a materialized query table is created, the REFRESH_TIME column of the row for the table in the SYSIBM.SYSVIEWS catalog table contains the default timestamp.

The owner of a materialized query table has all the table privileges with the grant option on the table irrespective of whether the owner has the necessary privileges on the base tables, views, functions, and sequences.

No unique constraints or unique indexes can be created for materialized query tables. Thus, a materialized query table cannot be a parent table in a referential constraint.

When you are creating user-maintained materialized query tables, you should create the materialized query table with query optimization disabled and then enable the table for query optimization after it is populated. Otherwise, DB2 might rewrite queries to use the empty materialized query table, and you will not get accurate results.

Considerations for implicitly hidden columns:

A column that is defined as implicitly hidden is not part of the result table of a query that specifies * in a SELECT list. However, an implicitly hidden column can be explicitly referenced in a query. For example, an implicitly hidden column can be referenced in the SELECT list or in a predicate in a query. Additionally, an implicitly hidden column can be explicitly referenced in a COMMENT, CREATE INDEX statement, ALTER TABLE statement, INSERT statement, MERGE statement, UPDATE statement, or RENAME statement. An implicitly hidden column can be referenced in a referential constraint. A REFERENCES clause that does not contain a column list refers implicitly to the primary key of the parent table. It is possible that the primary key of the parent table includes a column defined as implicitly hidden. Such a referential constraint is allowed.

If the SELECT list of the fullselect of a materialized query definition explicitly refers to an implicitly hidden column, that column will be part of the materialized query table.

If the SELECT list of the fullselect of a view definition (CREATE VIEW statement) explicitly refers to an implicitly hidden column, that column will be part of the view, however the view column is not considered 'hidden'.

Restrictions on field procedures, edit procedures, and validation exit procedures:

Field procedures, edit procedures, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table will be invalidated.

Consider using triggers to replace the functionality on field procedures, edit procedures, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

Restrictions on certain SQL statements in the same unit of work as CREATE TABLE:

- A CREATE TABLE statement that contains a PARTITION BY clause should not be followed in the same unit of work by SQL statements that change data.
- A CREATE TABLE statement that contains an IN ACCELERATOR clause should be issued in a separate unit of work from other SQL statements.

Creating a table while a utility runs:

You cannot use CREATE TABLE while a DB2 utility has control of the table space implicitly or explicitly specified by the IN clause.

Restriction on table spaces when there are pending changes to the definition:

A CREATE TABLE statement is not allowed if there are pending changes to the definition of the table space.

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
- NOMINVALUE (single clause) as a synonym for NO MINVALUE
- NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
- NOORDER (single clause) as a synonym for NO ORDER
- PART *integer* VALUES can be specified as an alternative to PARTITION *integer* ENDING AT.
- VALUES as a synonym for ENDING AT
- DEFINITION ONLY as a synonym for WITH NO DATA
- SUMMARY between CREATE and TABLE
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Create a table named DSN8A10.DEPT in the table space DSN8S10D of the database DSN8D10A. Name the five columns DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, and LOCATION, allowing only MGRNO and LOCATION to contain nulls, and designating DEPTNO as the only column in the primary key. All five columns hold character string data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, all five columns have the subtype SBCS.

```
CREATE TABLE DSN8A10.DEPT
(DEPTNO  CHAR(3)      NOT NULL,
 DEPTNAME VARCHAR(36) NOT NULL,
 MGRNO   CHAR(6)      ,
 ADMRDEPT CHAR(3)     NOT NULL,
 LOCATION CHAR(16)    ,
 PRIMARY KEY(DEPTNO) )
IN DSN8D10A.DSN8S10D;
```

Example 2: Create a table named DSN8A10.PROJ in an implicitly created table space of the database DSN8D10A. Assign the table a validation procedure named DSN8EAPR.

```
CREATE TABLE DSN8A10.PROJ
(PROJNO  CHAR(6)      NOT NULL,
 PROJNAME VARCHAR(24) NOT NULL,
 DEPTNO  CHAR(3)      NOT NULL,
 RESPEMP CHAR(6)      NOT NULL,
 PRSTAFF DECIMAL(5,2) ,
 PRSTDATE DATE        ,
 PRENDATE DATE        ,
 MAJPROJ CHAR(6)      NOT NULL)
IN DATABASE DSN8D10A
VALIDPROC DSN8EAPR;
```

Example 3: Assume that table PROJECT has a non-primary unique key that consists of columns DEPTNO and RESPEMP (the department number and employee responsible for a project). Create a project activity table named ACTIVITY with a foreign key on that unique key.

```

CREATE TABLE ACTIVITY
  (PROJNO CHAR(6) NOT NULL,
   ACTNO SMALLINT NOT NULL,
   ACTDEPT CHAR(3) NOT NULL,
   ACTOWNER CHAR(6) NOT NULL,
   ACSTAFF DECIMAL(5,2) ,
   ACSTDATE DATE NOT NULL,
   ACENDATE DATE ,
   FOREIGN KEY (ACTDEPT,ACTOWNER)
   REFERENCES PROJECT (DEPTNO,RESPEMP) ON DELETE RESTRICT)
IN DSN8D10A.DSN8S10D;

```

Example 4: Create an employee photo and resume table EMP_PHOTO_RESUME that complements the sample employee table. The table contains a photo and resume for each employee. Put the table in table space DSN8D10A.DSN8S10E. Let DB2 always generate the values for the ROWID column.

```

CREATE TABLE DSN8A10.EMP_PHOTO_RESUME
  (EMPNO CHAR(6) NOT NULL,
   EMP_ROWID ROWID NOT NULL GENERATED ALWAYS,
   EMP_PHOTO BLOB(110K),
   RESUME CLOB(5K),
   PRIMARY KEY (EMPNO))
IN DSN8D10A.DSN8S10E
CCSID EBCDIC;

```

Example 5: Create an EMPLOYEE table with an identity column named EMPNO. Define the identity column so that DB2 will always generate the values for the column. Use the default value, which is 1, for the first value that should be assigned and for the incremental difference between the subsequently generated consecutive numbers.

```

CREATE TABLE EMPLOYEE
  (EMPNO INTEGER GENERATED ALWAYS AS IDENTITY,
   ID SMALLINT,
   NAME CHAR(30),
   SALARY DECIMAL(5,2),
   DEPTNO SMALLINT)
IN DSN8D10A.DSN8S10D;

```

Example 6: Assume a very large transaction table named TRANS contains one row for each transaction processed by a company. The table is defined with many columns. Create a materialized query table for the TRANS table that contain daily summary data for the date and amount of a transaction.

```

CREATE TABLE STRANS AS
  (SELECT YEAR AS SYEAR, MONTH AS SMONTH, DAY AS SDAY, SUM(AMOUNT) AS SSUM
   FROM TRANS
   GROUP BY YEAR, MONTH, DAY)
DATA INITIALLY DEFERRED REFRESH DEFERRED;

```

Example 7: The following example creates a table in a partition-by-growth table space and includes the APPEND option:

```

CREATE TABLE TS01TB
  (C1 SMALLINT,
   C2 DECIMAL(9,2),
   C3 CHAR(4))
APPEND YES
IN TS01DB.TS01TS;

```

Example 8: The following example creates a table in a partition-by-growth table space where the table space is implicitly created:

```

CREATE TABLE TS02TB
  (C1 SMALLINT,
   C2 DECIMAL(9,2),
   C3 CHAR(4))
PARTITION BY SIZE EVERY 4G
IN DATABASE DSADB04;

```

Example 9: Create a table, EMP_INFO, that contains a phone number and address for each employee. Include a row change timestamp column in the table to track the modification of employee information:

```

CREATE TABLE EMP_INFO
  (EMPNO CHAR(6) NOT NULL,
   EMP_INFOCHANGE NOT NULL
   GENERATED ALWAYS FOR EACH ROW ON UPDATE
   AS ROW CHANGE TIMESTAMP,
   EMP_ADDRESS VARCHAR(300),
   EMP_PHONENO CHAR(4),
   PRIMARY KEY (EMPNO));

```

Example 10: Create a table, TB01, that uses a range partitioning scheme with a segment size of 4 and 4 partitions.

```

CREATE TABLE TB01 (
  ACCT_NUM          INTEGER,
  CUST_LAST_NM     CHAR(15),
  LAST_ACTIVITY_DT VARCHAR(25),
  COL2              CHAR(10),
  COL3              CHAR(25),
  COL4              CHAR(25),
  COL5              CHAR(25),
  COL6              CHAR(55),
  STATE            CHAR(55))
IN DBB.TS01

PARTITION BY (ACCT_NUM)
(PARTITION 1 ENDING AT (199),
 PARTITION 2 ENDING AT (299),
 PARTITION 3 ENDING AT (399),
 PARTITION 4 ENDING AT (MAXVALUE));

```

Example 11: Create a table, policy_info, that uses a SYSTEM_TIME period and create a history table, hist_policy_info. Then issue an ALTER TABLE statement to associate the policy_info table with the hist_policy_info table.

```

CREATE TABLE policy_info
  (policy_id CHAR(10) NOT NULL,
   coverage INT NOT NULL,
   sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
   sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
   create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
   PERIOD SYSTEM_TIME(sys_start,sys_end));

CREATE TABLE hist_policy_info
  (policy_id CHAR(10) NOT NULL,
   coverage INT NOT NULL,
   sys_start TIMESTAMP(12) NOT NULL,
   sys_end TIMESTAMP(12) NOT NULL,
   create_id TIMESTAMP(12));

ALTER TABLE policy_info
  ADD VERSIONING USE HISTORY TABLE hist_policy_info;

```

Example 12: Create a table, policy_info, that uses a BUSINESS_TIME period.

```

CREATE TABLE policy_info
  (policy_id CHAR(4) NOT NULL,
   coverage INT NOT NULL,

```

```
| bus_start DATE NOT NULL,  
| bus_end DATE NOT NULL,  
| PERIOD BUSINESS_TIME(bus_start, bus_end));
```

Example 13: Create a table, `policy_info`, that uses both a `SYSTEM_TIME` period and a `BUSINESS_TIME` period to keep historical rows and track a user-specified time period. A table that specifies both a `SYSTEM_TIME` period and a `BUSINESS_TIME` period is sometimes referred to as a *bitemporal table*. To enable retention of historical rows, a history table, `hist_policy_info`, also needs to be created and associated (using the `ALTER TABLE` statement) with the `policy_info` table.

```
| CREATE TABLE policy_info  
| (policy_id CHAR(4) NOT NULL,  
| coverage INT NOT NULL,  
| bus_start DATE NOT NULL,  
| bus_end DATE NOT NULL,  
| sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,  
| sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,  
| create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,  
| PERIOD BUSINESS_TIME(bus_start, bus_end),  
| PERIOD SYSTEM_TIME(sys_start, sys_end));  
|  
| CREATE TABLE hist_policy_info  
| (policy_id CHAR(4) NOT NULL,  
| coverage INT NOT NULL,  
| bus_start DATE NOT NULL,  
| bus_end DATE NOT NULL,  
| sys_start TIMESTAMP(12) NOT NULL,  
| sys_end TIMESTAMP(12) NOT NULL),  
| create_id TIMESTAMP(12));  
|  
| ALTER TABLE policy_info  
| ADD VERSIONING USE HISTORY TABLE hist_policy_info;
```

CREATE TABLESPACE

The CREATE TABLESPACE statement defines a segmented, partitioned, or universal table space at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

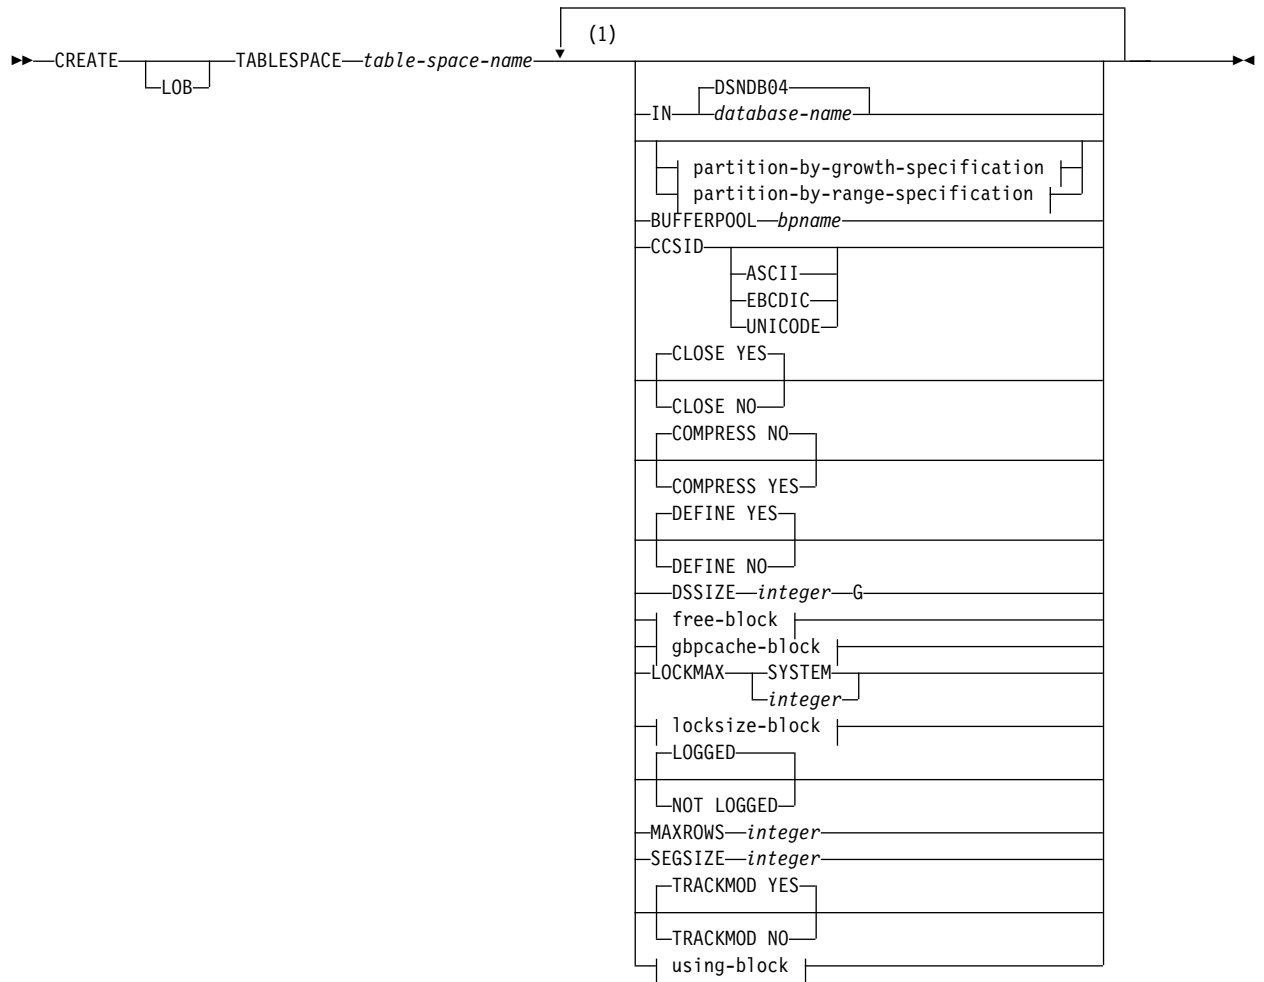

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax

Notes:

- 1 The same clause must not be specified more than one time.

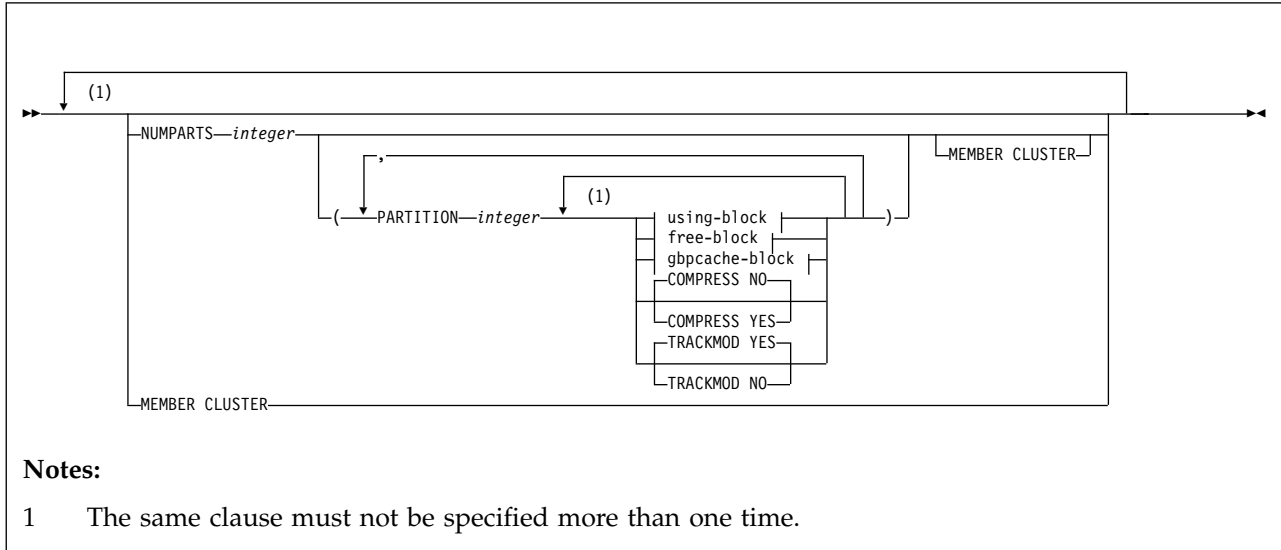

partition-by-growth-specification:

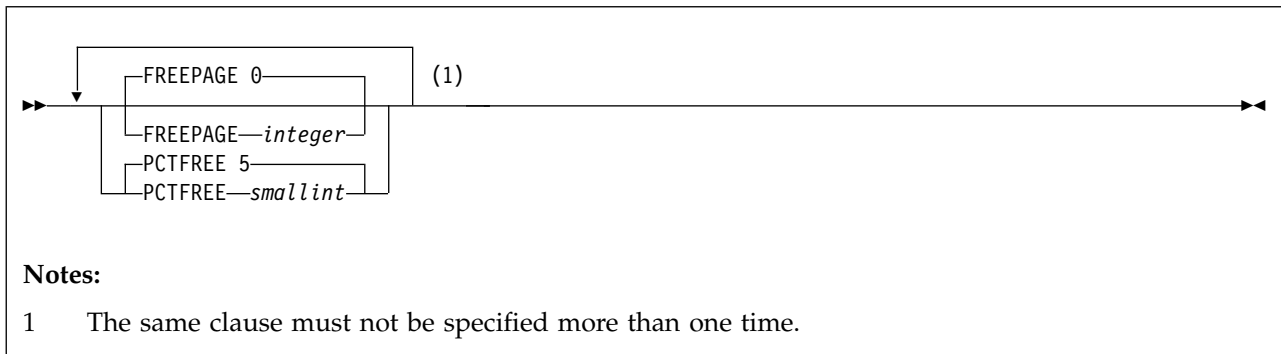

Notes:

- 1 The same clause must not be specified more than one time.

partition-by-range-specification:

free-block:

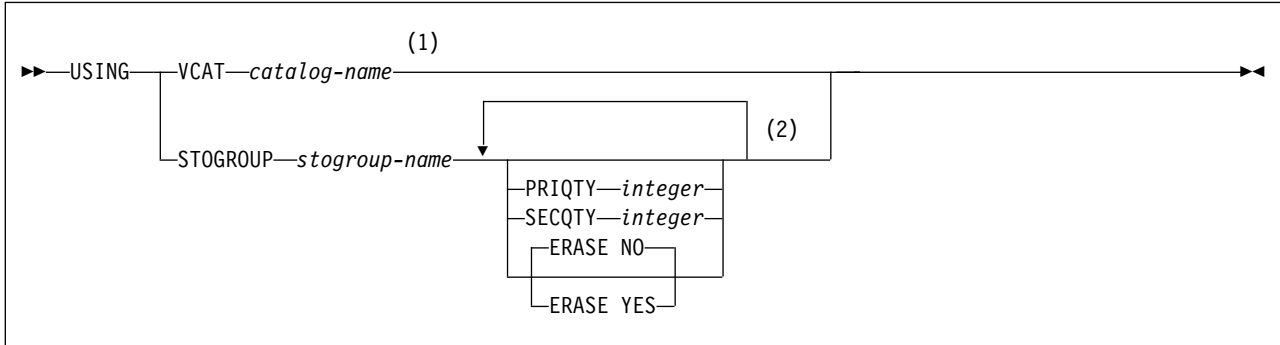

gbpcache-block:

locksize-block:

using-block:

Notes:

- 1 USING VCAT must not be specified if MAXPARTITIONS is also specified.
- 2 The same clause must not be specified more than one time.

Description

LOB

Identifies the table space as LOB table space. A LOB table space is used to hold LOB values.

The LOB table space must be in the same database as its associated base table space. Do not specify LOB for a table space in a work file database.

table-space-name

Names the table space. The name, qualified with the *database-name* implicitly or explicitly specified by the IN clause, must not identify a table space, index space, or LOB table space that exists at the current server or that exists in the SYSPENDINGOBJECTS catalog table.

A table space that is for declared temporary tables must be in the work file database. PUBLIC implicitly receives the USE privilege (without GRANT authority) on any table space created in the work file database. This implicit privilege is not recorded in the DB2 catalog, and it cannot be revoked.

IN *database-name*

Specifies the database in which the table space is created. *database-name* must identify a database that exists at the current server and must not specify the following:

- DSNDB06 for any type of table space
- A work file database for a LOB table space
- A TEMP database

- An implicitly created database

If the table space is for declared temporary tables or static scrollable cursors, the name of the work file database must be specified.

DSNDB04 is the default.

MAXPARTITIONS *integer*

Specifies that the table space is a partition-by-growth table space. The data set for the first partition is allocated unless the DEFINE NO clause is specified for the partition. The data sets for additional partitions are not allocated until they are needed.

integer specifies the maximum number of partitions to which the table space can grow. *integer* must be in the range of 1 to 4096, depending on the corresponding value of the DSSIZE clause. The following table shows the maximum value for MAXPARTITIONS in relation to the page size or DSSIZE value for the table space.

Table 177. Maximum value for MAXPARTITIONS given the page size or DSSIZE value for the table space

| DSSIZE value | 4K page size | 8K page size | 16K page size | 32K page size |
|------------------------|--------------|--------------|---------------|---------------|
| 1G - 4G (1 GB to 4 GB) | 4096 | 4096 | 4096 | 4096 |
| 8G (8 GB) | 2048 | 4096 | 4096 | 4096 |
| 16G (16 GB) | 1024 | 2048 | 4096 | 4096 |
| 32G (32 GB) | 512 | 1024 | 2048 | 4096 |
| 64G (64 GB) | 254 | 512 | 1024 | 2048 |
| 128G (128 GB) | 128 | 256 | 512 | 1024 |
| 256G (256 GB) | 64 | 128 | 256 | 512 |

If MAXPARTITIONS is specified for a table space in a work file database, the table space will be a partition-by-growth table space. If the DSSIZE or NUMPARTS clauses are not specified in addition to the MAXPARTITIONS clause for a table space in a work file database, the default values for DSSIZE and NUMPARTS will be used. If MAXPARTITIONS is not specified for a table space in a work file database, the table space will be a segmented table space.

Although physical data sets are not defined when the MAXPARTITIONS value is issued, there can be storage and cpu overhead. If an increase in the number of partitions is expected by using the MAXPARTITIONS clause, be aware that specifying an value larger than necessary, such as 4096 (the maximum value), as a default for all of your partition-by-growth table spaces can cause larger than expected storage requests.

MEMBER CLUSTER

Specifies that data inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. Instead, DB2 chooses where to locate the data in the table space based on available space.

Do not specify MEMBER CLUSTER for segmented table spaces.

Do not specify MEMBER CLUSTER for a LOB table space or a table space in a work file database.

MEMBER CLUSTER can be specified with MAXPARTITIONS.

NUMPARTS *integer*

integer

Specifies the number of partitions. If *n* is specified for a partition-by-growth table space, *integer* indicates the number of partitions that are initially created unless DEFINE NO is specified. *integer* must be a value between 1 and 4096 inclusive and must be less than or equal to the value that is specified for the MAXPARTITIONS clause.

The maximum size of each partition depends on the value that is specified for DSSIZE. If DSSIZE is not specified, the number of partitions that are specified determines the maximum size of each partition. For a summary of the values for the maximum size of each partition, see Table 178 on page 1783 and Table 179 on page 1783.

The maximum number of partitions that a table space with absolute numbering can have depends on the page size and DSSIZE. The total table space size depends on how many partitions it has and DSSIZE. Page size affects table size because it affects how many partitions a table space can have. Table 181 on page 1798 shows the maximum number of partitions for DSSIZE and page size and total table space size for both EA-enabled (extended addressability) and non-EA-enabled data sets. (Specifying a DSSIZE greater than 4GB requires EA-enabled data sets.)

For a description of the maximum size of a LOB table space (or the maximum size of LOB data for each column of a base table), see Large object table spaces (Introduction to DB2 for z/OS).

If you omit NUMPARTS and MAXPARTITIONS, the table space is segmented with a SEGSIZE of 4, LOCKSIZE ANY (unless it is explicitly specified), is not partitioned, and initially occupies one data set.

Do not specify NUMPARTS for a LOB table space. Do not specify NUMPARTS for a table space in a work file database unless the MAXPARTITIONS clause is also specified.

PARTITION *integer*

Specifies to which partition the following *using-block* or *free-block* applies. *integer* can range from 1 to the number of partitions given by NUMPARTS.

You can code the PARTITION clause (and any *using-block* or *free-block* that follows it) as many times as needed. If you use the same partition number more than once, only the last specification for that partition is used.

The PARTITION clause must not be specified if the table space is a partition-by-growth table space.

BUFFERPOOL *bpname*

Identifies the buffer pool to be used for the table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively. The *bpname* must identify an activated buffer pool, and the privilege set must include SYSADM or SYSCTRL authority, or the USE privilege on the buffer pool. If the table space is to be created in a work file database, you cannot specify 8KB and 16KB buffer pools.

If you do not specify the BUFFERPOOL clause, the default buffer pool of the database is used unless the table space that is being created is a LOB table space. If you do not specify the BUFFERPOOL clause and the table space that

is being created is a LOB table space, the default buffer pool is the buffer pool that is specified in the DEFAULT BUFFER POOL FOR USER LOB DATA field on installation panel DSNTIP1.

See “Naming conventions” on page 59 for more details about *bpname*. See `-ALTER BUFFERPOOL (DB2) (DB2 Commands)` for a description of active and inactive buffer pools.

CCSID *encoding-scheme*

Specifies the encoding scheme for tables stored in the table space.

If you do not specify a CCSID when it is allowed, the default is the encoding scheme of the database in which the table space resides, except for table spaces in database DSNDB04; for table spaces in DSNDB04, the default is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

ASCII Specifies that the data is to be encoded using ASCII CCSIDs. If the database in which the table space is to reside is already defined as ASCII, the ASCII CCSIDs associated with that database are used. Otherwise, the default ASCII CCSIDs of the server are used.

EBCDIC

Specifies that the data is to be encoded using EBCDIC CCSIDs.

UNICODE

Specifies that the data is to be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used.

All data stored within a table space must use the same encoding scheme unless the table space is in a work file database.

Do not specify CCSID for a LOB table space or a table space in a work file database. The encoding scheme for a LOB table space is inherited from the base table space. A table space in a work file database does not have an associated encoding scheme because the table space can contain created and declared temporary tables with a mixture of encoding schemes.

CLOSE

When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

YES

Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

NO Eligible for closing after all eligible CLOSE YES data sets are closed.

For a table space in a work file database, DB2 uses CLOSE NO regardless of the value specified.

COMPRESS

Specifies whether data compression applies to the rows of the table space or partition.

Do not specify COMPRESS for a LOB table space or a table space in a work file database.

For partitioned table spaces, the COMPRESS attribute for each partition is the value from the first of the following conditions that apply:

- The value specified in the COMPRESS clause in the PARTITION clause for the partition
- The value specified in the COMPRESS clause that is not in any PARTITION clause
- An implicit COMPRESS NO by default.

For more information about data compression, see *Compressing your data* (DB2 Performance).

YES

Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition, or until an insert operation is performed through the INSERT statement or the MERGE statement.

NO Specifies no data compression for the table space or partition.

DEFINE

Specifies when the underlying data sets for the table space are physically created.

YES

The data sets are created when the table space is created (the CREATE TABLESPACE statement is executed). YES is the default.

If MAXPARTITIONS is also specified, only the first partition is created when the table space is created. Additional partitions are created as needed.

NO The data sets are not created until data is inserted into the table space. DEFINE NO is applicable only for DB2-managed data sets (USING STOGROUP is specified). DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DB2 uses the SPACE column in catalog table SYSTABLEPART to record the status of the data sets (undefined or allocated).

Do not specify DEFINE NO for a table space in a work file database. DEFINE NO is not recommended if you intend to use any tools outside of DB2 to manipulate data, such as to load data, because data sets might then exist when DB2 does not expect them to exist. When DB2 encounters this inconsistent state, applications will receive an error.

For table spaces that are created with DEFINE NO, point-in-time recover will not work before data sets exist and before a recovery copy exists.

DSSIZE integer G

Specifies the maximum size for each partition, or for LOB table spaces, each data set. If you specify DSSIZE, you must also specify the NUMPARTS, MAXPARTITIONS, or LOB clause. Do not specify DSSIZE for a table space in a work file database unless MAXPARTITIONS is also specified.

The following values are valid:

- 1G** 1 gigabyte
- 2G** 2 gigabytes
- 4G** 4 gigabytes
- 8G** 8 gigabytes
- 16G** 16 gigabytes
- 32G** 32 gigabytes
- 64G** 64 gigabytes
- 128G** 128 gigabytes
- 256G** 256 gigabytes

To specify a value greater than 4G, the data sets for the table space must be associated with a DFSMS data class that has been specified with extended format and extended addressability.

If Numparts is also specified, the maximum size of each partition depends on the value of Numparts, as shown in the following table. Otherwise, the maximum size of each partition is 4G.

Table 178. Maximum partition size depending on value of Numparts

| Value of Numparts | Maximum partition size (default for DSSIZE) |
|-------------------|---|
| 1 to 16 | 4GB (4G) |
| 17 to 32 | 2GB (2G) |
| 33 to 64 | 1GB (1G) |
| 65 to 254 | 4GB (4G) |

If Numparts is greater than 254, the maximum partition size (and the default for DSSIZE) depends on the page size of the table space, as shown in the following table. The partition size shown is not necessarily the actual number of bytes used or allocated for any one partition; it is the largest number that can be logically addressed. Each partition occupies one data set.

Table 179. Maximum partition size depending on page size

| Page size | Maximum partition size (default for DSSIZE) |
|-----------|---|
| 4K | 4GB (4G) |
| 8K | 8GB (8G) |
| 16K | 16GB (16G) |
| 32K | 32GB (32G) |

If DSSIZE is explicitly specified, the maximum number of partitions that can be specified or is the default is limited by the maximum table space size. For example:

- For a partitioned table space with a 4K page size, if DSSIZE 64GB is specified, the maximum Numparts value is 256.
- For a partitioned table space with an 8K page size, if DSSIZE 64GB is specified, the maximum Numparts value is 512.
- For a partitioned table space with a 32K page size, if DSSIZE 128GB is specified, the maximum Numparts value is 1024.

See Table 181 on page 1798 for more information on the relationship between DSSIZE, Numparts, and the table space size.

For LOB table spaces, if DSSIZE is not specified, the default for the maximum size of each data set is 4GB. The maximum number of data sets is 254.

For a description of the maximum size of a LOB table space (or the maximum size of LOB data for each column of a base table), see Large object table spaces (Introduction to DB2 for z/OS).

FREEPAGE *integer*

Specifies how often to leave a page of free space when the table space or partition is loaded or reorganized. You must specify an integer in the range 0 to 255. If you specify 0, no pages are left as free space. Otherwise, one free page is left after every *n* pages, where *n* is the specified *integer* value. However,

if the table space is segmented and the integer you specify is not less than the segment size, *n* is one less than the segment size.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

The default is FREEPAGE 0, leaving no free pages. Do not specify FREEPAGE for a LOB table space or a table space in a work file database.

For XML table spaces, this change has no effect until data in the table space is reorganized.

FREEPAGE does not apply to hash-organized table spaces.

Related information:

Reserving free space for table spaces (DB2 Performance)

Reserving free spaces for indexes (DB2 Performance)

PCTFREE *smallint*

Indicates what percentage of each page to leave as free space when the table is loaded or reorganized. *smallint* is in the range from 0 to 99. The first record on each page is loaded without restriction. When additional records are loaded, at least *smallint* percent of free space is left on each page.

The default is PCTFREE 5, which means that 5% of the space on each page is reserved as free space. Do not specify PCTFREE for a LOB table space or a table space in a work file database.

For XML table spaces, this change has no effect until data in the table space is reorganized.

PCTFREE does not apply to table spaces for hash-organized tables except when AUTOESTSPACE(YES) is specified in a REORG TABLESPACE invocation.

If the table space is partitioned, the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that apply:

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition
- The values given in a *free-block* that is not in any PARTITION clause
- The default values are FREEPAGE 0 and PCTFREE 5.

Related information:

Reserving free space for table spaces (DB2 Performance)

Reserving free spaces for indexes (DB2 Performance)

GBPCACHE

In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or non-data-sharing).

CHANGED

When there is inter-DB2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W

interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

ALL

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating DB2 when no other DB2s have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

SYSTEM

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

Use SYSTEM only for a LOB table space.

NONE

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the table space or partition must not be in recover pending status and must be in the stopped state when the CREATE TABLESPACE statement is executed.

If the table space is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one *gbpcache-block* in any PARTITION clause.
2. The value given in a *gbpcache-block* that is not in any PARTITION clause.
3. The default value CHANGED.

LOCKMAX

Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented table is promoted to S or X mode. If you specify LOCKMAX for a table space in a work file database, DB2 ignores the value because these types of locks are not used.

integer

Specifies the number of locks allowed before escalating, in the range 0 to 2 147 483 647.

Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

SYSTEM

Indicates that the value of LOCKS PER TABLE(SPACE), on installation panel DSNTIPJ, specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

The following table summarizes the results of specifying a LOCKSIZE value while omitting LOCKMAX.

| LOCKSIZE | Resultant LOCKMAX |
|---|--------------------------|
| ANY | SYSTEM |
| TABLESPACE, TABLE, PAGE, 0 ROW, or LOB | |

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

For an application that uses Sysplex query parallelism, a lock count is maintained on each member.

LOCKSIZE

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not use this clause for a table space in a work file database.

ANY

Specifies that DB2 can use any lock size.

In most cases, DB2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (the NUMLKTS subsystem parameter), the page or LOB locks are released and locking is set at the next higher level.

If the table space is segmented, the next higher level is the table. If the table space is segmented and not partitioned, the next higher level is the table. If the table space is partitioned, the next higher level is the partition.

If the table space is implicitly created, DB2 uses LOCKSIZE ROW.

TABLESPACE

Specifies table space locks.

TABLE

Specifies table locks. Use TABLE only for a segmented table space. Do not use TABLE for a universal table space.

PAGE

Specifies page locks. Do not use PAGE for a LOB table space.

ROW

Specifies row locks. Do not use ROW for a LOB table space.

LOB

Specifies LOB locks. Use LOB only for a LOB table space.

LOGGED or NOT LOGGED

Specifies whether changes that are made to the data in the specified table space are recorded in the log.

LOGGED

Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables that are created in the specified table space and to all indexes of those tables. XML table spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

LOGGED cannot be specified for table spaces in DSNDB06 (the DB2 catalog) or in a work file database.

LOGGED is the default.

NOT LOGGED

Specifies that changes that are made to data in the specified table space are not recorded in the log. This parameter applies to all tables that are created in the specified table space and to all indexes of those tables. XML table spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space.

NOT LOGGED prevents undo and redo information from being recorded in the log; however, control information for the specified table space will continue to be recorded in the log.

NOT LOGGED cannot be specified for table spaces in the following databases:

- DSNDB06 (the DB2 catalog)
- a work file database

MAXROWS *integer*

Specifies the maximum number of rows that DB2 will consider placing on each data page. The integer can range from 1 through 255. This value is considered for insert operations, LOAD, and REORG. For LOAD and REORG (which do not apply for a table space in the work file database), the PCTFREE specification is considered before MAXROWS; therefore, fewer rows might be stored than the value you specify for MAXROWS.

If you do not specify MAXROWS, the default number of rows is 255.

Do not use MAXROWS for a LOB table space or a table space in a work file database.

SEGSIZE *integer*

Specifies the type of table space that will be created depending on the values of the SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses. *integer* specifies the number of pages that are to be assigned to each segment of the table space. *integer* must be a multiple of 4 between 0 and 64 (inclusive). *integer* cannot be 0 for an XML table space. Do not specify SEGSIZE for a LOB table space.

If SEGSIZE is not specified and only the NUMPARTS clause is specified, either a partitioned table space or a range-partitioned universal table space is created depending on the value of the DPSEGSZ subsystem parameter:

- If the value of DPSEGSZ is greater than 0 (zero), the table space will be a range-partitioned universal table with a SEGSIZE value that is equal to the value of DPSEGSZ.
- If the value of DPSEGSZ is equal to 0 (zero), the table space will be a partitioned table space.

If SEGSIZE is not specified and only the MAXPARTITIONS clause is specified, a partition-by-growth universal table space is created with a SEGSIZE that depends on the value of the DPSEGSZ subsystem parameter:

- If the value of DPSEGSZ is greater than 0 (zero), the table space will have a SEGSIZE value that is equal to the value of DPSEGSZ.
- If the value of DPSEGSZ is equal to 0 (zero), the table space will have a SEGSIZE value of 32.

The DPSEGSZ subsystem parameter has no effect on segmented table spaces.

The following table lists the type of table space depending on the specification of the SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses:

Table 180. Type of table space depending on value of SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses

| SEGSIZE clause | MAXPARTITIONS clause | NUMPARTS clause | Type of table space |
|-----------------------------|----------------------|-----------------|--|
| specified | specified | not specified | partition-by-growth table space |
| specified | not specified | not specified | segmented table space |
| specified | not specified | specified | range-partitioned universal table space |
| specified with a value of 0 | not specified | specified | partitioned table space |
| not specified | specified | specified | partition-by-growth table space <ul style="list-style-type: none"> • SEGSIZE = 32 if DPSEGSZ = 0 • SEGSIZE = <i>n</i> if DPSEGSZ = <i>n</i>, where <i>n</i> is a non-zero value for DPSEGSZ. |
| not specified | specified | not specified | partition-by-growth table space <ul style="list-style-type: none"> • SEGSIZE = 32 if DPSEGSZ = 0 • SEGSIZE = <i>n</i> if DPSEGSZ = <i>n</i>, where <i>n</i> is a non-zero value for DPSEGSZ. |
| not specified | not specified | specified | One of the following: <ul style="list-style-type: none"> • partitioned table space if DPSEGSZ is specified with a value of 0. • range-partitioned universal table space with a SEGSIZE = <i>n</i> if DPSEGSZ = <i>n</i>, where <i>n</i> is a non-zero value for DPSEGSZ. |
| not specified | not specified | not specified | segmented table space with an implicit specification of SEGSIZE 4 |

TRACKMOD

Specifies whether DB2 tracks modified pages in the space map pages of the

table space or partition. Do not specify TRACKMOD for a LOB table space. Do not specify TRACKMOD for a table space in a work file database.

YES

DB2 tracks changed pages in the space map pages to improve the performance of incremental image copy.

NO DB2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

If the table space is partitioned, the value of TRACKMOD for a particular partition is given by the first of these choices that applies:

1. The value of TRACKMOD given in the PARTITION clause for that partition.
2. The value given in a *trackmod-block* that is not in any PARTITION clause.
3. The default value YES.

If TRACKMOD is not specified, the default value as specified in the subsystem parameter IMPTKMOD is used.

The components of the USING block are discussed below, first for nonpartitioned table spaces and then for partitioned table spaces. If you omit USING, the default storage group of the database must exist.

USING block for nonpartitioned table spaces:

For nonpartitioned table spaces, the USING clause indicates whether the data set for the table space is defined by you or by DB2. If DB2 is to define the data set, the clause also gives space allocation parameters and an erase rule.

If you omit USING, DB2 defines the data sets using the default storage group of the database and the defaults for PRIQTY, SECQTY, and ERASE.

VCAT *catalog-name*

Specifies that the first data set for the table space is managed by the user, and following data sets, if needed, are also managed by the user.

The data sets defined for the table space are linear VSAM data sets cataloged in an integrated catalog facility catalog identified by *catalog-name*. An alias³⁵ must be used if the catalog name is longer than eight characters.

Conventions for table space data set names are given in *DB2 Administration Guide*. *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

VCAT must not be specified if MAXPARTITIONS is also specified.

STOGRUP *stogroup-name*

Specifies that DB2 will define and manage the data sets for the table space. Each data set will be defined on a volume of the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. The storage group supplies the name of a volume for the data set and the first-level qualifier for the data set name. The first-level qualifier is also the name of, or an alias³⁵ for, the integrated catalog facility catalog on which the data set is to

35. The alias of an integrated catalog facility catalog.

be cataloged. The naming conventions for the data set are the same as if the data set is managed by the user. As was mentioned above for VCAT, the first-level qualifier could cause naming conflicts if the local DB2 can share integrated catalog facility catalogs with other DB2 subsystems.

stogroup-name must identify a storage group that exists at the current server. SYSADM or SYSCTRL authority, or the USE privilege on the storage group, is required.

The description of the storage group must include at least one volume serial number, or it must indicate that the choice of volumes is left to Storage Management Subsystem (SMS). If volume serial numbers appear in the description, each must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must *not* contain an entry for the first data set of the table space. If the integrated catalog facility catalog is password protected, the description of the storage group must include a valid password.

PRIQTY *integer*

Specifies the minimum primary space allocation for a DB2-managed data set. *integer* must be a positive integer, or -1. In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is the value of *integer*.

However, the following exceptions exist:

For non-LOB table spaces, the exceptions are:

- For 4KB page sizes, if *integer* is greater than 0 and less than 12, *n* is 12.
- For 8KB page sizes, if *integer* is greater than 0 and less than 24, *n* is 24.
- For 16KB page sizes, if *integer* is greater than 0 and less than 48, *n* is 48.
- For 32KB page sizes, if *integer* is greater than 0 and less than 96, *n* is 96.
- For any page size, if *integer* is greater than 67108864, *n* is 67108864.

For LOB table spaces, the exceptions are:

- For 4KB page sizes, if *integer* is greater than 0 and less than 200, *n* is 200.
- For 8KB page sizes, if *integer* is greater than 0 and less than 400, *n* is 400.
- For 16KB page sizes, if *integer* is greater than 0 and less than 800, *n* is 800.
- For 32KB page sizes, if *integer* is greater than 0 and less than 1600, *n* is 1600.
- For any page size, if *integer* is greater than 67108864, *n* is 67108864.

If you do not specify PRIQTY, or specify PRIQTY with a value of -1, DB2 uses a default value for the primary space allocation; for information on how DB2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the

smallest multiple of p KB not less than n , where p is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. The amount of storage space requested must be available on some volume in the storage group based on VSAM space allocation restrictions. Otherwise, the primary space allocation will fail. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

Executing this statement causes only one data set to be created. However, you might have more data than this one data set can hold. DB2 automatically defines more data sets when they are needed. Regardless of the value in PRIQTY, when a data set reaches its maximum size, DB2 creates a new one. To enable a data set to reach its maximum size without running out of extents, it is recommended that you allow DB2 to automatically choose the value of the secondary space allocations for extents.

If you do choose to explicitly specify SECQTY, to avoid wasting space, use the following formula to make sure that PRIQTY and its associated secondary extent values do not exceed the maximum size of the data set:

$$\text{PRIQTY} + (\text{number of extents} * \text{SECQTY}) \leq \text{DSSIZE (implicit or explicit)}$$

SECQTY *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set. *integer* must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify SECQTY with a value of -1, DB2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of p KB not less than *integer*, where p is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE

Indicates whether the DB2-managed data sets for the table space or partition are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the table space.

NO Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2. This is the default.

YES

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

USING block for partitioned table spaces:

If the table space is partitioned, there is a USING clause for each partition; either one you give explicitly or one provided by default. Except as explained below, the meaning of the clause and the rules that apply to it are the same as for a nonpartitioned table space.

The USING clause for a particular partition is the first of these choices that can be found:

- A USING clause in the PARTITION clause for the partition
- A USING clause that is not in any PARTITION clause
- An implicit USING STOGROUP clause that identifies the default storage group of the database and accepts the defaults for PRIQTY, SECQTY, and ERASE

VCAT *catalog-name*

Indicates that the data set for the partition is managed by the user using the naming conventions set forth in *DB2 Administration Guide*. As was true for the nonpartitioned case, *catalog-name* identifies the catalog for the data set and supplies the first-level qualifier for the data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

STOGROUP *stogroup-name*

Indicates that DB2 will create a data set for the partition with the aid of a storage group named *stogroup-name*. The data set is defined during the execution of this statement. DB2 assumes one and only one data set for each partition.

The *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. The integrated catalog facility catalog used for the storage group must *not* contain an entry for that data set.

When USING STOGROUP is specified for a partition, the defaults for PRIQTY, SECQTY, and ERASE are the values specified in the USING STOGROUP clause that is not in any PARTITION clause. If that USING STOGROUP clause is not specified, the defaults are those specified in the description of PRIQTY, SECQTY, and ERASE.

Notes

Segmented table spaces:

If neither LOB, NUMPARTS, nor SEGSIZE are specified, the table space that is created is a segmented table space.

Related links: Types of DB2 table spaces (Introduction to DB2 for z/OS)

Universal table spaces:

If NUMPARTS and SEGSIZE are specified, the table space that is created is a range-partitioned universal table space. If MAXPARTITIONS or MAXPARTITIONS and SEGSIZE are specified, the table space that is created is a partition-by-growth universal table space. If a range-partitioned universal table space contains an XML column, the corresponding XML table space will be range-partitioned universal as well.

Related links: Universal table spaces (Introduction to DB2 for z/OS)

Applications that use currently committed access with table spaces that specify LOCKSIZE PAGE:

To ensure that readers of data in a table space that is defined with LOCKSIZE PAGE can always access currently committed data, set MAXROWS to 8 or less. If MAXROWS is greater than 8, readers might need to wait for insert or delete operations on tables in the table space to commit before the readers can access rows in the tables.

Related links: Accessing currently committed data to avoid lock contention (DB2 Performance)

Table spaces in a work file database:

The following restrictions apply to table spaces created in a work file database:

- They can be created for another member only if both the executing DB2 subsystem and the other member can access the work file data sets. That is required whether the data sets are user-managed or in a DB2 storage group.
- They cannot use 8 KB or 16 KB page sizes. (The buffer pool in which you define the table space determines the page size. For example, a table space that is defined in a 4 KB buffer pool has 4 KB page sizes.)
- When you create a table space in a work file database, the following clauses are not allowed:

| | | |
|---------------------|----------|-----------------------|
| CCSID | LARGE | MEMBER CLUSTER |
| COMPRESS | LOB | NOT LOGGED |
| DEFINE NO | LOCKPART | NUMPARTS ¹ |
| DSSIZE ¹ | LOCKSIZE | PCTFREE |
| FREEPAGE | LOGGED | TRACKMOD |
| GBPCACHE | MAXROWS | |

1: DSSIZE and NUMPARTS must not be specified for a table space in a work file database unless MAXPARTITIONS is also specified.

Table spaces for declared temporary tables:

Declared temporary tables and sensitive static scrollable cursors must reside in segmented table spaces in the work file database. At least one table space with a 32KB page size must exist in the work file database before a declared temporary table can be defined and used or before sensitive static scrollable cursors are opened.

Table spaces in the work file database are shared by work files, created and declared global temporary tables and sensitive static scrollable cursor result tables. You cannot specify which table space is to be used for any specific object.

When you create table spaces in the work file database, it is recommended that you give each table space the same segment size, with the same minimum primary and secondary space allocation values for the data sets, to maximize the use of all the table spaces for all objects in all application processes.

Creating LOB table spaces:

When you create a LOB table space, the following clauses are not allowed:

| | | |
|----------------|---------------|----------|
| CCSID | LOCKSIZE PAGE | PCTFREE |
| COMPRESS | LOCKSIZE ROW | SEGSIZE |
| FREEPAGE | MAXPARTITIONS | TRACKMOD |
| LOCKSIZE TABLE | NUMPARTS | |

Recommended GBPCACHE setting for LOB table spaces:

For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

Altering the logging attribute of a table space:

See “ Notes ” on page 1404 of “ALTER TABLESPACE” on page 1389 for information about altering the logging attributes of a table space.

Table space row formats:

Depending on the value of the RRF subsystem parameter, newly created table spaces will be in either re-ordered row format or basic row format. When the value of the RRF parameter is ENABLE, table spaces will be created in re-ordered row format. When the value of the RRF parameter is DISABLE, newly created table spaces will be created in basic row format. This includes universal table spaces, except for XML table spaces and hash table spaces, which are always created in re-ordered row format, regardless of the value of the RRF parameter.

Making a partitioned table space larger:

Depending on the needs of your application, you might need to increase the size of a partitioned table space to hold more data by either adding more partitions or by increasing the size of the existing partitions:

- To add more partitions, use the ALTER TABLE statement with the ADD PARTITION clause.
- To increase the size of the partitions, use the following steps:
 - If the table space is a range-partitioned universal table space, specify a larger DSSIZE using the ALTER TABLESPACE statement if the DSSIZE of the table space is not already at the maximum.
 - If the table space is not a range-partitioned universal table space:
 1. Convert the table space to a range-partitioned universal table space by specifying a SEGSIZE value and a NUMPARTS value using the ALTER TABLESPACE statement
 2. Run the REORG utility with the SHRLEVEL CHANGE or SHRLEVEL REFERENCE option on the table space to apply the new SEGSIZE value
 3. Specify a larger DSSIZE using the ALTER TABLESPACE statement

Related links:

“ALTER TABLESPACE” on page 1389
 REORG TABLESPACE (DB2 Utilities)

Redistributing data between existing partitions:

If you need to redistribute the data between the existing partitions to make better use of the space within the existing table, you can use either of these two methods:

- Use the ALTER TABLE statement with the ALTER PARTITION clause. You can alter the partitions to specify new partition boundaries to explicitly specify how to redistribute the data. Any affected partitions are set to REORG-pending status.
- Use the REORG utility with the REBALANCE keyword. REBALANCE specifies that the data is evenly redistributed across the partitions that are reorganized. See REORG TABLESPACE (DB2 Utilities) for information about using the REORG utility.

Rules for primary and secondary space allocation:

You can specify the primary and secondary space allocation for table spaces and indexes or allow DB2 to choose them. Having DB2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents.

In the following rules that describe how allocation works, these terms are used:

PRIQTY, SECQTY

The keywords for CREATE TABLESPACE, ALTER TABLESPACE, CREATE INDEX, and ALTER INDEX.

specified-priqty

The user-specified value for PRIQTY.

specified-secqty

The user-specified value for SECQTY.

actual-priqty

The actual primary space allocation, in kilobytes.

actual-priqty-cylinders

The actual primary space allocation, in cylinders.

actual-secqty

The actual secondary space allocation, in kilobytes.

actual-secqty-cylinders

The actual secondary space allocation, in cylinders.

calculated-extent-cylinders

A value that is calculated by DB2 using a *sliding scale*. A sliding scale means that the first secondary extent allocations are smaller than later secondary allocations. For example, Figure 35 on page 1796 shows the sliding scale of secondary extent allocations that DB2 uses for a 64-GB data set. The size of each secondary extent is larger for each secondary extent that is allocated up to the 127th extent. For the 127th secondary extent and any subsequent extents, the secondary size allocation is 559 cylinders.

Figure 35. Sliding scale allocation of secondary extents for a 64 GB data set

The rules are:

- **Rule 1 (for primary space allocation)**

If PRIQTY is specified and *specified-priqty* is not equal to -1, *actual-priqty* is at least *specified-priqty* KB.

If PRIQTY is not specified or *specified-priqty* is equal to -1, *actual-priqty* is determined as follows:

- For a table space, if the TSQTY subsystem parameter value is specified and is greater than 0, *actual-priqty* is at least the value of TSQTY.

If the TSQTY subsystem parameter is not specified or is 0, *actual-priqty* is one cylinder for a non-LOB table space. *actual-priqty* is 10 cylinders for a LOB table space.

- For an index, if the IXQTY subsystem parameter value is specified and is greater than 0, *actual-priqty* is at least the value of IXQTY.

If the IXQTY subsystem parameter is not specified or is 0, *actual-priqty* is one cylinder.

- **Rule 2 (for secondary space allocation)**

If SECQTY is not specified, the following formulas determine *actual-secqty*:

- If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:

$actual-secqty-cylinders = \text{MAX}(0.1 * actual-priqty-cylinders, \text{MIN}(calculated-extent-cylinders, 127))$

- If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:

$actual-secqty-cylinders = \text{MAX}(0.1 * actual-priqty-cylinders, \text{MIN}(calculated-extent-cylinders, 559))$

- **Rule 3 (for secondary space allocation)**

If SECQTY is 0, *actual-secqty* is 0.

- **Rule 4 (for secondary space allocation)**

This is the only rule that depends on the value of subsystem parameter MGEXTSZ (field OPTIMIZE EXTENT on installation panel DSNTIP7).

If MGEXTSZ is YES:

- If SECQTY is specified and *specified-secqty* is not equal to -1 or 0, the following formulas determine *actual-secqty*:
 - If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:

$$\text{actual-secqty-cylinders} = \text{MAX}(\text{MIN}(\text{calculated-extent-cylinders}, 127), \text{specified-secqty-cylinders})$$
 - If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:

$$\text{actual-secqty-cylinders} = \text{MAX}(\text{MIN}(\text{calculated-extent-cylinders}, 559), \text{specified-secqty-cylinders})$$

If MGEXTSZ is NO:

- For a table space, if SECQTY is *n*, the secondary space allocation is at least *n* kilobytes, with the following exceptions:
 - If SECQTY is greater than 4194304, *n* is 4194304 kilobytes.
 - For LOB table spaces:
 - For 4KB page sizes, if *integer* is greater than 0 and less than 200, *n* is 200.
 - For 8KB page sizes, if *integer* is greater than 0 and less than 400, *n* is 400.
 - For 16KB page sizes, if *integer* is greater than 0 and less than 800, *n* is 800.
 - For 32KB page sizes, if *integer* is greater than 0 and less than 1600, *n* is 1600.
 - For any page size, if *integer* is greater than 4194304, *n* is 4194304.
- For an index, if SECQTY is *integer*, the secondary space allocation is at least *n* kilobytes, where *n* is:

| | |
|----------------|---|
| 12 | If SECQTY and PRIQTY are omitted |
| 4194304 | If <i>integer</i> is greater than 4194304 |
| <i>integer</i> | If <i>integer</i> is not greater than 4194304 |

- **Rule 5 (for secondary space allocation):** When a table space requires a new piece, the primary allocation quantity of the new piece is determined as follows:

- If the value of subsystem parameter MGEXTSZ is NO, the primary quantity from rule 1 is used.
- Otherwise, the maximum of the following values is used:
 - The quantity that is calculated through sliding scale methodology
 - The primary quantity from rule 1
 - The specified SECQTY value

Determining the maximum number of partitions that a table space with absolute numbering can have

Table 181. Table space size given page size and partitions (for table spaces with absolute numbering)

| Type of RID | Page size | DSSIZE | Maximum number of partitions | Total table space size |
|-----------------------|-----------|--------|------------------------------|------------------------|
| 5-byte EA | 4KB | 1GB | 4096 | 4TB |
| 5-byte EA | 4KB | 2GB | 4096 | 8TB |
| 5-byte EA | 4KB | 4GB | 4096 | 16TB |
| 5-byte EA | 4KB | 8GB | 2048 | 16TB |
| 5-byte EA | 4KB | 16GB | 1024 | 16TB |
| 5-byte EA | 4KB | 32GB | 512 | 16TB |
| 5-byte EA | 4KB | 64GB | 256 | 16TB |
| 5-byte EA | 4KB | 128GB | 128 | 16TB |
| 5-byte EA | 4KB | 256GB | 64 | 16TB |

| 5-byte EA | 32KB | 16GB | 4096 | 64TB |
| 5-byte EA | 32KB | 32GB | 4096 | 128TB |
| 5-byte EA | 32KB | 64GB | 2048 | 128TB |
| 5-byte EA | 32KB | 128GB | 1024 | 128TB |
| 5-byte EA | 32KB | 256GB | 512 | 128TB |
| 5-byte (non-EA) LARGE | 4KB | (4GB) | 4096 | 16TB |

Alternative syntax and synonyms:

For compatibility with previous releases of DB2, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. Starting with Version 8, DB2 treats all table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, DB2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, DB2 locks every partition of the table space.
LOCKSIZE TABLESPACE and LOCKPART YES are mutually exclusive.
- When creating a partitioned table space, you can specify PART as a synonym for PARTITION.
- When specifying the logging attributes for a table space, you can specify LOG YES as a synonym for LOGGED, and you can specify LOG NO as a synonym for NOT LOGGED.
- You can specify the LARGE clause when creating partitioned table spaces, but DSSIZE is the preferred clause to use when specifying the partition size.

Although these keywords are supported as alternatives, they are not the preferred syntax.

Examples

Example 1: Create table space DSN8S10D in database DSN8D10A. Let DB2 define the data sets, using storage group DSN8G100. The primary space allocation is 52 kilobytes; the secondary, 20 kilobytes. The data sets need not be erased before they are deleted.

Locking on tables in the space is to take place at the page level. Associate the table space with buffer pool BP1. The data sets can be closed when no one is using the table space.

```
CREATE TABLESPACE DSN8S10D
  IN DSN8D10A
  USING STOGROUP DSN8G100
  PRIQTY 52
  SECQTY 20
  ERASE NO
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE YES;
```

For the above example, the underlying data sets for the table space will be created immediately, which is the default (DEFINE YES). If you want to defer the creation of the data sets until data is first inserted into the table space, you would specify DEFINE NO instead of accepting the default behavior.

Example 2: Assume that a large query database application uses a table space to record historical sales data for marketing statistics. Create large table space SALESHX in database DSN8D10A for the application. Create it with 82 partitions, specifying that the data in partitions 80 through 82 is to be compressed.

Let DB2 define the data sets for all the partitions in the table space, using storage group DSN8G100. For each data set, the primary space allocation is 4000 kilobytes,

and the secondary space allocation is 130 kilobytes. Except for the data set for partition 82, the data sets do not need to be erased before they are deleted.

Locking on the table is to take place at the page level. There can only be one table in a partitioned table space. Associate the table space with buffer pool BP1. The data sets cannot be closed when no one is using the table space. If there are no CLOSE YES data sets to close, DB2 might close the CLOSE NO data sets when the DSMAX is reached.

```
CREATE TABLESPACE SALESX
  IN DSN8D10A
  USING STOGROUP DSN8G100
  PRIQTY 4000
  SECQTY 130
  ERASE NO
  NUMPARTS 82
  (PARTITION 80
   COMPRESS YES,
  PARTITION 81
   COMPRESS YES,
  PARTITION 82
   COMPRESS YES
   ERASE YES)
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE NO;
```

Example 3: Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to the sample employee table for each employee's photo. Create LOB table space PHOTOLTS in database DSN8D10A for the auxiliary table that will hold the BLOB data.

Let DB2 define the data sets for the table space, using storage group DSN8G100. For each data set, the primary space allocation is 3200 kilobytes, and the secondary space allocation is 1600 kilobytes. The data sets do not need to be erased before they are deleted. (Because ERASE NO is the default, the clause does not have to be explicitly specified to get that behavior.)

```
CREATE LOB TABLESPACE PHOTOLTS
  IN DSN8D10A
  USING STOGROUP DSN8G100
  PRIQTY 3200
  SECQTY 1600
  LOCKSIZE LOB
  BUFFERPOOL BP16K0
  GBPCACHE SYSTEM
  NOT LOGGED
  CLOSE NO;
```

Example 4: The following example creates a range-partitioned universal table space, TS1, in database DSN8D10A using storage group DSN8G100. The table space has 16 pages per segment and has 55 partitions. It specifies LOCKSIZE ANY.

```
CREATE TABLESPACE TS1
  IN DSN8D10A
  USING STOGROUP DSN8G100
  NUMPARTS 55
  SEGSIZE 16
  LOCKSIZE ANY;
```

Example 5: The following example creates a range-partitioned universal table space, TS2, in database DSN8D10A using storage group DSN8G100. The table space has 64 pages per segment and has seven defer-defined partitions, where every other partition is compressed.

```
CREATE TABLESPACE TS2
  IN DSN8D10A
  USING STOGROUP DSN8G100
  Numparts 7
  (
    PARTITION 1 COMPRESS YES,
    PARTITION 3 COMPRESS YES,
    PARTITION 5 COMPRESS YES,
    PARTITION 7 COMPRESS YES
  )
  SEGSize 64
  DEFINE NO;
```

Example 6: The following example creates a partition-by-growth table space that has a maximum size of 2 GB for each partition, four pages per segment with a maximum of 24 partitions for the table space.

```
CREATE TABLESPACE TS01TS IN TS01DB USING STOGROUP SG1
  DSSize 2G
  MAXPARTITIONS 24
  LOCKSIZE ANY
  SEGSize 4;
```

CREATE TRIGGER

The CREATE TRIGGER statement defines a trigger in a schema and builds a trigger package at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

In defining a trigger on a table, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the table on which the trigger is defined, if the REFERENCING clause is included in the trigger definition
- The SELECT privilege on any table or view in the *search-condition* of the *triggered-action*
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the table, which must include at least one of the following:
 - The TRIGGER privilege on the table on which the trigger is defined
 - The ALTER privilege on the table on which the trigger is defined
 - DBADM authority on the database that contains the table
 - SYSCTRL authority
 - System DBADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

In defining a trigger on a view, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the view on which the trigger is defined, if the REFERENCING clause is included in the trigger definition
- The SELECT privilege on any table or view in the *search-condition* of the *triggered-action*
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the view, which must include at least one of the following:
 - Ownership of the view on which the trigger is defined
 - SYSCTRL authority
 - System DBADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the `ROLE AS OBJECT OWNER` clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

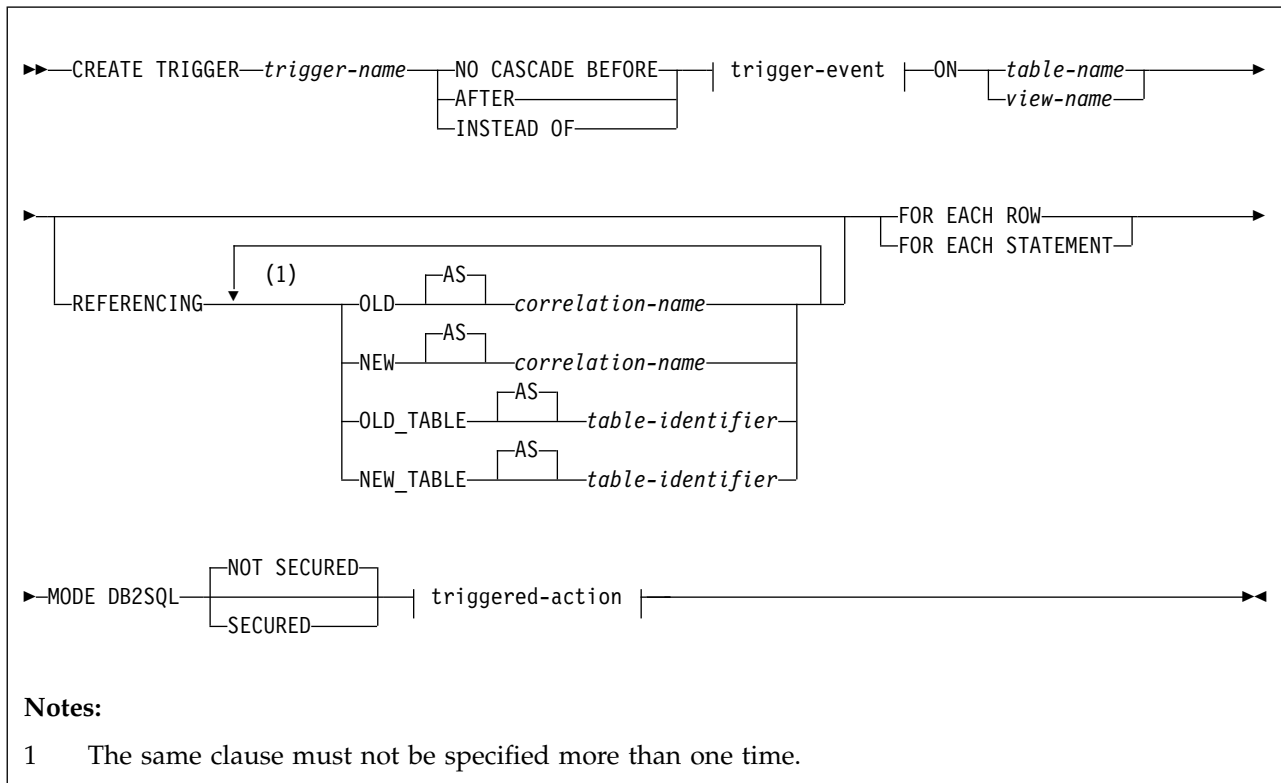

- The privilege set includes `SYSADM` or `SYSCTRL` authority.
- The SQL authorization ID of the process has the `CREATEIN` privilege on the schema.

At least one of the following privileges is required if the `SECURED` option is specified:

- `SECADM` authority
- `CREATE_SECURE_OBJECT` privilege

Note: If the `SEPARATE SECURITY` subsystem parameter is set to `NO`, `SYSADM` authority has implicit `SECADM` authority.

Syntax

trigger-event

triggered-action

SQL-trigger-body

Description

trigger-name

Names the trigger. The name, including the implicit or explicit schema name, must not identify a trigger that exists at the current server.

The name is also used to create the trigger package; therefore, the name must also not identify a package that is already described in the catalog. The schema name becomes the collection-id of the trigger package. Although *trigger-name* can be specified as an ordinary or delimited identifier, the name should conform to the rules for an ordinary identifier. Refer to The implicitly created trigger package for additional information.

The schema name must not begin with 'SYS' unless the name is 'SYSADM', or the schema name is 'SYSTOOLS' and the user who executes the CREATE statement has SYSADM or SYSCTRL privilege.

NO CASCADE BEFORE

Specifies that the trigger is a before trigger. DB2 executes the triggered action before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the triggered action does not activate other triggers because the triggered action of a before trigger cannot contain any updates.

NO CASCADE BEFORE must not be specified when *view-name* is also specified. FOR EACH ROW must be specified for a BEFORE trigger.

AFTER

Specifies that the trigger is an after trigger. DB2 executes the triggered action after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified if *view-name* is also specified.

INSTEAD OF

Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each type of operation on a given subject view. DB2 executes the *triggered-action* instead of the insert, update, or delete operation on the subject view.

INSTEAD OF must not be specified when *table-name* is also specified. The WHEN clause can not be specified for an INSTEAD OF trigger. FOR EACH STATEMENT must not be specified for an INSTEAD OF trigger.

ON *table-name*

Identifies the subject table of the BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server. It must not identify a materialized query table, a clone table, a temporary table, an auxiliary table, an alias, a synonym, a real-time statistics table, an accelerator-only table, or a catalog table.

ON *view-name*

Identifies the subject view of the INSTEAD OF trigger definition. The name must identify a view that exists at the current server.

view-name must not specify a view where any of the following conditions are true:

- The view is defined with the WITH CASCADED CHECK option (a symmetric view)
- The view on which a symmetric view has been defined
- The view references data that is encoded with different encoding schemes or CCSID values
- The view has a column that is a ROWID column
- The view has a column that is based on an underlying column of any of the following types:
 - A LOB, XML, or ROWID column
 - An identity column
 - A security label column
 - A row change timestamp column
 - A row-begin column
 - A row-end column
 - A transaction start ID column
- The view has columns that have field procedures
- All of the underlying tables of the view are catalog tables
- All of the underlying tables of the view are created global temporary tables
- All of the underlying tables of the view are clone tables
- The view has other views that are dependent on it

REFERENCING

Specifies the correlation names for the transition variables and the table names for the transition tables. For the rows in the subject table that are modified by the triggering SQL operation (insert, delete, or update), a correlation name identifies the columns of a specific row. *table-identifiers* identify the complete set of affected rows. Transition variables with XML types cannot be referenced inside of a trigger. If the column of a transition table is referenced, the data type of the column cannot be XML.

Each row that is affected by the triggering SQL operation is available to the triggered action by qualifying column names with *correlation-names* that are specified as follows:

OLD AS *correlation-name*

Specifies the correlation name that identifies the values in the row prior to the triggering SQL operation.

NEW AS *correlation-name*

Specifies the correlation name that identifies the values in the row as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed.

The complete set of rows that are affected by the triggering operation is available to the triggered action by using *table-identifiers* that are specified as follows:

OLD_TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows that are modified rows by the triggering SQL operation prior to any actual changes.

NEW_TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed.

Only one OLD and one NEW *correlation-name* can be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE *table-identifier* can be specified for a trigger. All of the *correlation-names* and *table-identifiers* must be unique from one another.

Table 182 on page 1807 summarizes the allowable combinations of transition variables and transition tables that you can specify for the various trigger types. The OLD *correlation-name* and the OLD_TABLE *table-identifier* are valid only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD *correlation-name* captures the values of the columns in the deleted row, and the OLD_TABLE *table-identifier* captures the values in the set of deleted rows. For an update operation, the OLD *correlation-name* captures the values of the columns of a row before the update operation, and the OLD_TABLE *table-identifier* captures the values in the set of updated rows.

The NEW *correlation-name* and the NEW_TABLE *table-identifier* are valid only if the triggering event is either an insert operation or an update operation. For both operations, the NEW *correlation-name* captures the values of the columns in the inserted or updated row and the NEW_TABLE *table-identifier* captures the values in the set of inserted or updated rows. For BEFORE triggers, the values of the updated rows include the changes from any SET statements in the triggered action of BEFORE triggers.

Table 182. Allowable combinations of attributes in a trigger definition

| Granularity | Activation time | Triggering SQL operation | Transition variables allowed1 | Transition tables allowed1 |
|--------------------|-----------------|--------------------------|-------------------------------|----------------------------|
| FOR EACH ROW | BEFORE | DELETE | OLD | None |
| | | INSERT | NEW | None |
| | | UPDATE | OLD, NEW | None |
| | AFTER | DELETE | OLD | OLD_TABLE |
| | | INSERT | NEW | NEW_TABLE |
| | | UPDATE | OLD, NEW | OLD_TABLE, NEW_TABLE |
| | INSTEAD OF | DELETE | OLD | OLD_TABLE |
| | | INSERT | NEW | NEW_TABLE |
| | | UPDATE | OLD, NEW | OLD_TABLE, NEW_TABLE |
| FOR EACH STATEMENT | AFTER | DELETE | None | OLD_TABLE |
| | | INSERT | None | NEW_TABLE |
| | | UPDATE | None | OLD_TABLE, NEW_TABLE |

Note:

1. If a transition table or variable is referenced where it is not allowed, an error is returned.

A transition variable that has a character data type inherits the subtype and CCSID of the column of the subject table. During the execution of the triggered action, the transition variables are treated like host variables. Therefore, character conversion might occur. However, unlike a host variable, a transition variable can have the bit data attribute, and character conversion never occurs for bit data. A transition variable is considered to be bit data if the column of the table to which it corresponds is bit data.

You cannot modify a transition table; transition tables are read-only. Although a transition table does not inherit any edit or validation procedures from the subject table, it does inherit the encoding scheme and field procedures of the subject table.

The scope of each *correlation-name* and each *table-identifier* is the entire trigger definition.

FOR EACH ROW or FOR EACH STATEMENT

Specifies the conditions for which DB2 executes the triggered action.

FOR EACH ROW

Specifies that DB2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed.

FOR EACH STATEMENT

Specifies that DB2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.

MODE DB2SQL

Specifies the mode of the trigger. MODE DB2SQL triggers are activated after all of the row operations have occurred.

NOT SECURED or SECURED

Specifies whether the trigger is considered secure. NOT SECURED is the default.

SECURED

Specifies the trigger is considered secure.

SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies the trigger is considered not secure.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

trigger-event

Specifies that the triggered action that is associated with the trigger is to be executed when the trigger event is applied to the subject table or view.

INSERT

Specifies that the trigger is an insert trigger. DB2 executes the triggered action whenever there is an insert operation on the subject table. However, if the insert trigger is defined on any explain table, and the insert operation was caused by DB2 adding a row to the table, the triggered action is not to be executed.

DELETE

Specifies that the trigger is a delete trigger. DB2 executes the triggered action whenever there is a delete operation on the subject table.

UPDATE

Specifies that the trigger is an update trigger. DB2 executes the triggered action whenever there is an update operation on the subject table.

If you do not specify a list of column names, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the triggered action.

OF *column-name*,...

Each *column-name* that you specify must be a column of the subject table and must appear in the list only once. An update operation on any of the listed columns activates the triggered action.

UPDATE OF *column-name* cannot be specified for an INSTEAD OF trigger.

triggered-action

Specifies the action to be performed when the trigger is activated. The *triggered-action* is composed of one or more SQL statements and an optional condition that controls whether the statements are executed.

WHEN (*search-condition*)

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the *search-condition* evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed.

The WHEN clause must not be specified for an INSTEAD OF trigger.

SQL-trigger-body

Specifies the SQL statements that are to be executed for the triggered action.

triggered-SQL-statement

Specifies the SQL statements that can be specified as the only statement in a trigger body.

BEGIN ATOMIC *triggered-SQL-statement*, ... END

Specifies a list of SQL statements that are to be executed for the triggered action. The statements are executed in the order in which they are specified.

Only certain SQL statements can be specified in the *SQL-trigger-body*.

Table 183. Allowable SQL statements

| SQL statement | Trigger activation time | | |
|----------------------------|-------------------------|-------|------------|
| | BEFORE | AFTER | INSTEAD OF |
| CALL | X | X | X |
| DELETE (<i>searched</i>) | | X | X |
| fullselect | X | X | X |
| INSERT | | X | X |
| MERGE | | X | X |
| REFRESH TABLE | | X | X |
| SET transition variable | X | | |
| SIGNAL | X | X | X |
| TRUNCATE | | X | X |
| UPDATE (<i>searched</i>) | | X | X |
| VALUES | X | X | X |

The statements in the triggered action have these restrictions:

- They must not refer to host variables, parameter markers, undefined transition variables, or declared temporary tables.
- They must only refer to a table or view that is at the current server.
- They must only invoke a stored procedure or user-defined function that is at the current server. An invoked routine can, however, access a server other than the current server.
- They must not contain a fullselect that refers to the subject table if the trigger is defined as BEFORE.
- They must not modify a column that is part of a BUSINESS_TIME period.
- If the trigger is a before trigger:

- The trigger body must not contain a DELETE, INSERT, MERGE, REFRESH TABLE, TRUNCATE, UPDATE statement, or SELECT FROM *data-change-statement*, and must not reference a procedure or function that is defined as MODIFIES SQL DATA.
- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure containing one of the following statements:
 - ALTER
 - COMMENT
 - CREATE
 - DELETE
 - DROP
 - EXCHANGE
 - GRANT
 - LABEL
 - LOCK TABLE
 - MERGE
 - REFRESH TABLE
 - RENAME
 - REVOKE
 - TRUNCATE
 - UPDATE

A CREATE TRIGGER statement cannot contain a hexadecimal graphic string (GX) constant.

The triggered action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

All tables, views, aliases, sequences, roles, user-defined data types, user-defined functions, and procedures referenced in the *triggered-action* must exist at the current server when the version of the trigger is defined. The table or view that an alias refers to must also exist when the version of the trigger is defined.

Notes

Owner privileges:

When an INSTEAD OF trigger is defined, the associated privilege (INSERT, UPDATE, or DELETE on the view) is given to the owner of the view. The owner is granted the privilege with the ability to grant that privilege to others. For more information about ownership of an object, see “Authorization, privileges, permissions, masks, and object ownership” on page 70.

Execution authorization:

The user executing the triggering SQL operation does not need authority to execute a *SQL-trigger-body*. An *SQL-trigger-body* executes using the authority of the owner of the trigger.

Activating a trigger:

Only insert, delete, or update operations can activate a trigger. The activation of a trigger might cause trigger cascading. *Trigger cascading* is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The

triggered actions might also cause updates as a result of the original modification, which can result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing a significant change to the database as a result of a single insert, delete, or update operation.

Loading a table with the LOAD utility does not activate any triggers that are defined for the table if the SHRLEVEL NONE option is specified or accepted as the default. If the LOAD statement includes the SHRLEVEL CHANGE option, triggers are activated when loading a table with the LOAD utility.

Adding triggers to enforce constraints:

Adding a trigger on a table that already has rows in it will not cause the *triggered-action* to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

Multiple triggers:

Multiple triggers that have the same triggering SQL operation and activation time can be defined on a table. The triggers are activated in the order in which they were created. For example, the trigger that was created first is executed first; the trigger that was created second is executed second.

Transition variables and transition tables:

The *triggered-action* can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

A transition variable has the same name, data type, and nullability attribute as the corresponding column of the table that the trigger is defined on. A transition variable contains the value of a column in an affected row. A transition variable is qualified by a correlation name that identifies whether the reference is to the old value (before the update) or the new value (after the update). A transition variable can be referenced in the search condition, or in an SQL statement in the trigger body, wherever a variable would be allowed if the reference was made outside the body of a trigger. A new transition variable can be assigned a value in a before update or insert trigger. The values of the updated rows include the changes from any assignments to transition variables in the *triggered-action* of a before trigger.

A transition table contains the complete set of affected rows: either the old values (before the update) or the new values (after the update). A transition table is read-only, and can be referenced in the *triggered-action* of an after or instead of trigger. A column of a transition table has the same name, data type, and null attribute as the corresponding column of the table that the trigger is defined on. A transition table is referenced using an associated table identifier that allows the complete set of affected rows to be treated as a table. A transition table can be referenced in a search condition, or in an SQL statement in the trigger body, wherever a table would be allowed if the reference was made outside the body of a trigger. In addition, a transition table can be passed as an argument to a user-defined function or procedure, specifying the TABLE keyword before the table identifier for the transition table. When the function or procedure is invoked, a table locator is passed for the transition table.

A transition variable or transition table is not affected after being returned from a procedure invoked from within a triggered action regardless of whether the corresponding parameter was defined in the CREATE PROCEDURE statement as IN, INOUT, or OUT.

Considerations for implicitly hidden columns:

In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced. A transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table. Likewise, a transition variable will exist for the column that is defined as implicitly hidden. A transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

Considerations for transition variables in AFTER and INSTEAD OF triggers:

Transition variables cannot be modified in an AFTER or INSTEAD OF trigger.

Considerations for INSTEAD OF triggers:

The addition of an INSTEAD OF trigger for a view affects the read only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

The creation of an INSTEAD OF trigger causes dependent packages, plans, and statements in the dynamic statement cache to be marked invalid if the view definition is not read-only.

The initial values for new transition variables or new transition table columns that are visible in an INSTEAD OF INSERT trigger are set as follows:

- If a value is explicitly specified for a column in the insert operation, the corresponding new transition variable is that explicitly specified value.
- If a value is not explicitly specified for a column in the insert operation or the DEFAULT clause is specified, the corresponding new transition variable is:
 - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
 - otherwise, the null value

If a view column is not nullable and does not have a default, the value must be explicitly specified in the insert operation.

The initial values for new transition variables that are visible in an INSTEAD OF UPDATE trigger are set as follows:

- If a value is explicitly specified for a column in the update operation, the corresponding new transition variable is that explicitly specified value
- If the DEFAULT clause is explicitly specified for a column in the update operation, the corresponding new transition variable is:
 - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
 - otherwise, the null value

If a view column is not nullable and does not have a default, the value must be explicitly specified in the update operation.

- Otherwise, the corresponding new transition variable is the existing value of the column in the row.

Considerations for a MERGE statement:

The MERGE statement can execute insert and update operations. The applicable triggers are activated for the MERGE statement for the data change operations that are executed.

Considerations for triggers that are defined on tables that contain XML columns:

Although a trigger can be defined on a table that contains an XML column:

- An XML column cannot be referenced with a trigger transition variable in the trigger body.
- An XML column of a transition table cannot be referenced in the trigger body.

Creating a trigger with the SECURED option:

Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who requires the privileges to create a secured trigger. After the trigger is created, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the CREATE TRIGGER statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, DB2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Creating a trigger with the NOT SECURED option:

The CREATE TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Row and column access control that is not enforced for transition variables and transition tables:

If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be created with the SECURED option. If a trigger is not secure, the CREATE TRIGGER statement returns an error.

Considerations for the special plan, statement, and function tables for EXPLAIN:

You can create a trigger on PLAN_TABLE, DSN_STATEMENT_TABLE, or DSN_FUNCTION_TABLE. However, insert triggers that are defined on these tables are not activated when DB2 adds rows to the tables.

Dependent objects:

A trigger is dependent on the triggering table and objects that are referenced in the trigger body.

Adding a column to a subject table or a table referenced in the *triggered-action*:

If a column is added to the subject table after triggers have been defined, the following rules apply:

- If the trigger is an update trigger that was defined without an explicit list of column names, an update to the new column activates the trigger.
- If the subject table is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.
- The OLD_TABLE and the NEW_TABLE transition tables contain the new column, but the column cannot be referenced unless the trigger is re-created. If the transition tables are passed to a user-defined function or a stored procedure, the user-defined function or stored procedure must be re-created with the new definition of the table (that is, the function or procedure must be dropped and re-created), and the package for the user-defined function or stored procedure must be rebound.

If a column is added to any table that is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.

Dropping a column from a subject table or a table referenced in the *triggered-action*:

A column cannot be dropped from a table for which a trigger is defined.

Altering the attributes of a column that the triggered action references:

If a column is altered in the table on which the trigger is defined (the subject table), the alter is processed, and the dependent trigger packages are invalidated.

Renaming the table for which the trigger is defined, or tables referenced in the *triggered-action*:

You cannot rename a table for which a trigger is defined (the subject table). Except for the subject table, you can rename any table to which the SQL statements in the triggered action refer. After renaming such a table, drop the trigger and then re-create the trigger so that it refers to the renamed table.

Dropping the table or view for which a trigger is defined:

If the table or view that a trigger is defined on is dropped, the trigger is also dropped.

Effects of dropping or revoking privileges on an object referenced in the *triggered-action*:

Dropping an object that is referenced in the body of a trigger, or revoking a privilege to an object that is referenced in the body of a trigger, might have the following results:

- Dropping any table, view, alias, or index that is referenced or used within the SQL statements in the triggered action causes the trigger and its package to be invalidated.

- Dropping a synonym that is referenced does not have any effect on the trigger or its package.
- Dropping a user-defined function that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Dropping a sequence that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Revoking a privilege on which the trigger depends causes the trigger and its package to be invalidated. If the appropriate privilege does not exist when the trigger package is rebound, the SQL statement that references the object fails.

Error handling in triggers:

A trigger can return errors, like other SQL statements. Applications need to account for the possible errors that can be expected when a trigger is invoked.

Special registers:

The values of the special registers that are used in the trigger body are determined when the trigger is activated. The value of the CURRENT PACKAGESET special register is set to the schema name of the trigger, and the values of the other special registers are inherited from the triggering SQL operation (insert, update, or delete). Special register values are saved when a trigger is activated and are restored on return from the trigger. The CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP special registers are not restored on return from the trigger.

Result sets for stored procedures:

If a trigger invokes a stored procedure that returns result sets, the application that activated the trigger cannot access those result sets.

Transaction isolation:

All of the statements in the *SQL-trigger-body* run under the isolation level that is in effect for the trigger.

Limiting processor time:

The DB2 resource limit facility allows you to specify the maximum amount of processor time for a dynamic, manipulative SQL statement such as SELECT or SQL data change statements. The execution of a trigger is counted as part of the triggering SQL statement.

Errors binding triggers:

When a CREATE TRIGGER statement is bound, the SQL statements within the triggered action might not be fully parsed. Syntax errors in those statements might not be caught until the CREATE TRIGGER statement is executed.

Characteristics of the package that is generated for a trigger:

The package that is associated with the trigger is named as follows:

- *location* is set to the value of the CURRENT SERVER special register.
- *collection-id* (schema) for the package is the same as the schema qualifier of the trigger.
- *package-id* is the same as the name of the trigger.
- *version-id* is an empty string.

DB2 creates the trigger package with the following initial attributes (some of these attributes can be modified using the REBIND TRIGGER PACKAGE command):

- ACTION(ADD)

- ARCHIVESENSITIVE(YES)
- BUSTIMESENSITIVE(YES)
- CURRENTDATA(NO)
- DBPROTOCOL(DRDA)
- DEGREE(1)
- DESCSTAT(value from the DESCSTAT subsystem parameter)
- DYNAMICRULES(BIND)
- ENABLE(*)
- ENCODING(0)
- EXPLAIN(NO)
- FLAG(I)
- ISOLATION(CS)
- REOPT(NONE)
- NODEFER(PREPARE)
- OPTHINT
- OWNER(authorization ID) or ROLE of appropriate
- PATH(path)
- RELEASE(COMMIT)
- ROUNDING(value from the CURRENT DECFLOAT ROUNDING MODE special register)
- SQLERROR(NOPACKAGE)
- SYSTIMESENSITIVE(YES)
- QUALIFIER(authorization ID)
- VALIDATE(BIND)

The values of OWNER, QUALIFIER, and PATH are set depending on whether the CREATE TRIGGER statement is embedded in a program or issued interactively. If the statement is embedded in a program, OWNER and QUALIFIER are the owner and qualifier of the package or plan. PATH is the value from the PATH bind option. If the statement is issued interactively, both OWNER and QUALIFIER are the SQL authorization ID. PATH is the value in the CURRENT PATH special register.

Multiple versions of a trigger package are not allowed. Use the REBIND command to explicitly rebind the trigger package. To specify the name of a trigger package for the bind commands, the trigger name must conform to the rules for an ordinary identifier.

A trigger package becomes invalid if an object or privilege on which it depends is dropped or revoked. The next time that the trigger is activated, DB2 attempts to rebind the invalid trigger package. If the automatic rebind is unsuccessful, the trigger package remains invalid.

You cannot create another package from the trigger package, such as with the BIND COPY command. The only way to drop a trigger package is to drop the trigger or the subject table. Dropping the trigger drops the trigger package; dropping the subject table drops the trigger and the trigger package.

Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the triggered action that are ended with semicolons. These processor programs accept multiple

SQL statements, each separated with a terminator character, as input. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE TRIGGER statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see Setting the SQL terminator character in a SPUFI input data set (DB2 Application programming and SQL) and DSNTEP2 and DSNTEP4 (DB2 Application programming and SQL).

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- OLD TABLE as a synonym for OLD_TABLE
- NEW TABLE as a synonym for NEW_TABLE

Examples

Example 1: Create two triggers that track the number of employees that a company manages. The subject table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY_STATS table. The tables have these columns:

EMPLOYEE table: ID, NAME, ADDRESS, and POSITION

COMPANY_STATS table: NBEMP, NBPRODUCT, and REVENUE

This example shows the use of transition variables in a row trigger to maintain summary data in another table.

Create the first trigger, NEW_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER NEW_HIRE
  AFTER INSERT ON EMPLOYEE
  FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
    UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
  END
```

Create the second trigger, FORM_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER FORM_EMP
  AFTER DELETE ON EMPLOYEE
  FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
    UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
  END
```

Example 2: Create a trigger, REORDER, that invokes user-defined function ISSUE_SHIP_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE_SHIP_REQUEST orders a quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity; the function also ensures that the request is sent to the appropriate supplier.

The parts records are in the PARTS table. Although the table has more columns, the trigger is activated only when columns ON_HAND and MAX_STOCKED are updated.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW AS NROW
  FOR EACH ROW MODE DB2SQL
  WHEN (NROW.ON_HAND < 0.10 * NROW.MAX_STOCKED)
  BEGIN ATOMIC
    VALUES(ISSUE_SHIP_REQUEST(NROW.MAX_STOCKED - NROW.ON_HAND, NROW.PARTNO));
  END
```

Example 3: Repeat the scenario in *Example 2* except use a fullselect instead of a VALUES statement to invoke the user-defined function. This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW TABLE AS NTABLE
  FOR EACH STATEMENT MODE DB2SQL
  BEGIN ATOMIC
    SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
    FROM NTABLE
    WHERE (ON_HAND < 0.10 * MAX_STOCKED);
  END
```

Example 4: Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL_ADJ, that prevents an update to an employee's salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of '75001' and a description. This example shows that the SIGNAL statement is useful for restricting changes that violate business rules.

```
CREATE TRIGGER SAL_ADJ
  AFTER UPDATE OF SALARY ON EMPLOYEE
  REFERENCING OLD AS OLD_EMP
              NEW AS NEW_EMP
  FOR EACH ROW MODE DB2SQL
  WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY * 1.20))
  BEGIN ATOMIC
    SIGNAL SQLSTATE '75001' ('Invalid Salary Increase - Exceeds 20');
  END
```

Example 5: Assume that the following statements create a table, WEATHER (which stores temperature values in Fahrenheit), and a view, CELSIUS_WEATHER for users who prefer to work in Celsius instead of Fahrenheit:

```
CREATE TABLE WEATHER
  (CITY VARCHAR(25),
  TEMPF DECIMAL(5,2));
CREATE VIEW CELSIUS_WEATHER (CITY, TEMPC) AS
  SELECT CITY, (TEMPF-32)/1.8
  FROM WEATHER;
```

The following INSTEAD OF trigger is used on the CELSIUS_WEATHER view to convert Celsius values to Fahrenheit values and then insert the Fahrenheit value into the WEATHER table:

```
CREATE TRIGGER CW_INSERT INSTEAD OF INSERT
  ON CELSIUS_WEATHER
  REFERENCING NEW AS NEWCW
  FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
```

```
INSERT INTO WEATHER VALUES
(NEWCW.CITY,
 1.8*NEWCW.TEMPC+32)
END;
```

CREATE TRUSTED CONTEXT

The CREATE TRUSTED CONTEXT statement defines a trusted context at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

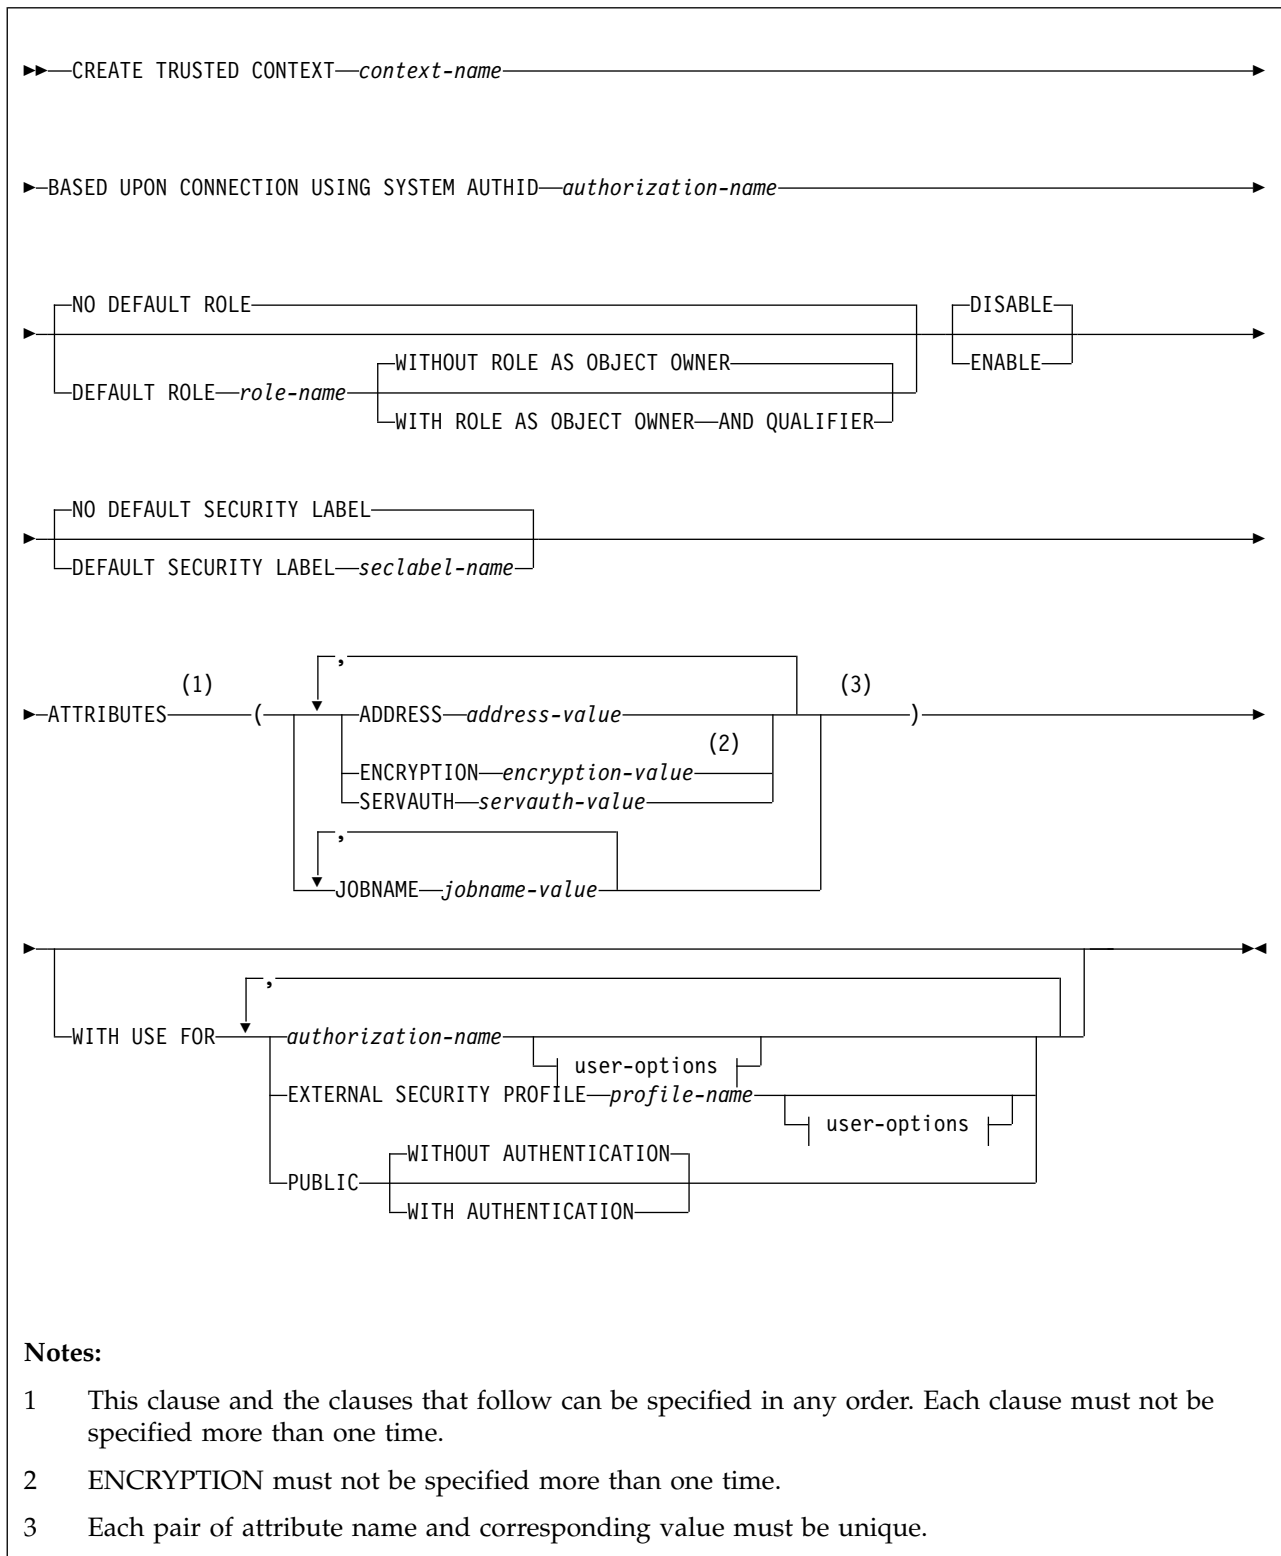

The privilege set that is defined below must include at least one of the following:

- SYSADM authority
- SECADM authority

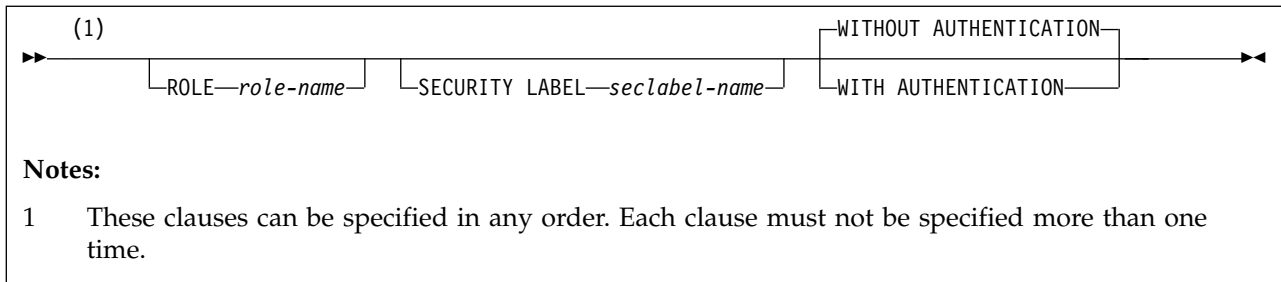

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax

user-options:

Description

context-name

Names the trusted context. The name must not identify a trusted context that exists at the current server.

BASED UPON CONNECTION USING SYSTEM AUTHID *authorization-name*

Specifies that the context is a connection that is established by the authorization ID that is specified by *authorization-name*. The system authorization ID is the primary authorization ID. For a remote connection, it is derived from the system user ID that is provided by an external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 184.

Table 184. System authorization ID for a local connection

| Source of local connection | System authorization ID |
|----------------------------|---|
| Started task (RRSAF) | USER parameter on JOB statement or RACF USER. |
| TSO | TSO logon ID |
| BATCH | USER parameter on JOB statement |

authorization-name must not be associated with an existing trusted context.

NO DEFAULT ROLE or **DEFAULT ROLE** *role-name*

Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context.

NO DEFAULT ROLE

Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

NO DEFAULT ROLE is the default.

DEFAULT ROLE *role-name*

Specifies that *role-name* is the role for the trusted context. *role-name* must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

WITHOUT ROLE AS OBJECT OWNER or **WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context.

WITHOUT ROLE AS OBJECT OWNER

Specifies that a role is not used as the owner of the objects that are created

using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

WITH ROLE AS OBJECT OWNER AND QUALIFIER

Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context and that role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

AND QUALIFIER

Specifies that *role-name* will be used as the default for the CURRENT SCHEMA special register. The *role-name* will also be included in the SQL PATH (in place of CURRENT SQLID).

When **WITH ROLE AS OBJECT OWNER AND QUALIFIER** is not specified, there is no change to the default for the CURRENT SCHEMA special register and the SQL PATH.

DISABLE or ENABLE

Specifies whether the trusted context is created in the enabled or disabled state.

DISABLE

Specified that the trusted context is disabled when it is created. A trusted context that is disabled is not considered when a trusted connection is established. DISABLE is the default.

ENABLE

Specifies that the trusted context is enabled when it is created.

NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL *seclabel-name*

Specifies whether the trusted connection has a default security label.

NO DEFAULT SECURITY LABEL

Specifies that the trusted context does not have a default security label.

DEFAULT SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the default security label for the trusted context and is the security label that is used for multilevel security verification. *seclabel-name* must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used for a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, *seclabel-name* must also identify one of the RACF SECLABEL values that is defined for the user.

ATTRIBUTES

Specifies a list of one or more connection trust attributes that are used to define the trusted context.

ADDRESS *address-value*

Specifies the actual communication address that is used by the connection

to communicate with the database manager. The protocol supported is only for TCP/IP. The ADDRESS attribute can be specified multiple times, but each *address-value* must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the defined values for the ADDRESS attribute of the trusted context.

address-value specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of *address-value* is done at the time the CREATE TRUSTED CONTEXT statement is processed. *address-value* must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111
- An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0800:200C:417A. This address can also be express in a compressed form as 2001:DB8::8:800:200C:417A.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

ENCRYPTION *encryption-value*

Specifies the minimum level of encryption of the data stream (network encryption).

encryption-value specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

The following table summarizes when a trusted context can be used depending on the encryption that is used by the existing connection. If the trusted context cannot be used for the connection, a warning is returned.

Table 185. Summary of when trusted context can be used by an existing connection

| Encryption that is used by the existing connection | Value of the ENCRYPTION clause for the trusted context | Can the trusted context be used for the connection? |
|--|--|---|
| No encryption | NONE | Yes |
| No encryption | LOW | No |
| No encryption | HIGH | No |
| Low encryption (64-bit) | NONE | Yes |
| Low encryption (64-bit) | LOW | Yes |
| Low encryption (64-bit) | HIGH | No |

Table 185. Summary of when trusted context can be used by an existing connection (continued)

| Encryption that is used by the existing connection | Value of the ENCRYPTION clause for the trusted context | Can the trusted context be used for the connection? |
|--|--|---|
| High encryption (128-bit) | NONE | Yes |
| High encryption (128-bit) | LOW | Yes |
| High encryption (128-bit) | HIGH | Yes |

JOBNAME *jobname-value*

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. The JOBNAME attribute can be specified multiple times, but each *jobname-value* must be unique.

jobname-value specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. *jobname-value* is an EBCDIC 8 byte value that specifies the job name or the started task name. The value must be left justified within the string constant. The last character in the name can be a wildcard character (*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that begin with the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space.

Table 186. Job name for local connection

| Source of the address space | Job name |
|-----------------------------|-------------------------------|
| RRSAF | Job name or started task name |
| TSO | TSO logon ID |
| BATCH | Job name on JOB statement |

SERVAUTH *servauth-value*

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with DB2. The SERVAUTH attribute can be specified multiple times but each *servauth-value* must be unique.

servauth-value specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. *servauth-value* is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. *servauth-value* must be left justified in the string constant. No validation of *servauth-value* is done at the time the CREATE TRUSTED CONTEXT statement is processed.

WITH USE FOR

Specifies who can use a trusted connection that is based on the specified trusted context.

authorization-name

Specifies that the trusted connection can be used by the specified *authorization-name*. This is the DB2 primary authorization ID. The *authorization-name* must not be specified more than one time in the WITH USE FOR clause.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted

connection is used by the specified *authorization-name*. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

EXTERNAL SECURITY PROFILE *profile-name*

Specifies that the trusted connection can be used by the DB2 primary authorization IDs that are permitted to use the specified *profile-name* in RACF. *profile-name* must not be specified more than one time in the WITH USE FOR clause.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID permitted to use the specified *profile-name* in RACF. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. **WITHOUT AUTHENTICATION** is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the **CONNECT** statement with the **USER** and **USING** clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

PUBLIC

Specifies that a trusted connection that is based on the specified trusted context can be used by any user. All users that are using a trusted connection that is defined with **PUBLIC** use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the **RACF SECLABEL** values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. **WITHOUT AUTHENTICATION** is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the **CONNECT** statement with the **USER** and **USING** clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

Notes

Owner privileges: There are no specific privileges on a trusted context.

Requirement for trusted connections: To use trusted connections, you cannot set the ALL subsystem parameter to ALL and set the RESTART subsystem parameter to DEFER on installation panel DSNTIPS.

Order of precedence for users of a trusted connection: The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- **EXTERNAL SECURITY PROFILE** *profile-name*
- **PUBLIC**

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

User-clause SYSTEM AUTHID considerations: If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same as the *authorization-name* that is specified in the user-clause *authorization-name*, the role or the security label that is specified for *authorization-name* takes precedence over the default value. The value that is specified for the *profile-name*, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the *user-clause* or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if *authorization-name* is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

Specifying a role in the definition of a trusted context: The definition of a trusted context can designate a role for a specific authorization ID, and a default role for use for an authorization ID for which a specific role has not been specified in the definition of the trusted context. This role can be used with a trusted connection that is based on the trusted context, but it does not make the role available outside of a trusted connection that is based on the trusted context. When an SQL statement that is not a CREATE, GRANT, or REVOKE statement is issued using a trusted connection, the privileges that are held by a role that is in effect for the authorization ID within the definition of the associated trusted context are considered in addition to other privileges that are directly held by the

authorization ID of the statement. The CREATE, GRANT, and REVOKE statements only consider the privileges of the role that is in effect for the trusted connection, or the authorization ID of the statement if a role is not in effect for the trusted connection. If ROLE AS OBJECT OWNER is in effect for a trusted connection, the role that is in effect for the authorization ID for the trusted connection becomes the owner of any object that is created while using the trusted connection.

When a newly created trusted context takes effect: The newly created trusted context takes effect after the CREATE TRUSTED CONTEXT statement is committed. If the CREATE TRUSTED CONTEXT statement results in an error or is rolled back, no trusted context is created.

Examples

Example 1: The following statement creates a trusted context called CTX1, which is based on a connection and can only be used by users JOE and SAM. Authentication information is required for JOE to use the trusted connection. The trusted context specifies a default role called CTXROLE. However, when JOE uses the trusted connection, the default role is overridden by the user role, ROLE1. When SAM uses the trusted connection, SAM uses the default role. CTX1 is enabled when it is created.

```
CREATE TRUSTED CONTEXT CTX1
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
  ATTRIBUTES (ADDRESS '9.30.131.203',
             ENCRYPTION 'LOW')
  DEFAULT ROLE CTXROLE
  ENABLE
  WITH USE FOR SAM, JOE ROLE ROLE1 WITH AUTHENTICATION;
```

Example 2: The following statement creates a trusted context, CTX2, for a started task, WASPROD. CTX2 is based on a connection, can be used by user SALLY, specifies a default role CTXROLE, and is enabled when it is created. SALLY uses the default role that is associated with the trusted context.

```
CREATE TRUSTED CONTEXT CTX2
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF002
  ATTRIBUTES (JOBNAME 'WASPROD')
  DEFAULT ROLE CTXROLE WITH ROLE AS OBJECT OWNER AND QUALIFIER
  ENABLE
  WITH USE FOR SALLY;
```

CREATE TYPE (distinct)

The CREATE TYPE (distinct) statement defines a distinct type, which is a data type that a user defines. A distinct type must be based on one of the built-in data types.

Successful execution of the statement also generates:

- A function to cast between the distinct type and its source type
- A function to cast between the source type and its distinct type
- As appropriate, support for the use of comparison operators with the distinct type

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

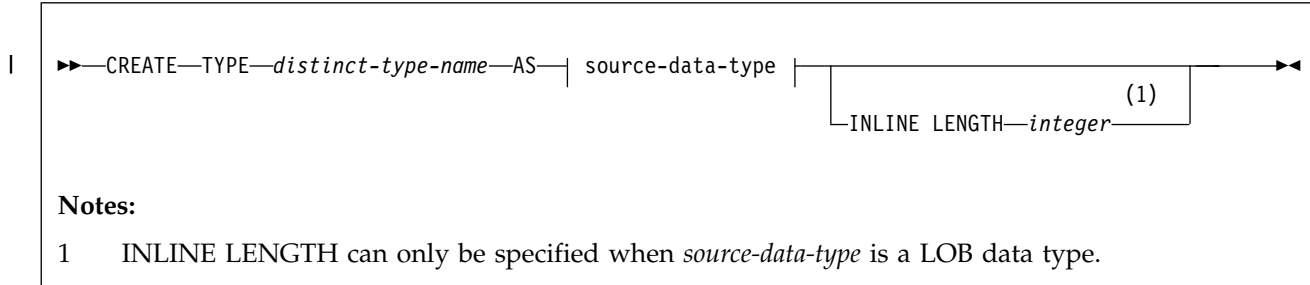

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

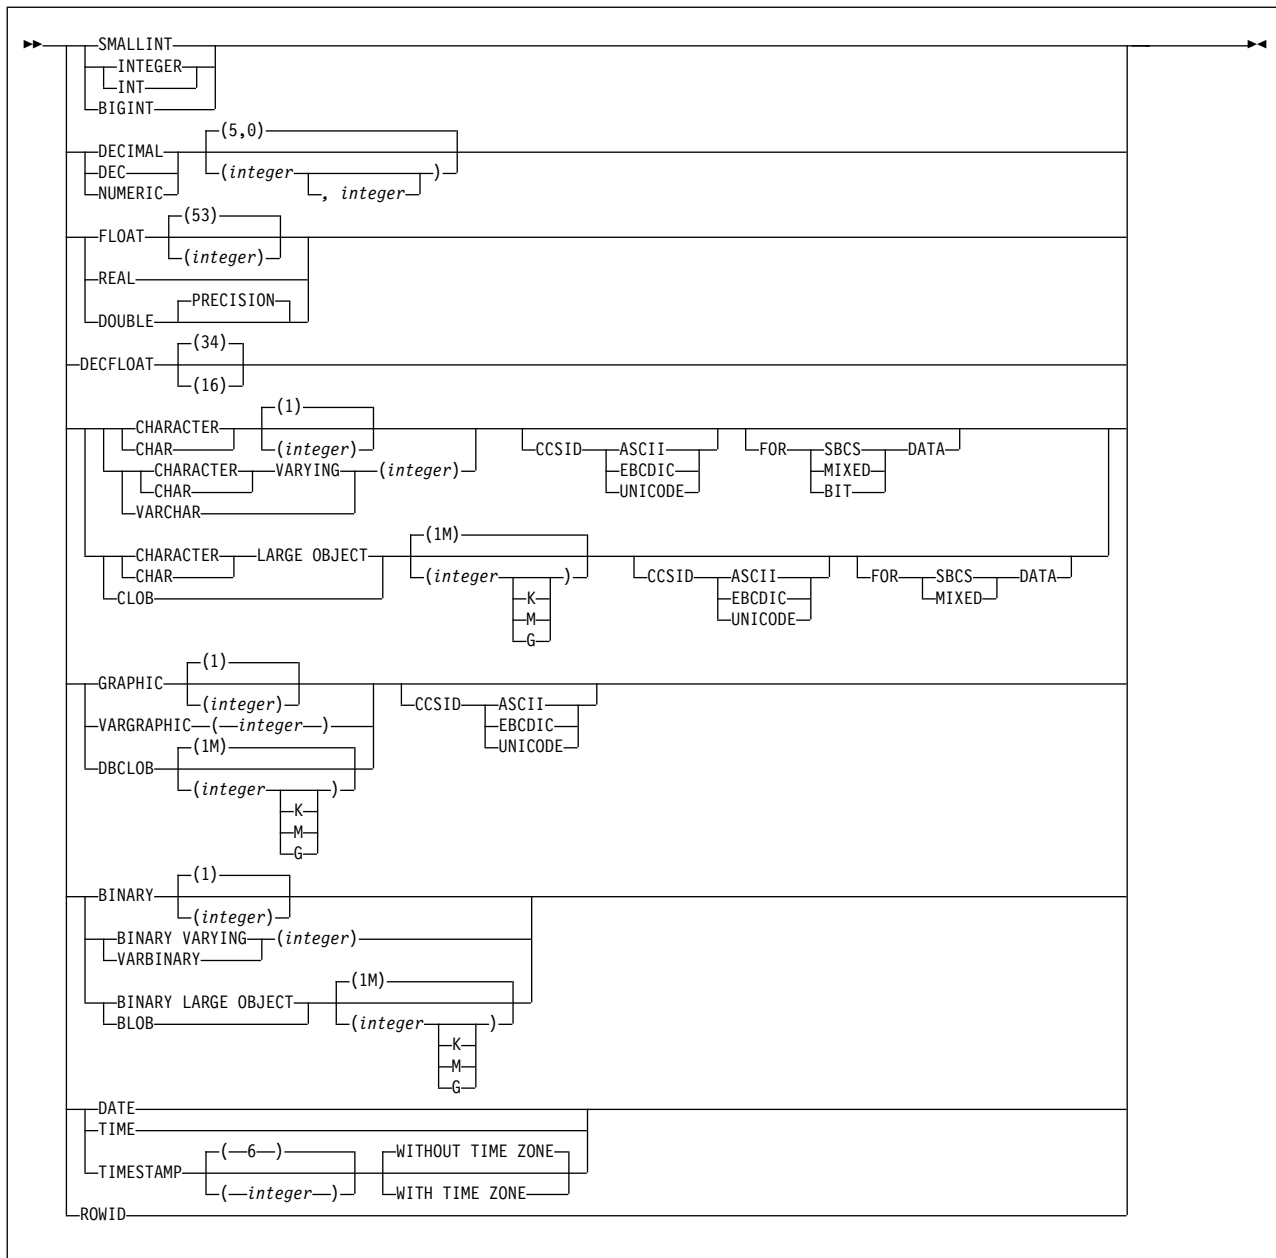

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified distinct type name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

source-data-type

Description

distinct-type-name

Names the distinct type. The name, including the implicit or explicit qualifier, must not identify a distinct type that exists at the current server.

- The unqualified form of *distinct-type-name* must not be the name of a built-in data type, BOOLEAN, or any of following system-reserved keywords even if you specify them as delimited identifiers:

| | | |
|----------|----------|---------|
| ALL | LIKE | UNIQUE |
| AND | MATCH | UNKNOWN |
| ANY | NOT | = |
| BETWEEN | NULL | ≠ |
| DISTINCT | ONLY | < |
| EXCEPT | OR | ≤ |
| EXISTS | OVERLAPS | ≠ |
| FALSE | SIMILAR | > |
| FOR | SOME | ≥ |
| FROM | TABLE | → |
| IN | TRUE | ↔ |
| IS | TYPE | |

- The qualified form of *distinct-type-name* is an SQL identifier (the schema name) followed by a period and an SQL identifier.

The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

source-data-type

Specifies the data type that is used as the basis for the internal representation of the distinct type. The data type must be a built-in data type. For more information on built-in data types, see built-in-type.

If the distinct type is based on a character or graphic string data type, the FOR clause indicates the subtype. If you do not specify the FOR clause, the distinct type is defined with the default subtype. For ASCII or EBCDIC data, the default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO. The default is MIXED when the value is YES. For UNICODE character data, the default subtype is mixed.

If the distinct type is based on a string data type, the CCSID clause indicates whether the encoding scheme of the data is ASCII, EBCDIC or UNICODE. If you do not specify CCSID ASCII, CCSID EBCDIC, or UNICODE, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

INLINE LENGTH *integer*

Specifies the default inline length for columns that reference the distinct type. INLINE LENGTH can only be specified when *source-data-type* is a LOB data type. Only columns in a table that is in a universal table space can inherit the specified inline length for the distinct type. If the table is not in a universal table space, the specified inline length is ignored.

Where *source-data-type* is BLOB and CLOB, *integer* specifies the maximum number of bytes that are stored in the base table space for columns that reference this distinct type. *integer* must be between 0 and 32680 (inclusive) for a BLOB or CLOB *source-data-type*.

Where *source-data-type* is DBCLOB, *integer* specifies the maximum number of double-byte characters that are stored in the table space for columns that reference the distinct type. *integer* must be between 0 and 16340 (inclusive) for a DBCLOB *source-data-type*.

If `INLINE LENGTH` is specified with a value of 0 for *integer*, any column that references the distinct type will not have an inline length unless the `CREATE TABLE` or `ALTER TABLE ADD` statement specifies an inline length for the column.

If `INLINE LENGTH` is not specified, any column that reference the distinct type takes its default vale from the value of the `LOB INLINE LENGTH` parameter on installation panel `DSNTIPD`.

integer cannot be greater than the maximum length of the distinct type.

Notes

Owner privileges:

The owner of the distinct type is authorized to define columns, parameters, or variables with the distinct type (`USAGE` privilege) with the ability to grant these privileges to others. See “`GRANT (type or JAR file privileges)`” on page 2030. The owner is also authorized to invoke the generated cast function (`EXECUTE` privilege; see “`GRANT (function or procedure privileges)`” on page 2008). The owner is given the `USAGE` and `EXECUTE` privileges with the `GRANT` option. For more information about ownership of the object, see “`Authorization, privileges, permissions, masks, and object ownership`” on page 70.

Source data types with DBCS or mixed data:

When the implicit or explicit encoding scheme is `ASCII` or `EBCDIC` and the source data type is graphic or a character type is `MIXED DATA`, then the value of field `FOR MIXED DATA` on installation panel `DSNTIPF` must be `YES`; otherwise, an error occurs.

Generated cast functions:

The successful execution of the `CREATE TYPE (distinct)` statement causes `DB2` to generate the following cast functions:

- A function to convert from the distinct type to its source data type
- A function to convert from the source data type to the distinct type
- A function to cast from a data type *A* to distinct type *DT*, where *A* is promotable to the source data type *S* of distinct type *DT*

For some source data types, `DB2` supports an additional function to convert from:

- `INTEGER` to the distinct type if the source type is `SMALLINT`
- `VARCHAR` to the distinct type if the source type is `CHAR`
- `VARGRAPHIC` to the distinct type if the source type is `GRAPHIC`
- `VARBINARY` to the distinct type if the source type is `BINARY`
- `DOUBLE` to the distinct type if the source type is `REAL`

The cast functions are created as if the following statements were executed:

```
CREATE FUNCTION source-type-name (distinct-type-name)
  RETURNS source-type-name ...
CREATE FUNCTION distinct-type-name (source-type-name)
  RETURNS distinct-type-name ...
```

Even if you specified a length, precision, or scale for the source data type in the `CREATE TYPE (distinct)` statement, the name of the cast function that converts from the distinct type to the source type is simply the name of the source data type. The data type of the value that the cast function returns includes any length, precision, or scale values that you specified for the source data type. (See Table 187 on page 1834 for details.)

The name of the cast function that converts from the source type to the distinct type is the name of the distinct type. The input parameter of the cast function has the same data type as the source data type, including the length, precision, and scale.

For example, assume that a distinct type named T_SHOESIZE is created with the following statement:

```
CREATE TYPE (distinct) CLAIRE.T_SHOESIZE AS VARCHAR(2)
```

When the statement is executed, DB2 also generates the following cast functions. VARCHAR converts from the distinct type to the source type, and T_SHOESIZE converts from the source type to the distinct type.

```
FUNCTION CLAIRE.VARCHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.VARCHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that function VARCHAR returns a value with a data type of VARCHAR(2) and that function T_SHOESIZE has an input parameter with a data type of VARCHAR(2).

The schema of the generated cast functions is the same as the schema of the distinct type. No other function with the same name and function signature must already exist in the database.

In the preceding example, if T_SHOESIZE had been sourced on a SMALLINT, CHAR, or GRAPHIC data type instead of a VARCHAR data type, another cast function would have been generated in addition to the two functions to cast between the distinct type and the source data type. For example, assume that T_SHOESIZE is created with this statement:

```
CREATE TYPE (distinct) CLAIRE.T_SHOESIZE AS CHAR(2)
```

When the statement is executed, DB2 generates these cast functions:

```
FUNCTION CLAIRE.CHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.CHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.CHAR (2)) RETURNS CLAIRE.T_SHOESIZE
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that the third function enables the casting of a VARCHAR(2) to T_SHOESIZE. This additional function is created to enable casting a constant, such as 'AB', directly to the distinct type. Without the additional function, you would have to first cast 'AB', which has a data type of VARCHAR, to a data type of CHAR and then cast it to the distinct type.

You cannot explicitly drop a generated cast function. The cast functions that are generated for a distinct type are implicitly dropped when the distinct type is dropped with the DROP statement.

For each built-in data type that can be the source data type for a distinct type, the following table gives the names of the generated cast functions, the data types of the input parameters, and the data types of the values that the functions returns.

Table 187. CAST functions on distinct types

| Source type name | Function name | Parameter-type | Return-type |
|------------------|---------------------------|---------------------------|---------------------------|
| SMALLINT | <i>distinct-type-name</i> | SMALLINT | <i>distinct-type-name</i> |
| | <i>distinct-type-name</i> | INTEGER | <i>distinct-type-name</i> |
| | SMALLINT | <i>distinct-type-name</i> | SMALLINT |
| INTEGER | <i>distinct-type-name</i> | INTEGER | <i>distinct-type-name</i> |
| | INTEGER | <i>distinct-type-name</i> | INTEGER |

Table 187. CAST functions on distinct types (continued)

| Source type name | Function name | Parameter-type | Return-type |
|--|---------------------------|---------------------------|---------------------------|
| BIGINT | <i>distinct-type-name</i> | BIGINT | <i>distinct-type-name</i> |
| | BIGINT | <i>distinct-type-name</i> | BIGINT |
| DECIMAL | <i>distinct-type-name</i> | DECIMAL (p,s) | <i>distinct-type-name</i> |
| | DECIMAL | <i>distinct-type-name</i> | DECIMAL (p,s) |
| NUMERIC | <i>distinct-type-name</i> | DECIMAL (p,s) | <i>distinct-type-name</i> |
| | DECIMAL | <i>distinct-type-name</i> | DECIMAL (p,s) |
| REAL | <i>distinct-type-name</i> | REAL | <i>distinct-type-name</i> |
| | <i>distinct-type-name</i> | DOUBLE | <i>distinct-type-name</i> |
| | REAL | <i>distinct-type-name</i> | REAL |
| DECFLOAT | <i>distinct-type-name</i> | DECFLOAT(n) | DECFLOAT(n) |
| | DECFLOAT | <i>distinct-type-name</i> | DECFLOAT(n) |
| FLOAT(n) where $n \leq 21$ | <i>distinct-type-name</i> | REAL | <i>distinct-type-name</i> |
| | <i>distinct-type-name</i> | DOUBLE | <i>distinct-type-name</i> |
| | REAL | <i>distinct-type-name</i> | REAL |
| FLOAT(n) where $n > 21$ | <i>distinct-type-name</i> | DOUBLE | <i>distinct-type-name</i> |
| | DOUBLE | <i>distinct-type-name</i> | DOUBLE |
| FLOAT | <i>distinct-type-name</i> | DOUBLE | <i>distinct-type-name</i> |
| | DOUBLE | <i>distinct-type-name</i> | DOUBLE |
| DOUBLE | <i>distinct-type-name</i> | DOUBLE | <i>distinct-type-name</i> |
| | DOUBLE | <i>distinct-type-name</i> | DOUBLE |
| DOUBLE PRECISION | <i>distinct-type-name</i> | DOUBLE | <i>distinct-type-name</i> |
| | <i>distinct-type-name</i> | CHAR (n) | <i>distinct-type-name</i> |
| | CHAR | <i>distinct-type-name</i> | CHAR (n) |
| | <i>distinct-type-name</i> | VARCHAR (n) | <i>distinct-type-name</i> |
| | DOUBLE | <i>distinct-type-name</i> | DOUBLE |
| CHAR CHARACTER | <i>distinct-type-name</i> | CHAR (n) | <i>distinct-type-name</i> |
| | CHAR | <i>distinct-type-name</i> | CHAR (n) |
| | <i>distinct-type-name</i> | VARCHAR (n) | <i>distinct-type-name</i> |
| VARCHAR CHARACTER VARYING CHAR VARYING | <i>distinct-type-name</i> | VARCHAR (n) | <i>distinct-type-name</i> |
| | VARCHAR | <i>distinct-type-name</i> | VARCHAR (n) |
| CLOB | <i>distinct-type-name</i> | CLOB (n) | <i>distinct-type-name</i> |
| | CLOB | <i>distinct-type-name</i> | CLOB (n) |
| GRAPHIC | <i>distinct-type-name</i> | GRAPHIC (n) | <i>distinct-type-name</i> |
| | GRAPHIC | <i>distinct-type-name</i> | GRAPHIC (n) |
| | <i>distinct-type-name</i> | VARGRAPHIC (n) | <i>distinct-type-name</i> |
| VARGRAPHIC | <i>distinct-type-name</i> | VARGRAPHIC (n) | <i>distinct-type-name</i> |
| | VARGRAPHIC | <i>distinct-type-name</i> | VARGRAPHIC (n) |
| DBCLOB | <i>distinct-type-name</i> | DBCLOB (n) | <i>distinct-type-name</i> |
| | DBCLOB | <i>distinct-type-name</i> | DBCLOB (n) |

Table 187. CAST functions on distinct types (continued)

| Source type name | Function name | Parameter-type | Return-type |
|-----------------------------|---------------------------|---------------------------|--------------------------------|
| BINARY | <i>distinct-type-name</i> | BINARY(n) | <i>distinct-type-name</i> |
| | BINARY | <i>distinct-type-name</i> | BINARY(n) |
| VARBINARY | <i>distinct-type-name</i> | VARBINARY(n) | <i>distinct-type-name</i> |
| | VARBINARY | <i>distinct-type-name</i> | VARBINARY(n) |
| BLOB | <i>distinct-type-name</i> | BLOB (n) | <i>distinct-type-name</i> |
| | BLOB | <i>distinct-type-name</i> | BLOB (n) |
| DATE | <i>distinct-type-name</i> | DATE | <i>distinct-type-name</i> |
| | DATE | <i>distinct-type-name</i> | DATE |
| TIME | <i>distinct-type-name</i> | TIME | <i>distinct-type-name</i> |
| | TIME | <i>distinct-type-name</i> | TIME |
| TIMESTAMP | <i>distinct-type-name</i> | TIMESTAMP | <i>distinct-type-name</i> |
| | TIMESTAMP | <i>distinct-type-name</i> | TIMESTAMP(p) WITHOUT TIME ZONE |
| TIMESTAMP(p) WITH TIME ZONE | <i>distinct-type-name</i> | TIMESTAMP WITH TIME ZONE | <i>distinct-type-name</i> |
| | TIMESTAMP_TZ | <i>distinct-type-name</i> | TIMESTAMP(p) WITH TIME ZONE |
| ROWID | <i>distinct-type-name</i> | ROWID | <i>distinct-type-name</i> |
| | ROWID | <i>distinct-type-name</i> | ROWID |

Notes: NUMERIC and FLOAT are not recommended when creating a distinct type for a portable application. Use DECIMAL and DOUBLE (or REAL) instead.

Built-in functions:

When a distinct type is defined, the built-in functions (such as AVG, MAX, and LENGTH) are not automatically supported for the distinct type. You can use a built-in function on a distinct type only after a sourced user-defined function, which is based on the built-in function, has been created for the distinct type. For information on defining sourced user-defined functions, see “CREATE FUNCTION (sourced)” on page 1555.

Arithmetic operators with distinct type operands:

A distinct type cannot be used with arithmetic operators even if its source data type is numeric.

For additional information see “Arithmetic with distinct type operands” on page 237.

Alternative syntax and synonyms:

The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement. Use WITH COMPARISONS only if it is required for compatibility with other products in the DB2 family. If the source data type is either BLOB, CLOB, or DBCLOB and WITH COMPARISONS is specified, a warning occurs as in previous releases.

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- DISTINCT TYPE as a synonym for TYPE
- TIMEZONE can be specified as an alternative to TIME ZONE

Examples

Example 1: Create a distinct type named SHOESIZE that is based on an INTEGER data type.

```
CREATE TYPE SHOESIZE AS INTEGER;
```

The successful execution of this statement also generates two cast functions. Function INTEGER(SHOESIZE) returns a value with data type INTEGER, and function SHOESIZE(INTEGER) returns a value with distinct type SHOESIZE.

Example 2: Create a distinct type named MILES that is based on a DOUBLE data type.

```
CREATE TYPE MILES AS DOUBLE;
```

The successful execution of this statement also generates two cast functions. Function DOUBLE(MILES) returns a value with data type DOUBLE, and function MILES(DOUBLE) returns a value with distinct type MILES.

CREATE VIEW

The CREATE VIEW statement creates a view on tables or views at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

For every table or view identified in the *fullselect*, the privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SQLADM authority (catalog tables only)
- System DBADM authority (catalog tables only)
- ACCESSCTRL authority (catalog tables only)
- SYSCtrl authority (catalog tables only)
- SECADM authority (catalog tables only)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Authority requirements depend in part on the choice of the owner of the view. For information on how to choose the owner, see the description of *view-name* in "Description" on page 1424.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

- If this privilege set includes SYSADM authority, the owner of the view can be any authorization ID. If that set includes SYSCtrl but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.

- If the privilege set includes system DBADM authority, the owner of the view can be any authorization ID. However, to create a view on a user table, either the owner of the view or the creator must have the SELECT privilege on all the tables or views in the CREATE VIEW statement.

- If the privilege set lacks system DBADM, SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be any authorization ID if all of the following conditions are true:
 - The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during DB2 installation.
 - The view is not based only on views.

Note: The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.

- If the privilege set lacks SYSADM, SYSCTRL, system DBADM, and DBADM authority, or if the authorization ID of the application plan or package fails to meet any of the previous conditions, the owner of the view must be the owner of the application plan or package.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, system DBADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, system DBADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes system DBADM authority, SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the following rules apply:

- If the SQL authorization ID of the process has SYSADM authority, the owner of the view can be any authorization ID. If that authorization ID has SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.

- If the SQL authorization ID of the process has system DBADM authority, the owner of the view can be any authorization ID. However, to create a view on a user table, either the owner of the view or the SQL authorization ID must have the SELECT privilege on all the tables or views in the CREATE VIEW statement.
- If SQL authorization ID of the process lacks system DBADM authority, SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be different from the SQL authorization ID if all of the following conditions are true:
 - The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during DB2 installation.
 - The view is not based only on views.

Note: The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.

- If the SQL authorization ID of the process lacks SYSADM, SYSCTRL, system DBADM authority, or DBADM authority, or if the SQL authorization ID of the process fails to meet any of the previous conditions, only the authorization IDs of the process can own the view. In this case, the privilege set is the privileges that are held by the authorization ID selected for ownership.

Syntax

Description

view-name

Names the view. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

column-name,...

Names the columns in the view. If you specify a list of column names, it must consist of as many names as there are columns in the result table of the fullselect. Each name must be unique and unqualified. If you do not specify a list of column names, the columns of the view inherit the names of the columns of the result table of the fullselect.

You must specify a list of column names if the result table of the fullselect has duplicate column names or an unnamed column (a column derived from a constant, function, or expression that was not given a name by the AS clause). For more details about unnamed columns, see the information about names of result columns under “select-clause” on page 1083.

AS Identifies the view definition.

WITH *common-table-expression*

Defines a common table expression for use with the fullselect that follows. The fullselect must not contain a period specification. For an explanation of common table expression, see “common-table-expression” on page 1132.

fullselect

Defines the view. At any time, the view consists of the rows that would result if the *fullselect* were executed.

The *fullselect* must conform to the following rules:

- The *fullselect* must not refer to any host variables or parameter markers (question marks).
- The *fullselect* must not refer to any declared temporary tables.
- The *fullselect* must not reference an accelerator-only table.
- The *fullselect* must not include an invocation of the UNPACK function.
- The *fullselect* must not contain a period specification.
- The FROM clause of the *fullselect* must not include a *data-change-table-reference*.
- The FROM clause of the *fullselect* must not include a view for which an INSTEAD OF trigger is defined.

For an explanation of *fullselect*, see “fullselect” on page 1123.

WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTIONS

Specifies that every row that is inserted or updated through the view must conform to the definition of the view. A row that does not conform to the definition of the view is a row that cannot be retrieved using that view.

The CHECK OPTION clause must not be specified if the view is read-only, includes a subquery, references a function that is not deterministic or has an external action, or if the *fullselect* of the view refers to a created temporary table. If the CHECK OPTION clause is specified for an updatable view that does not allow inserts, it applies to updates only.

If the CHECK OPTION clause is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes the CHECK OPTION clause. Because the definition of the view is not used, rows might be inserted or updated through the view that do not conform to the definition of the view.

The difference between the two forms of the check option, CASCADED and LOCAL, is meaningful only when a view is dependent on another view. The default is CASCADED. The view on which another view is directly or indirectly defined is an *underlying view*.

CASCADED

Update and insert operations on view V must satisfy the search conditions of view V and all underlying views, regardless of whether the underlying views were defined with a check option. Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V) as a constraint on insert or update operations. WITH CASCADED CHECK OPTION must not be specified if a view on which the specified view definition is dependent has an INSTEAD OF trigger defined.

LOCAL

Update and insert operations on view V must satisfy the search conditions of view V and underlying views that are defined with a check option (either WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTION). Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions

of view V and all underlying views of V that are defined with a check option) as a constraint on insert or update operations.

The LOCAL form of the CHECK option lets you update or insert rows that do not conform to the search condition of view V. You can perform these operations if the view is directly or indirectly defined on a view that was defined without a check option.

Table 188 illustrates the effect of using the default check option, CASCADED. The information in Table 188 is based on the following views:

- CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10
- CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CASCADED CHECK OPTION
- CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100

Table 188. Examples using default check option, CASCADED

| SQL statement | Description of result |
|----------------------------|---|
| INSERT INTO V1 VALUES(5) | Succeeds because V1 does not have a check option and it is not dependent on any other view that has a check option. |
| INSERT INTO V2 VALUES(5) | Results in an error because the inserted row does not conform to the search condition of V1 which is implicitly is part of the definition of V2. |
| INSERT INTO V3 VALUES(5) | Results in an error because the inserted row does not conform to the search condition of V1. |
| INSERT INTO V3 VALUES(200) | Succeeds even though it does not conform to the definition of V3 (V3 does not have the view check option specified); it does conform to the definition of V2 (which does have the view check option specified). |

The difference between CASCADED and LOCAL is shown best by example. Consider the following updatable views, where x and y represent either LOCAL or CASCADED:

- V1 is defined on Table T0.
- V2 is defined on V1 WITH x CHECK OPTION.
- V3 is defined on V2.
- V4 is defined on V3 WITH y CHECK OPTION.
- V5 is defined on V4.

This example shows V1 as an *underlying view* for V2 and V2 as *dependent* on V1.

Table 189 shows the views in which search conditions are checked during an insert or update operation:

Table 189. Views in which search conditions are checked during insert and update operations

| View used in INSERT or UPDATE operation | x = LOCAL y = LOCAL | x = CASCADED y = CASCADED | x = LOCAL y = CASCADED | x = CASCADED y = LOCAL |
|---|------------------------|------------------------------|---------------------------|---------------------------|
| V1 | None | None | None | None |
| V2 | V2 | V2, V1 | V2 | V2, V1 |
| V3 | V2 | V2, V1 | V2 | V2, V1 |
| V4 | V4, V2 | V4, V3, V2, V1 | V4, V3, V2, V1 | V4, V2, V1 |

Table 189. Views in which search conditions are checked during insert and update operations (continued)

| View used in INSERT or UPDATE operation | x = LOCAL y = LOCAL | x = CASCADED y = CASCADED | x = LOCAL y = CASCADED | x = CASCADED y = LOCAL |
|---|------------------------|------------------------------|---------------------------|---------------------------|
| V5 | V4, V2 | V4, V3, V2, V1 | V4, V3, V2, V1 | V4, V2, V1 |

Notes

Owner privileges

The owner of a view always acquires the SELECT privilege on the view and the authority to drop the view. If all of the privileges that are required to create the view are held with the GRANT option before the view is created, the owner of the view receives the SELECT privilege with the GRANT option. Otherwise, the owner receives the SELECT privilege without the GRANT option. For example, assume that a view definition also refers to a user-defined function. If the owner's EXECUTE privilege on the user-defined function is held without the GRANT option, the owner acquires the SELECT privilege on the view without the GRANT option.

The owner can also acquire INSERT, UPDATE, and DELETE privileges on the view. Acquiring these privileges is possible if the view is not "read-only", which means a single table or view is identified in the first FROM clause of the fullselect. For each privilege that the owner has on the identified table or view (INSERT, UPDATE, and DELETE) before the new view is created, the owner acquires that privilege on the view. The owner receives the privilege with the GRANT option if the privilege is held on the table or view with the GRANT option. Otherwise, the owner receives the privileges without the GRANT option.

With appropriate DB2 authority, a process can create views for those who have no authority to create the views themselves. The owner of such a view has the SELECT privilege on the view, without the GRANT option, and can drop the view.

For more information on the ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 70.

Authorization for views created for other users:

When a process with appropriate authority creates a view for another user that does not have authorization for the underlying table or view, the SELECT privilege for the created view is implicitly granted to the user.

Considerations for row access control and column access control:

The view definition might reference a table for which row access control or column access control is activated. If the view definition references a table for which row access control or column access control is activated, the WITH CHECK OPTION clause must not be specified if the search conditions from the view or from the underlying views will be checked during an insert or update operation. Note that the WITH CHECK OPTION clause is ignored if such search conditions do not exist.

Read-only views:

A view is *read-only* if one or more of the following statements is true of its definition:

- The first FROM clause identifies more than one table or view, or identifies a table function, a nested table expression, or a common table expression.

- The first SELECT clause specifies the keyword DISTINCT.
- The outer fullselect contains a GROUP BY clause.
- The outer fullselect contains a HAVING clause.
- The first SELECT clause contains an aggregate function.
- It contains a subquery such that the base object of the outer fullselect, and of the subquery, is the same table.
- The first FROM clause identifies a read-only view.
- The first FROM clause identifies a system-maintained materialized query table.
- The outer fullselect is not a subselect (contains a set operator).

A read-only view cannot be the object of an SQL data change statement or a TRUNCATE statement. A view that includes GROUP BY or HAVING cannot be referred to in a subquery of a basic predicate.

Insertable views:

A view is insertable if an INSTEAD OF trigger for the insert operation has been defined for the view, or if at least one column of the view is updatable (independent of an INSTEAD OF trigger for update).

Considerations for implicitly hidden columns:

It is possible that the result table of the fullselect will include a column of a base table that is defined as implicitly hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.

Testing a view definition:

You can test the semantics of your view definition by executing SELECT * FROM *view-name*.

The two forms of a view definition:

Both the source and the operational form of a view definition are stored in the DB2 catalog. Those two forms are not necessarily equivalent because the operational form reflects the state that exists when the view is created. For example, consider the following statement:

```
CREATE VIEW V AS SELECT * FROM S;
```

In this example, S is a synonym or alias for A.T, which is a table with columns C1, C2, and C3[®]. The operational form of the view definition is equivalent to:

```
SELECT C1, C2, C3 FROM A.T;
```

Adding columns to A.T using ALTER TABLE and dropping S does not affect the operational form of the view definition. Thus, if columns are added to A.T or if S is redefined, the source form of the view definition can be misleading.

View restrictions:

A view definition cannot contain references to remote objects. A view definition cannot map to more than 15 base table instances. A view definition cannot reference a declared global temporary table.

Considerations for inline LOB columns:

If the view references a table that contains an inline LOB column and DB2

|
|

determines that the inline attribute can be passed on to the view, the view will then inherit the inline attribute, otherwise the inline attribute is not inherited by the view.

Considerations for XML columns:

If the view has an XML column and the column of the underlying base table for the view has an XML type modifier, the view column has the same type modifier. However, if there is an instead of trigger defined on the view, validation of the column, according to XML schemas in the type modifier, is not enforced during insert or update to this view.

Examples

Example 1: Create the view DSN8A10.VPROJRE1. PROJNO, PROJNAME, PROJDEP, RESPEMP, FIRSTNME, MIDINIT, and LASTNAME are column names. The view is a join of tables and is therefore read-only.

```
CREATE VIEW DSN8A10.VPROJRE1
  (PROJNO,PROJNAME,PROJDEP,RESPEMP,
   FIRSTNME,MIDINIT,LASTNAME)
AS SELECT ALL
  PROJNO,PROJNAME,DEPTNO,EMPNO,
  FIRSTNME,MIDINIT,LASTNAME
FROM DSN8A10.PROJ, DSN8A10.EMP
WHERE RESPEMP = EMPNO;
```

In the example, the WHERE clause refers to the column EMPNO, which is contained in one of the base tables but is not part of the view. In general, a column named in the WHERE, GROUP BY, or HAVING clause need not be part of the view.

Example 2: Create the view DSN8A10.FIRSTQTR that is the UNION ALL of three fullselects, one for each month of the first quarter of 2000. The common names are SNO, CHARGES, and DATE.

```
CREATE VIEW DSN8A10.FIRSTQTR (SNO, CHARGES, DATE) AS
SELECT SNO, CHARGES, DATE
FROM MONTH1
WHERE DATE BETWEEN '01/01/2000' and '01/31/2000'
UNION ALL
SELECT SNO, CHARGES, DATE
FROM MONTH2
WHERE DATE BETWEEN '02/01/2000' and '02/29/2000'
UNION ALL
SELECT SNO, CHARGES, DATE
FROM MONTH3
WHERE DATE BETWEEN '03/01/2000' and '03/31/2000';
```

DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java.

Authorization

For each table or view identified in the SELECT statement of the cursor, the privilege set must include at least one of the following:

- The SELECT privilege
- Ownership of the object
- DBADM authority for the corresponding database (tables only)
- SYSADM authority
- SYSCtrl authority (catalog tables only)
- DATAACCESS authority

If the *select-statement* contains an SQL data change statement, the authorization requirements of that statement also apply to the DECLARE CURSOR statement.

The SELECT statement of the cursor is one of the following:

- The prepared select statement identified by *statement-name*
- The specified *select-statement*

If *statement-name* is specified:

- The privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 147 on page 1153. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 75.)
- The authorization check is performed when the SELECT statement is prepared.
- The cursor cannot be opened unless the SELECT statement is successfully prepared.

If *select-statement* is specified:

- The privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package.
- If the plan or package is bound with VALIDATE(BIND), the authorization check is performed at bind time, and the bind is unsuccessful if any required privilege does not exist.
- If the plan or package is bound with VALIDATE(RUN), an authorization check is performed at bind time, but all required privileges need not exist at that time. If all privileges exist at bind time, no authorization checking is performed when the cursor is opened. If any privilege does not exist at bind time, an authorization check is performed the first time the cursor is opened within a unit of work. The OPEN is unsuccessful if any required privilege does not exist.

Syntax

holdability:

returnability:

rowset-positioning:

Description

cursor-name

Names the cursor. The name must not identify a cursor that has already been

declared in the source program. The name is usually VARCHAR(128); however, if the cursor is defined WITH RETURN, the name is limited to VARCHAR(30).

NO SCROLL or SCROLL

Specifies whether the cursor is scrollable or not scrollable.

NO SCROLL

Specifies that the cursor is not scrollable. This is the default.

SCROLL

Specifies that the cursor is scrollable. For a scrollable cursor, whether the cursor has sensitivity to inserts, updates, or deletes depends on the cursor sensitivity option in effect for the cursor. If a sensitivity option is not specified, ASENSITIVE is the default.

ASENSITIVE

Specifies that the cursor should be as sensitive as possible. This is the default.

A cursor that defined as ASENSITIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 2077.

The sensitivity of a cursor is a factor in the choice of access path. Explicitly specify the sensitivity level that you need, instead of specifying ASENSITIVE.

INSENSITIVE

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or *attribute-string* of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

SENSITIVE

Specifies that the cursor has sensitivity to changes that are made to the database after the result table is materialized. The cursor is always sensitive to updates and deletes that are made using the cursor (that is, positioned updates and deletes using the same cursor). When the current value of a row no longer satisfies the *select-statement* or *statement-name*, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

If DB2 cannot make changes visible to the cursor, then an error is issued at bind time for OPEN CURSOR. DB2 cannot make changes visible to the cursor when the cursor implicitly becomes read-only. For example, when the result table must be materialized, as when the FROM clause of the SELECT statement contains more than one table or view. The current list of conditions that result in an implicit read-only cursor can be found in Read-only cursors.

The default is DYNAMIC.

DYNAMIC

Specifies that the result table of the cursor is dynamic, meaning that the size of the result table might change after the cursor is

opened as rows are inserted into or deleted from the underlying table, and the order of the rows might change. Rows that are inserted, deleted, or updated by statements that are executed by the same application process as the cursor are visible to the cursor immediately. Rows that are inserted, deleted, or updated by statements that are executed by other application processes are visible only after the statements are committed. If a column for an ORDER BY clause is updated via a cursor or any means outside the process, the next FETCH statement behaves as if the updated row was deleted and re-inserted into the result table at its correct location. At the time of a positioned update, the cursor is positioned before the next row of the original location and there is no current row, making the row appear to have moved.

If a SENSITIVE DYNAMIC cursor is not possible, an error is returned. For example, if a temporary table is needed an error is returned. The SELECT statement of a cursor that is defined as SENSITIVE DYNAMIC cannot contain an SQL data change statement.

The FETCH FIRST *n* ROWS ONLY clause must not be specified for the outermost fullselect for a sensitive dynamic cursor.

STATIC

Specifies that the size of the result table and the order of the rows do not change after the cursor is opened. Rows inserted into the underlying table are not added to the result table regardless of how the rows are inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized. Positioned updates and deletes are allowed if the result table is updatable. The SELECT statement of a cursor that is defined as SENSITIVE STATIC cannot contain an SQL data change statement.

A STATIC cursor has visibility to changes made by *this* cursor using positioned updates or deletes. Committed changes made outside this cursor are visible with the SENSITIVE option of the FETCH statement. A FETCH SENSITIVE can result in a *hole* in the result table (that is, a difference between the result table and its underlying base table). If an updated row in the base table of a cursor no longer satisfies the predicate of its SELECT statement, an update hole occurs in the result table. If a row of a cursor was deleted in the base table, a delete hole occurs in the result table. When a FETCH SENSITIVE detects an update hole, no data is returned (a warning is issued), and the cursor is left positioned on the update hole. When a FETCH SENSITIVE detects a delete hole, no data is returned (a warning is issued), and the cursor is left positioned on the delete hole.

Updates through a cursor result in an automatic re-fetch of the row. This re-fetch means that updates can create a hole themselves. The re-fetched row also reflects changes as a result of triggers updating the same row. It is important to reflect these changes to maintain the consistency of data in the row.

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of the *select-statement* or *statement-name* of a SENSITIVE STATIC cursor can cause misleading results. This situation occurs because DB2 constructs a temporary result table

and retrieves rows from this table for FETCH INSENSITIVE statements. When DB2 processes a FETCH SENSITIVE statement, rows are fetched from the underlying table and predicates are re-evaluated. Using a function that is not deterministic can yield a different result on each FETCH SENSITIVE of the same row, which could also result in the row no longer being considered a match.

A FETCH INSENSITIVE on a SENSITIVE STATIC SCROLL cursor is not sensitive to changes made outside the cursor, unless a previous FETCH SENSITIVE has already refreshed that row; however, positioned updates and delete changes with the cursor are visible.

STATIC cursors are insensitive to insertions.

WITHOUT HOLD or WITH HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

WITHOUT HOLD

Does not prevent the cursor from being closed as a consequence of a commit operation. This is the default.

WITH HOLD

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared with WITH HOLD is closed at commit time if one of the following is true:

- The connection associated with the cursor is in the release pending status.
- The bind option DISCONNECT(AUTOMATIC) is in effect.
- The environment is one in which the option WITH HOLD is ignored.

When WITH HOLD is specified, a commit operation commits all of the changes in the current unit of work. For example, with a non-scrollable cursor, an initial FETCH statement is needed after a COMMIT statement to position the cursor on the row that follows the row that the cursor was positioned on before the commit operation.

WITH HOLD has no effect on an SQL data change statement within a SELECT statement. When a COMMIT is issued, the changes caused by the SQL data change statement are committed, regardless of whether or not the cursor is declared WITH HOLD.

All cursors are implicitly closed by a connect (Type 1) or rollback operation. A cursor is also implicitly closed by a commit operation if WITH HOLD is ignored or not specified.

Cursors that are declared with WITH HOLD in CICS or in IMS non-message-driven programs will not be closed by a rollback operation if the cursor was opened in a previous unit of work and no changes have been made to the database in the current unit of work. The cursor cannot be closed because CICS and IMS do not broadcast the rollback request to DB2 for a null unit of work.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the option WITH HOLD.

WITH HOLD is ignored in IMS message driven programs (MPP, IFP, and message-driven BMP). WITH HOLD maintains the cursor position in a CICS pseudo-conversational program until the end-of-task (EOT).

For details on restrictions that apply to declaring cursors with WITH HOLD, see *DB2 Application Programming and SQL Guide*.

WITHOUT RETURN or WITH RETURN

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is **WITHOUT RETURN**.

WITHOUT RETURN

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

WITH RETURN

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is relevant only if the DECLARE CURSOR statement is contained within the source code for a procedure. In other cases, the precompiler might accept the clause, but it has no effect.

When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or routine, that cursor defines a result set from the program or routine. Use the CLOSE statement to close a cursor that is not intended to be a result set from the program or routine. Although DB2 will automatically close any cursors that are not declared using with a WITH RETURN clause, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

TO CALLER

Specifies that the cursor can return a result set to the caller of the procedure. The caller is the program or routine that executed the SQL CALL statement that invokes the procedure that contains the DECLARE CURSOR statement. For example, if the caller is a procedure, the result set is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

If the statement is contained within the source code for a procedure, WITH RETURN TO CALLER specifies that the cursor can be used as a result set cursor. A result set cursor is used when the result table of a cursor is to be returned from a procedure. Specifying TO CALLER is optional.

In other cases, the clause is ignored and the cursor cannot be used as a result set cursor.

TO CLIENT

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger calls the procedure (either directly or indirectly), the result set cannot be returned to the client and the cursor will be closed after the procedure finishes.

rowset-positioning

Specifies whether multiple rows of data can be accessed as a rowset on a single FETCH statement for the cursor. The default is WITHOUT ROWSET POSITIONING.

WITHOUT ROWSET POSITIONING

Specifies that the cursor can be used only with row-positioned FETCH statements. The cursor is to return a single row for each FETCH statement and the FOR *n* ROWS clause cannot be specified on a FETCH statement for this cursor. WITHOUT ROWSET POSITIONING or single row access refers to how data is fetched from the database engine. For remote access, data might be blocked and returned to the client in blocks.

WITH ROWSET POSITIONING

Specifies that the cursor can be used with either row-positioned or rowset-positioned FETCH statements. This cursor can be used to return either a single row or multiple rows, as a rowset, with a single FETCH statement. ROWSET POSITIONING refers to how data is fetched from the database engine. For remote access, if any row qualifies, at least 1 row is returned as a rowset. The size of the rowset depends on the number of rows specified on the FETCH statement and on the number of rows that qualify. Data might be blocked and returned to the client in blocks.

DB2 REXX applications do not support cursors that are declared WITH ROWSET POSITIONING. To allow a cursor for a SELECT statement in a DB2 REXX application to be used with row-positioned or rowset-positioned FETCH statements, specify WITH ROWSET POSITIONING in the attribute string of the PREPARE statement for the SELECT statement.

select-statement

Specifies the result table of the cursor. See “select-statement” on page 1131 for an explanation of *select-statement*.

The *select-statement* must not include parameter markers (except for REXX), but can include references to host variables. In host languages, other than REXX, the declarations of the host variables must precede the DECLARE CURSOR statement in the source program. In REXX, parameter markers must be used in place of host variables and the statement must be prepared.

The USING clause of the OPEN statement can be used to specify host variables that will override the values of the host variables or parameter markers that are specified as part of the statement in the DECLARE CURSOR statement.

The *select-statement* must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

statement-name

Identifies the prepared *select-statement* that specifies the result table of the cursor whenever the cursor is opened. The *statement-name* must not be identical to a statement name specified in another DECLARE CURSOR statement of the source program. For an explanation of prepared SELECT statements, see “PREPARE” on page 2083.

The prepared *select-statement* must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

Notes

A cursor in the open state designates a result table and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.

Read-only cursors:

If the result table is *read-only*, the cursor is *read-only*. The cursor that references a view with instead of triggers are read-only since positioned UPDATE and positioned DELETE statements are not allowed using those cursors. The result table is *read-only* if one or more of the following statements is true about the *select-statement* of the cursor:

- The first FROM clause identifies or contains any of the following:
 - More than one table or view
 - A catalog table with no updatable columns
 - A read-only view
 - A nested table expression
 - A table function
 - A system-maintained materialized query table
 - A single table that is a system-period temporal table and a period specification is used
- The first SELECT clause specifies the keyword DISTINCT, contains an aggregate function, or uses both
- It contains an SQL data change statement
- The outer subselect contains a GROUP BY clause, a HAVING clause, or both clauses
- It contains a subquery such that the base object of the outer subselect, and of the subquery, is the same table
- Any of the following operators or clauses are specified:
 - A set operator
 - An ORDER BY clause (except when the cursor is declared as SENSITIVE STATIC scrollable)
 - A FOR READ ONLY clause
- It is executed with isolation level UR and a FOR UPDATE clause is not specified.
- It is a VALUES clause.

If the result table is not read-only, the cursor can be used to update or delete the underlying rows of the result table.

Tables for which row or column access controls are enforced:

The *select-statement* of the cursor can reference a table for which row or column access controls are enforced. The row or column access controls do not effect the determination of whether the cursor is read-only and do not effect the cursor sensitivity.

Work file database requirement for static scrollable cursors:

To use a static scrollable cursor, you must first create a work file database and at least one table space with a 32KB page size in this database because a static scrollable cursor requires a temporary table for its result table while the cursor is open. DB2 chooses a table space to use for the temporary result table. Dynamic scrollable cursors do not require a declared temporary table.

For static scrollable cursor declarations that contain empty strings, DB2 assigns one byte in the temporary table space for each empty string. The following example shows a scrollable cursor declaration with an empty string:

```
EXEC SQL DECLARE CSROWSTAT SENSITIVE STATIC SCROLL CURSOR
  WITH ROWSET POSITIONING WITH HOLD FOR
  SELECT ID1, ''
  FROM TB;
```

Cursors in COBOL and Fortran programs:

In COBOL and Fortran source programs, the DECLARE CURSOR statement must precede all statements that explicitly refer to the cursor by name. This rule does not necessarily apply to the other host languages because the precompiler provides a two-pass option for these languages. This rule applies to other host languages if the two-pass option is not used.

Cursors in REXX:

If host variables are used in a DECLARE CURSOR statement within a REXX procedure, the DECLARE CURSOR statement must be the object of a PREPARE and EXECUTE.

Scope of a cursor:

The scope of *cursor-name* is the source program in which it is defined; that is, the application program submitted to the precompiler. Thus, you can only refer to a cursor by statements that are precompiled with the cursor declaration. For example, a COBOL program called from another program cannot use a cursor that was opened by the calling program. Furthermore, a cursor defined in a Fortran subprogram can only be referred to in that subprogram. Cursors that specify WITH RETURN in a procedure and are left open are returned as result sets.

Although the scope of a cursor is the program in which it is declared, each package (or DBRM of a plan) created from the program includes a separate instance of the cursor, and more than one instance of the cursor can be used in the same execution of the program. For example, assume a program is precompiled with the CONNECT(2) option and its DBRM is used to create a package at location X and a package at location Y. The program contains the following SQL statements:

```
DECLARE C CURSOR FOR ...
CONNECT TO X
OPEN C
FETCH C INTO ...
CONNECT TO Y
OPEN C
FETCH C INTO ...
```

The second OPEN C statement does not cause an error because it refers to a different instance of cursor C. The same notion applies to a single location if the packages are in different collections.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results can be different. If the SELECT statement of the cursor contains CURRENT DATE, CURRENT TIME or CURRENT TIMESTAMP, all references to these special registers yields the same respective datetime value on each FETCH operation. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

Blocking of data:

To process data more efficiently, DB2 might block data for read-only cursors. If a cursor is not going to be used in a positioned UPDATE or positioned DELETE statement, define the cursor as FOR READ ONLY.

Positioned deletes and isolation level UR:

Specify FOR UPDATE if you want to use the cursor for a positioned DELETE and the isolation level is UR because of a BIND option. In this case, the isolation level is CS.

Returning a result set from a stored procedure:

A cursor that is declared in a stored procedure returns a result set when all of the following conditions are true:

- The cursor is declared with the WITH RETURN option. In a distributed environment, blocks of each result set of the cursor's data are returned with the CALL statement reply.
- The cursor is left open after exiting from the stored procedure. A cursor declared with the SCROLL option must be left positioned *before* the first row before exiting from the stored procedure.
- The cursor is declared with the WITH HOLD option if the stored procedure is defined to commit on return.

The result set is the set of all rows after the current position of the cursor after exiting the stored procedure. The result set is assumed to be read-only. If that same procedure is invoked again, open result set cursors for a stored procedure at a given site are automatically closed by the database management system.

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. (However, the value of a function that is not deterministic in the WHERE clause of a scrollable cursor is captured when the cursor is opened and remains unchanged until the cursor is closed.) Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Multiple instances of a cursor that is defined with RETURN TO CLIENT:

If the cursor is declared in a native SQL procedure, a cursor that is declared as WITH RETURN TO CLIENT can be opened even when a cursor with the same name is already in the open state. In this case, the already open cursor becomes a result set cursor and is no longer accessible by using its cursor name. A new cursor is opened and becomes accessible by using the cursor name. When a CLOSE statement is issued, the last instance of the cursor will be closed. Closing the new cursor does not make the cursor that was previously accessible by that name accessible by the cursor name again. Cursors that become result set cursors in this way cannot be accessed at the server and can be processed only at the client.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Declare C1 as the cursor of a query to retrieve data from the table DSN8A10.DEPT. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8A10.DEPT
  WHERE ADMRDEPT = 'A00';
```

Example 2: Declare C1 as the cursor of a query to retrieve data from the table DSN8810.DEPT. Assume that the data will be updated later with a searched update and should be locked when the query executes. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8A10.DEPT
  WHERE ADMRDEPT = 'A00'
  FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;
```

Example 3: Declare C2 as the cursor for a statement named STMT2.

```
EXEC SQL DECLARE C2 CURSOR FOR STMT2;
```

Example 4: Declare C3 as the cursor for a query to be used in positioned updates of the table DSN8A10.EMP. Allow the completed updates to be committed from time to time without closing the cursor.

```
EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR
  SELECT * FROM DSN8A10.EMP
  FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;
```

Instead of specifying which columns should be updated, you could use a FOR UPDATE clause without the names of the columns to indicate that all updatable columns are updated.

Example 5: In stored procedure SP1, declare C4 as the cursor for a query of the table DSN8A10.PROJ. Enable the cursor to return a result set to the caller of SP1, which performs a commit on return.

```
EXEC SQL DECLARE C4 CURSOR WITH HOLD WITH RETURN FOR
  SELECT PROJNO, PROJNAME
  FROM DSN8A10.PROJ
  WHERE DEPTNO = 'A01';
```

Example 6: In the following example, the DECLARE CURSOR statement associates the cursor name C5 with the results of the SELECT and specifies that the cursor is scrollable. C5 allows positioned updates and deletes because the result table can be updated.

```
EXEC SQL DECLARE C5 SENSITIVE STATIC SCROLL CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8A10.DEPT
  WHERE ADMRDEPT = 'A00';
```

Example 7: In the following example, the DECLARE CURSOR statement associates the cursor name C6 with the results of the SELECT and specifies that the cursor is scrollable.

```
EXEC SQL DECLARE C6 INSENSITIVE SCROLL CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8A10.DEPT
  WHERE DEPTNO;
```

Example 8: The following example illustrates how an application program might use dynamic scrollable cursors. First create and populate a table.

```
CREATE TABLE ORDER
  (ORDERNUM INTEGER,
  CUSTNUM INTEGER,
  CUSTNAME VARCHAR(20),
  ORDERDATE CHAR(8),
  ORDERAMT DECIMAL(8,3),
  COMMENTS VARCHAR(20));
```

Populate the table by inserting or loading about 500 rows.

```
EXEC SQL DECLARE CURSOR ORDERSROLL
SENSITIVE DYNAMIC SCROLL FOR
SELECT ORDERNUM, CUSTNAME, ORDERAMT, ORDERDATE FROM ORDER
WHERE ORDERAMT > 1000
FOR UPDATE OF COMMENTS;
```

Open the scrollable cursor.

```
OPEN CURSOR ORDERSROLL;
```

Fetch forward from the scrollable cursor.

```
-- Loop-to-fill-screen
-- do 10 times
  FETCH FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
-- end
```

Fetch RELATIVE from the scrollable cursor.

```
-- Skip-forward-100-rows
  FETCH RELATIVE +100
  FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
-- Skip-backward-50-rows
  FETCH RELATIVE -50
  FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch ABSOLUTE from the scrollable cursor.

```
-- Re-read-the-third-row
  FETCH ABSOLUTE +3
  FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch RELATIVE from scrollable cursor.

```
-- Read-the-third-row-from current position
  FETCH SENSITIVE RELATIVE +3
  FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Do a positioned update through the scrollable cursor.

```
-- Update-the-current-row
  UPDATE ORDER SET COMMENTS = "Expedite"
  WHERE CURRENT OF ORDERSROLL;
```

Close the scrollable cursor.

```
CLOSE CURSOR ORDERSROLL;
```

Example 9: Declare C1 as the cursor of a query to retrieve a rowset from the table DEPT. The prepared statement is MYCURSOR.

```
EXEC SQL DECLARE C1 CURSOR
  WITH ROWSET POSITIONING FOR MYCURSOR;
```

DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table resides in the work file database and its description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description and instance of the temporary table. When the application process terminates, the temporary table is dropped.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

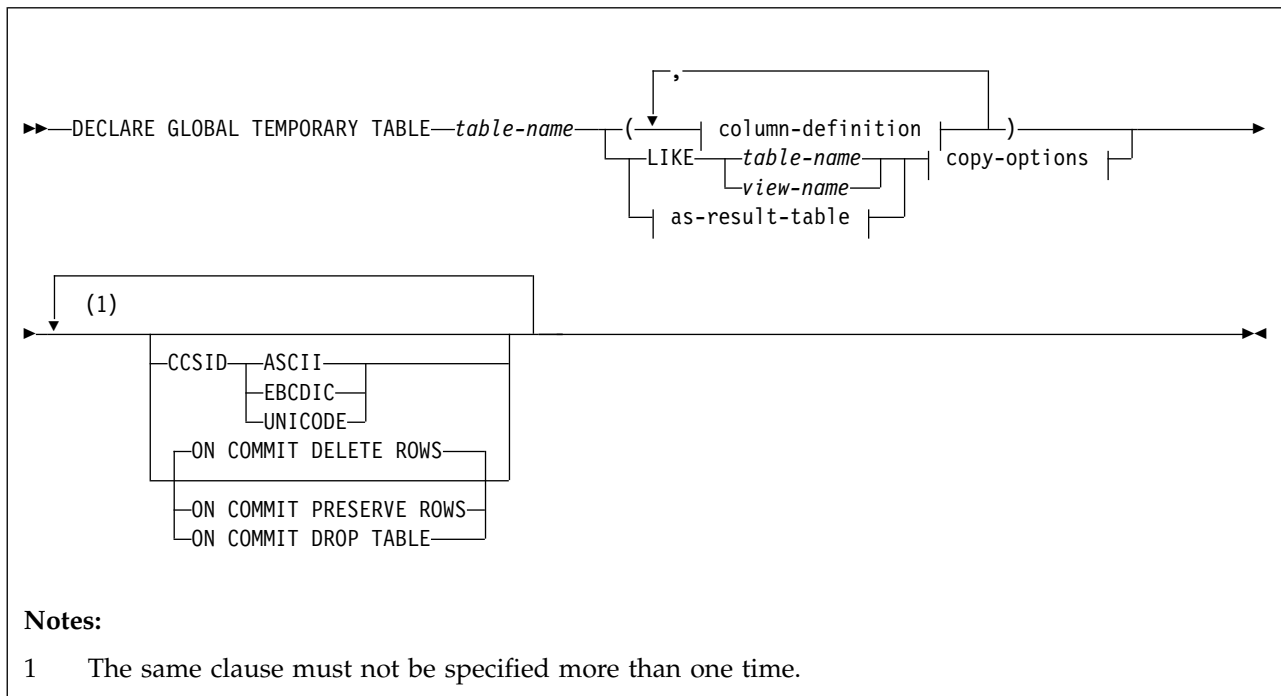

None are required, unless the LIKE clause or AS *fullselect* is specified. In those cases, additional privileges might be required.

PUBLIC implicitly has the following privileges without GRANT authority for declared temporary tables:

- The CREATETAB privilege to define a declared temporary table in the database that is defined AS WORKFILE, which is the database for declared temporary tables.
- The USE privilege to use the table spaces in the database that is defined as WORKFILE.
- All table privileges on the table and authority to drop the table. (Table privileges for a declared temporary table cannot be granted or revoked.)

These implicit privileges are not recorded in the DB2 catalog and cannot be revoked.

Syntax

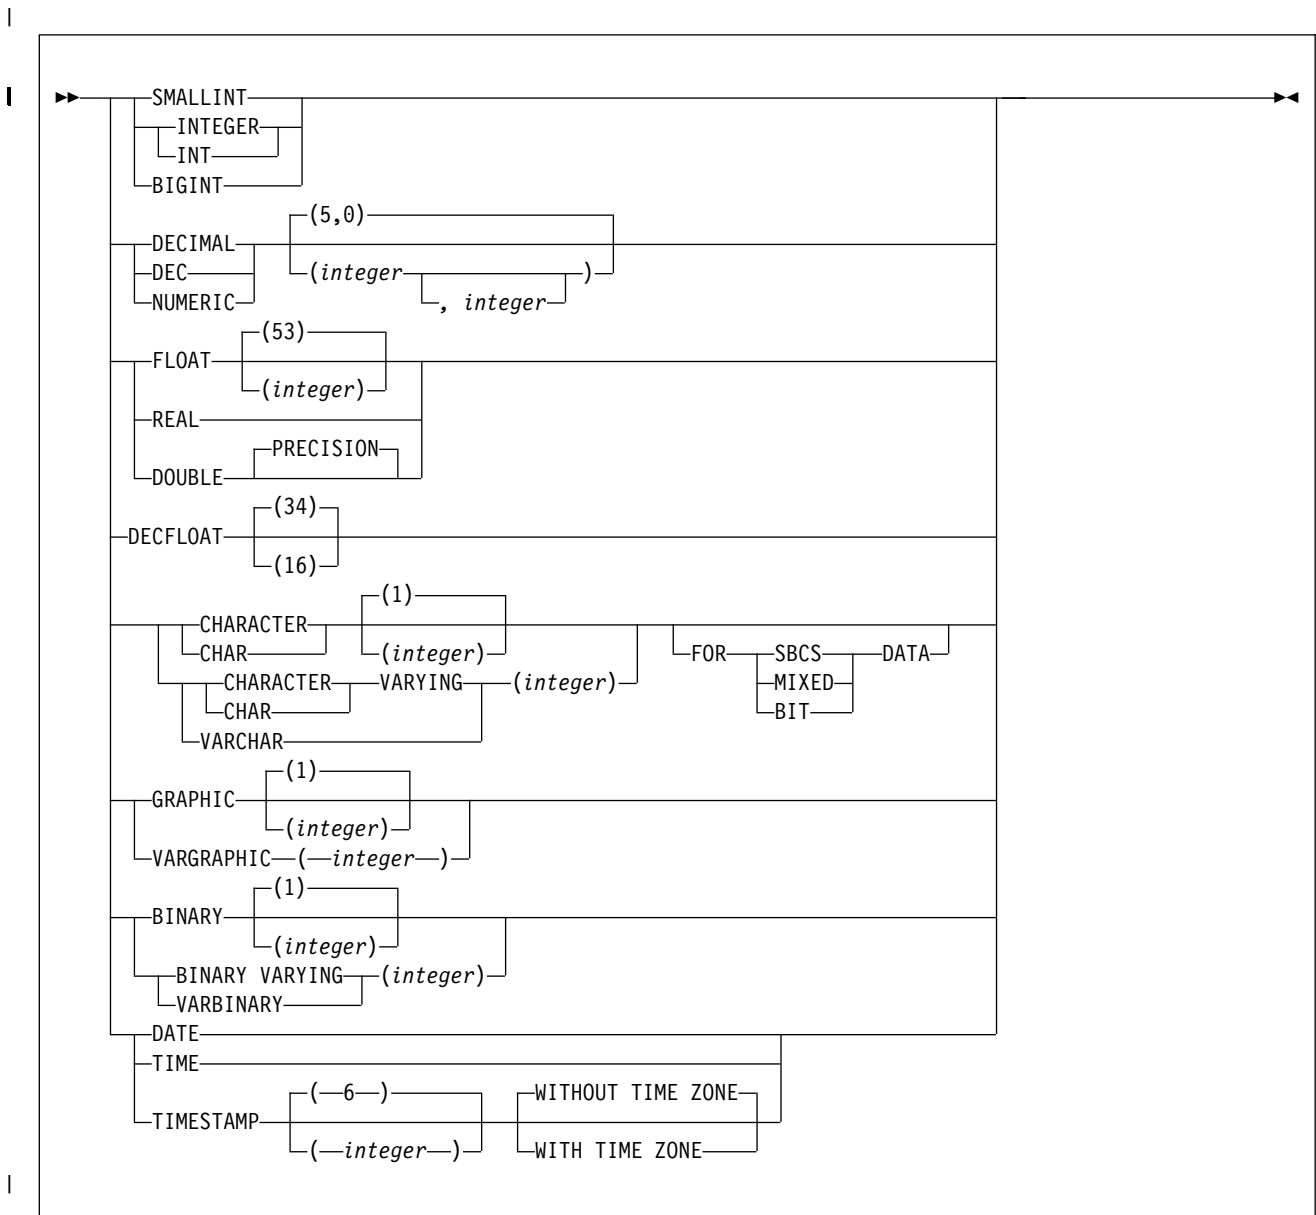

column-definition:

data-type:

built-in-type:

as-result-table:

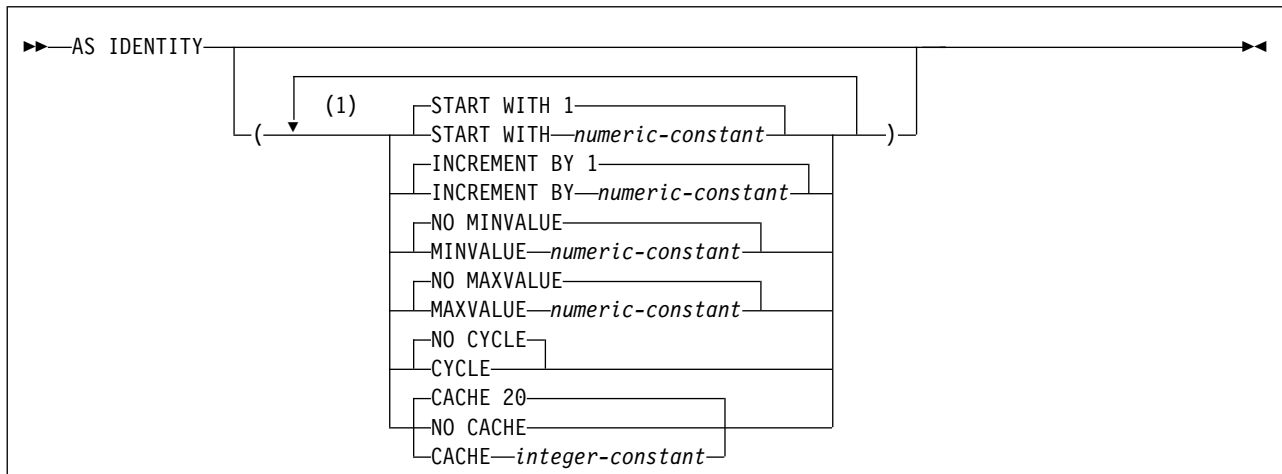

copy-options:

Notes:

- 1 These clauses can be specified in any order and must not be specified more than one time.
- 2 EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified with the LIKE clause.

identity-options:

Notes:

- 1 Separator commas can be specified between the attributes when an identity column is defined

Description

table-name

Names the temporary table. The qualifier, if specified explicitly, must be SESSION. If the qualifier is not specified, it is implicitly defined to be SESSION.

If a table, view, synonym, or alias already exists with the same name and an implicit or explicit qualifier of SESSION:

- The declared temporary table is still defined with SESSION.*table-name*. An error is not issued because the resolution of a declared temporary table name does not include the persistent and shared names in the DB2 catalog tables.

- Any references to `SESSION.table-name` will resolve to the declared temporary table rather than to any existing `SESSION.table-name` whose definition is persistent and is in the DB2 catalog tables.

column-definition

Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32683 bytes. The maximum row size must not exceed 32675 bytes (8 bytes less than the maximum record size).

column-name

Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

data-type

Specifies the data type of the column. The data type can be any built-in data type that can be specified for the CREATE TABLE statement except for a LOB (BLOB, CLOB, and DBCLOB), ROWID, or XML type. The FOR *subtype* DATA clause can be specified as part of *data-type*. For more information on the data types and the rules that apply to them, see built-in-type.

DEFAULT

Specifies a default value for the column. This clause must not be specified more than once in the same *column-definition*.

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

If DEFAULT is specified without a value after it, the default value of the column depends on the data type of the column, as follows:

Data type

Default value

Numeric

0

Fixed-length character string

A string of blanks

Fixed-length graphic string

A string of blanks

Fixed-length binary string

Hexadecimal zeros

Varying-length string

A string of length 0

Date CURRENT DATE

Time CURRENT TIME

Timestamp

CURRENT_TIMESTAMP(*p*) where *p* is the corresponding timestamp precision.

Timestamp with time zone

CURRENT_TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

A default value other than the one that is listed above can be specified in one of the following forms:

constant

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column. A hexadecimal graphic string constant (GX) cannot be specified.

SESSION_USER or USER

Specifies the value of the SESSION_USER (USER) special register at the time of an insert or update operation or LOAD as the default value for the column. The data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the SESSION_USER special register.

CURRENT SQLID

Specifies the value of the SQL authorization ID of the process at the time of an SQL data change statement or LOAD as the default value for the column. The data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL

Specifies null as the default value for the column. If NOT NULL was specified, DEFAULT NULL must not be specified within the same *column-definition*.

GENERATED

Specifies that DB2 generates values for the column. GENERATED must be specified if the column is to be considered an IDENTITY column. If DEFAULT is specified for the column for an update operation, DB2 generates a value for both GENERATED ALWAYS and GENERATED BY DEFAULT.

ALWAYS

Specifies that DB2 always generates a value for the column when a row is inserted into the table.

BY DEFAULT

Specifies that DB2 generates a value for the column when a row is inserted into the table unless a value is specified. BY DEFAULT is the recommended value only when you are using data propagation.

Defining a column as GENERATED BY DEFAULT does not necessarily guarantee the uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the column.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero).

An identity column is implicitly NOT NULL. An identity column cannot have a DEFAULT clause. For the descriptions of the identity attributes, see the description of the AS IDENTITY clause in "CREATE TABLE" on page 1706.

NOT NULL

Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

LIKE *table-name* or *view-name*

Specifies that the columns of the table have the same name, data type, and nullability attributes as the columns of the identified table or view. If a table is identified, the column default attributes are also defined by that table. If row permissions or column access control is enforced for the table specified by *table-name*, row and column access controls are not inherited by the new table. The name specified must identify a table, view, synonym, or alias that exists at the current server. The identified table must not be an auxiliary table or an accelerator-only table.

The privilege set must include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If LIKE results in a column having a LOB data type, a ROWID data type, or distinct type, the DECLARE GLOBAL TEMPORARY TABLE statement fails.
- In addition to these data type restrictions, if any column has any other attribute value that is not allowed in a declared temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.

When the identified object is a table, the column name, data type, nullability, and default attributes are determined from the columns of the specified table; any identity column attributes are inherited only if the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified.

as-result-table

Specifies that the table definition is based on the column definitions from the result of a query expression.

The behavior of these column attributes is controlled with the INCLUDING or USING TYPE DEFAULTS clauses, which are defined below.

AS (*fullselect*)

Specifies an implicit definition of n columns for the declared global temporary table, where n is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names. The implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. Row and column access controls that are enforced on the base table are not inherited by the new table.

The result table of the *fullselect* must not contain a column that has a LOB data type, a ROWID data type, an XML data type or a distinct type.

If *fullselect* results in other column attributes that are not applicable for a declared temporary table, those attributes are ignored in the implicit definition for the declared temporary table.

If *fullselect* results in a row change timestamp column, the corresponding column of the new table inherits only the data type of the row change timestamp column. The new column is not considered as a generated column.

The *fullselect* must not refer to host variables or include parameter markers (question marks). The outermost SELECT list of the *fullselect* must not reference data that is encoded with different encoding schemes.

WITH NO DATA

Specifies that the *fullselect* is not executed. You can use the INSERT INTO statement with the same *fullselect* specified in the AS clause to populate the declared temporary table with the set of rows from the result table of the *fullselect*.

copy-options

Specifies whether identity column attributes and column defaults are inherited from the definition of the source of the result table.

EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies whether identity column attributes are inherited from the columns resulting from the *fullselect*, *table-name*, or *view-name*.

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table does not inherit the identity attributes of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table inherits the identity attributes, if any, of the columns resulting from the *fullselect* or *table-name*. In general, the identity attributes are copied if the element of the corresponding column in the table or *fullselect* is the name of a table column that directly or indirectly maps to the name of a base table column that is an identity column.

If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS fullselect clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the *fullselect* includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the *fullselect* includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The *fullselect* includes a set operation.

If INCLUDING IDENTITY COLUMN ATTRIBUTES is not specified, the new table will not have an identity column.

If the LIKE clause identifies a view, INCLUDING IDENTITY COLUMN ATTRIBUTES must not be specified.

EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS

Specifies whether the table inherits the default values of the columns of the fullselect. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

EXCLUDING COLUMN DEFAULTS

Specifies that the table does not inherit the default values of the columns of the fullselect. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert operation for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that the table inherits the default values of the columns of the fullselect. A default value is the value that is assigned to the column when a value is not specified on an insert operation or LOAD.

Columns resulting from the fullselect that are not updatable will not have a default defined in the corresponding column of the created table.

USING TYPE DEFAULTS

Specifies that the default values for the declared temporary table depend on the data type of the columns that result from *fullselect*, as follows:

Data type

Default value

Numeric

0

Fixed-length character string

Blanks

Fixed-length graphic string

Blanks

Fixed-length binary string

Hexadecimal zeros

Varying-length string

A string of length 0

Date CURRENT DATE

Time CURRENT TIME

Timestamp

CURRENT TIMESTAMP(*p*) where *p* is the corresponding timestamp precision.

Timestamp(*integer*) with time zone

CURRENT TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

CCSID *encoding-scheme*

Specifies the encoding scheme for string data that is stored in the table. For declared temporary tables, the encoding scheme for the data cannot be specified for the table space or database, and all data in one table space or the database need not use the same encoding scheme. Because there can be only one work file database for all declared temporary tables for each DB2 member, there can be a mixture of encoding schemes in both the database and each table space.

For declared temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause or as the scheme for the table identified by the AS (fullselect) clause.

ASCII Specifies that the data is encoded by using the ASCII CCSIDs of the server.

EBCDIC

Specifies that the data is encoded by using the EBCDIC CCSIDs of the server.

UNICODE

Specifies that the data is encoded by using the UNICODE CCSIDs of the server.

An error occurs if the CCSIDs for the encoding scheme have not been defined. Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

ON COMMIT

Specifies what happens to the table for a commit operation. The default is ON COMMIT DELETE ROWS.

DELETE ROWS

Specifies that all of the rows of the table are deleted if there is no open cursor that is defined as WITH HOLD that references the table.

PRESERVE ROWS

Specifies that all of the rows of the table are preserved. Thread reuse capability is not available to any application process or thread that contains, at its most recent commit, an active declared temporary table that was defined with the ON COMMIT PRESERVE ROWS clause.

DROP TABLE

Specifies that the table is implicitly dropped at commit if there is no open cursor that is defined as WITH HOLD that references the table. If there is an open cursor defined as WITH HOLD on the table at commit, the rows are preserved.

Notes

Instantiation, scope, and termination: For the following explanations, P denotes an application process, and T is a declared temporary table executed in P:

- An empty instance of T is created when a DECLARE GLOBAL TEMPORARY TABLE statement is executed in P.
- Any SQL statement in P can reference T, and any of those references to T in P is a reference to that same instance of T. ()

If a DECLARE GLOBAL TEMPORARY statement is specified within an SQL PL compound statement, the scope of the declared temporary table is the application process and not just the compound statement. A declared temporary table cannot be defined multiple times by the same name in other compound statements in that application process, unless the table has been dropped explicitly.

- If T was declared at a remote server, the reference to T must use the same DB2 connection that was used to declare T and that connection must not have been terminated after T was declared. When the connection to the database server at which T was declared terminates, T is dropped.
- If T was defined with the ON COMMIT DELETE ROWS clause specified implicitly or explicitly, when a commit operation terminates a unit of work in P and there is no open WITH HOLD cursor in P that is dependent on T, the commit deletes all rows from T.
- If T is defined with the ON COMMIT DROP TABLE clause, when a commit operation terminates a unit of work in P and no program in P has a WITH HOLD cursor open that is dependent on T, the commit includes the operation DROP TABLE T.
- When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the changes to table T are undone.

When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the rollback drops table T.

When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the drop of the declaration of declared temporary table SESSION.T, the rollback undoes the drop of table T.

- When the application process that declared T terminates, T is dropped.

Privileges: When a declared temporary table is defined, PUBLIC is implicitly granted all table privileges on the table and authority to drop the table. These implicit privileges are not recorded in the DB2 catalog and cannot be revoked. This enables any SQL statement in the application process to reference a declared temporary table that has already been defined in that application process.

Referring to a declared temporary table in other SQL statements: Many SQL statements support declared temporary tables. To refer to a declared temporary table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE, you must qualify the table name with SESSION. You can either specify SESSION explicitly in the table name or use the QUALIFIER bind option to specify SESSION as the qualifier for all SQL statements in the plan or package.

If you use SESSION as the qualifier for a table name but the application process does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the table name, DB2 assumes that you are not referring to a declared temporary table. DB2 resolves such table references to a table whose definition is persistent and appears in the DB2 catalog tables.

With the exception of the DECLARE GLOBAL TEMPORARY TABLE statement, any static SQL statement that references a declared temporary table is incrementally bound at run time. This is because the definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY statement is executed in the application process that contains those SQL statements and the definition does not persist when the application process finishes running.

When a plan or package is bound, any static SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement) that references a *table-name* that is qualified by SESSION, regardless of whether the reference is for a declared temporary table, is not completely bound. However, the bind of the plan or package succeeds if there are no other errors. These static SQL statements are then incrementally bound at run time when the static SQL statement is issued. Object dependencies are not recorded in SYSIBM.SYSPLANDEP or SYSIBM.SYSPACKDEP tables. These incremental binds are necessary because:

- The definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY TABLE statement for the table is executed in the same application process that contains those SQL statements. Therefore, DB2 must wait until the plan or package is run to determine if SESSION.*table-name* refers to a base table or a declared temporary table.
- The definition of a declared temporary table does not persist after the table it is explicitly dropped (DROP statement), implicitly dropped (ON COMMIT DROP TABLE), or the application process that defined it finishes running. When the application process terminates or is re-used as a reusable application thread, the instantiated rows of the table are deleted and the definition of the declared temporary table is dropped if it has not already been explicitly or implicitly dropped.

After the plan or package is bound, any static SQL statement that refers to a *table-name* that is qualified by SESSION has a new statement status of M in the DB2 catalog table (STATUS column of SYSIBM.SYSSTMT or SYSIBM.SYSPACKSTMT).

Thread reuse: If a declared temporary table is defined in an application process that is running as a local thread, the application process or local thread that declared the table qualifies for explicit thread reuse if:

- The table was defined with the ON COMMIT DELETE ROWS attribute, which is the default.
- The table was defined with the ON COMMIT PRESERVE ROWS attribute and the table was explicitly dropped with the DROP TABLE statement before the thread's commit operation.
- The table was defined with the ON COMMIT DROP TABLE attribute. When a declared temporary table is defined with the ON COMMIT DROP TABLE and a commit occurs, the table is implicitly dropped if there are no open cursors defined with the WITH HOLD option.

When the thread is reused, the declared temporary table is dropped and its rows are destroyed. However, if you do not explicitly or implicitly drop all declared temporary tables before or when your thread performs a commit and the thread becomes idle waiting to be reused, as with all thread reuse situations, the idle thread holds resources and locks. This includes some declared temporary table resources and locks on the table spaces and the database descriptor (DBD) for the work file database. So, instead of using the implicit drop feature of thread reuse to drop your declared temporary tables, it is recommended that you:

- Use the DROP TABLE statement to explicitly drop your declared temporary tables before the thread performs a commit and becomes idle.
- Define the declared temporary tables with ON COMMIT DROP TABLE clause so that the tables are implicitly dropped when a commit occurs.

Explicitly dropping the tables before a commit occurs or having them implicitly dropped when the commit occurs enables you to maximize the use of declared temporary table resources and release locks when multiple threads are using declared temporary table.

Remote threads qualify for thread reuse differently than local threads. If a declared temporary table is defined (with or without ON COMMIT DELETE ROWS) in an application process that is running as a remote or DDF thread (also known as Database Access Thread or DBAT), the remote thread qualifies for thread reuse only when the declared temporary table is explicitly dropped before the thread performs a commit operation. Dropping the declared temporary table enables the remote thread to qualify for the implicit thread reuse that is supported for DDF threads via connection pooling and to become an inactive DBAT (type 1 inactive thread) or an inactive connection (type 2 inactive thread).

Parallelism support: Only I/O and CP parallelism are supported. Any query that involves a declared temporary table is limited to parallel tasks on a single CPC.

Restrictions on the use of declared temporary tables: Declared temporary tables cannot:

- Be specified in referential constraints.
- Be referenced in any SQL statements that are defined in an SQL function body (CREATE FUNCTION or ALTER FUNCTION statements), a trigger body (CREATE TRIGGER statement). If you refer a table name that is qualified with SESSION in a trigger body, DB2 assumes that you are referring to a base table.
- Be referenced in a CREATE INDEX statement unless the schema name of the index is SESSION.

In addition, do not refer to a declared temporary table in any of the following statements.

| | |
|--------------------------------------|-----------------------------------|
| ALTER INDEX | CREATE VIEW |
| ALTER TABLE | GRANT (table or view privileges) |
| COMMENT | LABEL |
| CREATE ALIAS | LOCK TABLE |
| CREATE FUNCTION (TABLE LIKE clause) | REFRESH TABLE |
| CREATE PROCEDURE (TABLE LIKE clause) | RENAME |
| CREATE TRIGGER | REVOKE (table or view privileges) |

Declared global temporary tables and dynamic statement caching: The DB2 dynamic statement cache feature does not support dynamic SQL statements that reference declared temporary tables, even if the SQL statement also includes references to base or persistent tables. DB2 will not insert such statements into the dynamic statement cache. Instead, these dynamic statements are processed as if statement caching is not in effect. Declared temporary tables are unique and specific to an application process or DB2 thread, cannot be shared across threads, are not described in the DB2 catalog, and do not persist beyond termination of the DB2 thread or application process. These attributes prevent the use of the dynamic statement cache feature where tables and SQL statements are shared across threads or application processes.

Table space requirements in the work file database: DB2 stores all declared temporary tables in the work file database. You cannot define a declared temporary table unless a table space with at least an 32KB page size exists in the work file database.

Alternative syntax and synonyms: To provide compatibility with previous releases, DB2 allows you to specify:

- LONG VARCHAR as a synonym for VARCHAR(*integer*) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(*integer*) when defining the data type of a column.

However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

- DEFINITION ONLY as a synonym for WITH NO DATA.
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.

```
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
(EMPNO    CHAR(6)    NOT NULL,
 SALARY   DECIMAL(9, 2),
 BONUS    DECIMAL(9, 2),
 COMM     DECIMAL(9, 2))
CCSID EBCDIC
ON COMMIT PRESERVE ROWS;
```

Example 2: Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
  LIKE USER1.EMPTAB
  INCLUDING IDENTITY
  ON COMMIT PRESERVE ROWS;
```

In the above example, DB2 uses SESSION as the implicit qualifier for TEMPTAB1.

DECLARE STATEMENT

The DECLARE STATEMENT statement is used for application program documentation. It declares names that are used to identify prepared SQL statements.

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

Description

statement-name STATEMENT

Lists one or more names that are used in your application program to identify prepared SQL statements.

Example

This example shows the use of the DECLARE STATEMENT statement in a PL/I program.

```
EXEC SQL DECLARE OBJECT_STATEMENT STATEMENT;  
  
EXEC SQL INCLUDE SQLDA;  
EXEC SQL DECLARE C1 CURSOR FOR OBJECT_STATEMENT;  
  
( SOURCE_STATEMENT IS "SELECT DEPTNO, DEPTNAME,  
  MGRNO FROM DSN8A10.DEPT WHERE ADMRDEPT = 'A00'" )  
  
EXEC SQL PREPARE OBJECT_STATEMENT FROM SOURCE_STATEMENT;  
EXEC SQL DESCRIBE OBJECT_STATEMENT INTO SQLDA;  
  
/* Examine SQLDA */  
  
EXEC SQL OPEN C1;  
  
DO WHILE (SQLCODE = 0);  
  EXEC SQL FETCH C1 USING DESCRIPTOR SQLDA;  
  
/* Print results */  
  
END;  
  
EXEC SQL CLOSE C1;
```

DECLARE TABLE

The DECLARE TABLE statement is used for application program documentation. It also provides the precompiler with information used to check your embedded SQL statements. (The DCLGEN subcommand can be used to generate declarations for tables and views described in any accessible DB2 catalog.)

For more on DCLGEN, see *DB2 Application Programming and SQL Guide* and *DB2 Command Reference*.)

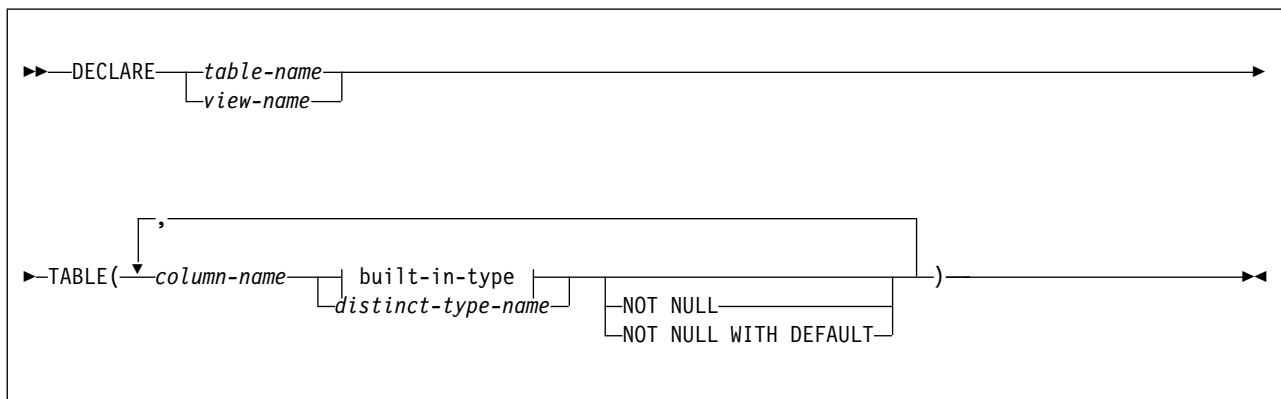

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

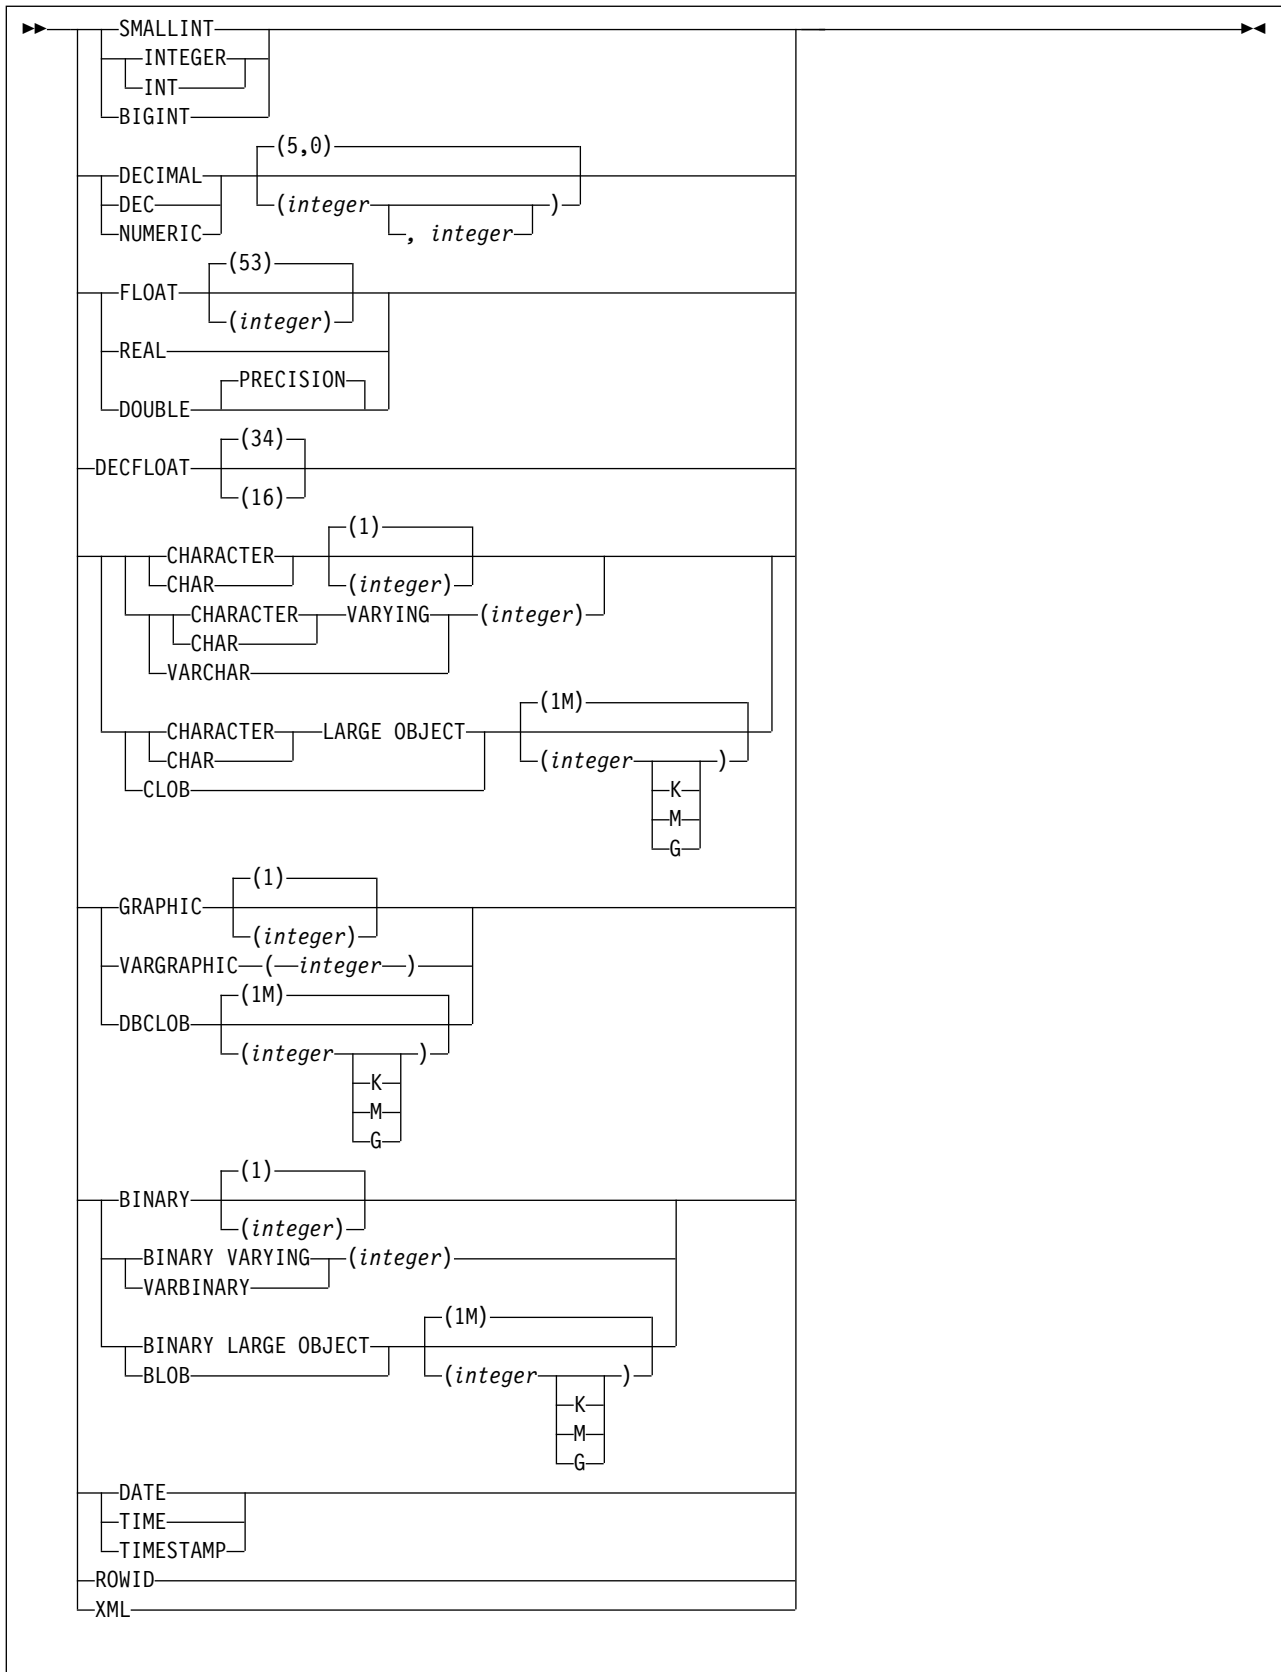

Authorization

None required.

Syntax

built-in-type:

Description

table-name or view-name

Specifies the name of the table or view to document. If the table is defined in your application program, the description of the table in the SQL statement in which it is defined (for example, CREATE TABLE or DECLARE GLOBAL TEMPORARY TABLE statement) and the DECLARE TABLE statement must be identical.

column-name

Specifies the name of a column of the table or view.

The precompiler uses these names to check for consistency of names within your SQL statements. It also uses the data type to check for consistency of names and data types within your SQL statements.

built-in-type

Specifies the built-in data type of the column. Use one of the built-in data types.

SMALLINT

For a small integer.

INTEGER or INT

For a large integer.

BIGINT

For a big integer.

DECIMAL(*integer*, *integer*) or DEC(*integer*, *integer*)

DECIMAL(*integer*) or DEC(*integer*)

DECIMAL or DEC

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p*,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

FLOAT(*integer*)

FLOAT

For a floating-point number. If *integer* is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

REAL

For single precision floating-point.

DOUBLE or DOUBLE PRECISION

For double precision floating-point

DECFLOAT(*integer*)

For a decimal floating-point number. The value of *integer* must be either 16

or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

CHARACTER(*integer*) or CHAR(*integer*)

CHARACTER or CHAR

For a fixed-length character string of length *integer*, which can range from 1 to 255. If the length specification is omitted, a length of 1 character is assumed.

VARCHAR(*integer*), CHAR VARYING(*integer*), or CHARACTER VARYING(*integer*)

For a varying-length character string of maximum length *integer*, which can range from 1 to the maximum record size minus 10 bytes. See Table 174 on page 1768 to determine the maximum record size.

CLOB(*integer* [K|M|G]), CHAR LARGE OBJECT(*integer* [K|M|G]), or CHARACTER LARGE OBJECT(*integer* [K|M|G])

CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 to 2 147 483 647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 97.

When *integer* is not specified, the default length is 1M. The maximum value that can be specified for *integer* depends on whether a units indicator is also specified as shown in the following list.

integer The maximum value for *integer* is 2 147 483 647. The maximum length of the string is *integer*.

integer **K**

The maximum value for *integer* is 2 097 152. The maximum length is 1024 times *integer*.

integer **M**

The maximum value for *integer* is 2048. The maximum length is 1 048 576 times *integer*.

integer **G**

The maximum value for *integer* is 2. The maximum length is 1 073 741 824 times *integer*.

If you specify a value that evaluates to 2 gigabytes (2 147 483 648), DB2 uses a value that is one byte less, or 2 147 483 647.

GRAPHIC(*integer*)

GRAPHIC

For a fixed-length graphic string of length *integer*, which can range from 1 to 127. If the length specification is omitted, a length of 1 character is assumed.

VARGRAPHIC(*integer*)

For a varying-length graphic string of maximum length *integer*, which must range from 1 to $n/2$, where n is the maximum row size minus 2 bytes.

DBCLOB(*integer* [K|M|G])

DBCLOB

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1 through 1 073 741 823. A DBCLOB column has a

varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 97.

When *integer* is not specified, the default length is **1M**. The meaning of *integer* **K|M|G** is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

BINARY(*integer*)

A fixed-length binary string of length *integer*. The *integer* can range from 1 through 255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(*integer*) or VARBINARY(*integer*)

A varying-length binary string of maximum length *integer*, which can range from 1 through 32704. The length is limited by the page size of the table space.

**BLOB (*integer* [K|M|G] or BINARY LARGE OBJECT(*integer* [K|M|G])
BLOB or BINARY LARGE OBJECT**

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2 147 483 647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 97.

When *integer* is not specified, the default length is **1M**. The meaning of *integer* **K|M|G** is the same as for CLOB.

DATE

For a date.

TIME

For a time.

TIMESTAMP(*integer*) WITHOUT TIME ZONE

For a timestamp. *integer* specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(*integer*) WITH TIME ZONE

For a timestamp with time zone. *integer* specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

ROWID

For a row ID type.

A table can have only one ROWID column. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

XML

For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.

distinct-type-name

Specifies the distinct type (user-defined data type) of the column. An implicit or explicit schema name qualifies the name.

NOT NULL

Specifies that the column does not allow null values and does not provide a default value.

NOT NULL WITH DEFAULT

Specifies that the column does not allow null values but provides a default value.

Notes

Error handling during processing: If an error occurs during the processing of the DECLARE TABLE statement, a warning message is issued, and the precompiler continues processing your source program.

Documenting a distinct type column: Although you can specify the name of a distinct type as the data type of a column in the DECLARE TABLE statement, use the built-in data type on which the distinct type is based instead. Using the base type enables the precompiler to check the embedded SQL statements for errors; otherwise, error checking is deferred until bind time.

To determine the source data type of the distinct type, check the value of column SOURCETYPE in catalog table SYSDATATYPES.

Examples

Example 1: Declare the sample employee table, DSN8A10.EMP.

```
EXEC SQL DECLARE DSN8A10.EMP TABLE
  (EMPNO      CHAR(6)      NOT NULL,
   FIRSTNME   VARCHAR(12) NOT NULL,
   MIDINIT    CHAR(1)      NOT NULL,
   LASTNAME   VARCHAR(15) NOT NULL,
   WORKDEPT   CHAR(3)      ,
   PHONENO    CHAR(4)      ,
   HIREDATE   DATE         ,
   JOB        CHAR(8)      ,
   EDLEVEL    SMALLINT     ,
   SEX        CHAR(1)      ,
   BIRTHDATE  DATE         ,
   SALARY     DECIMAL(9,2) ,
   BONUS      DECIMAL(9,2) ,
   COMM       DECIMAL(9,2) );
```

Example 2: Assume that table CANADIAN_SALES keeps information for your company's sales in Canada. The table was created with the following definition:

```
CREATE TABLE CANADIAN_SALES
  (PRODUCT_ITEM  INTEGER,
   MONTH         INTEGER,
   YEAR          INTEGER,
   TOTAL         CANADIAN_DOLLAR);
```

CANADIAN_DOLLAR is a distinct type that was created with the following statement:

```
CREATE TYPE CANADIAN_DOLLAR AS DECIMAL(9,2);
```

Declare the CANADIAN_SALES table, using the source type for CANADIAN_DOLLAR instead of the distinct type name.

```
DECLARE TABLE CANADIAN_SALES
  (PRODUCT_ITEM  INTEGER,
   MONTH         INTEGER,
   YEAR          INTEGER,
   TOTAL        DECIMAL(9,2);
```

DECLARE VARIABLE

The DECLARE VARIABLE statement defines a CCSID for a host variable and the subtype of the variable. When it appears in an application program, the DECLARE VARIABLE statement causes the DB2 precompiler to tag a host variable with a specific CCSID. When the host variable appears in an SQL statement, the DB2 precompiler places this CCSID into the structures that it generates for the SQL statement.

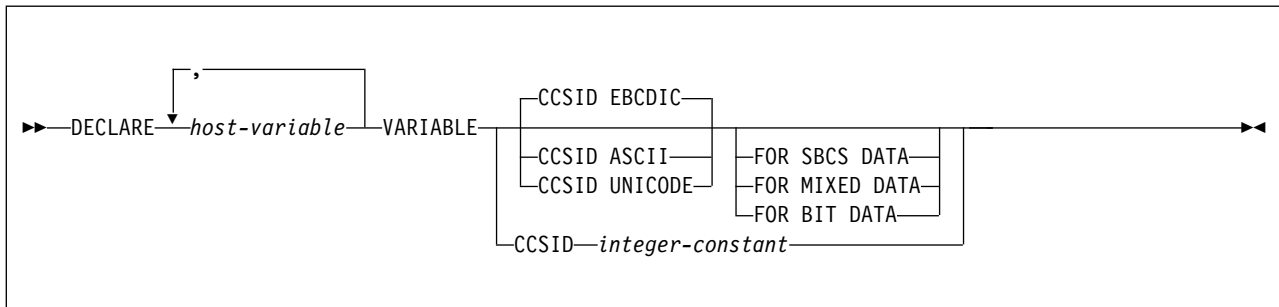

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

Description

host-variable

Identifies a character or graphic string host variable defined in the program. An indicator variable cannot be specified for the host-variable.

CCSID ASCII, EBCDIC, or UNICODE

Specifies that the appropriate default CCSID for the specified encoding scheme of the server should be used.

CCSID ASCII

Specifies that the default ASCII CCSID for the type of the variable at the server should be used.

CCSID EBCDIC

Specifies that the default EBCDIC CCSID for the type of the variable at the server should be used. CCSID EBCDIC is the default if this option is not specified.

CCSID UNICODE

Specifies that the default UNICODE CCSID for the type of the variable at the server should be used.

FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA

Specifies the type of data contained in the variable *host-variable*. The FOR clause cannot be specified when declaring a graphic host variable.

For ASCII or EBCDIC data, if this clause is not specified when declaring a character host variable, the default is FOR SBCS DATA if MIXED DATA = NO on the installation panel DSNTIPIF. The default is FOR MIXED DATA if MIXED DATA = YES on the installation panel DSNTIPIF.

For UNICODE data, the default is always FOR MIXED DATA, regardless of the setting of MIXED DATA on the installation panel DSNTIPIF.

FOR SBCS DATA

Specifies that the values of the host variable can contain only SBCS (single-byte character set) data.

FOR MIXED DATA

Specifies that the values of the host variable can contain both SBCS data and DBCS data.

FOR BIT DATA

Specifies that the values of the host-variable are not associated with a coded character set and, therefore, are never converted. The CCSID of a FOR BIT DATA host variable is 65535.

CCSID *integer-constant*

Specifies that the values of the host variable contain data that is encoded using CCSID *integer-constant*. If the integer is an SBCS CCSID, the host variable is SBCS data. If the integer is a mixed data CCSID, the host variable is mixed data. For character host variables, the CCSID specified must be an SBCS, mixed CCSID, or UNICODE (UTF-8) CCSID. For graphic host variables, the CCSID specified must be a DBCS or UNICODE (UTF-16) CCSID. The valid range of values for the integer is 1 - 65533.

Notes

Placement of statement: The DECLARE VARIABLE statement can be specified anywhere in an application program that SQL statements are valid with the following exception. The DECLARE VARIABLE statement must occur before an SQL statement that refers to a host variable specified in the DECLARE VARIABLE statement.

CCSID exceptions for EXECUTE IMMEDIATE or PREPARE: When the host variable appears in an SQL statement, the DB2 precompiler places the appropriate numeric CCSID into the structures it generates for the SQL statement. This placement of the CCSID occurs for any SQL statement other than the EXECUTE IMMEDIATE or PREPARE statements. The placement of the CCSID also occurs for a *host-variable* in an EXECUTE IMMEDIATE or PREPARE statement, but it does not occur for a variable in a *string-expression* in an EXECUTE IMMEDIATE or PREPARE statement.

If a PL/1 application program contains at least one DECLARE VARIABLE statement, a *string-expression* in any EXECUTE IMMEDIATE or PREPARE statement cannot be preceded by a colon. An expression that consists of just a variable name preceded by a colon is interpreted as a *host-variable*.

Specific host languages: If a DECLARE VARIABLE statement is used in an assembler source program, the ONEPASS SQL processing option must not be used. If a DECLARE VARIABLE statement is used in a C, C++, or PL/I source program, the TWOPASS SQL processing option must be used. For those languages, or COBOL, the host-variable definition can either precede or follow a DECLARE VARIABLE statement that refers to that variable. If a DECLARE VARIABLE

statement is used in a FORTRAN source program, then the host-variable definition must precede the DECLARE VARIABLE statement.

Example

Example: Define the following host variables using PL/I data types: FRED as fixed length bit data, JEAN as fixed length UTF-8 (mixed) data, DAVE as varying length UTF-8 (mixed) data, PETE as fixed length graphic UTF-16 data, and AMBER as varying length graphic UTF-16 data.

Use the DECLARE VARIABLE statement to specify a data subtype or CCSID for these host variables: FRED as CCSID EBCDIC, JEAN as CCSID 1208 or CCSID UNICODE, DAVE as CCSID 1208 or CCSID UNICODE, PETE as CCSID 1200 or CCSID UNICODE, and AMBER as CCSID 1200 or CCSID UNICODE.

```
| EXEC SQL BEGIN DECLARE SECTION;
| DCL FRED CHAR(10);
| EXEC SQL DECLARE :FRED VARIABLE CCSID EBCDIC FOR BIT DATA;
| DCL JEAN CHAR(30);
| EXEC SQL DECLARE :JEAN VARIABLE CCSID 1208;
| DCL DAVE CHAR(9) VARYING;
| EXEC SQL DECLARE :DAVE VARIABLE CCSID UNICODE;
| DCL PETE GRAPHIC(10);
| EXEC SQL DECLARE :PETE VARIABLE CCSID 1200;
| DCL AMBER GRAPHIC(20) VARYING;
| EXEC SQL DECLARE :AMBER VARIABLE CCSID UNICODE;
| EXEC SQL END DECLARE SECTION;
```

DELETE

The DELETE statement deletes rows from a table or view or activates an instead of delete trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Deleting a row from a view deletes the row from the table on which the view is based if no instead of trigger is defined for the delete operation on this view. If such a trigger is defined, the trigger is activated instead of the delete operation.

There are two forms of this statement:

- The *searched* DELETE form is used to delete one or more rows, optionally determined by a search condition.
- The *positioned* DELETE form specifies that one or more rows corresponding to the current cursor position are to be deleted.

Invocation

This statement can be embedded in an application program or issued interactively. A positioned DELETE is embedded in an application program. Both the embedded and interactive forms are executable statements that can be dynamically prepared.

Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table, or a view, and whether the statement is a searched DELETE and SQL standard rules are in effect:

When a table other than a catalog table is identified: The privilege set must include at least one of the following:

- The DELETE privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:

- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority

When a view is identified: The privilege set must include at least one of the following:

- The DELETE privilege on the view
- SYSADM authority

If the *search-condition* in a searched DELETE contains a reference to a column of the table or view, or the *expression* in the *assignment-clause* contains a reference to a column of the table or view, the privilege set must include at least one of the following:

- The SELECT privilege on the table or view

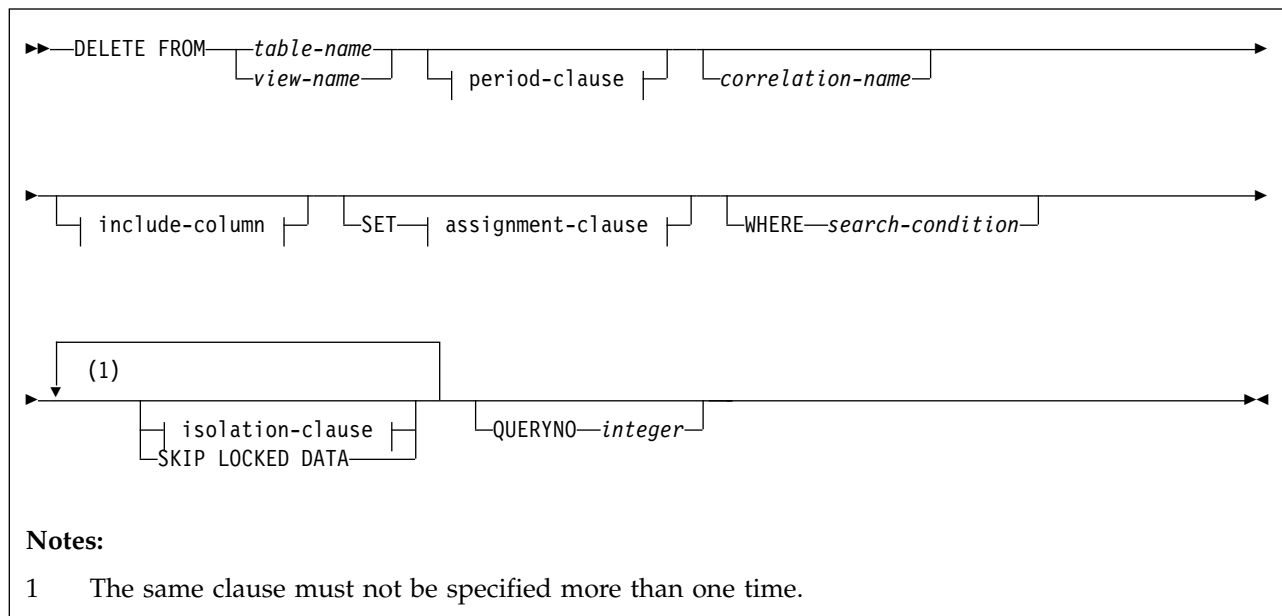

- Ownership of the table or view
- DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
- DATAACCESS
- SYSADM authority

If the *search-condition* in a searched DELETE includes a subquery, or if the *assignment-clause* includes a *scalar-fullselect* or a *row-fullselect*, see “Authorization” on page 1080 for an explanation of the authorization required.

The owner of a view, unlike the owner of a table, might not have DELETE authority on the view (or might have DELETE authority without being able to grant it to others). The nature of the view itself can preclude its use for DELETE. For more information, see the description of authority in “CREATE VIEW” on page 1838.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 147 on page 1153. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 75.)

searched delete:

positioned delete:

|
| **period-clause:**

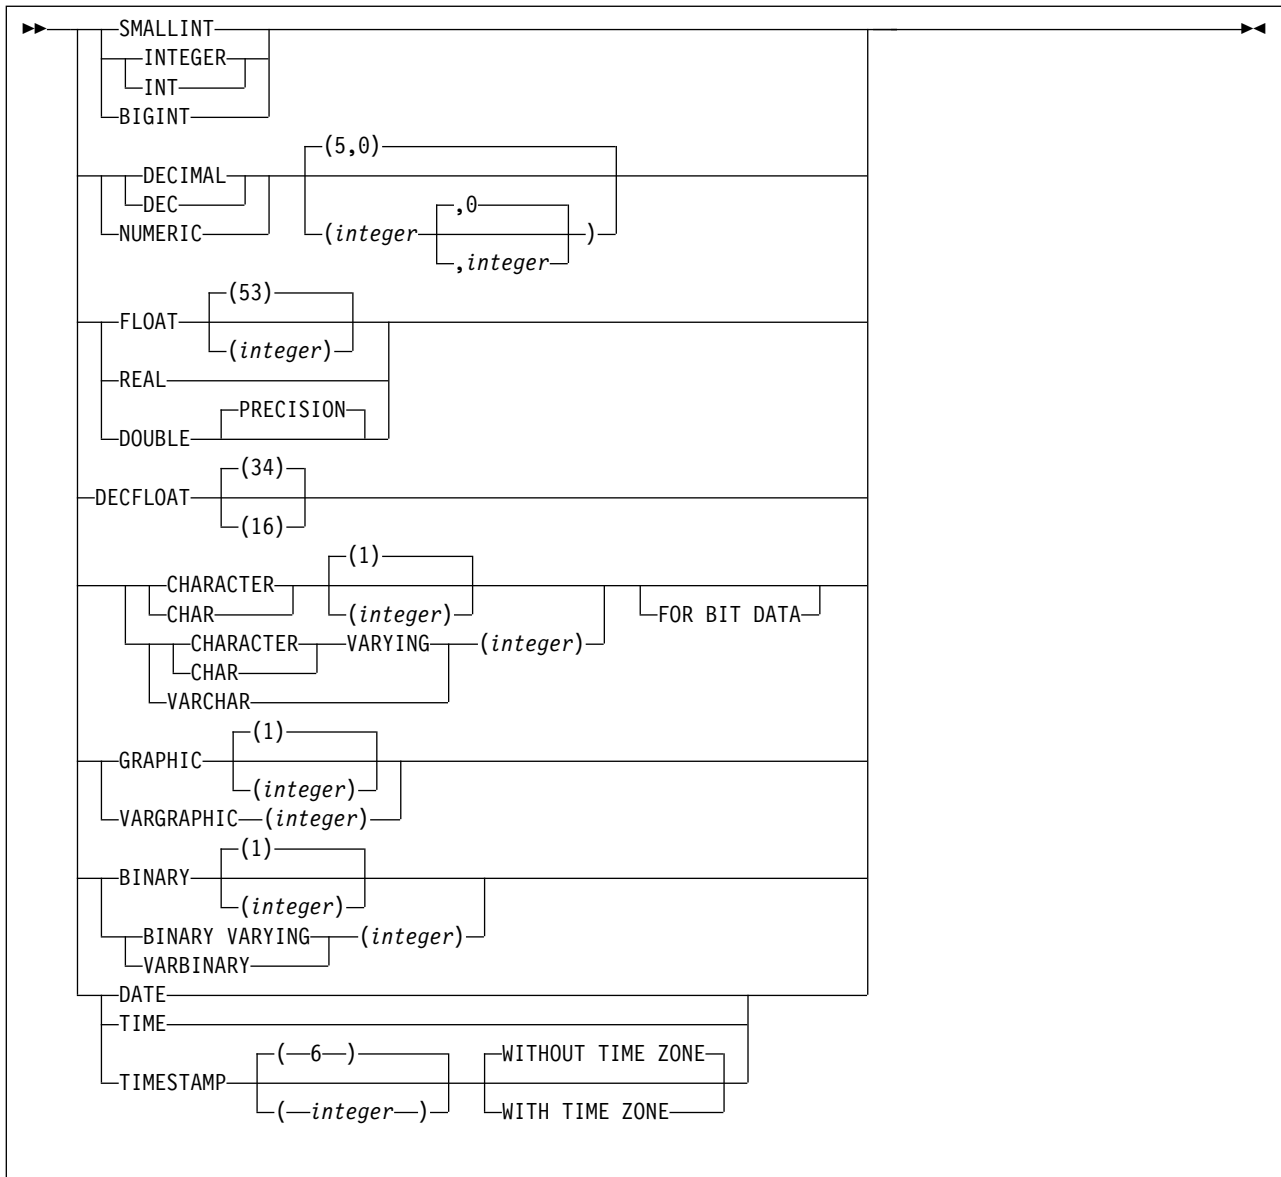

include-column:

data-type:

built-in-type:

assignment clause:

Notes:

- 1 The number of *expressions* and NULL keywords must match the number of *column-names*.
- 2 The number of columns in the select list must match the number of *column-names*.

isolation-clause:

Description

FROM table-name or view-name

Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the DB2 subsystem that is identified by the implicitly or explicitly specified location name. The name must not identify:

- An auxiliary table
- A catalog table for which deletes are not allowed
- A view of such a catalog table
- A read-only view (see CREATE VIEW)
- A system-maintained materialized query table
- A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

period-clause

Specifies that a period clause applies to the target of the delete operation. The same period name must not be specified more than one time. The table reference must not specify a view.

FOR PORTION OF BUSINESS_TIME

Specifies that the delete only applies to row values for the portion of the BUSINESS_TIME period in the row that is specified by the period clause. BUSINESS_TIME must be a period that is defined on the table.

FOR PORTION OF BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL when the BUSTIMESENSITIVE bind option is set to YES.

| **FROM *value1* TO *value2***

| Specifies that the delete operation applies to rows for the period that is
| specified from *value1* to *value2*. No rows are deleted if *value1* is greater than
| or equal to *value2*, or if *value1* or *value2* is the null value.

| For the period condition that is specified with **FROM *value1* TO *value2***, the
| period that is specified by *period-name* in a row of the target table of the
| delete:

- | • Overlaps the beginning of the specified period if the value of the begin
| column is less than *value1* and the value of the end column is greater
| than *value1*.
- | • Overlaps the end of the specified period if the value of the end column
| is greater than or equal to *value2* and the value of the begin column is
| less than *value2*.
- | • Is fully contained within the specified period if the value for the begin
| column for *period-name* in the row is greater than or equal to *value1* and
| the value for the corresponding end column in the row is less than or
| equal to *value2*.
